The place of science and science education in nations across the globe is, ever increasingly, a focus, and a hope, for building the capacity to solve some of the most pressing challenges facing the earth. Daily acts of sovereignty are connected to professions or policy are currently intertwined with science, for example, the management of tribal lands, food production and basic physical infrastructures (water, housing, sewage, buildings). I will argue that a core construct in science and science education (among many other domains of western thought) has been built on bisection culture and nature, and positioned humans in places of privilege, dominance, and entitlement to land (e.g. Deloria, 1999; Cajeet, 2000; Kawagle, 1995). This bisection however is a cultural product of western forms of thought but has been named as a universal cultural construct that permeates how we understand, study and construct theories of human cognition and development (e.g. Medin et. al, 2010) and by extension the ways in which systems of education are built. For indigenous communities whose worldviews do not rest on this bisection, most configurations of science and science education are epistemologically and ontologically hegemonic and enclose us in cycles of colonialism (e.g. Deloria, 1979; Yazzie-Burkhart, 2004; Marker, 2006). I will present findings, and reflect on a 6-year mixed-methods research project, which centred on community-based design of learning environments, while also conducting basic cognitive research. We found that community-based design, used as a tool in decolonisation, created the space for transnational praxis in science learning environments to emerge (Smith, 1997; Smith, 2005; Alfreid, 2005), and simultaneous-
ly expanded broad understandings of cognition and child development.

IKS, human development, and the role of the academy
Catherine Hoppers Canada
Canada
Human development as a working concept seems to have been eluded in most parts of the world where the paradigm of "development" is anchored in the Western system of thought. Everywhere "development" has gone, it is followed by the toxic associations with serial displacements, linearity, epistemological disenfranchisement, and the logic of consumption, accumulation and progress. Although the prefix 'human' does not completely save 'development' from its inherent baggage, introducing 'human' to the phrase adds a multidimensional approach to social change, in which human-ness linked to livelihood, as a chain of being connects life with life-cycle, life worlds and cosmology. Looking at the 21st century, the global South is rebelling against the developments as touted by the West, sequentially, linearly according to the idea of progress where the tribal and the peasant evolved into an industrial system with the associated violence explained as necessary. African scholars are linking up with organic intellectuals, elders, other scholars in the global South, and some conscientious people from the North (read "West") to develop an epistemology of the South in a model in which the tribe, the peasant, the rural and industry must co-evolve. This gestures towards new points of departure in rethinking the future of knowledge, learning, innovation, social justice and human agency within a new conception of knowledge economy and information society. Some of these points of departure include putting knowledge in the plural, linking epistemology and democracy, cognitive justice and the right of traditions of knowledge to co-exist and unfold without duress.

Universal psychological science needs indigenous psychologies
Janak Pandey Central University of Bihar, India
The statement that science is truly without borders may not be true for human sciences like Psychology. Developments in cultural, societal, ethnic and indigenous psychologies have demonstrated the way psychological processes and behaviors are influenced by culture, questioning universal nature of psychological theories. More than natural sciences, psychologists of various cultural backgrounds not only choose to investigate different questions, but may approach the same questions in different ways. In their scientific work, they use perspectives, assumptions, hypothesis and select methods according to their cultural social upbringing, education and training. Thus, Knowl edge and theories are conditioned by the scientists epistemological perspectives limiting universality of science. Thus, one may argue that science benefits greatly from a scientific community that approaches problems in a variety of creative ways. This argument suggests that diverse background of psychologists engaged in vibrant indigenous psychologies may potentially facilitate evolution of a universal psychological science.

Reconstruction of knowledge through science education: Arguing for African community-based research
Berte Van Wyk Stellenbosch University, South Africa
A general aim of science is to always strive to know in greater and deeper detail. Since 1994 there has been a renewed scholarly interest in acquiring new knowledge(s) about the complexities of South African society and there have been numerous attempts to revisit, revive, and re-assert unique and sometimes pre-colonial perspectives with the purpose to educate and (re)construct knowledge. Thus, there is not a unity of science in South Africa as there are diverse cultural virtues, ways of knowing, knowledge traditions. Often there are uncertainties between what is regarded as indigenous and colonial or post-colonial cultures. The result is that the local and indigenous are sometimes in conflict with the global, and there is a tension between the orientation toward indigenous values and problems on the one hand and addressing global problems on the other. This tension can be alleviated or resolved by communication across cultural boundaries. This paper argues for a form of African community-based research that seeks to enhance the capacity of community members to participate in the process that shapes research approaches and intervention strategies. Community-based research opens new opportunities for the integration of indigenous and community-based knowledge systems into existing knowledge systems. Importantly, community-based research does not attempt only to revive and reinstate indigenous African knowledge systems but take into account the impact of modernity and industrialisation.

Symposium title: Parental styles: Universals and cultural specificities
Convenor: Gonca Soygut

Symposium overview
Gonca Soygut Hacettepe University, Turkey
This symposium will address the role of parental styles in development of self in the context of universal and culture specific aspects. It will bring together researchers having different theoretical backgrounds from different fields of psychology. The first presentation will focus on pattern of perceived maternal and paternal behaviours including emotional warmth, rejection, intrusion, guilt induction, and comparison reported both by parents and children in a large Turkish sample. The second presentation will discuss the effect of parental styles on Arab adolescent-familly connectedness and on adolescents’ mental health. The discussion will focus on the adolescent-family connectedness, and its relationship with better mental health of adolescents. The third presentation will report the relationships between parental control dimensions and adolescents’ psycho-social functioning (internalised and externalised problem behaviours) and discuss some mediating familial and individual variables. The fourth will touch on universal and culture specific aspects of early maladaptive/interpersonal schema by bringing into focus the question of "whether schema are universal or culture specific?" Schema-focused models and overall findings of our studies conducted in Turkey, between 1994 and 2009 will be addressed. The final presentation will be based on "the Families across Cultures project", which focused on psychological variables across countries. The links between the socio-economic level and dominant religion of countries, family networks, family roles, and the psychological variables: Family values, personal values, personality traits, and emotional bonds in 27 countries around the globe will be presented.

Symposium title: Presidential symposium: Acculturation of diaspora migrants
Cultural identity: Returning home to Hong Kong and mainland China
Nan Sussman College of Staten Island, United States of America
The Cultural Identity Model (CIM) of cultural transitions proposes four identity profiles following an international sojourn: Subtractive, additive, affirmative, and global. These identities are primed and become salient upon return to one’s country of origin. Subtractive identities, exhibited primarily by Westerners, are characterised by decreased identification with home culture and affective distress. Additive identities result in adding a new cultural layer, either as hybrid or bicultural. Affirmative identities are characterised by strengthened home country identity and global identifiers who have weakened identity with home and sojourner countries due to multiple sojourns. Two studies investigated the CIM among return-migrants. In Study 1, Hong Kong remigrants completed structured interviews and a battery of psychological scales that included measures of acculturation, self-construal, satisfaction with life, and repatriation distress. Utilising the cultural values of flexibility and integrative harmony, Hong Kongers exhibited an “Additive/bicultural” cultural identity, layering their Chinese/Hong Kong, and Western cultural background and experiencing little repatriation distress. In Study 2, Mainland Chinese biculturals, who studied in the U.S., completed a questionnaire prior to returning to China or following their return, either in English or Mandarin. When their “American frame” was primed, returnees show Affirmative social identities (positive Chinese attitudes) and Additive individualistic ones. When their “Chinese frame” was primed, additive identity resulted in a group-oriented self-concept. Results of these studies highlight the cultural-specific nature of cultural transitions, the universal applicability of the Cultural Identity Model.

Migrant worker acculturation in China
John Berry Queen’s University, South Africa; Yong Zheng; Yangxia Gui
Chinese migrant workers form a substantial body of people who move to large cities from rural areas to seek employment. As they settle into the large urban cities, these internal migrants experience challenges that are similar to those of international migrants, and of members of ethnic groups who engage in the process of acculturation. Many see this flow as a problem, one that needs to be understood through research using evidence based on concepts and methods used in international acculturation research.
In the present study, we examine the urban identity of 787 migrants, using the Migrant Workers’ Urban Identity Questionnaire developed by Gui (2010). This instrument distinguishes two aspects of urban identity: social identity and place identity. Findings show that the acculturation strategies model based on international immigrants’ identity can apply to the seasonal migrant workers’ identity. With respect to their acculturation strategies: (1) Different operationalisations of the second dimension in the two dimension model lead to a different classification of acculturation strategies; the ‘deeper’ the psychological phenomena the less migrant workers want to engage the new society; (2) Different acculturation strategies were favoured in social identity and place identity domains; (3) Data from the Satisfaction with Life Scale and the Global Self-worth Scale shows that by and large, integration is the best acculturation strategy (and marginalisation the worst) for achieving wellbeing in both social identity and in place identity. This corresponds to findings and conclusions of much of the previous research on accultur- ation based on international migration.

Health, literacy, empowerment, and family expansion: A study of Cambodian women who escape toxic workplaces
Ian Lubeck University of Guelph, Canada/UNSW, Australia; Helen Lee; Mee Wong; Neela Griffiths; Sarahat Kros; Michelle Tolson
Since 2000, Cambodian NGO “SIRCHESI” combats health risks among sellers of international beers, found at high-risk for HIV/AIDS with 21.7% prevalence. Employers underpaid them by 50%, forcing some to sell sex. Without universal anti-retroviral treatments, many died. Researchers document workplace violence, coercion, and hazardous/harmful nightly beer consumption (4-8 standard drinks). Industry response was sluggish, so SIRCHESI supplemented its community health-promotion programs with a “primary” intervention. Twenty-six beer-sellers left “toxic” workplaces for a 24-month Hotel Apprentice Program (HAP), featuring Khmer literacy, English, health, social and life skills. For 8 months, they attended SIRCHESI’s morning school, combined with 9-hour shifts of on-the-job skill-training in 9 partner hotels. They received a stipend of $110. They were monitored throughout the 24 months of their initial hotel contracts, and follow-ups continue at 4-month intervals. In contrast to beer-sellers, HAP students showed long-term effects of raised self-esteem and job-satisfaction, while health risks declined. Unexpected discourse about “family” events dominated the 2011 interviews. Co-worker marriages, pooled efforts, and family leaves were discussed, while infants joined the interviews. These events seemed logical, social/family outcomes of the HAP health/literacy/career mobility intervention, in sharp contrast to life-stories of those selling beer in 2010-2011. For the latter, other empowerment paths evolved, as when 53 joined the CFSWF union in Siem Reap (2010).

Religiosity, acculturation processes and perceptions of discrimination among second generation adolescents living in a country with a high value of laicity
Colette Sabatier United States of America
Religiosity is beginning to be an important social issue especially for immigrant people. The question of the relationship between different confessional groups is an open question in the most western countries. In the 21st century, religion and faith seem to take a special importance for people. Because religion is a multifaceted phenomenon, people may find many resources for their well-being and sense of worth. In a context of intercultural relationships, religion may be an element that fosters the cohesion of the ethnic group and make the distinction with other groups; and may enhance the perception of being discriminated against; it may also offer an opportunity for social cohesiveness or to support values and meaning of life. In a study with five ethnic groups in France, we have examined the link between the salience of religion for individuals and their French and ethnic identity, their strategies of acculturation and their perception of discrimination. Results indicate no correlation between religiosity and perception of discrimination but variations of the link between the salience of religion and acculturation and identity variables across ethnic groups. No correlation has been found for Vietnamese (N=65). While for Portuguese (N = 101), Moroccans (N = 142), Turks (N = 59) and Algerians (N = 110), religiosity sustains ethnic identity and the attitude of separation. In sum, it appears that for many groups the religiosity including those who are Catholic, the main religion of the host country enforces the sense of belonging to a group, but do not sustain the perception to be rejected because of it.

Symposium title: African-centered psychology: Then and now

Convenor: Omowale Amuleru-Marshall

Black, African-centred, Afrocentric or Africentric psychology: Different terms or different systems?
Omowale Amuleru-Marshall St. George’s University, Grenada
Black psychology, African-centred psychology, and Africentric or Afrocentric psychology may no longer refer to the same paradigm. These terms are certainly used interchangeably in some, but not all, discussions. Emerging as black psychology in the 1960s, the effort to situate black and African-origin persons within normative and abnormal frameworks that were constructed on the black cultural experience has sprouted many tributaries. Today what is considered an Africentric psychology, by some psychologists, may be fundamentally different from the work that launched the paradigmatic shift from theories and models that were constructed on a white cultural experience. This symposium will be introduced with a comparative reflection on the terms and constructs that are found in this literature. This segment will be limited to a consideration of definitions of euphemistic labels and, at least occasionally, emerging theoretical differences. An argument for diversity and richness will be juxtaposed against a more theoretical, even ideological, orthodoxy which may have limited applicability to the totality of the Pan-African experience.

Early efforts: Seminal contributions and contributors to a psychology of black experience
Zuri Amuleru-Marshall St. George’s University, Grenada
The seminal work that laid the foundation for the development of black/African-centred/Africentric Psychology will be highlighted. The rejection of the Eurocentric model of psychology for African-descended people ushered in a period of intense intellectual activity and production by African-descended social scientists. Their pioneering work, characterised by collective self-definition and self-determination, forced a paradigm shift, moving beyond a mere focus on the black experience to the construction of a psychological framework/model that is based in and on an African worldview. With a commitment to the Africentric idea, these scholars catalysed a movement that shaped our discourse in the field of psychology, that spawned organisational development and institutional change, and that continues to energise and provide direction to a growing community of psychologists and social scientists. In the spirit of Sankofa, this presentation will “go back and fetch” the groundbreaking work that laid the foundation for a psychology that, by any name, seeks to advance and protect the psychosocial integrity of African-descended people.

Directions of acculturation research
Fons Van De Vijver Tilburg University, Netherlands
In this part of the symposium, contemporary directions in the field of acculturation research is discussed and new developments in the area, with a particular reference to the first four presentations, are examined. Social and cultural issues relevant to the topic of acculturation research is presented.

African philosophy and practice: Foundations of an authentic Africentric psychology
Cheryl Grills Loyola Marymount University, United States of America
African Centred Psychology, as a concept within the academy is still very much in its infancy. Its
foundations and practice are centuries old. Central to its ongoing evolution is an articulation of what in fact are the distinctive and indispensable elements of an Africentric psychological paradigm. Initial thoughts will be presented as a stimulus for much needed dialogue and development of shared meaning on the subject. Such scholarly debate is essential to the ongoing evolution of the Africentric paradigm. However, it must be a debate that is neither constrained to the lens of, nor concedes to, the self-scribed authority of Western psychology.

This segment will propose an articulation of the essential concepts and structures of knowledge in African Centred Psychology (e.g., centrality of community, spirituality, consubstantiation, pre- rational knowledge in human behaviour and consciousness) and their related implications for research, teaching and praxis. By necessity, what emerges is an interdisciplinary understanding of human behaviour grounded in an African cultural worldview that has transcended time and place. The issues presented will also beg the question: what lies ahead in the future of African Centred Psychology and that will be briefly examined along with pertinent issues for consideration as African Centred Psychology moves forward.

Black psychology in the contemporary American classroom
Shani Harris Spelman College, United States of America
Black Psychology, African American Psychology, and in some instances, Africentric Psychology courses can be found at nearly every institution of higher learning in the United States. Those colleges and universities that have historically served African Americans are uniquely challenged to create leaders in the field of “Black” Psychology while ensuring that their curriculum is equally, and often-times, over-weighted with traditional, European-informed psychological topics. Certain institutions confront this challenge by creating stand-alone courses and by making the deliberate choice to infuse their overall curriculum with information derived from the theories, studies, and scholars of Black Psychology. The latter effort is fluid and often includes principles from Africentric, Afrocentric, and Black Psychology; though it makes clear to distinguish between the multiple perspectives. This presentation considers the practice of presenting and examining Black Psychology within the contemporary American classroom by presenting, as a case study, the evolution of Black Psychology as a requirement in the curriculum at a small, American, Historically Black College for women.

Competition in schools: A Chinese cultural analysis
Ronnel King United States of America; David Watkins; Marta Fulop
In the Western psychological literature, competition has usually been viewed in a negative light because it has been shown to be associated with maladaptive outcomes. However, research in cross-cultural psychology has indicated that competitiveness may hold different meanings for people from different cultures. In particular, individuals from the collectivist Chinese culture seem to hold a more positive view of competition. The aim of the current study was to investigate the meaning and correlates of competitiveness among Chinese students. Three inter-related studies were conducted. Studies 1 and 2 were qualitative studies that assessed how secondary students felt about competing with their peers. Study 3 was a quantitative study that investigated the effects of competitiveness on different educational outcomes. Utilising the hierarchical model of achievement motivation, it examined the relationships among individual differences (trait mastery and trait competitiveness), achievement goals (mastery and performance goals), and learning strategies (deep and surface learning strategies). Path models indicated that there were important differences in the pattern of relationships among the variables in our study compared to previous findings in the West. Taken together, the studies show that competition is associated with positive elements in the Chinese context. The qualitative studies showed that students were able to identify the positive effects of competition on various outcomes. The quantitative study further supported this conclusion by showing that contrary to Western studies, trait competitiveness was predictive of mastery goals and not only of performance goals. Second, performance goals positively predicted the adoption of deep learning strategies.

Symposium title: Developmental trajectories of vulnerable boys
Convenor: Oscar Barbarin
Symposium summary
Oscar Barbarin Tulane University, United States of America
In developing countries, girls are often disadvantaged and their access to education is often impeded. In the US and much of the developed world, boys tend to lag behind in education and present a variety of challenges with respect to behavioural and socio-emotional adjustment at school; this is particularly the case with boys of colour and those from stigmatised groups. This symposium traces the evolution of these difficulties by examining data on early social and cognitive development that may underlie the difficulties observed among boys of colour in later years.

Understanding competition through associational group analysis among Indian college students
Anjali Ghosh Indian Statistical Institute, India
Competition is an important concept in today’s world, whether it is in education, business or sports or for fame. The present study was done on a group of 220 undergraduate college students selected from different colleges of Calcutta, India. Students were instructed to write as many possible free associations which come to their mind in response to the stimulus word “competition”. Responses were categorised under different groups depending upon its meaning. It was observed that Indian students’ immediate responses mainly centred on the category of achievement, emotion, winning/losing and sports. Though Indians are collectivist in nature their immediate responses indicate their urge to achieve something or winning. Results in terms of gender were also discussed.

Symposium title: Competition and cooperation in cross-cultural perspective
Convenor: Marta Fulop
Attitudes towards competition in business life in different societies: A comparison of Chinese, Hungarian, Russian and Belgian business students’ views
Marta Fulop Institute for Psychology, Hungary; Tamás Nagy; Mihaly Berkics; Ilya Garber; Bai Xuejun
Market economy and competition as key concepts and phenomena of capitalism are under constant debate since the economic crisis started in 2008. The way competition is seen by future business people in different societies may have an impact on economic decisions taken in the future. In the present study, Chinese (531), Hungarian (150), Russian (150) and Belgian (131) business and economics students’ attitudes towards competition were compared at three different levels: attitudes towards competition in general, personal attitude towards competition, and perception of the role of and attitudes towards competition in the economic life. A closed-ended questionnaire was used that consisted of different types of questions: multiple-choice answers and a 23-item Attitude Scale consisting of statements related to the personal-social and economic functions and consequences of competition. This study was carried out in two post-socialist countries: Hungary and Russia, in a socialist market economy; and China and the Flemish part of Belgium with a centuries-old entrepreneurial culture. Our results are interpreted in relation to these different contexts.

Russian business students’ representation of economic versus sports aspects of competition
Ilya Garber Saratov State University, Russian Federation
The comparison of Russian business students’ representation of economic and sports aspects of competition is made as part of the cross-cultural investigation. M. Fulop’s questionnaire (Russian version with additional question) was used. The total number of questions was 27. Five of them were open-ended (including demographic), one semi-closed and 21 close-ended. The sample consists of N = 389 university students of business or economics and is balanced by gender (Male = 53%; mean age = 19.5; SD = 2.2). Psychological characteristics compared are attitudes, estimates of rivals and self-esteem, assessment of typical situations, intentions, stereotypes etc. The historical and social contexts are taken into account. Our major theoretical contribution is that we differentiated economic aspects of competition from sports ones and used this construction in an empirical study. The data obtained and the scheme of their interpretation allow and suppose cross-cultural perspective.
Boys of color: Trajectories of social competence and academic achievement
Oscar Barbarin Tulane University, United States of America
This presentation reviews early childhood data depicting the developmental trajectories of boys with respect to self-regulation, social competence and their relationship to academic development. Social competence is the opposite and positive side of the coin to concerns about behavior and emotional difficulties. Here the emphasis is on the protective and promotive health-related aspects of development that might be considered the foundation of resilience. Social competence is defined in terms of self-regulation of behavior, attention and emotions, positive relations with peers and adults and the capacity to adapt to and meet the demands of the social environment. Specifically, data are presented on the status of Latino and African American boys of color with respect to social competence, compared to girls and to Euro-American boys. The presentation will provide data for and discuss race and gender differences in trajectories of social development in early life and its relation to academic achievement.

Innovation and entrepreneurship: A Chinese perspective
Kwok Leung Hong Kong; Japhet Law
Innovation is a major feature of entrepreneurship, but innovative performance is subjected to the influence of cultural dynamics. A major characteristic of the Chinese culture is relationalism, which refers to the emphasis on interpersonal issues. Following an indigenously derived method, the relationship of the relational orientation of Chinese employees with their innovative behaviour was evaluated in China with a cross-level design. Results generally show that relational orientation is detrimental to innovative behaviour in the Chinese context, but only when innovative climate is low. A major implication of these findings for entrepreneurship is that relational orientation, when coupled with an emphasis on innovation, may actually be beneficial to entrepreneurship in the Chinese context. As an illustration, the development of business schools in Chinese societies is analysed as a case study. A number of business schools in Chinese societies have achieved very high international rankings in the past decade, which provides a case study of successful entrepreneurship. One major strategy deployed by such schools is to form alliances with well-known universities, suggesting a relational approach. An analysis of their ascendance from a relational perspective is provided.

Organisational learning and change leadership among Chinese entrepreneurial firms
Zhongming Wang Zhejiang University, China
Chinese entrepreneurial firms are facing tremendous organisational change and industrial upgrading in the recent years since the world's financial crisis. There have been three major types of changes, which have made the most significant impact upon leadership and entrepreneurship in China: Global and domestic mergers and acquisitions, industrial upgrading with high-tech and green tech and entrepreneurial leadership competence development. This paper reports the results of some recent organisational change and entrepreneurship research using a change leadership model to facilitate organisational learning and entrepreneurial change on the basis of empirical studies among Chinese entrepreneurial firms and organisations. The change leadership model describes the three key leadership dynamic capability elements: Adaptation, Selection and Development (ASD). The organisational learning facilitates and upgrades these change leadership capabilities and enhances organisational innovation and global entrepreneurship. Theoretical and practical implications of this ASD change leadership model (NSFC: 70732001) are then highlighted with international collaborative research.

Social categorisation, leader’s behaviours, and attributional punitiveness: Attitude, not outrage, as mediator
Ramadhar Singh Indian Institute of Management, India; Hui Lim
Male and female participants (N = 112) learnt about in-group-favour or fairness of a leader categorised as out-group or in-group by gender, and made a number of responses (outrage, attitude, attribution, and punishment). From the model of people-as-fair-but-biased-yet-correctible, the authors predicted and found that participants rated a fair leader more positively than the in-group favouring one. More important, attitude and attributional punitiveness (dispositional, attribution and punishment recommendations) to the leader were more marked when the in-group leader favoured the in-group but the out-group leader acted as fair. Although such self-serving bias was more in attitude than outrage, the mediator of the Social categorisation x Behaviour effect on attributional punitiveness was attitude. Apparently, people can be fair in some responses but biased in others while evaluating the same leader.
schema-focused models and the overall findings of our studies conducted in Turkey between 1994 and 2009 will be summarized. Secondly, findings of some research carried out in Turkey and reflecting other related models (e.g. acceptance-rejection, attachment) will be presented. In the overall evaluation, the findings and clinical observations were broadly similar to the preliminary research findings conducted in Western societies and confirm theoretical predictions. However, given that the Schema Therapy model has built in an individualistic cultural context, it is important to discuss the implications of this model with regard to our collectivist culture. As it has been emphasized, there are major cross-cultural differences in perception of parental control and warmth; and parenting styles that have a determining role in self development. At this point, we believe that, although schemas and parental styles have some universality in relation to their impacts on psychological health, it is necessary to address their implications and possible paternal and gender differences in our collectivistic cultural context.

How different and how similar are families across cultures?

Gonca Soygut Hacettepe University, Turkey

Over 100 years of cultural anthropological studies have documented the diversity of family types, role relationships, kin relationships, values, symbols, behaviours in thousands of societies throughout the world and how different family types are embedded in ecological and cultural factors. The Families across Cultures project focused on psychological variables across countries. It studied the links between the socioeconomic level and dominant religion of countries, family networks, family roles, and the psychological variables in 27 countries around the globe. The findings indicated differences between countries on these psychological variables, but also a number of similarities that appear to be universals across cultures. The socioeconomic index of countries was the most powerful source of variation of the variables, followed by the dominant religion of countries. The largest differences between countries were, in descending order, the hierarchical values of mother and father, relationships with family and kin values, expressive roles of mothers and fathers, and family networks. Universals among countries were: emotional bonds with the nuclear family did not differ across countries, nor the degree of bonds with its members; financial roles of fathers were higher than mothers; child care roles of mothers were higher than fathers; and expressive roles of mothers were higher than the child care roles of fathers. The findings are relevant to current issues regarding the degree of changes in family structures and functions in cultures. Sp. families in countries of the majority world will inevitably follow the same path as in N. America and N. Europe as predicted by modernization and globalization theories.

Linkages, support and reciprocity: Essential ingredients in building psychology capacity

Merry Bullock United States of America

One outcome of CRP2011 was a commitment to form a regional, Caribbean psychology organisation. In this presentation existing regional associations of psychology will be described in terms of their structures, missions, and relations with national, international, and content-based associations. Psychology organisations can provide a forum for discussion, development, advocacy, information, and public education, and can serve as a strong voice for the discipline. The role of regional organisations as catalysts for capacity building for psychology and psychologists will be explored, as well as models for regional linkages and interaction with national, regional and international bodies.

Caribbean synergy in collaboration to achieve Caribbean region conference of psychology mission

Rita Dudley Grant Virgin Islands Behavioral Serv., Virgin Islands, United States of America

A critical aspect of constructing a successful conference of psychology in the Caribbean and moving forward to create a Caribbean psychology organisation is the synergy of shared mission among the organisers. Members of the Central Organising Committee (COC) represented the diversity of the region in language, culture, ethnicity, age, gender and theoretical orientation. The English, Spanish and French languages were primary in the COC. Members came from independent countries, including Bahamas, Haiti, and Trinidad, and from the United States Commonwealth and territories of Puerto Rico and the US Virgin Islands, with a liaison from the International Community based in the United States. While primarily American trained, COC members have worked and practiced internationally. This presentation will briefly review the ethnic and cultural diversity of the Caribbean region. Consideration will be given to the role that culture and ethnicity play in the mental health and well being of the region and the challenges of collaboration across these cultures. The synergy created between and among COC members will be reviewed in terms of its serving as a model for the ongoing collaboration necessary to create a successful Caribbean Psychology organisation.

The early career psychologist: Critical role in building a sustainable psychology

Ishitar Govia University of the West Indies, Jamaica

Within the past 30–50 years, psychology has become an increasingly popular career path in the Caribbean region. While some Caribbean nations are just establishing undergraduate psychology majors, others have been witnessing an exponential growth in the numbers of students graduating with psychology majors. These psychology majors and early career psychologists have been, and continue to make important contributions to the region’s pressing issues. Their areas of both applied and research focus alert the public to the complexity of the discipline. These students and early career professionals also alert the discipline to the multiple challenges facing the development of a maturing profession, which include, but are not limited to, not being able to secure funding for research, being faced with limited career options upon graduation, and challenges in addressing experiencing marginalisation from other generations of psychologists. This presentation will highlight both the challenges and opportunities that face students and early career professionals as psychology in the Caribbean region continues to develop. It will describe sentiments expressed at multiple sessions of the CRP 2011 (e.g. networking breakfast, special luncheon, and information/advice session with APAGS representative and a representative from one of the regional universities). Networking and entrepreneurship provide solid models of how the profession can advance in the Caribbean region.

Addressing language and culture matters to build bridges for Caribbean psychology

Guero Nicolas University of Miami, United States of America

Situated largely on the Caribbean Plate, the Caribbean region comprises more than 7,000 islands, islets, reefs, and cays. As such, the region comprises many cultures and languages. This is especially evident by the different languages that are spoken in the region: English, French, Haitian Creole, Spanish, Papiamento, and Dutch. At the historical Caribbean Regional Psychology Conference held in November 15–18th in Nassau Bahamas, many different cultures and languages were represented. The process for addressing the languages and cultural differences represented at the conference will be discussed. In addition, some of the lessons learned will be shared as well as some of our plans moving forward with further initiatives in the regions. Given that the Caribbean is not only multilingual but transnational, it is crucial that the voices of these different cultures are reflective in activities and events that are pertinent to these groups.

Creation of CRP 2011: From vision to reality

Ava Thompson College of The Bahamns, Bahamas

Psychology is a relatively new discipline to the Caribbean region but since its introduction, Caribbean psychologists have made noteworthy individual, organisational and small group intra- and inter-country contributions in a range of settings. However, regional psychologists have had considerable challenges establishing the national and regional psychological infrastructure necessary to promote collaboration and collective effort to advance the development of the discipline. These challenges have also affected regional psychologists’ ability to develop theoretical models that reflect the psychological realities of the Caribbean, ensure culturally-appropriate application and engage meaningfully with colleagues in the global psychological community. This presentation will provide an overview of the vision for the Caribbean Regional Conference of Psychology 2011, which was conceptualised as a critical step in enhancing regional capacity to utilise psychological science to promote human and community development. In addition to a brief chronology of events, emphasis will be placed on the Caribbean worldviews, Caribbean realities and an overarching appreciation for the multiple roles for psychologists in the region.

Presentation title: Psychology in the service of the Caribbean development: CRCP 2011 and the establishment of a Caribbean psychology organization

Convenor: Rita Dudley Grant

Gonca Soygut Hacettepe University, Turkey

Over 100 years of cultural anthropological studies have documented the diversity of family types, role relationships, kin relationships, values, symbols, behaviours in thousands of societies throughout the world and how different family types are embedded in ecological and cultural factors. The Families across Cultures project focused on psychological variables across countries. It studied the links between the socioeconomic level and dominant religion of countries, family networks, family roles, and the psychological variables in 27 countries around the globe. The findings indicated differences between countries on these psychological variables, but also a number of similarities that appear to be universals across cultures. The socioeconomic index of countries was the most powerful source of variation of the variables, followed by the dominant religion of countries. The largest differences between countries were, in descending order, the hierarchical values of mother and father, relationships with family and kin values, expressive roles of mothers and fathers, and family networks. Universals among countries were: emotional bonds with the nuclear family did not differ across countries, nor the degree of bonds with its members; financial roles of fathers were higher than mothers; child care roles of mothers were higher than fathers; and expressive roles of mothers were higher than the child care roles of fathers. The findings are relevant to current issues regarding the degree of changes in family structures and functions in cultures. Sp. families in countries of the majority world will inevitably follow the same path as in N. America and N. Europe as predicted by modernization and globalization theories.
These factors served as the foundation for establishing the various committees, identifying the conference aims, objectives and specific outcomes, determining the conference themes and subthemes and developing the overall conference architecture. The presentation will conclude with a brief summary of the conference and a discussion of the challenges and the opportunities for psychological science to serve the humanity of the Caribbean people.

**Symposium title: Reflections on Sudhir Kakar’s contribution to psychology and social theory**

Convener: Manasi Kumar

The co-existence and confluence of intellectual traditions in Sudhir Kakar’s writings

Christiane Hartnack United States of America

The central thesis of this presentation is that a confluence of different intellectual traditions informs much of Sudhir Kakar’s written work. A close reading of Kakar’s publications reveals that he brings the particular and the universal, the linear and the cyclic, the static and the fluid, as well as the individual and the social, into creative tension. Moreover, some of his publications demonstrate that he skilfully included mono- as well as poly-dimensional perspectives, and that he resolved the subject-object dichotomy that is a characteristic of Western thought, including in the fields of psychology and psychoanalysis. While not unique, the ability to hold and at times even fuse different perspectives is certainly noteworthy. Prior to Kakar, the Indian psychologist Girindrasekhar Bose (1887–1953) blended Indian intellectual traditions with then state-of-the-art Western psychological and psychoanalytical thought. This presentation will conclude with an examination of the commonalities between these two researchers. What is the source of their creativity and how relevant is their perspective today with regard to the psychological challenges posed by post-colonial societies in a global ecosystem?

A conversation with Sudhir Kakar

Manasi Kumar University of Nairobi, Kenya

The conversation will discuss Kakar’s writings, his wide repertoire of non-fiction and fiction written over more than three decades now. This discussion will focus on a critical appraisal of his contributions to psychology and through his writings relocate the emerging identity and reflect on the struggles of psychoanalysis in India today. In this sense, Kakar’s move away from the clinic, a bent towards psycho-historical fiction: How has this broadened the scope of psychoanalytic inquiry in the cultural/historical/political domain? A parallel process of mapping his personal journey and his embracing of psychoanalysis (as a process of seeking greater self-knowledge and also to nurture the ‘scientific minded’ artist in himself would be a good starting point: What were the learnings and unlearnings of his life as a social scientist and what unique insights psychoanalysis provided in this journey? We inquire from him about his fascination for historical characters, a fresh approach to fiction writing which is at once personal, provocative and yet historically embedded; there is a continuous struggle to examine and re-examine the past.

**Sudhir Kakar: Psychoanalytic wine from Indian terroir towards a compassionate psychoanalysis**

Anurag Mishra India

Nossiter writes in his book on wine, ‘Liquid Memory’, “A true expression of terroir... is a very precise means to share the beauty of a specific identity, specific culture, with the rest of the world. It is using the local not to exclude, but to include any one of us in the mystery and distinctive beauty of an ‘other’. Any other.” In an era of psychological universalism Kakar has ventured to produce a fine psychoanalytical wine from the Indian terroir. He writes, “I believe that the traditional Indian view of the person who is open, porous and connected to all of existence is an intangible human heritage that needs to be preserved and defended against those adherents of the modern model who would not brook the existence of a competing model of the person.” Visualising the unconscious as an engine that runs on parallel tracks of desire and the divine he writes, “[E]mpathy, and the meditative state that underlies it, may well be the sluice through which the spiritual enters consulting room, where the art and science of psychoanalysis flow together in the practice of psychotherapy.” Kakar’s writing illuminates the rainbow of passion, creativity, mysticism, empathy and compassion arching between desire and divine. His bringing Compassionate Knowing and Being centre stage is not only of metapsychological interest but is also relevant for praxis of psychotherapy which will be explored further here.

**Child is father of the man: Understanding Obama’s global identity through Erikson and Kakar**

Dinesh Sharma IICCP St Francis College, United States of America

Deploying a psychological, cultural and historical approach to biography used by the psychoanalyst and writer Sudhir Kakar, this paper will examine the first 18 years of president Obama’s life, from his birth in 1961 to his departure for college in 1979. He spent these years in Hawaii and Indonesia, these years fundamentally shaped the traits for which the adult Obama is noted—his protein identity, his nuanced appreciation of multiple views of the same object, his cosmopolitan breadth of view, and his self-rooted "outpost" patriotism. Relying on Erik Erikson’s stages of the lifecycle and Kakar’s application of cultural psychoanalysis to different social worlds, Obama’s life transitions will be examined with attention to his dreams, motivations and political identity. We will deliberate on how the Eriksonian approach as applied by Kakar and others meets the needs of a rapidly globalising world.

**Human rights and women’s health in Turkey**

Ayse Giffa United States of America

According to Global Gender Gap Report 2010 (World Economic Forum), Turkey is number 129 ranked among 134 countries even though Turkey is one of the first countries in the world where women had the right to elect and be elected since the beginning of the 1930s. The modern Republic of Turkey is a paradox since it is neither European, Asian nor Middle Eastern, but rather has characteristics from all. Turkey is the only country with 99% Muslim population that has made secular, progressive reforms regarding the family code and affecting women’s lives. The Turkish civil code, which is based on the Swiss Civil Code, has replaced the Koran-formed family law in 2001. Domestic violence began to be discussed in the 1980s after the feminist movement. In January 1998, a new law against domestic violence was ratified after 20 years of women’s movement and two independent women’s shelters. More recently, there has been an increase in the reports of the domestic violence against women in media. There are controversial arguments about this increase. The debate is whether this increase is due to increased awareness versus increased violence. In this presentation, the author will present cases from court reports as well as media reports on violence against women. Most of these cases will be honor killings. Furthermore, the statistics about women health, specifically mental health, will be provided in light of violence against women.

**Social justice and mental health: Global perspectives**

Arpana Inman Lehigh University, United States of America

Wellness is a positive state of being influenced by a balanced and synergistic link between the personal, relational, and collective. For wellness to be present in each of these spheres, justice has to be prevalent in each of these areas. In essence, care, justice, equality, and dignity, values that are foundational to all societies, are important precursors to good mental health and positive wellbeing. Relatedly, we require “well-enough” social, political, and economic conditions that are free of economic exploitation and human rights abuse. We need environments that are healthy, free, and safe, to promote capacity, opportunity, and empowerment at different levels of being. Further, a strong personal front (e.g., sense of self-efficacy, self-esteem, hope) cannot be present without a strong relational (e.g., social support) or collective (e.g., access to health care, safety nets) emphasis. In this presentation, we highlight the intersection of human rights and social justice and address potential mental health implications in four countries: Nigeria, Liberia, Tanzania, and the United States. This paper will provide a theoretical and conceptual framework to highlight the intersection of social justice, human rights, and mental health that provides a framework for the next four presentations: Harmful practices in Nigeria; Rebuilding Motivation for School Following Conflict and Disaster in Liberia and U.S.; Understanding how attributions, or beliefs about the causes of mental illness, influence stigma toward Tanzanian people suffering from mental illness; and addressing Human Rights issues for women in Turkey.

**Symposium title: Social justice and mental health: Perspectives from Nigeria, Liberia, Tanzania, United States and Turkey**

Convener: Arpana Inman
In this paper I describe the general context for refugees in South Africa, which was learnt from working with various individuals from the refugee population during my nine years as a counsellor at a Trauma Centre in Cape Town, and in particular, the violent xenophobia that many experience. I go on to relate the story of a women refugee from the Democratic Republic of Congo, as told to me in counselling sessions over some months. The shifts she was able to make in a very constricted life were expressed in a complex metaphor. I show how external events led to the virtual collapse of the holding environment and I explore the interacting subjectivities of therapist and client in order to bring some understanding to my subsequent actions.
Male and female identity processing styles in relation to academic achievement and self-esteem
Leila Abdool Gafoor South Africa
The adolescent years are typically marked by the exploration of different roles and lifestyles with experience culminating into a crystallised sense of self (Chao, 2001). According to de Man, Harvey, Ward and Benoit (2008) adolescents who have achieved ego identity generally have higher levels of self-esteem and tend to be more decisive, self-directed, good at problem solving and able to cope with changing environmental demands. Currently there is a lack of identity research in South Africa that encompasses gender, self-esteem and academic achievement. The purpose of this research study sets about to fill such a gap. This study attempted to investigate the differences in males’ and females’ identity processing style in relation to academic achievement and self-esteem. A sample of 428 first year psychology students at a well known South African university participated in this study. A biographical questionnaire, the Identity Style Inventory (ISI-3), the Rosenberg Self-Esteem Scale (SES) and 2009 June examination results were utilised. Findings of the study revealed no significant differences in males and females’ identity processing style in relation to academic achievement and self-esteem. There was however significant difference between the three identity processing styles, in favour of the Informational group on academic achievement. A significant difference was found between the gender groups only on the Normative variable in favour of the females. Implications for further theory and practice and recommendations for future research are provided.

Drawing profiles of the psychological characteristics of adolescence according to specialists and adolescents in Isfahan
Fereshteh Afsar Department of Psychology, Khoras, Islamic Republic of Iran; Asghar Aghaei Jeshaghani; Aboulaqhem Nouri; Mohsen Golparvar; Leila Esmaeili Department of Psychology, Khoras, Islamic Republic of Iran
The purpose of this study was to compare the various points of view of specialists and adolescents in Isfahan, about the psychological characteristics of the adolescents. The statistical population included all adolescence (students) in the age range of 12–25 years, and their parents in Isfahan (Iran) in 2011. The statistical sample included 400 adolescents (197 girls and 203 boys) and 186 specialists. The research instruments included a questionnaire. Cronbach alphas were calculated for the questionnaire and its sub-scales and all were at a reasonable level. The result of the statistical data analysis test (Manova and Scheffe) to compare the two groups, showed that there was significant differences between the points of view of adolescents and specialists about the psychological characteristics of adolescence (p < .01). That there are differences between the two views show the disparity in the developmental issue of adolescents. It also points to the need and challenges specialists and adolescence are facing and will explain the separation between the generations.

Parenting and co-parenting: Developmental consequences
Lieselotte Ahnert University of Vienna, Austria; Darcy Santor; Rachel Calam; John Hunley
All over the world, children typically live with and are cared for primarily by their parents, but also receive care from siblings, extended family members, neighbors, friends, and paid care providers. Increased reliance on paid child care in modern industrialist countries has fostered intense research over the past 40 years. According to many theorists, child care may be particularly problematic for infants, toddlers and preschoolers. Attachment theory, for example, proposed that continuous care (i.e. unbroken by separation) was essential to the development and maintenance of attachments which influence children’s emotional regulation and social behaviours, both contemporaneously and later on in life. Because nonparental child care involves separations from primary attachment figures, attachment theorists were concerned that it might damage the primary attachments and thus have adverse effects on socio-emotional development. Furthermore, other researchers have argued that unrelated care providers are, on average, not as committed to their child care responsibilities as parents would be, and that the quality of those secondary attachments is a function of the degree of relatedness between care providers and children. Thus, the poorest attachment quality should be expected from unrelated care providers. The present paper focuses on the co-parenting function of professional care providers and other aspects of the broader care ecology, reflecting multiple attachment patterns, both primary and secondary types. We will describe similarities and differences among multiple attachments based on research carried out in Europe and Malawi, including the experiences gained by children with regard to the intersection between parenting and co-parenting.

Adolescent stage stereotype as it impacts university students
Justina Aire St George’s University, Grenada
Adolescence is arguably the most dramatic of all the human developmental stages. It is a challenging period for parents, teachers and the children themselves. Human development is measured by age and ability, and is distinguished by key stages of scientifically maintained psychomotor development, that is, progress in mental and motor skill activity. Three stages of adolescence are scientifically identified: Early 12–14 years, middle 15–17 years, and late 18–21 years. Typical of human development, there is flexibility in the age at which each stage is reached and the level and quality of individual experience at each stage. This is often due to environmental and nurturing factors, physical development, and hormone balance. The focus here includes the ways in which adolescents make some of their transition experiences in the Freshman and Sophomore years, and how these impact their psychological well-being through Junior and Senior years. Havighurst (1952) suggests that two important areas of development include work and relationships, while Super (1963) indicates that exploring and crystallising vocational choice are important to older adolescents. Erikson (1968), James Marcia (1980), and La Guardia (2009) stress intimacy and commitment to goals. Of the 333 teenage students drawn from St Georges University, Grenada, the classical behaviour pattern persisted in the males, while the female behaviour was career driven. There were no significant differences between gender attitudes towards intimacy and commitment aspirations. Suggestions and limitations are included.

The effect of parent-based pivotal response treatment on autistic children
Mohnaz Alakbari Dekhdori Payame Noor University, Islamic Republic of Iran; Ahmad Alipor; Narges Chimeh; Tayebeh Mohtashami
The study was designed to evaluate the effect of parent-based Pivotal Response Treatment (PRT) on the functional improvement of autistic children. The statistical population included autistic children referred to the Beh’ara Education and Rehabilitation Centre in Tehran. 20 parents with autistic children were selected through availability sampling and randomly assigned to two control and experimental groups. The research used a pre-test and post-test design with a control group and follow-up. The experimental group were trained in PRT over three months. The Childhood Autism Rating Scale (CARS) and Autism Treatment Evaluation Checklist (ATEC) were used as instruments for measuring improvement in autistic children. Results showed that PRT significantly decreased CARS scores and increased ATEC scores. The most outstanding result of this study was the decrease in autism symptoms, in addition to the improvement of speech/language, sociability and communication (P<0.05). Parental intervention in treatment and increasing therapy sessions for autistic children was found to be important, and we recommend that this therapy method be used in conjunction with conventional methods of training of parents of autistic children, especially mothers.

The baseline survey report of older persons in Kayunga District
Peter Baguma Makerere University, Uganda
The survey was intended to better understand the livelihoods of older persons and orphans living with them, so as to be able to guide the selection of beneficiaries, areas and interventions to improve the poor living standards of older persons in Kayunga district. The study was a descriptive situational survey type, cross-sectional in nature that applied both qualitative and quantitative methods of data collection. It focused on ascertaining the social economic, health, housing, rehabilitation and education status among older persons and OVC in Kayunga district. Kayunga District as a whole was the focus of the survey. Persons aged 55 years participated in the study. Random and purposive sampling strategies were used to select 280 households of older persons who participated in the study plus the OVC under their care. The participants were interviewed, systematic observations made and photographs taken. Ethical procedures were followed including the obtaining of verbal consent. Data obtained were analysed using percentages, chi-square, and thematic analysis. Verbatim quotations were used to enrich the
interpretation of data. Findings indicated a poor social economic, health, housing and education status and poor psychosocial conditions among older persons and their OVC. Vulnerability factors were identified.

Cognitive and brain aging: Using information computing technology to reduce cognitive decline
Soledad Ballesteros Unv. Nac. Educ a Dist (UNED), Spain
Interest in aging research has expanded greatly due to the personal, social and economic implications of the unprecedented growth of the number of aging persons living in our societies. First, I will review the main cognitive and brain changes that occur with age, especially in certain key mental functions. I will present behavioural data indicating that some mental processes as implicit memory did not decline with age. However, recent electrophysiological and functional magnetic resonance imaging results have shown that the neural correlates supporting behaviour differ in young and older adults. Older adults may compensate the low posterior brain functioning by recruiting more anterior sites. How can the negative effects of cognitive decline be reduced? This will be the second topic addressed in the talk. The question asked is whether the use of novel cutting-edge information computing technology solutions reduces the effect of cognitive age-related declines in executive control and episodic long-term memory functions - those mental processes that deteriorate most with age. I will address the role of new interactive technologies in maintaining mental health and independent living in the elderly and how computer technology may provide social integration and mental stimulation in older adults living alone.

Development of racial-ethnic identity in indigenous Canadian children
Corenblum Barry Brandon University, Canada; Helen Armstrong
The development of racial-ethnic identity was explored in Native Canadian children enrolled in early to mid primary grades and living in one of four Native Canadian communities. Children completed measures of cognitive development, racial-ethnic identity, implicit and explicit measures of self-esteem, implicit and explicit measures of ingroup attitudes, and a gender comparison task in which the importance of ten social identities, including being an Aboriginal person, were rated. Descriptive analysis revealed inverse relations between age and implicit ingroup attitudes, explicit self-esteem and racial-ethnic identity. On the other hand, older children expressed more positive explicit attitudes and more favourable implicit self-esteem. Latent variable analyses indicated significant associations between level of cognitive maturity, racial-ethnic identity, positive ingroup evaluations and high levels of self-esteem. Increases in the level of cognitive development predicted increases in racial-ethnic identity, and that, in turn, predicted increases on measures of implicit and explicit self-esteem, implicit and explicit ingroup attitudes, and the rated importance of being an Aboriginal person. Results support predictions from social identity theory and theories on racial-ethnic identity development. Development of racial-ethnic identity in children from racial-ethnic minority groups is a dynamic, affect-laden process involving integration of developmental, social, and contextual factors into an understanding of what it means to be a member of a racial-ethnic minority group.

Individualistic tendencies moderate and mediate between femininity and cybervictimisation
Fatih Bayraktar Eastern Mediterranean University, Cyprus
The research on cyberbullying-cybervictimisation has started recently with the growing inclusion of the Internet and mobile phones to human life. The study has tried to find out whether cyberbullying-cybervictimisation were the continuation of traditional bullying-victimisation. In line with the literature, this research aimed to analyse the associations between victimisation and Hofstede’s cultural dimensions (i.e. individualism-collectivism, femininity-masculinity) which were found to be related with traditional victimization in the previous studies. A total of 393 students were recruited from various universities of North Cyprus (Mean Age = 23.2; SD = 2.51). The Independent and Interdependent Self Scale (α = .89), the Revised Cyberbullying Inventory (α = .79), and the BEM Sex Roles Inventory (α = .84) were used as measurement tools. Moderated regression analyses revealed that individualistic tendencies moderated between femininity and cybervictimisation (F=3.91, p<.001, R2=.04). The interaction showed that participants with the highest level of individualism and femininity scores had lowest cybervictimisation scores, on the other hand the participants who had the lowest level of individualism and femininity scores had highest cybervictimisation scores. The mediator role of individualism between femininity and cybervictimisation was tested with Structural Equation Modelling. The Goodness of Fit indexes of mediation model was very good (χ²/df = 3.73, p = .28, RMSEA = .03, GFI=.99, AGFI=.98, CFI= 1.00, NNFI=.99). The model revealed that individualistic tendencies significantly mediated between femininity and cybervictimisation (standardised coefficient for indirect effect = .06, p<.01).

Childhood relocation and its psychological aftermath: A home attachment perspective
Yoav Bergman Bar-Ilan University, Israel; Mario Mikulincer
The objective of the current study was to examine childhood relocation (CR) in light of an extrapolation of Attachment theory, termed “home attachment.” According to attachment theory, the absence of the attachment figure during critical periods in childhood can be detrimental to development. Based on several preliminary studies, we established that patterns of anxiety and avoidance also exist with relation to home, and examined whether CR, which is viewed as the loss of the home as an attachment object, is a concordant/disconcordant elderly behaviours on perceptions of old age, ageist attitudes, and compassion toward older adults. Israeli undergraduates (N=130) were randomly assigned to two experimental conditions: (1) A 3-minute video displaying a chorus of elderly adults, with wheelchairs and walkers in view (stereotypical “age-appropriate” behaviour; S-AP), (2) A similar video depicting older adults performing a complex synchronised dance (stereotypical “age-inappropriate” behaviour; S-AI). Subsequently, all participants filled out scales measuring ageism and compassion. Multivariate analyses revealed that subjects who viewed the S-AP video demonstrated not only more ageist attitudes, but also higher levels of distress, anxiety and compassion. However, when defining lines between younger and older people are challenged, we may resort to ageist attitudes in order to keep our personal sense of self-worth. However, since we all age, this process can also be accompanied by feelings of compassion towards the elderly. In order to examine these issues, we investigated the effects of concordant/disconcordant elderly behaviours on perceptions of old age, ageist attitudes, and compassion toward older adults.

Sociomoral reasoning in children with respect to exclusion and inclusion relationships
Elfriede Billmann-Maherca Germany; Jaime Yanez-Canal
The goal of this study is the analysis of judgements by children and adolescents with regard to inclusion and exclusion in its moral, personal, and social senses. Interviews were conducted with 96 Colombian children and adolescents of diverse social origins and of different age groups (5, 9, 13, and 17 years). The interviews focused on three types of situations in which peers were excluded from group activities. The qualitative and quantitative analyses show that children and adolescents gradually gain complexity in their descriptions of situations, and their judgements become more flexible, differentiated and integrated. Different models of moral development are discussed, and in conclusion, we propose that moral development can be best understood as a process of increasing complexity and of differentiation-integration of domains.

Be your age: Effects of perceived “age-appropriate behaviours” of older adults on compassion and ageism
Fatih Bayraktar Eastern Mediterranean University, Cyprus; Yoav Bergman
Social identity theory postulates that we need to distinguish ourselves from out-groups in order to maintain personal identity and self-worth. Accordingly, when defining lines between younger and older people are challenged, we may resort to ageist attitudes in order to keep our personal sense of self-worth. However, since we all age, this process can also be accompanied by feelings of compassion toward the elderly. In order to examine these issues, we investigated the effects of concordant/disconcordant elderly behaviours on perceptions of old age, ageist attitudes, and compassion toward older adults. Israeli undergraduates (N=130) were randomly assigned to two experimental conditions: (1) A 3-minute video displaying a chorus of elderly adults, with wheelchairs and walkers in view (stereotypical “age-appropriate” behaviour; S-AP), (2) A similar video depicting older adults performing a complex synchronised dance (stereotypical “age-inappropriate” behaviour; S-AI). Subsequently, all participants filled out scales measuring ageism and compassion. Multivariate analyses revealed that subjects who viewed the S-AP video demonstrated not only more ageist attitudes, but also higher levels of distress, anxiety and compassion.
of compassion and feelings of less personal distance and diffusion. These contradictory findings can be seen from the perspective of Terror Management Theory. Since the S-AP video demonstrates helplessness and physical vulnerability in old age, this makes mortality more salient, and leads to out-group distancing. However, this form of distancing effectively negates death anxiety, and enables individuals to feel emotionally closer toward the elderly. A model depicting this process will be presented.

Surviving the adolescent transition: A new look at developmental processes of attachment in adolescence
Filipa Calado Faculty of Psychology, Portugal; Joao Moreira
This study aims to investigate in what way attachment behaviours are transferred from parents to reciprocal partners in adolescence, an important aspect of social development. In spite of some research, it is still unclear how attachment bonds are transferred to peers, and which resources adolescents could take advantage of to successfully negotiate this transition. 100 Portuguese adolescents and young adults volunteered to complete the Inventory of Parents and Peers Attachment, and the Attachment Functions Transfer Index Questionnaire, the latter having been constructed for this study. The impact of romantic relationship status and perceived attachment quality on the timing and extent of transfer were examined. The results revealed that attachment functions are transferred from parents to peers in a sequence which goes through proximity seeking, safe haven, secure base and separation protest, thereby not replicating previous research. Adolescents who had formed a romantic relationship showed a stronger transfer to peers compared to those who had not. The results showed that, among females, father attachment has an influence on the transfer of separation protest which undergoes a turning point at age 20. This means that, while it is negative for young women under 20, it becomes positive for those older than 20. It appears that quality of father attachment protects girls from a premature transfer of attachment functions to peers, but enhances this transfer at a developmentally appropriate age. Among males, only age has a significant effect on the transfer of attachment bonds. Clinical implications of these findings are further discussed.

Evaluation of an intervention programme to promote self-esteem in preschoolers
Rodrigo Carcedo University of Salamanca, Spain; Isabel Paez; Alejandra Gomez; Isabel del Canto; Diosa Moreira
Having a positive self-concept is one of the most important aspects to promote in children in order to achieve good social and emotional development. The sooner this intervention can be developed, the better is for the development of the child. For this reason, we created and developed a programme for preschoolers. Twenty-four sessions of 20–30 minutes were conducted with 5 year old children. Four sessions focused on physical self-concept, 4 on academic self-concept, 8 on social self-concept, and 8 on family self-concept. The Cuestionario de Percepción del Autoconcepto Infantil (PAI; Perception of Child Self-Concept Questionnaire) (Villa & Aus-

The effect of computer based learning as cognitive training for children with autism
Anindita Chatterjee Manovikas Kendra, India; Mahuya Paul
Autism is a developmental disorder where, in spite of little or no intellectual impairment, learning disability is well recorded. The present study is based on action research approach. The purpose of this study is to enhance the learning skill among autism spectrum disorder (ASD) children with a computer pen device. A group of 20 children with mild degree ASD (CARS) with learning disability and average intelligence were selected for the study. The domains were selected as cognition and communication. The areas of cognition focused on in the study were attention, imitation, perception and intelligence (both verbal and performance), and both receptive and expressive communication skills. Computer based intervention (CBI) was given to improve the literacy skills. The study was based on a team work approach involving psychologist and special educator. Focus was on qualitative improvement in learning skill. The areas of intervention have been decided on the basis of priorities set after pre-testing as well as case history as discussed with the care-givers. An individualized education plan (IEP) was set for each child with goals and instructions and a training period for 3 months. Prerequisite skills were assessed on the basis of the Carolina Checklist, followed by training and again reviewing their learning skills. The study has shown a very significant improvement in cognitive skills in comparison to that of communication skill.

Ignorance means getting it wrong: 4 to 6 year old children’s understanding about ignorant beliefs
Yulu Chen Peking University, China; Yanjie Su
Previous researches on theory of mind have investigated preschoolers’ belief understanding, finding that four-year-olds could accurately attribute true and false beliefs. Three experiments involving 182 preschoolers who passed false belief understanding tasks and 99 adults as comparison addressed whether young children could attribute ignorance, beliefs presenting neither true nor false contents. In Experiment 1, participants were told that an agent was going to open two cupboards to fetch the toy but had not seen which cupboard the teacher placed the toy in. The participants were questioned as to which cupboard the agent would open first, why, and whether it was probable that the agent opened the other cupboard first. Most of preschoolers predicted that the agent would open the cupboard without the toy first because of not knowing where the toy was placed. However, most 6-year-olds answered that the agent was also likely to open the other cupboard first, while most 4-year-olds thought it was improbable. Experiment 2 and 3 disconfirmed alternate explanations that placing the object by others as tricking or emphasising the word ‘first’ when questioning led to such results. Findings show that children begin to understand ignorant belief at the age of 6, however, they tend to use the wrong rule of ‘ignorance means getting it wrong’. It suggests that children’s failure to reason other’s mind as accurately as adults may result from falsely using reasoning laws about theory of mind.

Preschoolers’ understanding of the inversion concept of addition and subtraction and its influencing factors
Yinghe Chen Beijing Normal University, China; Shiyong Cao; Congcong Han
The reverse relationship of addition and subtraction is critical in children’s learning of addition and subtraction. Eighty-three children aged four to six participated in this study. The Algebraic Reasoning Paradigm, Cardinal tasks, Magnitude Comparison task, and Running Memory task were administered to examine the developmental trend of their inversion concept about addition and subtraction, and how this trajectory was influenced by Cardinal, Quantity Comparison and Memory-Updating. The results showed that: (1) 4- and 5-year-old children’s accuracy was not above the chance level in non-symbolic or symbolic inverse problems. Few 5- and 5-year-old children solved the inverse problems. However, 6-year-old children showed great progress in both non-symbolic and symbolic inverse problems. Almost half of the 6-year-old children solved the symbolic inverse problems. (2) According to
children’s response patterns, pre-schoolers were prone to one side of addition and subtraction. Usually they did not connect the two operations. (3) Magnitude Comparison and Memory Updating had salient and positive prediction for children’s understanding of the inversion concept. These two factors may play a critical role in pre-schoolers resolving inverse problems. (4) Those pre-schoolers who had already grasped cardinals and those who had not, showed great differences in the development of the inversion concept. However, children’s understanding of the inversion concept cannot be predicted by their knowledge of cardinals.

**Golden snub-nosed monkey (Rhinopithecus roxellana) number cognition**

*Tao Chen, Peking University, China; Yanjie Su*

Number cognition plays an important role in animal and human functioning. Usually number cognition is considered to be controlled by the Object-file model and Analogue Number Model. Our experiments are used to test the ability of Golden snub-nosed monkey. In the experiment, the Relative Numerous Judgment paradigm was used to test the monkeys’ number discriminating ability. The results support the Object-file model. The results are analyzed from an evolutionary perspective. We consider that the living environments of Golden snub-nosed monkeys are vital to their number cognition. Number cognition is a kind of adaptation to environments. Future research could pay attention to environmental influences on number cognition.

**Chinese adolescents’ autonomy in academics and friendship: Its influences**

*Kuei-lan Chen, Art and Law Department, China; Zongkui Zhou; Zhao Zhang*

Self-determination theory asserts that autonomy can predict optimal functioning in social, academic and other domains. The relationships between autonomy, support, and the functioning of adolescents in the academic and friendship domains were explored by questionnaires among 1047 Chinese high school students. A 2 (verbal priming VS nonverbal priming) × 3 (autonomous condition, controlled condition and nondirection group) × 2 (nondirected learning VS conceptual learning) design experiment was conducted to show the relationship between autonomy and text learning. The results showed that: (a) Academic autonomy played a partially mediating role in the relationship between autonomous support from parents and teachers and academic competence. Autonomous support from the mother and teacher could positively predict adolescent academic competence. Autonomous and controlled motivation exerted a combined impact on academic competence. Those with higher scores on academic autonomy scored higher on academic competence and GPA than those with lower scores in academic competence. (b) The experiment indicated that those under the condition of autonomous support got higher scores on the text learning than the controlled group and nondirection group. Girls outperformed boys in text learning. The group under the condition of verbal directions performed significantly better than other groups. (c) Friendship autonomy played a partially mediating role in the relationships between autonomous support from parents and friendship quality. Those who scored higher on friendship autonomy had higher friendship quality while those who scored lower both on autonomous and controlled motivations, got the lowest scores in friendship quality.

**What is more important? Comparison between parents’ and teachers’ beliefs about school readiness**

*Xin Chen, Peking University, China; Yanjie Su; Qing-xue Zhao; Shuang Di*

School readiness refers to all sorts of key characteristics or basic qualifications that preschoolers need to benefit from formal school education. The beliefs of parents, kindergarten teachers, and elementary school teachers about what characteristics are important for school adjustment may influence their educational and evaluational methods. Differences between their beliefs may lead to a series of problems. Though important, research about these issues is still limited in China. According to interviews with 29 parents whose children would enter elementary school several months later, previous interviews with teachers, and the school readiness model of the American National Education Goals Panel, we developed a questionnaire and conducted a survey about parents’ and teachers’ beliefs about school readiness. 348 parents whose children had just entered elementary school, 173 kindergarten teachers, and 318 elementary school teachers answered the questionnaire. The survey results show that Chinese parents and teachers believe the level of preparation for a child to attend school consists of 6 dimensions, namely health and movement, academy related sociality, daily life related sociality, learning capacity, academic knowledge, and ‘hobby’. The average point value of the whole questionnaire and the average point value of most dimensions differs between parents, kindergarten teachers, and elementary school teachers. The structure of Chinese parents’ and teachers’ beliefs suggests that they pay more attention to children’s academic development, and the differences between their beliefs indicate a need for further communication to promote children’s school readiness.

**On the current situation of the psychological development of rural left-at-home children**

*Minxin Cheng, School of Psychology, CCNU, China; Cuiling Fan*

Left-at-home children, who are under 17 years and left at registered permanent residences, mostly in rural districts, by their parents migrated to somewhere else, amount to over 58,000,000, and is a noticeable phenomenon in China. Previous researches revealed inferior positions in psychological developments of left-at-home children compared to other children. Nevertheless, all these results are based on self-reported information of left-at-home children. This study aims to investigate the current psychological development of rural left-at-home children through their teachers’ perspective. By using a questionnaire, a total of 2679 teachers from 49 towns or counties in China were tested to evaluate left-at-home children in General Evaluation, Adaptation in Studying, Morality, and Daily Behaviours, Emotions and Interpersonal Relationship, from 2007 to 2009. The findings show the following: (1) The evaluation of rural left-at-home children’s General Evaluation, Adaptation in Studying, Morality and Daily Behaviours, Emotions and Interpersonal Re-

**Phenomenology of the game culture traditions: Some experience of theoretical reconstruction**

*Anna Chernaya, Southern Federal University, Russian Federation*

The present study was an attempt to the theoretical reconstruction of the game culture traditions as a condition of personality (ontogenetical) development. Vygotskian methodology and objectively-analytical method is applied to the game culture traditions. The subject of the theoretical reconstruction is the main characteristics of ontogenetical development. The data base includes more than 2000 images and descriptions of children, adolescents’, adults’ plays, games, toys, play equipment. The main findings are as follows. (1) Mastering of the subject area of the game culture traditions supports early developmental trends which include subject-manipulations, subject-specific, subject-mediated and subject-replacement actions with natural and utilitarian objects and the archaic toys (a rattle, a top, a ball, etc.). (2) Mastering of the imagery-sign area of the game culture traditions provides the natural sign systems (the body scheme, gesture as a generalised play sign, conventional play signs etc.), the imagery signs in combination with symbolic means. (3) Mastering of the natural area of the game culture traditions forms systems of representations of the natural objects and enriches the individual heuristic experience while interacting with nature. (4) Mastering of the social-normative area of the game culture traditions develops social schemes reflecting “ethnos play biography” and universal social tactics such as social reflections, attractions, personal positions of social tolerance and rigid social norms, it happens only in a game with rules. The results of the research show that the game culture traditions are applied to the practical-oriented sphere of the psychological support of personal development.

**Research on preadolescents’ differential evaluations of normative and deviant members based on conventional and moral norms**

*Fan Cuiling, School of Psychology, Central Ch, China; Zongkui Zhou; Wang Mingzhong*

This study analysed factors that affect children’s evaluation of normative and deviant members based on conventional or moral norms. Generally, adolescents evaluate normative members more positively than deviant members based on conventional as well as moral norms. As the deviant members increase their deviance from the conventional norms, preadolescents show in-group favoritism toward normative members. As their intergroup bias increases, adolescents evaluate conventionally normative members more positively while they evaluate conventionally deviant members more negatively. When their judgment is based on members’ moral behavior, adolescents’ evaluation of members is not affected by the evaluated members’ membership or the evaluator’s intergroup bias.
The relationship between college students' personality traits and loneliness: The mediating effect of self-esteem
Fan Cuiying, School of Psychology, Central Chi, China; Zongkui Zhou; You Zhiq; Fan Cuiying
To explore the relationship model among college students’ personality traits, self-esteem and loneliness, 300 college students were measured with UCLA, SES and EPQ scales. The results indicated that: (1) there was significant gender difference in the loneliness of college students, and females experienced lower loneliness than males, but there was no significant grade difference in it; (2) personality traits, self-esteem and loneliness had significant correlation. Further structural equation modeling analysis showed that personality traits could significantly predict loneliness of college students, and self-esteem had partial mediating effect in the relations between personality traits and loneliness. It is concluded that college students’ loneliness differs according to gender, and self-esteem mediates the relationship between personality traits and loneliness.

Speech as a problem-solving tool in children and young adults: a comparative analysis
Maria Damianova Monash South Africa, South Africa
Founded in Vygotksiy’s (1986) seminal work on speech as an instrument of thought, this study examined the dynamics of speech internalisation and verbal mediation of problem-solving in children and young adults, with specific focus on the use of social, private and inner speech in task execution. A total of 120 preschool, primary school and secondary school children divided into four age groups, and a sample of 15 university students completed the Coloured and the Standard version of the Raven’s Progressive Matrices, respectively. Task completion was video-recorded and utterances produced were classified into three speech types: social, private or inner speech. The results indicated that across childhood and early adulthood, social speech followed a complex polynomial trend, primarily compliant with features of a linear decrease, whereas the occurrence of inner and private speech conformed to a curvilinear trajectory. The profiles of speech production of young children and adults, showed both similarities and differences. Preschoolers used extensively social speech, then private speech and least of all—inner speech. Young adults also preferentially relied on social speech but unlike pre-schoolers, they produced inner speech at a higher rate and engaged minimally with private speech. The findings support Vygotksiy’s view on the role of peer collaboration for mediating individuals’ cognitive functioning and serve as empirical validation that with age, rather than disappearing, private speech “goes underground.” It was concluded that verbal mediation is age-variant and that explicitly social forms of verbal mediation permeate individuals’ cognitive repertoire continually from childhood to adulthood.

Lessons from an evaluation of South African community-based early childhood interventions
Andy Dawes University of Cape Town, South Africa; Lynn Hendricks; Linda Blisterhe; Andrew Dawes
 provision of effective early childhood (ECD) interventions are essential if the risks to child development of malnutrition, poverty, parental illness and depression, and low levels of language and cognitive stimulation are to be mitigated and school outcomes improved. The present study seeks to contribute to the South African evidence-base for interventions to improve cognitive, language and numeracy outcomes in poor children aged 36–60 months. Interventions in five rural and informal communities were evaluated. They included holistic two-generation home visiting interventions, community playgroups, and community preschool practitioner training. Children’s growth status was assessed at baseline, and cognitive and language development was assessed at three data points: Baseline, on completion of the intervention, and in Grade R (the year prior to formal schooling). In Grade R, 270 children who had attended one of the interventions were compared to those who had not been in a programme. The study found that children whose caregivers had received home visiting did not make significant developmental gains. High levels of participation in playgroups increased the odds of being within the norm for age for cognition; hierarchical regression showed that growth status (weight for height Z score), and baseline cognitive level moderated the effects of this intervention on cognitive and language outcomes. Children who had attended preschools performed better on all domains when compared to children from the same communities who had no ECD inputs or who had received home visits or community playgroups. Implications for programming are discussed.

The influence of adolescents’ personality and self-regulation on PIU
Li Dongmei The Department of Psychology, China
Pathological Internet Use (PIU) has been an important focus in recent years. This study explored the relationships among personality, self regulation and PIU of 306 Chinese adolescents. The results show that: First, there has been a significant interaction effect between gender and grade on PIU. Second, adolescents’ self regulation has a significant direct negative effect on PIU. Third, neuroticism has an indirect influence on PIU through self regulation. Finally, conscientiousness has a significant direct negative effect on PIU, and it also has an indirect effect on PIU through self regulation.

Influence of senior high school students’ implicit personality theory on their learning motivation and confidence
Xiaoji Duan Institute of Psychology, CAS, China; Jianlong Shi; Ting Tao
Dweck distinguishes between two implicit personality theories of intelligence. Those who have an “entity theory” believe that intelligence is a stable entity and will not change. This should generally be seen as maladaptive. Those who have an “incremental theory” believe that their success is based on hard work and learning. This should generally be seen as adaptive. In contrast, Albert postulates that Dweck’s entity theory should have maladaptive consequences if a person shows ability deficits and it should have positive consequences if a person shows high abilities. Furthermore, they also postulate that an incremental theory and therewith the firm belief that aspects of one’s own self can be modified is of particular importance when dealing with deficiencies of one’s own ability. These are called “stability belief” and “modifiability belief” respectively. The present study focused on the influence of senior high school students’ implicit personality theory on their learning motivation and confidence. The participants included 332 senior high school students aged 15 to 18. The students were asked to complete questionnaires concerning implicit personality theory, learning motivation and confidence. The results showed that Dweck’s implicit theory can significantly predict performance goal approach and performance goal avoidance positively, while stability belief and modifiability belief can significantly predict mastery goal, performance goal approach and learning confidence positively. These findings showed that Zielger’s theory is more suitable in explaining children’s motivation and confidence.

Perceived economic strain and parent-adolescent relationships: The adolescents’ and parents’ perspective
Aysun Ergul Ankara University, Turkey; Aysen Gure
In recent years, a growing number of researchers have indicated that economic strain in a family negatively influences parental behaviours and the nature of parent-child relationships. It has been proposed that the experience of economic strain is psychologically stressful for both adolescents and parents, which undermines the quality of family relationships. The aim of the current study is to investigate the extent to which both adolescent’s perceived and family’s experienced economic strain predict parent-child behaviour and the quality of parent-adolescent relationships. The present study included 364 male and female students from secondary and high schools and their mothers and fathers. Perceived Economic Strain Scale, Parenting Behaviour Questionnaire and Quality of the Parent-Adolescent Relationship, and an Economic Measures Index were used for collecting data. For secondary school, preliminary analyses showed that adolescents’ reports of economic strain negatively predicted both mothers’ and fathers’ support and positive quality of relationship. While mothers’ reports of financial cutbacks negatively predicted support, fathers’ reports of financial concerns negatively predicted authoritative control. Furthermore, mothers’ and fathers’ reports of financial concerns negatively predicted positive quality of relationship. For high school, results indicated those only fathers’ reports of financial concerns negatively predicted authoritative control. In general, the findings revealed that there is a different pattern of relationships between perceived economic strain and parent-adolescent relationship for both parents and adolescents.

Body mass index, teasing, eating disorders and social anxiety: the mediation effect of body dissatisfaction among Chinese female university students
Ping Fan Central China Normal University, China; Zongkui Zhou
Body dissatisfaction is one essential aspect of body image, relating to an individual’s degree of dissatisfaction with particular parts of the body. Disagreement exists regarding the influential factors of body dissatisfaction, the relation between body dissatisfaction, eating disorders and social anxiety, that may be more complex than is often implied in
previous literature. The present study was to investigate the relationship between Body Mass Index (BMI), perceived teasing, eating disorders, social anxiety and body dissatisfaction of female university students. The negative physical self scale (NPSS), the perception of teasing scale (TPTS), abnormal eating disorders scale (AEDS) and interaction anxiety scale (IAS) were administered to 293 female university students. Major results are as follows: (1) BMI groups of female students (low weight group, normal group, overweight group, obesity group) were significantly different on fat dimension, whole dimension and total score. The score of obesity group female students was significantly higher than the low weight, normal and overweight groups (p<0.01). (2) Eating disorders were significantly related to BMI (r=0.16, p<0.01), perceived teasing (r=0.26, p<0.01), body dissatisfaction (r=0.45, p<0.01) and social anxiety (r=0.21, p<0.01). Social anxiety was significantly related to perceived teasing (r=0.22, p<0.01), body dissatisfaction (r=0.29, p<0.01). (3) Structural equation modelling analysis indicated BMI exerted, and had its influence on, eating disorders through body dissatisfaction, and teasing exerted, and had its influence on eating disorders and social anxiety through body dissatisfaction.

Criterion and predictive validity of Child Development Scale
Diana Fecene
Psychological Test Laboratory, Poland

The subject of this presentation is to discuss validation studies of the Child Development Scale (a test created and published by the Psychological Tests Laboratory of Polish Psychological Association). The Child Development Scale is a tool for measuring the current level of development of young children (3–36 months). Validity was tested in two aspects: criterion-related and predictive criterion validity. Studies involved comparing the results of the clinical group (N = 32), consisting of the children with suspected neurological disorders (aged from 3 to 12 months) with the results of the control group (normalisation sample). Results obtained by comparison of overall performance distributions in both groups as well as the distribution of subtest scores have confirmed the criterion validity of the tool – in comparison to the normal population significantly smaller percentage of children with suspected neurological disorders obtained average or high scores. Analysis also indicated Motor Performance subtest as the most discriminating factor between different regions, grades, ethnic groups and between single child and those who have brothers or sisters. However, there was no significant evidence that the interactions at home, at school and in the street have their own dynamics. For children, school is a place to live their childhood. Children are not passive in situations of entertainment, they are dynamic actors. They point out that play is part of life and therefore part of their childhoods, marking their social and emotional relationships with adults, other children and animals. They do not express a single representation of childhood, but have different perspectives. The research contributes to the elucidation of the multiple ways of living a childhood, and that work with children needs to take into account their own ways of understanding their childhoods.

The role of motivation for development and the role of development for motivation
Alexandra Freund
University of Zurich, Switzerland

One of the most striking changes across the lifespan is the changing ratio of developmental gains and losses. Whereas younger ages are best characterized as times of acquiring new skills and resources and relatively few losses, middle and particularly older adulthood are affected by increasing losses. The losses are particularly prevalent in physical and cognitive functioning, social roles, as well as remaining lifetime. In this talk, I will argue with changes in resources affect motivational processes, which in turn influence developmental outcomes. More specifically, I will present studies centering around three key motivational constructs: (1) goal orientation, (2) goal focus, (3) interrelations among goals. For all three constructs, I will show developmental trends as well as age-related differences in their consequences. Taken together, the empirical studies suggest that motivational changes are subject to the changing ratio of gains and losses and help in managing the acquisition and maintenance of, and coping with losses of resources. In conclusion, I will argue that age matters for understanding motivation and that motivation matters for understanding development.

Research on parent-adolescent cohesion and parental awareness of adolescent parents
Minghong Fu Yunnan Normal University, China

To understand the relationship between parent-adolescent cohesion and parental awareness, a questionnaire (Robinson et al., 1995), Torrance Tests of Creative Thinking (Torrance, 1993), and a curiosity test developed and validated by the authors. Analyses of the data revealed that child rearing practices were associated with creativity in students. High school students who were raised by the democratic style were higher in creativity; their scores were especially higher in the originality sub-scale of the creative thinking scale. In addition, data revealed that mothers with accepting attitudes and style of parenting raised more curious children. The current study revealed that child-rearing styles were effective in the nurturing of creative thinking and curiosity of adolescents who were studying in high schools. Theoretical implications and practical applications of the study have been delineated in the original paper.

Numerical abilities of school-age children with developmental coordination disorder
Alice Gomez INSERM U562 Unité de Neuroimagerie, France; Stanislas Dehaene; Ghislaine Dehaene-Lambertz; Karla Monzalvo; Antoinette Jodar; Caroline Huron; Manuela Piazza

Developmental Coordination Disorder (DCD) is characterized by a marked impairment in the development of motor coordination, interfering significantly with academic achievement or activities of daily living, which cannot be attributed to mental retardation or general medical condition. Most studies conducted in DCD have focused on motor capacities, showing that children with DCD show deficits and larger variability in a wide range of motor activities (e.g., finger tapping, ball catching, hand foot coordination, and writing). These deficits no significant difference between different ethnic groups of China. (2) Parental awareness of adolescent parents showed significant differences between different regions, grades, ethnic groups and between single child and those who have brothers or sisters. However, there was no significant evidence that could link change of genders to change of parental awareness of parent-adolescent relationship. (3) The stronger the parental awareness of adolescent parents has, the better the relationships between adolescents and their parents are. The correlation coefficient between parent-adolescent relationship and the parental awareness of the parents shows significant difference between different genders, grades and between single child and those who have brothers or sisters. There are no significant differences between different ethnic groups and different regions.

Relationship between child-rearing styles with creativity and curiosity of female high school students in Tehran
Bagher Ghobari Bonab University of Tehran, Islamic Republic of Iran; Marzieh Dousti University of Tehran, Islamic Republic of Iran

The aim of the study was to investigate the relationship among child-rearing practices and (democratic versus authoritarian, accepting versus rejecting, permissive versus authoritative), creativity, and curiosity in high school students. Two hundred students were selected by means of multistage cluster sampling from high schools located in Tehran, the capital city of Iran, and the following instruments were administered: parenting style questionnaire (Robinson et al., 1995), Torrance Tests of Creative Thinking (Torrance, 1993), and a curiosity test developed and validated by the authors. Analyses of the data revealed that child rearing practices were associated with creativity in students. High school students who were raised by the democratic style were higher in creativity; their scores were especially higher in the originality sub-scale of the creative thinking scale. In addition, data revealed that mothers with accepting attitudes and style of parenting raised more curious children. The current study revealed that child-rearing styles were effective in the nurturing of creative thinking and curiosity of adolescents who were studying in high schools. Theoretical implications and practical applications of the study have been delineated in the original paper.

How children represent childhood from the use of drawings of a free day
Marcia Franco Cesuca Faculdade INEDI, Brazil

Education, society and childhood, raise discourses and knowledge that must be understood. The objective of this presentation is to understand the possibilities of childhood as articulated in the vision of children aged 6 to 12 years of Cachoeirinha, municipality of Rio Grande do Sul – Brazil. This study’s sample consisted of 134 volunteers. The study used the instrument known as a “test of episodes”, material used by Schmid-Kitsikis (1994). Data was analysed using content analysis with categories based on the talk and drawings of the child participants. The analysis identified seven categories and three spaces (home, street, school) that the children inhabit during the day. The data clearly indicate that the interactions at home, at school and in the street have their own dynamics. For children, school is a place to live their childhood. Children are not passive in situations of entertainment, they are dynamic actors. They point out that play is part of life and therefore part of their childhoods, marking their social and emotional relationships with adults, other children and animals. They do not express a single representation of childhood, but have different perspectives. The research contributes to the elucidation of the multiple ways of living a childhood, and that work with children needs to take into account their own ways of understanding their childhoods.

Developmental
could be due to a dysfunction of parietal regions (e.g., Zwicker, 2009, Wilson et al., 1997). Although educational psychologists and teachers often report that children with DCD have difficulties with numerical aspects of mathematics, there appears to be no detailed published research (Yeo, 2007). We aim to compare the behavioural performance of children (ranging from 7–10 years old) with DCD (score on the Movement Assessment Battery for Children

The role of children's empathy-related responding and emotion regulation in the prediction of prosocial behavior

Mandy Grumm Goethe-University & IDeA, Germany; Michael Fingerle; Sascha Hein

Empathy plays a pivotal role in various processes of social adjustment and competence during child development. Recently it has been argued that socially competent behavior (e.g., prosocial behavior) depends not solely on the level of empathy but also on the ability to regulate vicariously experienced emotions. The main goal of the present study was to predict children’s prosocial behavioral tendencies with the help of situational empathy-related responding (assessed with the help of an interview procedure) and dispositional empathy (assessed with the help of questionnaires). Particularly, it was hypothesized that situational empathy depends on emotion regulation skills, especially when an emotional experience occurred. A sample of 157 children in the fourth-grade of elementary schools participated in a two-tiered interview procedure that used situational descriptions to assess aspects of situational empathy. In both steps, children were asked to read a story about a character in distress, which is argued to elicit sadness in the children. Children were then asked questions that captured aspects of situational empathy and prosocial behavior. Between these two blocks children were asked to recall a situation in which they felt sad. Results from a latent difference model indicated that the increase in situational empathy and prosocial behavioral tendencies from block one to block two was significantly predicted by emotion regulation skills. The implications of this study will be discussed on the background of prevention programs that foster empathy-related skills and emotion regulation.

Linking social validity and effectiveness of aggression prevention

Mandy Grumm Goethe-University & IDeA, Germany; Michael Fingerle; Sascha Hein

Many programmes aimed at preventing aggressive behaviours have been implemented at German schools. However, only a few studies take individual perceptions (social validity) of participants into account. This contribution attempts to emphasise the importance of social validity in the prevention of aggressive behaviours. Social validity refers to the level of acceptance associated with a prevention programme and three major components can be distinguished (importance of goals, appropriateness of methods and importance of effects). Results of three research projects will be presented and it will be outlined how children perceive aggression prevention programmes and how effectiveness and acceptance are related. In this research project, children in elementary schools were asked to fill in questionnaires prior to and after the completion of prevention programmes. The results indicated that some children evaluated the effects of prevention programmes as important, while others devalued the effects of the programme. These individual perceptions can be crucial for the transfer of programme contents into the everyday life. Moreover, it could be demonstrated that individual evaluations of the programme were differentially related to pre-post test changes in the prevention studies. Findings will be discussed with regard to the further development of aggression prevention programmes. We should gain broader insights into the contents that are evaluated as socially valid in addition to knowledge that we already have about the effectiveness of a programme, because this might enable us to make prevention more developmentally appropriate.

The situational effect of social creativity of primary school children: An empirical study

Chuanhua Gu Central China Normal University, China

To investigate the effect of interactive situations of social creativity, 194 primary school children (third to sixth graders, 113 boys, 81 girls) with a mean age of 10.5 years were sampled randomly to be interviewed individually based on nine hypothetical life situations and three true life situations in which participants’ responses were rated by five postgraduates according to the same criteria. The differences between social creativity in hypothetical situations and that in true situations, and among social creativity in the three situations of peer relationships, the teacher-student relationship, and the parent-child relationship, were analyzed with a paired samples T-Test and repeated measures F-test. The findings indicated that significant situational effects existed on social creativity of primary school children, and overall social creativity, originality, fluency, flexibility, complexity, risk-taking, curiosity, appropriateness, and validity in hypothetical situations were more remarkable than those in true situations. Furthermore, overall social creativity, originality, fluency, flexibility, and risk-taking in teacher-student situations were more remarkable than those in peer and parent-child situations, and appropriateness and validity were the reverse. In addition, curiosity in peer situations was stronger than that in the other two situations. This implies that social creativity in true situations should be discriminated from that in hypothetical situations, and the interaction of teachers with students in Chinese culture should be strengthened to improve social creativity of primary school children.

An ecological approach to intervention development: The Early Home Learning Study

Naomi Hackworth Preventing Parenting Research Centre, Australia; Jan Nicholson; Donna Berthelsen; Misel Trnovaski; Warren Cann; Jan Matthews

Research indicates that an ecological approach to intervention development leads to programs that have greater feasibility, effectiveness and sustainability. Furthermore, thorough planning with the involvement of end users when developing interventions makes it more likely that they will be delivered as planned and achieve the desired outcomes. The aim of the Early Home Learning Study is to develop, implement and conduct a cluster randomised controlled trial of smalltalk. This community based parenting intervention aims to support parents facing vulnerable circumstances to provide an enriched home learning environment for their very young children. It is designed for delivery through two existing service delivery platforms - Maternal and Child Health and supported playgroups. This paper documents the collaborative process undertaken in the development of smalltalk to ensure its optimal tailoring for the service contexts. The paper considers the way in which collaboration with end users, including families and service providers informed the development of content, materials and mode of delivery and reports data on the potential impact that this has had on acceptability of intervention inputs, processes and attrition. The design enabled the successful recruitment to the study of parents with high rates of risk factors for poor parenting compared to a normative Australian sample. 93% reporting socio-economic disadvantage, mental health difficulties and/or low parenting competence, and 73% had problems across one or more risk factors. Rates of participant recruitment and retention to 4–5 month follow-up are very high relative to those achieved by other Australian and international trials with similar populations.

Development of number line representation in 2–4 grade Chinese children with mathematical learning disability

Congcong Han Beijing Normal University, China; Yinghe Chen

Children with a mathematical learning disability (MLD, n = 21 in 2nd, n = 23 in 3rd, n = 26 in 4th) and low achieving (LA, n = 24 in 2nd, n = 31 in 3rd, n = 35 in 4th) children were identified using
Caregiver–child attachment classification styles as correlates of treatment compliance among HIV-positive children

Given Hapunda University of Zambia, Zambia

Taking anti-HIV medication consistently and properly is a critical issue for patients infected with HIV. Drug regimens are complex and when not taken properly, HIV can become resistant to the drug. Children and adolescents infected with HIV face unique challenges of taking HIV medication properly, partly because of their social, emotional and behavioral proclivities. Weinfeld et al. (1999) postulated that most emotional and behavioural predispositions of children are a result of the nature of the caregiver–child attachment. The nature of the attachment is a strong predictor of social and behavioural outcomes in different situations. Thus, the purpose of this study was to examine the relationship between caregiver–child attachment and treatment compliance among HIV-positive children. Forty (40) participants were recruited from health centres. The sample consisted of 20 caregivers and 20 of their HIV-positive children aged 3-5 years. All caregivers who consented to participate in the study responded to a number of questionnaires and the children completed the Attachment Story Completion Task (ASCT). A chi-square test showed that there was a significant relationship between compliance to treatment and caregiver–child attachment. The results support that a significant amount of the variance in the score of compliance to treatment is accounted for by the nature of the caregiver–child attachment. Therefore, interventions that aim to maximise caregiver–child attachment should be incorporated in clinical practice.

Early precursors of school achievement in reading and mathematics

Marcus Hasselhorn German Institute for International Educational Research, Germany

In this symposium, we discuss various approaches to identify important precursors of reading and mathematics performance that can already assessed either before school entrance or immediately thereafter. Researchers from Austria, Germany, Switzerland, and the United Kingdom will present longitudinal studies. For instance, using a very large database of tens of thousands of children in England, Peter Tymms, Christine Merrell and their colleagues assessed the relative importance of measures collected at the ages of 3, 4, 5 and 6 to attainment in reading and maths at age 11, as well as characteristics of the schools and the teachers included in this study. These data come from large-scale monitoring projects run by the Centre for Evaluation and Monitoring at Durham University, UK, with data representative of the country. In a German study supervised by Marcus Hasselhorn, Wolfgang Schneider and their colleagues, a large sample of kindergarten children were recruited about 18 months before entering elementary school and carefully screened regarding their cognitive competencies. Children at-risk were given specific treatments during the last year of kindergarten, and long-term effects on school performance in reading and maths were subsequently assessed. Similar approaches were used by Karin Landerl and her colleagues in Austria and Alexander Grob and his team in Switzerland. One major aim of the symposium is to identify early precursors of subsequent school achievement that seem to be influential in all of the countries represented in this symposium.

Enhancing methods to address the needs of diverse learners

Gopalakriahnan Hemalatha IASE, SAIDAPET, Chennai; India

The purpose of the study is to investigate the suitable instructional methods to address the needs of diverse learners. The investigator has chosen pictorial representation, multimedia representation and democratic interactive methods for satisfying the needs of 200 diverse learners at higher secondary level based on their learning style, attention, memory power and academic performance. Research was conducted in the frame work of multiple group repeated measures experimental design model. The sample was classified based on their language fluency, intelligent quotient (IQ) and academic performance. The instruments used to collect data for this study were: (1) Kolb’s learning style inventory (2005) (2) Memory tool prepared by Hemalatha and Saraladevi (2011) (3) Attention tool by De W Vos and Schepers (1993). Three methods were adopted for all the groups for about six weeks. Pre-test, Post-test measures were collected from the sample and analysed through t-test, product moment correlation, two way ANOVA and stepwise partial regression analysis. The results confirmed that the different methods had influenced their learning style, memory, attention and academic performance differently for different types of learners. It was also concluded that multimedia presentation remarkably promoted the level of visual learning, academic performance, attention and memory levels of sample.

Effectiveness of storytelling therapy on the reduction of aggression and stubbornness in children with oppositional defiant disorder

Samaneh Hosseini Science and Resarch Azad University, Islamic Republic of Iran; Ghassem Naziry Science and Research Azad University, Islamic Republic of Iran

Storytelling is as old as human history. The aim of the present history is to evaluate the effects of storytelling therapy in decreasing aggressive and oppositional behaviors in 7 to 9 year old children with oppositional defiant disorder. In a semi-experimental study, 20 children with oppositional defiant disorder in the 7 to 9 year old age group were randomly assigned to control wait list and storytelling groups. The cases in the storytelling group received 12 sessions of storytelling therapy twice a week. Both groups were studied before the intervention, and after 6 weeks, using behavioral disorder questionnaire, aggression inventory, oppositionality inventory, and clinical interview. There were significant reductions in the scores of all of the above mentioned questionnaires in the storytelling group after six weeks. Storytelling may be a useful method in the treatment of children with oppositional and aggressive behaviours.

Migration experience, resilience and mental health outcomes: A mixed-methods study of Iranian immigrants in Australia

Ashrafalsadat Hosseini University of Melbourne, Australia; Melanie Donven; William Evans; Ritsuko Kakuma; Harry Minas

Mental health problems are an increasing problem in Australia and worldwide. The World Health Organisation (WHO, 2010) has predicted that Depression will be the number one health issue in the world in 2020. Psychologists and mental health professionals have increasingly shifted their research focus to exploring human talents and capabilities rather than the previous sole preoccupation with abnormalities and impairments. The complexity of resilience as both outcome and process has been linked to wellbeing in a wide range of populations and contexts (Garmezy & Masten, 1991). Improved knowledge of factors that determine resilience can provide a foundation for a comprehensive and integrated approach that considers illness and pathology and that seeks to understand and enhance health and wellbeing. The process of immigration is complex in that it encompasses a wide variety of motivations and personal experiences of migrants. This study addresses the relationship between migration experiences, socio-demographic factors, resilience and mental health outcomes (subjective wellbeing, depression, stress and anxiety) in Iranian immigrants living in Australia. A mixed methods design, with qualitative and quantitative data collected, will be used. Qualitative and quantitative data will be used for a more in depth exploration of resilience factors and their relationships with migration experiences, socio-demographic factors, resilience and mental health outcomes, than could be provided by either questionnaire or interview data alone (Creswell & PlanoClark, 2011). The findings will be used to inform intervention programmes that seek to assist with adaptation issues, promote individual wellbeing, and to realize the full potential of Iranian immigrants in Australian society.

The relationship between forgiveness and wellbeing

Ashrafalsadat Hosseini University of Melbourne, Australia; Zahra Hosseini; Hadis Aryanpur

The purpose of this research was to examine the association between forgiveness and well-being.
This study investigated forgiveness and well-being in couples who were selected by convenient sampling in Tehran, Iran. Demographic questionnaires, the Family Forgiveness Scale (FFS) and General Health Questionnaire (GHQ-28) were used. The result of the study demonstrates a positive relationship between forgiveness and well-being (r=.54). Findings reveal the correlation between high level of forgiveness and less anxiety and depression. Results also show a meaningful association between forgiveness with age (r = .14), marital duration (r=.11) and education levels of couples (r=.21). However, it does not show any significant relationship between the number of children and forgiveness. According to further results of this study, there is a difference in the level of forgiveness between couples as men show a higher level of forgiveness than women. The results of this study inform intervention programs that seek to assist couples’ well-being.

The relationships between personality traits, peer relations, and social adjustments in Taiwanese adolescents

Kung-Yu Hsu National Chung Cheng University, Taiwan, R.O.C.

The main purpose of this study is to examine the direct and mediated effects of temperament and peer relations on internalizing and externalizing problem behaviours (IPBs and EPBs) in Taiwanese adolescents. Two main research questions were investigated: (1) Does peer relation mediate the influence of personality traits on IPBs and EPBs? (2) Does IPBs and EPBs have impacts on peer relations? A two-year research was conducted. There were 1375 adolescents, between the ages of 13 to 16, followed for up to two years. In the first and second years, Youth Self-Report was used to measure Adolescent’s IPBs (Anxiety, Somatic Complain, and Social Withdrawal) and EPBs (Aggression and Rule-breaking). In the second year peer nomination in a class was used to measure the sociometric and perceived popularity, and HEXACO-PI-R was used to measure the participants’ six personality traits (Honesty/humility, Emotionality, Extraversion, Agreeableness, Conscientiousness, and Openness). After controlling the effects of IPBs and EPBs during the first year, the only mediated effects that was found was that the effects of Agreeableness on Aggression were partially mediated by the effects of sociometric popularity. Rule-breaking had negative impacts and anxiety had positive impacts on two kinds of popularities only for girls, after controlling all of the problem behaviours at first year. The cultural and gender implications for the relationships among personality traits, peer relation and social adjustment are discussed.

Research on the characteristics of mobile media and its influences upon adolescent values

Quiping Hui Xinyang Normal University, China; Anming He Xinyang Normal University, China

With the coming of the 3G age, the mobile phone has become the emerging fifth mass media after the newspapers, radio, TV and the internet. In the mobile media age, the proportion of adolescents who are using mobile phones is increasing quickly, while originally only graduates used mobile phones, more and more adolescents have become part of the "mobile generation". As a new social factor, mobile media affects the formation and development of adolescent values via its unprecedented fashion and power, moreover, it impacts upon their healthy growth and success. This paper aimed to address the limitations of current studies, focusing on the scientific development of youth values as a research perspective, uniting qualitative and quantitative approaches and the macro and micro harmoniously. This paper not only analyses the mobile media characteristics of a huge user group, with wide-area coverage, low threshold, real-time, and portability, bearing rich information, but also systematically explores its positive and negative influences upon all aspects of values including political values, moral values, interpersonal values, academic values, and self-values.

The development of adolescents’ internalization of parental authority

Chang Hui-Tzu National Chiao Tung University, Taiwan, R.O.C.

Research has shown that the different perceptions of legitimacy of parental authority often result in parent-adolescent conflict. Although studies have demonstrated that the legitimacy of parental authority decreases as adolescents increase in age, recognition of parental authority, to some extent, indicates an acceptance of parental values that are primarily informed by social convention. This study attempted to explore how adolescents internalize parental authority. An in-depth interview was used to understand the process of internalization of parental authority. A total of 171 adolescents (81 boys and 90 girls; 58 fifth grade, 59 eighth grade and 54 eleventh grade) from Taiwan participated in the study. Data were collected in 2008. The results showed that there were four types of internalization of parental authority on the part of adolescents: (1) 'Obedience to authority', which refers to that adolescent obedience to parental authority due to external factors, such as fear of punishment. (2) 'Trust of authority', which indicates that adolescents agree with authority because parents are doing something for their own good. (3) 'Identification of authority', which refers to adolescents identifying parental authority, but simultaneously doubting whether that authority is absolutely right. (4) 'Negotiation of authority', which indicates that adolescents negotiate with parents about what should be done by stating and discussing the positions of both parties. In conclusion, this study found four types of internalization of parental authority: obedience to authority, trust of authority, identification of authority, and negotiation of authority. There is a developmental trend of the authority types, with identification and negotiation of authority more likely to be shown in older age groups.

Empirical study of professional-parent-child interaction in healthcare decision-making

Coyne Imelda Trinity College Dublin, Ireland

The aim of this study is to investigate children’s participation in decision-making from the perspectives of children and adolescents, their parents, and healthcare professionals. Through voice, it is argued, children’s views can be asserted and represented as valid in their own right with respect to their perspectives and understanding of the social world. There is now greater recognition of the power imbalances between adults and children which has led to increased focus on uncovering the different roles parents, children and health professionals occupy in triadic healthcare interactions. Data were obtained from 70 participants via interviews, observations and focus groups. The sample consisted of hospitalised children aged 7-16 years.
A limited time perspective causes preferential visual fixation on positive stimuli

Aleksandra Jaskolowska, Warsaw School of Social Science, Poland; Marzena Cypryanska; Izabela Krejtz; Alicja Kulawiak

Recent findings suggest that the limited time perspective related to advanced age may be the key variable in the motivational shift in emotion regulation towards the positivity bias. An experimental study disentangles the motivational effects of the limited time perspective from chronological age on the positivity bias in visual attention. The eye-tracking methodology was used to examine visual fixations on faces expressing positive vs. negative emotions (vs. neutral) in the limited life-time perspective vs. mortality salience vs. neutral conditions among young adults. The results confirm that the limited time perspective causes a positivity bias in emotional regulation at an early stage of information processing, following visual scrutiny. Young adults gazed more at happy than at sad or neutral faces, when they were asked to imagine they had only 3 years to live, than they did in the neutral conditions or when asked to imagine they will die in 3 years. The results support findings of previous studies for young adults in neutral conditions. The participants paid more visual attention to sad and fearful faces than happy and neutral ones. The present findings are discussed in light of the socio-emotional selectivity theory. These findings have an applied value suggesting that temporary changes to the time perspective result in attention bias towards positive emotional stimuli. Under mortality salience the participants fixated their gaze on fearful, happy and disgusted faces more than on neutral ones. These results are consistent with the terror management theory literature.

A comparison of the interactive play behaviours between children with albinism and their siblings and children without albinism and their non-albino siblings

Gwatinera Javangwe, University of Zimbabwe, Zimbabwe; Rachel Mukondyo

The study explored the nature of the interactive play behaviours of children with albinism and their siblings and children without albinism and their non-albino siblings and compared the interactive behaviours of both children with albinism and children without albinism. After obtaining parental consent and the children’s assent, a total of 16 participants were recruited through snowballing and were divided into two groups, the experimental group and the control group. The children came from 8 families. Naturalistic observations were conducted during 15 minute periods of free play, using the interactive play behaviour checklist aided by video recordings on three different days. The children were observed within their homes. The children were aged between six and eight years with a mean age of 6.75 with a standard deviation of 0.88. The findings of the study showed that children without albinism showed more pro-social play behaviours, aggressive play behaviours, affiliative play behaviours and possession-related play behaviours, compared to children with albinism. A significant difference was noted in the pro-social and possession-related play behaviours between children with albinism and children without albinism. Children without albinism showed more interactive play behaviours compared with children with albinism. Both groups of children showed the same amount of aggressive and affiliative play behaviours, while children without albinism showed more pro-social and possession-related behaviours.

Toward a socially responsible psychology of human development

Cigdem Kaglicibas; Koc University, Turkey

‘Psychology Serving Humanity’, the title of the congress, could very well be the title of this presentation. Throughout the decades I have been involved in psychology, I have been increasingly concerned with its vision and mission of serving human well-being. Has this vision/mission been accepted and recognized by both the community of psychologists and by the outside world? And more importantly, has it been realized? Is it hard to answer these questions in the affirmative. There are many factors responsible for this situation. One is the predominantly individual focus of psychology which renders it rather ‘irrelevant’ to the attempts at solving some large scale human problems. Related to this, there is the image of psychology as a ‘Western’ endeavor. Another factor is the persistent tendency of favoring ‘experimental’ over ‘applied’ research. These issues are not insurmountable as some recent work combining sound scientific methodology and a socially relevant problem-oriented approach has demonstrated. In particular, developmental perspectives which also take into consideration changing contexts and adaptation to them promise to contribute to human well-being. Intervention research projects carried out in early childhood and early adolescence are discussed as cases in point. Such studies, emerging from various countries, exemplify how research can lead to policy and sustainable applications serving the developing child. They also contribute in significant ways to our understanding of human development and thus to our psychological science.

Image perception problems as a component of sense-value space: theoretical understanding

Zhanna Kara; Southern Federal University, Russian Federation

Psychology tries to look into the inner life of a person more deeply. Therefore, the problem of studying different forms of non-perceptual figurative phenomena of a multivariate description in the inner life of a person is raised. One of the forms of displays of a person’s inner life are figurative phenomena, such as images of imagination, how the individual views images about himself/herself and the world, images of memory, fantasies, dreams, etc. There is an interrelation of figurative and personal components in an acute psychological problem of a personal-sense comprehension by a person of all completeness of subjective experience. Secondary images can be determined as images of subjects and phenomena, having their existence in the person’s subjective world in the absence of prototype-stimulator directly effecting them. But a powerful component of psychological constituents, namely the person’s secondary images, can be a presence of his/her own personal sense as it is included in a subclass of regulatory sense structures directly influencing processes of activity and mental reflection. Personal sense presented in secondary images is also a necessary condition for forming sense-creating components of person’s sense sphere. There is always a subjective personal predilection in an image. During direct perception and representation, objects and phenomena of the reality appear in us ‘painted’ in that personal sense which they have for us owing to the objective place taken in our life and in the realization of our needs. Thus, we can emphasise the urgency and the demand of the given research direction determined by science and society.

The motivations of altruistic behaviour in young children

Zhang Kang; Peking University, China; Yanjie Su

Altruistic behaviour is a specific form of pro-social behaviour. The aim of this study was to explore the motivation of altruistic behaviour. The altruistic behaviour of 4 to 6 year old preschoolers (n=120) was investigated using a two-alternative choice task, which focused on the process of sharing. In the preliminary experiment, children with altruistic behaviours were selected by testing whether they would deliver tokens to their partner at no cost. Thereafter, 53 preschoolers with altruistic tendencies participated in the formal experiment, which was designed to explore the reason why children would behave altruistically using the two-alternative choice task. Results showed that there were three kinds of children who could be altruistic. The first kind of child could serve the tokens only in the condition of no cost to themselves, the second kind of child could deliver the tokens when the partner had nothing, and the third kind of child could share the tokens equally. Moreover, altruistic behaviour was strongly shaped by the cost of being altruistic. These findings indicated that other regarding preference, empathy, and fairness might be the motivations of children’s altruistic behaviour, in other words, altruistic behaviour was motivated by several factors jointly and were shaped selectively by the cost of altruistic behaviour.

Insights to resiliency: Examining values in the acculturation process of African emerging adults in Canada

Ernest Khlemo; HSRC, South Africa; Sophie Yohani; HSRC, South Africa; Rosslynn Zulla; HSRC, South Africa

Whilst the concept of acculturation has been a well-recognised and important area of study (Berry,
Life-sense strategy as a trajectory of a person’s development: Theoretical research

Liudmila Kruteleva Southern Federal University, Russian Federation

The sense-value sphere of each person is strictly individual and is being formed during ontogenesis on the basis of assimilation of personal experience and culture in which the individual develops. The Life-sense strategy of a person is a complex mental formation, an inside-reduced program of a possible action, determined by content and motivational-dynamic structural elements of the person’s sense-value sphere. The basic components of a person’s life-sense strategy are: (1) deep life-sense orientations which are shown as an attitude of the person to the world and to himself/herself and determine his/her cognitive orientation; (2) the life-sense conception which includes a hierarchical system of sense-value structures of the person and represents an individual generalized system of views on purposes, process and results of the own life; features of self-actualization; a self-appraisal and motivation system. The life-sense strategy sets a trajectory of the person’s development and optimizes his/her activity in interrelations with the objective reality. Its dynamic character means flexibility and an opportunity for change depending on certain conditions of daily life, and also the person’s constant assimilation of socio-cultural values and senses. A person has usually got a whole complex of various life-sense strategies produced in the course of life. Each of them, pursuing one and the same main purpose, includes different contents, i.e. different sense-value sub-goals of which achievement is accompanied by different behavioural responses. Quantity and quality of the strategies which the person can possess are not potentially limited and depend on individual experience and sense-value orientations of each particular person.

An empirical look at the relation between language and emotional competence in child development

Irina Kumschick Excellence-Cluster Languages of Emotion, Germany; Luna Beck; Michael Eid; Gisela Klann-Delius

Whether there is any relation between emotion and language is a controversial issue, which has not been a prominent one in developmental research. In recent years, some studies have supported the view that language and emotional competence might be related. This research has focused on the early stages of childhood. It is still an open question whether emotional competence and language competence are related in later stages of development. As the transition from kindergarten to school constitutes a sensitive period for socio-emotional and cognitive development, this is an important issue. Thus, the purpose of this interdisciplinary study was to evaluate whether language competence continues to be related to children’s emotional competence once they reach middle childhood. More specifically, our aim was to examine which of the components of language and emotional competences contribute most to this relationship. Therefore, we measured multiple components of children’s receptive and expressive language, as well as emotion understanding and expression. 210 primary-school children participated in this study. A canonical correlation analysis was calculated in order to appropriately consider the multivariate relationships among the variables. Results identified a positive relationship between language and emotional competences. Receptive vocabulary and declarative emotion knowledge were identified to contribute most to this relationship. These findings underscore the assumption that children’s emotional development is intricately intertwined with language competence, even in middle childhood.

Filial piety as a moderator between parent-adolescent relationships and adolescent autonomy in Taiwan

Chao-Sheng Kuo Education(IED), NCTU, Taiwan, R. O.C.; Yih-Lan Liu

Autonomy is one of the most important tasks of adolescent development. Empirical evidence shows that parent-adolescent relationship is positively correlated with adolescent autonomy. Furthermore, filial piety is the traditional concept that portrays how Chinese children should interact with parents. Yeh (2003; 2006) adopted a dual approach to describing the characteristics of autonomy (e.g., individual and relating autonomy) and filial piety (e.g., reciprocal and authoritarian piety) in Taiwan. This study examined whether different filial piety styles have moderating effects on the relationship between parent-adolescent relationships and dual autonomy in Taiwan. Participants were 440 adolescents (227 boys and 213 girls; 215 10th grade and 225 7th grade students) from northern Taiwan. Structural Equation Modeling was conducted to examine whether filial piety moderates the relationship between parent-adolescent relationships and autonomy. Results showed that both reciprocal filial piety and parent-adolescent relationships positively predicted relating autonomy (all models showed excellent fitness, $\chi^2=89~102$, df=48, p.In conclusion, results indicated that filial piety moderated the relationship between parent-adolescent relationships and autonomy. However, only authoritarian filial piety moderated the relationship of mother-adolescent relationship with relating autonomy in Taiwan.

Discipline with love

Asmah Lahlah Intervict, Tilburg Law School, Netherlands

Theorists have proposed a causal link between parents’ use of physical punishment and child aggression. Numerous studies have found that children subjected to harsh physical disciplining tend to be more aggressive than children whose parents use alternative disciplinary strategies and often commit delinquent crimes. Unfortunately most of this research does not control for other dimensions of parental behaviour, such as parental connectedness and warmth. This omission is important because the impact of severe punishment may be mediated by parental connectedness. The sample consists of 477 Dutch and Moroccan adolescent boys. History of physical disciplining, parental connectedness, and violent delinquency are assessed with self-report instruments. Physical disciplining is positively associated with delinquency. In addition, low parental connectedness has a positive and significant contribution to the prediction of violent delinquency. To test for interaction effects, we ran separate models for Dutch and Moroccan boys. Stepwise hierarchical regression analyses for Moroccan boys revealed that physical disciplining accounted for 16.2% of the variance in violent delinquency. The addition of parental connectedness contributed an additional 13.7% of variance, with emotional warmth mother being moderately significant predictive of violent delinquency. For Dutch boys, physical disciplining accounted for 9% of the variance in violent delinquency. The addition of emotional warmth for father and mother was non-significant. The results suggest the importance of exploring the links between physical disciplining and delinquency within the context of parent-adolescent relationship. In addition, this study identifies a need to further look at the cultural context in which physical punishment occurs.

The remediation of arithmetical difficulties in two young people on the Autism spectrum: Two case studies

Christine Lawson United Kingdom; Hongyan Bi; Yuan Deng; Hui Hu; Yang Yang; Qinlin Li; Jing Zhao

Often research concerning individuals on the autism spectrum emphasizes differences in terms of their presentations and the interventions implemented to facilitate their development in comparison with those who are not of a similar disposition. Two case reports are presented here of young people who have demonstrated difficulties associated with the autism spectrum and aspects of their numerical development. Both individuals participated in a program to help them make progress in relation to their social and communication skills as well as other aspects of their development. The current presentation specifically considered the numerical difficulties demonstrated by the young people. One of the individuals discussed here experienced problems in learning the
multiplication tables. He participated in a program involving a Dyscalculia Test Battery Assessment and a specific multisensory technique designed by the present author to facilitate learning the multiplication tables and discussed by Lawson (1995b, 2000b, 2001a, 2002, 2005b, 2008b, 2011a). The second young person experienced difficulties associated with particular types of addition exercises and he participated in another program designed by the present author. In relation to research by Friend (1979) concerning specific non-rectangular addition exercises, the current author developed assessment exercises and a conceptually based strategy involving a particular remedial technique to facilitate the development of arithmetical skills and numerical concepts (Lawson, 1986, 1989, 1990, 1995a, b, 2000a, b, c, 2001a, 2002, 2008b, 2009, 2010, 2011a). Both young people discussed here overcame their specific difficulties and indicated increased understanding in relation to their numerical conceptual development and other areas of mathematics.

Development and validation of the child and youth resilience measure (CYRM-28)

Linda Liebenberg Resilience Research Centre, Canada; Fans van de Vijver; Michael Ungar

The presentation will document the development of the Child and Youth Resilience Measure (CYRM-28), a culturally and contextually relevant measure of resilience process in the lives of youth. The presentation will review briefly the initial development of the 28-item measure that accounts for individual, relational and contextual resources implicated in resilience processes. This process involved an iterative, mixed methods design with 1451 youth (13–23 years) in 14 international sites purposively selected to maximise diversity regarding context and the risks that youth face. The presentation will then focus in detail on sub-scale identification and validation of the CYRM-28 among two samples of youth with complex needs in Atlantic Canada (n1 = 497; n2 = 410). Three subscales were identified using exploratory factor analysis. Internal reliability of these scales was assessed using Cronbach’s alpha (range: .65 to .91), paired sample t-tests (no significant differences were found) and Interclass Correlation Coefficients (absolute agreement; range: .583 to .773) on time one and two responses. Scales were then confirmed using Confirmatory Factor Analysis (χ2/df = 4.10 = 98.00, p < .001; TLI = .957; CFI = .979; RMSEA = .046). Findings add support to the CYRM-28 as a reliable and valid self-report instrument that measures three components of resilience processes in the lives of complex needs youth. Advanced statistical modeling yielded evidence that the scale, originally developed for use in various countries, can be used to assess resilience in youth from various ethnocultural backgrounds in Atlantic Canada.

Relationship between ego identity status and parenting styles in Chinese college students

Hui Ling Hunan Normal University, China; Jian-ren Zhang

The aim of this study is to explore the status of Chinese college students’ ego-identity, parenting styles, and their relationships. A sample of 330 college students were administered the Extend Objective Measure of Ego Identity Status-2 (EOM-EIS-2) and the Parental Bonding Instrument (PBI). The results show that: (1) There were significant differences between male and female students in parenting styles, with the female students getting higher scores in the Mother Care factor than male students, and male students getting higher score in Mother and Father Control factors. (2) The parents care, parents encouraging autonomy were significantly positively correlated to students’ identity achievement, while negatively correlated to students’ identity foreclosure and identity diffusion. The parents control were positively correlated to students’ identity foreclosure and identity diffusion. Parenting styles played an important role to the development of college students’ ego-identity, parents care and parents encouraging autonomy had contributed to children’s identity achievement.

The relationships among parental control, adolescent temperament, self-regulation and obedience to parental authority: Test of a moderated mediation model

Yih-Lan Liu National Chiao Tung University, Taiwan, R.O.C.

This study proposed a moderated mediation model to investigate how adolescent temperament (e.g. inhibitory control, activation control) moderated the mediating process of self regulation on the relationship between parental vs. maternal control (e.g. psychological control, behavioral control) and obedience to parental authority in Taiwan. Participants were 606 adolescents from northern Taiwan (323 boys, 281 girls, and one unidentified). Based on Culler and Judd’s (2005) suggestion of moderated mediation analysis, multiple regression analyses were conducted to examine the moderating effects of inhibitory control and activation control on the mediating process. Paternal vs. maternal behavioural control showed direct and indirect effects on obedience, with indirect paths via self-regulation. Activation control moderated the mediating process of self-regulation on the relationship between maternal behavioral control and obedience. Activation control also moderated the relationship between paternal vs. maternal psychological control and obedience. Inhibitory control did not show any moderation effect. This study found that both paternal and maternal psychological control were positively related to adolescent intentional self-regulation, which further positively correlated with their obedience. For adolescents with high activation control, the mediating process of self-regulation on the relationship between maternal behavioral control and obedience was stronger than ones with low activation control. The negative relationships of paternal vs. maternal psychological control with self-regulation were stronger for adolescents with low activation control than high activation control.

Assessing the fears of children with varying degrees of visual impairment

Helene Loxton Stellenbosch University, South Africa; Thomas Ollendick; Lisa Visage

The study aimed to determine whether significant differences exist between the fear profiles of South African children with varying degrees of visual impairment. This often-marginalised population is one which has been neglected in past research. As far as we could ascertain, no research on this topic has been carried out within the past nineteen years, and studies within the South African context are non-existent. It has been suggested that children with a physical disability are more prone than their non-disabled peers for the development of psychological difficulties, including fears and anxieties. Therefore, it is important that these children’s fears are identified so that those involved in their day-to-day lives can gain a greater understanding of their emotional world. Assessing children attending two special schools in the Western Cape Province of South Africa participated in the study. Children were administered a biographical questionnaire and the South African version of the Fear Survey Schedule for Children. These measures were adapted for administration according to the children’s degree of visual impairment. The final sample consisted of 67 children with varying degrees of visual impairment (totally blind n = 9, severely visually impaired n = 11 and partially sighted n = 47). Results indicated that significant quantitative differences in self-reported fears existed among the three visual groups. Children with severe visual impairment reported the highest instances of fear reactivity (across number, level and pattern of fear). Results are discussed in terms of possible factors which could have brought about these differences.

Epigenetics and developmental psychology: Searching for common ground

Vannessa Lux ZfL Berlin, Germany

Only recently have geneticists started to question their former notion of genetic determinism. Empirical findings indicate that gene–gene and gene–protein interactions, cell differentiation, chromosomal aging, nutrition and psychosocial stress influence gene expression. The growing field of molecular epigenetics studies the underlying processes of gene regulation (e.g. DNA methylation, RNA interference), their possible role in ontogenetic development and their transgenerational stability. Complex interactions between biological, psychological and social/cultural aspects of development during ontogeny have been studied for a long time in developmental psychology. Some of the central concepts of molecular epigenetics today (e.g. ‘epigenetic landscape’/‘developmental pathway’, ‘imprinting’/‘critical period’) are commonly referred to in psychological models of development. However, these concepts as well as the term ‘epigenetics’ are used very differently in molecular genetics and developmental psychology. This indicates a conceptual gap between the disciplines. The aim of this paper is to outline the common ground but also some of the key differences in terminology and developmental theory between molecular epigenetics and developmental psychology. First, the mechanisms studied in molecular epigenetics and some of the findings expected to contribute to the understanding of psychological concepts (e.g. memory, learning) and psychopathology (e.g. PTSD, autism) are reviewed. Second, it is reconstructed how the term “epigenetic” and associated concepts (e.g. “genetic/genesis”, “pathway”) are used in developmental psychology (e.g. J. Piaget, E.H. Erikson, J. Bowlby, G. Gottlieb). Finally, the relationship between molecular epigenetics and developmental psychology is discussed from an anti-reductionist perspective.
Resilience and mental health among adolescents with low parental support

Xiaohui Ma Renmin University of China, China; Li Lei

The objectives of this study were to identify dimensions of resilience of adolescents who cannot be supported well by their families, and to explore the influence of resilience on their mental health. 173 adolescents (90 boys, 83 girls) with low parental support and 180 adolescents (92 boys, 88 girls) with high parental support were asked to complete questionnaires about resilience and other measures on mental health. Major measures included the Adolescent Resilience Scale, the Beck Depression Inventory, and the degree of life satisfaction and index of subjective well-being. Results were as follows: (1) Compared with high supported teenagers, the low supported group did not display significant psychopathology with respect to depressive symptom scales; (2) The level of resilience was positively associated with life satisfaction and subjective well-being. And for the low supported teenagers, correspondence between resilience and mental health was high; (3) A further analysis on the concerning influence of the elasticity ability showed that teenagers’ resilience can positively predict mental health, and better effect was found among the low support group. It was concluded that high resilience can protect teenagers with low parental support from mental illness, and attention to their mental health may build and promote their resilience.

The structure of moral judgment based upon altruism and human relationships

Hong Keung Ma Hong Kong Baptist University, Hong Kong

It is a common finding that Westerners tend to make moral judgments based on social law and justice. Our research indicated that Chinese people tend to make moral judgment based on humanity and relationships. The structure of moral judgment development of Chinese people was studied in terms of altruism and human relationships. A five-stage structure of altruism judgment was proposed: Stage 1: Obedience and Egoism. Stage 2: Instrumental Purpose, Opportunistic Hedonism, and Reciprocal Altruism. Stage 3: Primary Group Affection and Altruism. Stage 4: Golden Mean Orientation and Social Altruism. Stage 5: Utilitarian Altruism and Basic Rights. Two hypothetical dilemmas of the Moral Development Test (MDT) were used and the sample consisted of 698 students. By combining Stages 1 and 2 together, results of factor analysis indicated that the four stages (Stages 1/2, 3, 4, and 5) form a simplex-like pattern. In addition, 212 participants of the sample also answered the Defining Issues Test (DIT). The relation between Altruism (AL) Stages and DIT stages also exhibited a consistent pattern. The same results of factor analysis indicated that the four stages were used and the sample consisted of 698 students with low parental support from mental illness, and attention to their mental health may build and promote their resilience.

Psychosocial determinants of work/education decisions among graduates in Ghana

Sherrif Mahama Friedrich-Schiller University, Ghana; Rainer Silbereisen

Decisions to continue with postgraduate education are complex with long-term implications, especially for youth in sub-Saharan Africa where graduates form an elite group (5% of high school students in Ghana). This study sought to investigate this decision among Ghanaian graduates after the mandatory national service programme amidst changing societal conditions. The Jena social change model and the expectancy-value model were combined to capture intrinsic and contextual factors influencing this decision. In the Jena model, demands refer to the individual’s perceived uncertainties concerning their work opportunities. It was expected that heightened demands would correspond with the decision for postgraduate education, based on literature showing that current work environment uncertainties led to youth prolonging their education. The relationship between larvae stage and demands was expected to be mediated by expectations and subjective task values. Pilot data collected using questionnaires from a sample of 105 Ghanaian students revealed that students highly endorsed further education (87%) and lower demands meaning students generally felt that their opportunities in the work place were not getting progressively worse. Further analysis showed that students who rated lower demands were more likely to have higher expectations about their success in furthering their education and also likely to endorse a decision to continue with their education. Results from the main study highlighting the mediation relationship and the dimensions of decisions will be presented in the poster at the ICP 2012 conference.

Methodological issues in birth order research: A practical exploration

Kyla Mills University of the Witwatersrand, South Africa; Gillian Mooney

Four different methods for ranking birth order have emerged in birth order research; namely the categorical, dichotomous, serial, and continuous methods of ranking. The categorical ranking organises birth order into four categories – only child, first born, middle born (between oldest and youngest) and last born. The dichotomous method ranks first borns as 1 and all later-borns as 2. The serial method follows the actual birth order with first borns having a rank of 1, second borns having a rank of 2 and so forth. Finally, the continuous method divides the number of older siblings of an individual by the total number of siblings the individual has. An exploration into these methods of ranking birth order was conducted in order to examine their various strengths and limitations. Research using the Situational Test of Emotional Understanding was introduced to demonstrate the discrepant results obtained from the various methods on the same sample – a group of 156 undergraduate psychology students from the University of the Witwatersrand. Implications regarding the results of birth order research are discussed and possible methods for conducting future research on birth order are presented.

Interpersonal competence mediating paths from social perspective taking and public self-consciousness to emotional adaption of high school students

Wang Mingzhang Central China Normal University, China; Zhou Zongkui

The aim of this study was to explore how high school students’ social perspective taking and public self-consciousness would influence their emotional adaption. 465 high school students from China were investigated using such tools as the public self-consciousness and social anxiety subscales of the Self Consciousness Scale, the Interpersonal Competence Scale and the UCLA Loneliness Scale. The results revealed that both social perspective taking and public self-consciousness could directly positively predict students’ interpersonal competence and social anxiety. In addition, low interpersonal competence could negatively predict their loneliness and social anxiety. Interpersonal competence was an important mediator on the path from social perspective-taking and public self-consciousness to loneliness and social anxiety. The educational implications for the results were discussed.

Substance abuse amongst adolescents

Irene Mohasoa UNISA, South Africa; Eduard Fourie

Substance use by adolescents is a major problem facing the world today. Therefore, the strategies to curb adolescent substance use need to be identified. The study was conducted in the rural areas of Zeerust, North West Province of South Africa. The participants included 12 African male adolescents, whose ages ranged from 12 to 15 years. A qualitative, explorative design was employed. Data was gathered using semi-structured interviews, genograms, and observations. Thematic analysis was used to analyze audio-taped data. The study found that substances abused by the adolescents include beer, cigarettes, cannabis and heroin. Their reasons for using these substances include individual, family and environmental factors. However, peer group pressure was identified as the primary factor for adolescent substance use. This study emphasizes the painful nature of substance abuse among adolescents, yet at the same time it succeeds in highlighting the strategies that can be employed to address substance abuse among adolescents. In addition, this study recommends a concerted effort by all stakeholders in addressing the substance abuse problem.

The effect of training of pivotal response treatment to mothers of autistic children on family functioning

Tayebeh Mohtashami Payame Noor University, Islamic Republic of Iran; Ahmad Alipor; Mahnaz Aliakbari Dehkordi; Narges Chimeh

This study was designed to evaluate the effect of Pivotal Response Treatment (PRT) training with mothers of autistic children on family functioning. The statistical population included all mothers of autistic children in Tehran. Twenty mothers were selected as the study sample by means of non-convenience sampling and randomly assigned to two control and experimental groups. The research used a pretest- posttest design with a control group and follow-up. The experimental group were...
What role does intelligence play in leadership emergence in preschool children’s groups? 
Romana Morda Victoria University, Australia

Research exploring the relationship between leadership and intelligence has traditionally focused on adults in business settings. This study examined leadership in young children’s groups and the characteristics and skills of emergent leaders. Using a mixed methods approach, this study specifically investigated the role that cognitive and social intelligence played in leader emergence in a sample of preschool children. A battery of measures was used to assess children’s general cognitive intelligence, social cognitive and social behavioural skills, and leadership play behaviours. An exploratory cluster analysis of play behaviours was undertaken in order to identify groups of children with similar play profiles. Three clusters were identified: Mixed play behaviour style, Peripheral play behaviour style and Leaders. The study’s findings suggested that both cognitive and social intelligence played a role in leader emergence. Children who emerged as leaders had significantly higher Abstract/Visual reasoning scores than children in the Mixed and Peripheral groups. There were no significant between-group differences in social intelligence. However, a case study analysis of quantitative and qualitative data indicated that children in the Leader group, in comparison to the Mixed and Peripheral groups, showed that leaders were more likely to show synchrony between their social cognitive and social behavioural skills. It is not the author’s contention that all children should be leaders, however on the basis of this study’s findings recommendations are made for how activities to foster leadership may be incorporated into the preschool curriculum.

Identity formation, its role in optimal human development: A psychobiographical study of artist Jackson Pollock
Toni Muller NMMU, South Africa; Louise Stroud

Celebrated artist Jackson Pollock challenged the very concept of art. Unconventional in all that he did, Pollock moved beyond paintbrush and easel to throwing paint across canvases laid out on the floor. Around these emerging artworks he would move and dance, mesmerising those present by the way he made art immediate using his entire body to create the abstract image. However, despite this capacity for originality, Pollock’s life was bracketed by alcoholism and emotional instability. In this paper the importance of identity formation for healthy development is illustrated through a psychobiographical study of the life of Jackson Pollock. Pollock’s difficulties in establishing a stable sense of self seemed to play an integral part in impeding a positive life course. The developmental theory of Erik Erikson (1950) was the lens through which Pollock’s life was studied, with a focus on Erikson’s proposed fifth stage of development, that of Identity versus Role Confusion. What emerged from the study was that it was largely the individuals who surrounded Pollock who shaped him into what they wanted him to be, with Pollock lacking the stable sense of self to protect him from a society that treated both him and the art he poured himself into as a commodity to be celebrated and vilified on whim. Alcoholism would cause his death at the age of 44, when, while heavily intoxicated, Jackson Pollock drove his car into a tree a few metres from his home.

Day in the life of thriving immigrant five-year-olds in transition to school
Lynda Phillips Douglas College, Canada; Catherine Cameron

The aim of this paper is to describe pilot ecological studies of immigrant children in transition to school from a home culture that is divergent from the settlement community. This extends current resilience research, adding to the discourse on young children’s acculturation and explores kindergarten experiences of immigrant five-year-olds ‘doing well’ in ecological context. The approach involves an innovative visual ‘Day in the Life (DITL)’ procedure that was developed to investigate everyday lives of thriving toddlers in seven global locations (Authors, 2010) as well as resilient mobile adolescents in eight communities internationally (Author, 2011). This DITL adaptation involves interviews with parents, teachers and children to obtain information respecting perspectives on home and school transitional expectations. A Full Day in the Life of kindergarten children is filmed and field-notes taken. A photo elicitation involves the children photographing people, places, and things important to them with a disposable camera. A half-hour compilation is made of the day, and shown to the teacher, parents and child to elicit reflective comments. Preliminary analyses document the children’s security strivings in exchanges with family, teacher and peers. The relationship between emergent literacy activities at home and school will also be identified. Conclusions and recommendations include highlighting the value of observing an entire day in a child’s life during their transition to school in order to identify ‘promotive transactions’ (Sameroff, 2010) in the multiple cultures and contexts in which children are seen to ‘do well’ (Authors, in press).

An exploration of the experiences of adolescents living with HIV
Leanie Pienaar Tshwane University of Technology, South Africa

This research endeavours to explore and describe the experiences of adolescents living with HIV that undergoes chronic disease management and aims to describe how these experiences inform their identity. Six adolescents, attending the Kalafong Hospital Paediatric HIV clinic (Pretoria) for ongoing disease management, were interviewed using a social constructionist narrative approach. Two semi-structured interviews and drawings were used to collect data. Through collaboratively exploring the adolescents’ experiences it became possible to co-construct the meanings that they attached to their experiences of HIV that informed their identities. The three-dimensional space approach by Clandinin and Connelly (2000) was used to analyse their stories in different contexts such as the medical and home context. The adolescents constructed multiple identities in various contexts. Their experiences as patients significantly shaped how they perceived themselves in other areas of their lives. They expressed different views about the role of ART in their lives. They had limited opportunities to discuss their experiences with friends or family members and felt conflicted about the future disclosure of their HIV status. Lack of communication and impersonal staff interactions with patients were identified as barriers to disease management. The research recommends that the clinic should provide ongoing support to the adolescents with regards to disclosure of their status and adherence to medication. The results were communicated to the multi-disciplinary team at the clinic. This aimed to enhance their understanding of the reality of the adolescent when attending the clinic for disease management.

Redefining disorganised attachment: An exploration of subcategories of disorganisation in middle childhood using the ASCT
Alexa Pilt Wits, South Africa

Disorganised attachment is the only attachment that is not considered an adaptive or functional strategy for maintaining the caregiver-child dyad and is often a result of having abusive or neglectful caregiving relationships. Children with disorganised
attachment are at higher risk for developing severe emotional and psychological problems. This study aims to further analyse disorganised attachment within a South African sample which offers a unique context and high rate of youth at risk. Using the Attachment Story Completion Test, 17 disorganised children between the ages of 8–12 were selected from children’s homes and hospitals and their story stems were analysed using a thematic content analysis. Results indicated clear subcategories of disorganised attachment ranging on a spectrum of severity. This study has possible implications for the classification and treatment of disorganised attachment as well as move towards predicting the possibility and severity of future pathology.

Infants’ mistrust of inaccurate and unhelpful adults
Diane Poulin-Dubois Concordia University, Canada
Ivy Brooker

The primary aim of the study was to examine how the reliability of a model influences infants’ selective learning and prosocial behaviours. This issue was examined by manipulating both the experimenter’s epistemic and socio-emotional reliability. Infants aged 18 months (n=55) were thus divided into one of two groups: (1) Both epistemically and socioemotionally reliable or (2) epistemically and socioemotionally unreliable. The epistemic domain was manipulated by means of the experimenter’s accuracy in labelling and demonstrating a property of a familiar object. The socio-emotional domain was manipulated according to the experimenter’s benevolence, specifically her responsiveness to the infants’ communicative cues. We examined whether the culmination of these factors would influence infants’ word learning, imitation, and helping behaviours. Results indicated that only infants in the unreliable condition increased their looking time at their parent, while decreasing their latency to do so, from the first to last trial of the training phase. Infants’ performance in learning novel words did not differ across the groups. However, infants in the reliable condition tended to better understand the prior intentions of the model (e.g. pulling a pin before opening a door). Finally, comparison of the infants’ performance on the helping tasks showed that infants in the reliable condition were more likely to help the experimenter on both tasks combined than with those in the unreliable condition. Overall, these findings support the hypothesis that infants are sensitive to a model’s behaviours from a very young age, with a stronger effect being found on social behaviours.

Resilience: Contributions of this concept for coping with vicissitudes in educational relations
Vivian Carla Bohm Rachman PUC-SP, Brazil; Claudia Davis

The primary objective of this research was to ascertain how the concept of resilience has been studied by Brazilian researchers in the areas of Education and Educational Psychology. The main views of resilience adopted by Brazilian scholars will be presented, as well as situations in which this concept is studied and methods employed for doing so. Theses and dissertations produced at renowned universities in Brazil between 2002 and 2007 were studied, and were selected among those meeting the specific criteria of the studies being digitally available, and involving the concept of resilience with an educational intention, and considering it as a psychological phenomenon (n = 14). The analysis carried out showed that educational studies mainly adopted the concept of resilience as a personality trait, making it an innocuous concept for this area, without major implications for educational practices. A new look at this issue is proposed, based on sociocultural psychology, considering resilience as a process through which the teacher can deliberately help students give new meaning to the vicissitudes they face. This new approach can contribute who are directly or indirectly involved with students who are in crisis, allowing them to grasp a more positive attitude to explain what has happened in their lives.

Cultural and human development: Towards the development of an African psychological theory on child development
Mashahogene Ramokopoa University of Limpopo, South Africa

Though human development is a universal phenomenon, there are studies that have suggested that culture is critical in defining how this takes place. This paper is based on the results of a study that was aimed at investigating the developmental stages of an African child in a rural environment. The study was conducted in Bolobedu district – a rural area in Limpopo Province (South Africa). This area, which is under the jurisdiction of Queen Modjadji the III, was chosen because of its relatively un-spotted and uninterrupted African cultural practices. A total number of 150 participants (63 male = 63; female = 87), aged between 55 to 82 years were selected through random sampling. All the participants were interviewed using a structured questionnaire that contained both open-ended and close-ended questions. Among others, the study found that each developmental stage in the African community was defined, not by age, but mainly by the readiness and ability to perform roles. Furthermore, the study found that the participants tended to perceive cooperation, interdependence and collective responsibility as critical values that shape positive human development. The results are discussed in relation to Erik Erikson’s psychosocial stages of human development.

When age matters: Developmental perspectives on processing and regulating emotions
Michaela Riediger MPI for Human Development, Germany

Much of what we know about the nature of emotional experiences and competencies stems from investigations of young adults. Such research has fundamentally shaped contemporary views on emotional functioning. Insights from young adult populations, however, do not readily generalise to other age groups. Individuals from various age groups differ in how they process emotional information and in how they control their own emotional experiences. This symposium brings together an international group of researchers who demonstrate from various perspectives that combining social-psychological and developmental perspectives deepens our understanding of emotional functioning. Eben and colleagues use eye tracking to show adult age differences in the processing of emotional faces, and their dependencies on the age and emotion expressed in the face. Fung and colleagues also employ eye tracking to demonstrate that older, in contrast to younger and middle-aged, adults selectively disengage their visual attention from overly positive images of aging. Riediger et al. focus on the age range from adolescence to old age. They present evidence from a longitudinal experience-sampling project and from Implicit Association Tests on age-related differences in the prevalence and functions of pro- and contra- hedonic orientations. Voelkle and colleagues use an extensive repeated measures design to demonstrate adult age difference in how people regulate their mood in the face of recurring and unavoidable unpleasant situations. Isaacowitz and colleagues highlight the role of the context for understanding adult age differences in the perception of emotional stimuli for the regulation of emotion. Alexandra Freund, finally, discusses and integrates the five papers.

Racialized in refugee: A comparison of developmental contexts and adaptation among the children of resettled refugees and voluntary migrants
Julie Robinson Flinders University, Australia

Many adult refugees flee war and oppression primarily to secure a better future, peace and freedom for their children. However, even the minority who are offered a place in a country of resettlement, often find that the future for them and their children is limited by poverty, acculturation stress, discrimination and their past exposure to traumatic events. This study aimed to identify unique characteristics of developmental contexts and outcomes for the young children of refugees by comparing data for children of forced and voluntary migrants in a large nationally representative database in Australia. The Longitudinal Study of Australian Children traces the development of two cohorts, infants and preschool-age children, every two years. This paper focuses on data collected from both cohorts when children were aged 4 to 6 years. It compares young children whose parents were born in Non-English speaking refugee source countries with those whose parents were born in Non-English speaking immigrant source countries. Information about children’s developmental context and their social and emotional problems were obtained from parents and preschool/school teachers using the Strengths and Difficulties Questionnaire. Teachers also reported on preschool/school adjustment using the Student-Teacher Relationship Scale. Children of forced migrants were more likely than children in other groups to experience disadvantage in several dimensions of their developmental context. Outcome variables differed in the extent to which parents’ migration status explained independent variance in outcomes. Parent- and teacher-reports showed that both groups of children were resilient on some dimensions of development.

A relational theory applied to intergenerational relations in South Africa
Vera Roos North-West University, South Africa

Researchers’ attempts to focus attention on the importance of relationships to explain intergenerational relations as well as to promote intergenerational solidarity, provide little insight to explain the relational nature of intergenerational relationships. The aims of this presentation are to describe intergener-
Does the gaze of two-year-old children serve as an indicator of disposition? Observations in a day-care centre
Junko Sagara Seiotsu University, Japan; Kazu Murata

The aim of this study was to examine if the gaze of two-year-old children in a group nursing situation, serve as an indicator of individual differences in terms of interest towards objects and people. At a private day-care centre in Tokyo, 6 participants (3 males, and 3 females) were observed, using a videotape recorder, while they played freely at the ages of 24 months, 30 months, and 36 months old respectively. How long they looked at "objects" and "people" were analysed. We also compared the observation time of the objects operated by themselves and by other children. We found that there were some children who concentrated on objects and seldom looked at “people.” We also observed that children spent more time looking at objects operated by themselves, than at other children operating objects, except one child, whose gaze was shared equally between her operation of objects and the other children’s operation of objects. The results suggested that the gaze direction of two-year-old children, in a group nursing situation, can be used as an indicator of individual differences of their dispositions.

Long-term cognitive outcomes in children with hydrocephalus
Kazue Saito The Jikei Univ. School of Med., Japan; Eri Maeda; Tomoru Miwa; Yuichiro Nonaka; Hiro-oyuki Ida; Hiroko Murakami

To study the long-term cognitive outcomes in children with hydrocephalus, and to guide continuous developmental testing in, and implementing a developmental aid, for children with hydrocephalus in the department of pediatrics of a university hospital in Japan, this present study aimed to examine the psychological development of children with hydrocephalus who have been followed up since infancy. The subjects were 163 children who had undergone developmental testing at our university hospital in Tokyo since April 2002. The Kyoto Scale of Psychological Development was used (correlation with Wechsler Intelligence Scales is 0.87; p < 0.01). A full-scale developmental quotient (FSQD) and developmental quotients (DQs) for 3 sub-scales—posture-motor (PMDQ), cognition-adaptation (CADQ), and language-social (LSDQ)—were calculated and collected once a year. The results of testing were compared with such factors as developmental area, type of hydrocephalus and its cause. In children with 3.5 years old or younger with hydrocephalus, the mean PMDQ (75.3 ± 24.6) was significantly lower than the CADQ (82.7 ± 23.3) or LSDQ (85.4 ± 25.2). The PMDQ (72.0 ± 25.5) was also significantly lower than the CADQ (82.5 ± 24.5) or LSDQ (83.9 ± 26.4) in children with congenital hydrocephalus. Cognitive skills and language can improve with postnatal growth. However, the impairment of motor development before birth can affect development during infancy. Regarding the type of hydrocephalus, in children with ventricular dilatation, development in all spheres was delayed. As for causes of hydrocephalus, both vascular disease and infectious disease were associated with higher rates of a DQ of 70 or less (69.0% and 81.8%, respectively) than other causes.

Researches argued that the social competence in preschoolers and their attachment security are related. However it is also suggested that in this relationship there are some precedent factors as well as some consequences. From that point of view, the aim of this study is to investigate the mediating role of the children’s attachment security in the relationship of mother sensitivity and the children’s social competence. Another purpose of this study is to investigate the moderating role of children temperament in the same relationship. Participants are 50 children who are 36–48 months old from three different preschools and their mothers. Mother Child dyads interactions are observed in a preschool setting. The observation lasts approximately 1hr 30 minutes. School psychologists, teachers, parents and researchers have completed some questionnaires and scales. School psychologists, teachers and parents have completed ”The Social Competence and Behaviour Evaluation-30 Scale”, the mothers have completed ”Children’s Behaviour Questionnaire”, the researcher have completed ”Attachment-Q Sort” to measure attachment security of the children and ”Mother Behavior Q Sort” to measure mother sensitivity. The research is at the data collection stage. The findings will be discussed within the relevant literature.

Study of identity typology in modern adolescents and young adults
Olga Savina Moscow State University Psychol, Russian Federation
The article covers the problems of personal identity formation, identity transformations vs stability. The special focus of the work is personal identity formation of adolescents, their "moving into adulthood" in the situation of social-economic instability and crisis. As criteria for defining identity in adolescents we use stability of self-conceptions in time, and readiness to make independent decisions in life. Thus different combinations of various levels of stability and readiness to make decisions would determine identity typology. In order to build an empirical identity typology cluster analysis of self descriptions and biographical interviews were done. In the groups of adolescents (439 young men and women, 14–20 years old), four clusters had been found: (1) Unformed identity that includes unstable self concepts, low readiness at decision making, adolescents with this identity type do not reflect the social roles and perspectives, they haven’t chosen their profession yet. (2) Formed identity that includes stability and readiness in life-time decision-making, the adolescents are reflexive of their social roles, plan future perspectives, they usually have already chosen their profession. (3) Identity with low level of decision-making that includes enhanced attention to one’s self, absence of future perspective, identity with unstable self concepts in the past, present and future, adolescents that reflect social roles, plan their future life, and profession. The data could be further interpreted in the context of psycho-transformative paradigms as identity-constructing processes.

The relationship between attachment to parents and siblings regarding the autonomy of adolescents
Mojgan Sepahmansour Islamic Azad University, Islamic Republic of Iran

Mojgan Sepahmansour

Mother sensitivity and social competence: The mediational role of attachment style and moderational role of temperament
Nazli Savasan Okan University, Turkey; Dilek Sirvan-Il-Ozen; Ceyhan Yildiz

The article covers the problems of personal identity formation, identity transformations vs stability. The special focus of the work is personal identity formation of adolescents, their "moving into adulthood" in the situation of social-economic instability and crisis. As criteria for defining identity in adolescents we use stability of self-conceptions in time, and readiness to make independent decisions in life. Thus different combinations of various levels of stability and readiness to make decisions would determine identity typology. In order to build an empirical identity typology cluster analysis of self descriptions and biographical interviews were done. In the groups of adolescents (439 young men and women, 14–20 years old), four clusters had been found: (1) Unformed identity that includes unstable self concepts, low readiness at decision making, adolescents with this identity type do not reflect the social roles and perspectives, they haven’t chosen their profession yet. (2) Formed identity that includes stability and readiness in life-time decision-making, the adolescents are reflexive of their social roles, plan future perspectives, they usually have already chosen their profession. (3) Identity with low level of decision-making that includes enhanced attention to one’s self, absence of future perspective, identity with unstable self concepts in the past, present and future, adolescents that reflect social roles, plan their future life, and profession. The data could be further interpreted in the context of psycho-transformative paradigms as identity-constructing processes.
This research examined the relationship between attachment to parents and peers with regard to autonomy in adolescents. Two hundred and fifty adolescents (125 girls and 125 boys) completed the Attachment of Parents and Peers (IPPA) and Adolescents Autonomy Questionnaires (AAQ). The results showed that there is a positive relationship between attachment to parents and peers in girls. Also, the attachment to parents and peers is higher in girls than boys.

The relationship between maternal acceptance/rejection and marital satisfaction: Mediation role of intimate partner acceptance/rejection

Dilek Sirvanli-Ozen; Okan University, Turkey; Ilkay Toprak; Mettem Dikkanoglu

Contemporary psychological theories have a consensus on the utter importance of childhood on healthy psychological and social development. In this regard, many studies were conducted to find out the effects of a child’s perceived parental acceptance/rejection on psychological development and adjustment during adulthood. These studies also denoted that a relation might exist between perceived parental acceptance/rejection in childhood and intimate partner acceptance/rejection in close relationships established in adulthood. Furthermore, the literature shows that a mother’s effect on the child has a higher significance than that of father’s. From this point of view, this study aimed to analyse the relationship between perceived maternal acceptance/rejection in childhood and marital satisfaction in adulthood, from the perspectives of two different genders, as well as the mediational role taken by perceived intimate partner acceptance/rejection, within the framework of the PARTheory. "Demographical Data Form", "Parental Acceptance/Rejection Questionnaire/Maternal Form", "Intimate Partner Acceptance/Rejection Questionnaire", and "Marital Satisfaction Scale" were applied to 187 subjects (95 women and 92 men), aged between 23 and 73, living in Istanbul. The results of the analyses indicated a significant relation between perceived maternal acceptance/rejection and marital satisfaction for both male and female subjects. Also perceived intimate partner acceptance/rejection was found to have a mediational role in this relation for women. However, for men, perceived intimate partner acceptance/rejection acted as a partial mediator. The findings were discussed within the framework of the PARTheory.

The development of selective trust in Brazilian children

Debora Souza Universidade Federal Sao Carlos, Brazil; Natalia Velludo; Melissa Koening

This paper presents preliminary findings of a collaborative study investigating possible effects of culture and social cognition in the development of selective trust. Recent studies have demonstrated that North American children keep track of whether an individual was ignorant or inaccurate in the past and selectively prefer to learn new information from previously reliable informants, but there is little evidence about the development of selective trust in other cultures. Moreover, the possible relationship between mental state understanding and selective trust needs to be further explored. The present study is the first to investigate this developmental process in a sample of Brazilian 3- and 4-year-old children. A standard selective trust task (Corriveau, Meints & Harris, 2009) was used which included three conditions: (1) inaccurate x accurate informant; (2) inaccurate x neutral informant and (3) accurate x neutral informant. Participants were also administered the Scale of Theory-of-Mind Tasks (Wellman & Liu, 2004) and the Peabody Picture Vocabulary Test (PPVT). Preliminary results suggest that both 3- and 4-year-olds in the accurate x inaccurate condition perform above chance, showing a clear preference

Inculcating human values in primary school children using creative drama

Charuu Sharma University of Delhi, India

Getting into the shoes of others’ helps one develop empathy and compassion for our fellow human beings. The present Indian education system requires instilling human values in children to churn cultured, compassionate adults who do not indulge in episodes of rape, road rage, bullying of the weak and more such heinous acts. The classrooms should be developed into an experimental space where competition is substituted by cooperation and aggression is substituted by compassion. This transformation needs to begin from primary schools in order to ensure that it is well engrained in the psyche of children and lasts for long. Creative Drama can be used as a transformational mode via which children improvise and indulge in creating myriad characters and situations. They get an opportunity to live and re-live situations thus leading towards better understanding of people and of life. The paper shall draw special focus on a study conducted with primary school children in schools located in Delhi and will highlight the impact of Creative Drama on the social and cognitive development of children.

The combined effect of parents’ attachment styles on the emergence of their kids’ attachment styles

Marcilio Silva UFPE, Brazil; Antonio Roazzi

This study aims at investigating the effect of parents’ attachment styles’ interaction on the emergence of their children’s attachment styles. It offers a review of the attachment styles literature from John Bowlby’s first theory drawings to what has been done most recently in this field. It also offers a short review on methodology issues. The methods chosen take a reference the facett theory, and three different approaches are going to be applied: Attili’s (2001) modified version of the SAT (Separation Anxiety Test (SAT), de Klagsbrun e Bowlby (1976)) for the evaluation of children’s attachment styles; the ECR (Experiences in Close Relationship) questionnaire for the evaluation of couples’ attachment styles; and in loci video footages of the families’ interactions. The intention is to investigate around 50 economically non-privileged Brazilian families of the north-east region of the country. The data analysis will encompass correlational tests and the SSA (Similarity Structure Analysis), a variant of the Multidimensional Scaling Analysis. As hypotheses, the author expects that children’s attachment styles will be directly influenced by the predominant styles of their parents: parents who show secure attachment will have children with the same pattern of attachment; parents with insecure attachment styles will have children with insecure attachment patterns; whereas in cases in which one parent has a secure attachment style and the other an insecure style, the children will tend to show secure attachment styles.

Endowment effects of children aged 3 to 6 years old

Zhe Shang Department of Psychology, China; Tingyong Feng; Lei Wang Department of Psychology, China; Shang Zhe

The present research examined the endowment effect of young children in three experimental conditions using several sets of watercolor pens for exchange. Results indicated that children aged 3.5 years old performed endowment effect; the 3.5 year olds were significantly superior to the 3 year olds in the objects exchange tasks; there was no significant difference between the 4 and 3.5 year olds in the objects exchange tasks; the 4 year olds were remarkably superior to the 4.5 year olds; There was significant difference among the 4.5, 5, 5.5 and 6 year olds. The study concluded that, children performed endowment effect as early as 3.5 years old. And the development of self-consciousness in young children has a strong correlation with endowment effect change across ages.
for the more reliable/correct informant. In contrast, in the correct x neutral condition, most participants (75%) show no preference for either the correct or for neutral informant. When children determine whether to believe the claims of another, examples of when a speaker has been wrong may be weighted more heavily than examples of when they have been right.

Ironic understanding in Brazilian children
Debora Souza Universidade Federal Sao Carlos, Brazil; Nadia Villa
This paper presents findings of a study investigating the development of ironic understanding in Brazilian school-aged children. Sixty-seven children (7- and 9-year-olds) were administered: 1) the Scale of Theory-of-Mind Tasks (Wellman & Liu, 2004); 2) the Peabody Picture Vocabulary Test (PPVT) and 3) the Ironic Understanding Task created by Filli-pova and Astington (2008; 2010). This task was the first to include both the social-cognitive aspects of irony discourse (understanding the speaker’s meaning, belief, intention and motivation) and its social-communicative functions. Results suggest a similar developmental pattern to the one found in Canadian children. With regard to the social-cognitive measures, 8- and 9-year-olds perform significantly better than 7-year-olds. A significant correlation was found between children’s performance in the ironic task and in the Theory-of-Mind Scale. Moreover, Brazilian children have more difficulty in detecting hyperbolic irony (speaker exaggerates what he/she means) than contrastal irony (the speaker says the opposite of what he/she means). No effects of age were found for the social-communicative measures. More than half of the participants did not find the ironic statements funny. The type of irony that was found to be the funniest was hyperbolic praise and the one found to be the meanest was hyperbolic criticism.

Links among inductions, empathy, and prosocial moral reasoning in Mexican- and European-American adolescents
Cara Streit University of Missouri, United States of America; George Knight; Gustavo Carlo; Alexandra Davis
Scholars have asserted that parental discipline is important in promoting moral development (Hoffman, 2000). Positive inductions refer to parents’ use of reasoning and explanations to foster awareness of others in a transgression context (Carlo et al., 2011). Positive induction has been positively linked to children’s prosocial development (Krevena & Gibbs, 1996) and is positively associated with moral reasoning (Hoffman, 2000). However, such prior research has examined prohibition-oriented moral reasoning rather than prosocial moral reasoning (i.e. thinking about helping situations in the absence of laws or formal rules, Eisenberg, 1986). Thus, the current study will examine the relations between parental positive inductions and prosocial moral reasoning through the mediating roles of perspective taking and empathic concern in a sample of Mexican American and European American early adolescents. Three hundred and thirteen early adolescents (205 Mexican American; girls, n=157; M age=10.96 years) participated. Participants completed measures of parental positive inductions, perspective taking, empathic concern, and prosocial moral reasoning. Preliminary structural equation modeling (models had adequate fit, CFI>.92, RMSEA <.098) indicated that parental positive inductions positively predicted perspective taking and empathic concern. Perspective taking positively predicted empathic concern. Empathic concern was positively associated with high levels of prosocial moral reasoning, and negatively associated with low levels of prosocial moral reasoning. Follow-up analyses will examine the moderating roles of ethnicity and gender. Discussion will focus on the role of discipline in fostering prosocial moral development, and the mediating roles of empathy in early adolescents from different culture groups.

Acquisition and transfer of dual-task coordination skills in older adults
Tilo Strobach Ludwig-Maximilians-University M, Germany; Peter Frensch; Torsten Schubert; Hermann Mueller
Younger and older adults reduce dual-task performance costs when contrasted to single-task performance with extensive practice. In younger adults, there exists evidence for a contribution of dual-task coordination skills to this reduction. These skills improve the control of two simultaneous tasks. They are acquired under conditions of dual-task, but not single-task practice, and are independent from the practiced dual-task situation and transferable to new situations. For older adults, however, the contribution of dual-task coordination skills to the reduction of dual-task costs is still an open issue in studies on cognitive aging. Therefore, we practiced older adults either under dual-task or under single-task conditions and subsequently performed a test of their dual-task performance level in the practiced and in transfer situations. In both types of situations, dual-task performance was improved after dual-task practice. Thus, for the first time in older adults, the present findings provide evidence for the acquisition of dual-task coordination skills that are transferable to new situations. These findings are discussed in the context of the cognitive training literature.

Reflective functioning in parent-child interventions
Siobhan Sweeney Rhodes University, South Africa; Lisa Saville-Young
Sensitive understanding and accurate responsiveness to a child’s needs forms a secure attachment between mother and child which is associated with positive later development. In adverse circumstances of poverty and single parenting, however, parenting can become a negative experience with identity conflicts for mothers, and thus, negatively impact a child’s development. In developing parental reflective functioning or a sense of “wondering”, mothers become more sensitive to their child’s needs—a crucial element in secure attachment. The “Watch, Wait, and Wonder” (W.W.W) and “Mind-ing the Baby” interventions have previously shown promising results in promoting secure attachments between mothers and infants as well as maternal reflective functioning (Cohen et al., 1999; Sadler, Slade & Mayes, 2006). Although there is a need for mother-child interventions for at risk populations in scarcely-resourced South African communities, the majority of interventions involve infants rather than children. Drawing from the W.W.W and MTT intervention, a tailored group-based intervention for single mothers and their 6 year old children was implemented in a scarcely-resourced South African community. Using data collected pre- and post-intervention, an outcome assessment evaluating the impact of such an intervention on two factors, (1) the quality of attachment and (2) reflective functioning, was conducted through analysis of variance. The correlation between these two factors was investigated. Furthermore, constructs of maternal identity were explored in psychosocial interviews and questionnaires assessed perceptions of the intervention and therapeutic experience. Results of the impact of the intervention on these factors and recommended adjustments necessary in the South African context are reported.

How the Chinese perceive themselves post-1980s: A pilot study
Ningyu Tang Shanghai Jiaotong University, China; Chao Chen; Chen Jamie
People born in China after 1980 (Huang, 2008; Dong & Gao, 2009), are the “new blood” in Chinese society. However, they bring challenges and complexity, and are thus an interesting topic for research in China. The understanding of the millennial workers is awayed mostly prevalent negative assumptions and stereotypes rather than by empirical studies (Tang, Chen, Zheng, Shi, 2012). In order to compare them with the older generation, the public needs to understand how this generation perceive themselves. By asking open-ended questions to 44 graduate students in a key Chinese university, this paper did a pilot study to explore how Chinese post-1980s look at themselves. The results showed that (1) Compared to other generations, Chinese post-1980s valued independence, innovation, individualism, freedom and work-life balance more; had a higher level of education and higher competition in schools, job seeking and career development; (2) The negative side of Chinese post-1980s are: self-centeredness, low social responsibility, lack of conscientiousness, and a defeatist attitude in the face of difficulty; (3) Though realising the negative side of Chinese Post-1980s,
most of the samples (80%) identified with this generation. The paper also gives suggestions on what can be done empirically in future.

**Developmental trajectory of emotion understanding in primary school children: A Chinese perspective**

Yuehua Tong, University of Jinan, China

Emotion understanding refers to the ability to discern and understand others’ emotions, using situational and expressive cues that have some degree of cultural consensus as to their emotional meaning. It includes one’s knowledge about emotional states, interpreting the cause of emotion and the possibility of regulating emotions. The present research aimed at examining the developmental trend of emotion understanding in Chinese primary school children. 170 children in Grade two, Grade four, and Grade six participated in the study. Emotion vignettes were used to collect research data. The findings of the present study showed that the development of emotion understanding was a slow and progressive process. Primary school children were able to explain emotions by means of external and internal reasons. No significant gender differences were found in understanding emotion states and emotion regulation. Girls in Grade six had better understanding in the causality of emotions than boys. The implications of the study for emotion education are discussed.

**Psychosocial responses to media’s thin-body ideal [re]directed by online peer comments**

Jolanda Veldhuis, VU University Amsterdam, Netherlands; Elly Konijn

Media serve as an important source of aesthetic standards including the Western thin-body ideal, especially for adolescent girls. However, via social reinforcement, socio-emotional pressure, and modeling mechanisms, peers also exert an influence on adolescent girls’ body ideals. Thus, peers may further strengthen or weaken girls’ body dissatisfaction, distorted weight perceptions, and intentions to change (e.g., via eating disorders or plastic surgery). Therefore, the present study investigated the combined influence of media’s thin-body ideal and peers’ feedback on such media images on adolescent girls’ weight-related psychosocial responses. Hypotheses were tested in a 3 (media models’ body shape: extremely thin vs. thin vs. normal weight) x 3 (peer comments: 6kg-underweight vs. 3kg-underweight vs. normal-weight) x 2 (appearance schematicity: low vs. high) quasi-experimental design (N = 216, age range of 11-17 years old). Media models and peer comments were presented as an incorporated entity designed in a YouTube format. Results of multivariate tests and contrast analyses showed that peer comments interacted with the media models’ body shapes in affecting participants’ body and weight perceptions, in particular for girls high in appearance schematicity.

**Relationship between personality traits, positive affect, negative affect and life satisfaction**

Wan Shahrazad, Wan Sulaiman, Universiti Kebangsaan Malaysia, Malaysia; Nor B’yah Abdul Kadir; Fatimah Omar; Fatimah Wati Halim

Adolescence is an important developmental stage for every individual as it is a transition period from childhood to adulthood. Hence, many variables contribute to the feelings of life satisfaction among adolescents. It is therefore prudent to investigate what adolescents deem as important in influencing their life satisfaction. The objective of this study was to examine the relationship between personality traits, positive and negative affect with adolescents’ life satisfaction. A total of 230 respondents aged between 18 to 20 years old participated in this study. Three standardized instruments were used, namely the NEO Five Factor Inventory (NEO-FFI) to measure personality, the Positive and Negative Affect Scale (PANAS) and the Satisfaction with Life Scale (SWLS). Results showed that there was negative and significant relationship between neuroticism and positive affect and life satisfaction. The findings also indicated positive and significant correlation between neuroticism and negative affect. On the other hand, results showed that there were positive and significant relationships between conscientiousness with positive affect and life satisfaction while a negative and significant relationship was obtained between conscientiousness and negative affect. Finally, there were also significant correlations between positive and negative affect with life satisfaction. In conclusion, adolescents who were satisfied with their lives were those who have high positive affect, low negative affect and personality traits of emotional stability and conscientiousness.

**Loneliness in middle childhood and its relation to multi-level peer experience**

Sun Xiaojian, Central China Normal University, China; Cuiying Fan; Zhongkui Zhou; Huaoshan Liu

The goals of the current study were to investigate relations between children’s social behaviour, peer relationships, perceived social competence and loneliness, multi-mediation between social behaviour and loneliness, and analyse constructs of different levels in peer interaction with a sample of 450 children from Grade 4 to Grade 6. The results showed that: There are significant gender and grade differences in social behavior, peer relationship, perceived social competence and loneliness. Social preference associates with loneliness only through the mediation of perceived social competence, there are mediating and direct relations between friendship quality and loneliness, among variables in four levels of peer interaction, the strongest predictability on loneliness is from perceived social competence, and the less strong are friendship quality, social behavior and social preference respectively.

**Bias of children’s perceived peer acceptance: Prospective associations with loneliness**

Zhiqi You, Central China Normal University, China; Zongkui Zhou; Fan Cuiying; Zhong Fengjuan

Is loneliness in childhood associated with realistic social self-perception to a certain extent? In order to find the relation between bias of perceived peer acceptance and loneliness in childhood, 371 Chinese primary school students (206 male and 165 female) in third, fourth and fifth grade, were randomly selected from a primary school in the city of Wuhan, China. Children in the current study rated how much they liked their classmates and completed self-report measures of self-perceived social competence and loneliness questionnaires twice (once each year). Their systematically under- or over-estimated peer acceptance was measured by standardized residuals derived by regressing children’s responses to the Social Acceptance subscale of the SPPC onto peer acceptance ratings. The results indicated that there was significantly negative correlation between bias of perceived peer acceptance and loneliness. Negative bias of perceived peer acceptance predicted increase in loneliness, which showed that children who underestimated social self-perception would increase loneliness.

**Research on the relationship between school belonging and achievement motivation for college students**

Guifong Yang, Guizhou Normal University, China; Yun Pan

This study investigated the relationship between school belonging and achievement motivation of 540 college students by using a questionnaire for school belonging and achievement motivation. The results showed that undergraduates had significant sexual differences scores. The college mens’ scores were significantly higher than womens in the motivation of achieving success and achievement motivation, while the womens’ scores were significantly higher than mens in the motivation of avoiding failure. There was a significant positive correlation relationship between motivation of achieving success and school belonging, but there was a significant negative correlation relationship between motivation of avoiding failure and the only factor of campus peer relationship recognition in school belonging, and without significant correlation for other factors in school belonging. It has a significant impact on the factor of sense of responsibilities and campus peer relationship recognition in school belonging for undergraduates’ motivation of achieving success.
city, China. Mediating effect tests indicated that self-perceived social competence was the mediator on the separate relations between peer interaction variables (prestige, social liking and friendship quality) and loneliness. Path analysis showed that self-perceived social competence no longer had mediating effect on association of prestige and loneliness when considering the influences of social liking and friendship quality. The findings suggested that the quality and quantity of direct friends had more contribution to keep children away from loneliness, meanwhile indirect friendships had lower but significant influence on children’s loneliness.

An analysis of children's cognitive transition patterns and test invariance

Jiahui Zhang; Beijing Normal University, China; Wei Tian; Tao Xin

This study aimed to address cognitive development patterns of children between 4- to 6-years-old. The measurement invariance of the self-developed cognitive battery was also tested in the study. Two research questions were of interest: (1) Whether early cognition or the structure of early cognition is stable over time, (2) what the transition and its patterns across the latent classes (based on the factor scores pattern) are. A two-tier full-information item factor analysis model was applied to the data of a three-year longitudinal research. Data were drawn from a large-scale project in China and included 1,484 children who had scores for early cognition from age 4 through to school entry. The measurement instrument is a cognitive battery developed by psychologists and primary educational experts. The battery included following tasks: (1) Quantitative comparison, (2) orientation, (3) plus-minus, (4) geometric puzzle, (5) classification, (6) ordering, (7) schema, (8) measurement, and (9) exaction. Each task is polytomously scored. Data analysis was realized by IRTPRO and Mplus 4.2. The result showed that the structure of the cognition test is stable over time, and the transition pattern is consistent with the hypothesis. The results of this study shed light on the development pattern of children who were enrolled in kindergarten before they entered primary school, and thus suggested the effectiveness of kindergarten education in boosting children’s school readiness. The importance of measurement invariance and its testing methods were also discussed.

Developmental characteristics of ego-identity in adolescent students

Jianren Zhang; Hunan Normal University, China; Hui Ling

The aim of this study is to explore the developmental characteristics of young people’s ego-identity. 337 high school students (male:177; female:160) and 368 university students (male:182; female:186) in Changsha were randomly selected and measured using the EOM-EIS-II. The results show the following: (1) There were significant differences in the dimension of identity achievement and foreclosure between male and female, with the boys getting higher scores than girls. (2) There were significant differences in the dimension of identity achievement and foreclosure between urban and rural. (3) There were some differences between high school group and university group, with the sophomores and junior students getting the highest score in identity foreclosure, the twelfth grade students getting the lowest score in identity foreclosure, and the first year high-school students getting the highest score in identity diffusion. Generally, the development of ego-identity of adolescents is unsteady and out of balance, and there are significant differences between sexes, urban and rural.

The relationship between emotional display rules cognition and peer acceptance of 9–11 year-old children

Jing Zhang; School of Psychology, China; Ri-Xin Tang; Ni Li

This study investigated the relationship between children’s emotional display rules cognition (EDRC) and peer acceptance. A sample of 127 9–11 year-old children participated in two experiments. Story context interview was used in the first experiment to examine the EDRC of children with different ages and gender, and the EDRC of children in different moods. In the second experiment, the method of peer nomination was adopted to measure peer acceptance. The results showed that: (1) The EDRC of children developed with age, (2) 9–11 year-old children tended to use social orientation goals to guide their emotional expression, (3) more neutralisation strategies and masking strategies were used by children in positive emotional situations than in negative situations, (4) emotional role knowledge, social orientation goals and masking strategies of children correlated positively with peer acceptance. These findings may indicate that the EDRC of 9–11 year-old children correlated positively with peer acceptance.

The influence of gender roles and class environment on the development of pathological internet use in adolescence

Guohua Zhang; Renmin University of China, China; Li Lei

The objective of this study was to investigate the influence of gender roles and class environment on the development of Pathological Internet Use. The term ‘Pathological Internet Use (PIU)’ has been used to describe problematic, excessive, or mal-adaptive use of the Internet. This study investigated 123 adolescents in a longitudinal design from a middle school in Beijing. The Adolescent Pathological Internet Use Scale (APIUS), which consisted of six dimensions, has been assessed six times in 18 months, including for salience, mood alteration, social comfort, tolerance, compulsive internet use/withdrawal symptoms, and negative outcomes. Simultaneously, the Class Environment Questionnaire was used to access their perceived class environment, this scale consisted of five dimensions, including Relationship between teachers and students, Relationship among classmates, Order and discipline, Competition, and Learning load. In addition, the Bem Sex Role Inventory was used to access their gender roles. The longitudinal panel data was analyzed through the Hierarchical Linear Model (HLM) and SPSS. The results showed that (1) the growth of PIU had no significant difference between genders, but an effect of gender roles on the PIU was found, in which the higher the level of masculine, the higher the initial PIU, and feminine level could ease the growth rate of PIU; (2) PIU has a positive relationship with Relationship with classmates, which also could positively predict the development of PIU. It was concluded that gender roles and relationships with classmates could predict the development of Adolescents’ Pathological Internet Use.

Relationship between suicide ideation, self-esteem and family environment of primary school students

Ziqing Zhao; Beijing Forestry University, China

In order to understand the suicide ideation of primary school students in Beijing, and to clear the relationship between suicide ideation, self-esteem and family environment, 716 primary school students were sampled from six primary schools in Beijing by multiple sampling. Subjects were measured by Family Environment Scale (FES), SEI and others to clear their psychological status and family environment situation. We analyzed the primary school students’ suicide ideation, and the multiple logistic regression analysis was used to identify significant factors for suicide ideation of children. 28.3% students reported they have suicide ideation. Self-Esteem and Family Environment were significantly related. Self-Esteem positively correlated with Cohesion, Expressiveness and Independence in family; and negatively correlated with Conflict. Both Self-esteem and Family Environment were significantly correlated with Suicide ideation. The ideation positively correlated with family conflict; and negatively correlated with Cohesion, Expressiveness, Intellectual-Cultural Orientation and Organization in family. Children with higher self-esteem have a lower incidence of suicide ideation. At the same time, Self-Esteem influenced suicide ideation as a mediator factor. Multiple logistic regression analysis shows that the major factor for children’s suicide ideation is age, whether being taken care by their parents or elders, family conflict, cohesion and self-esteem.

Effects of structured teaching on autistic children

Ziqing Zhao; Beijing Forestry University, China; Xiuyu Lei

The objective of the study was to explore the therapeutic effects of the structured teaching(TEACCH) on autistic children. A total of 32 autistic children were trained following the TEACCH method for 6 months, for more than 6 hours a week, carried out with individual and team teaching. The structured teaching pattern was applied in training including visual clues used in every action area. The structured work-rest time, educational environment and work organisation were emphasised. All children were assessed by C-PEP at begin and after 6 months. The average C-PEP score was significantly increased, P<0.01, especially in language ability, emotional expression and cognitive comprehension. Moreover, teachers, parents and staff reported that most children were improved in compliance and self-control. Emotional stability was also improved. For children with autism, the structured teaching treatment is an effective training strategy.

Popular peers’ influence on early adolescents: A longitudinal study

Shuangguo Zhen; South China Normal University, China; Wei Zhang; Hongling Xie; Dongping Li; Song Tang; South China Normal University, China

In order to understand the student peer group in China, and to clear the relationship between peer group and student behaviors, 1,484 children who had scores for early cognition or the structure of early cognition is developed with age, (2) 9–11 year-old children tended to use social orientation goals to guide their emotional expression, (3) more neutralisation strategies and masking strategies were used by children in positive emotional situations than in negative situations, (4) emotional role knowledge, social orientation goals and masking strategies of children correlated positively with peer acceptance. These findings may indicate that the EDRC of 9–11 year-old children correlated positively with peer acceptance.
Existing studies have provided compelling evidence that peers exert a strong influence on shaping adolescents’ behaviours. However, most current studies examined peer influence without taking into account that peer influence is not equally distributed in peer social networks. Developmental theories and social psychological theories suggest that a peer’s influence may be related to his/her social status. Thus, in a six-month follow-up study, we explored the influence that high status peers (i.e., popular peers) have on early adolescents’ physical aggression and prosocial behaviours. 321 7th grade students (55% girls) from three middle schools in the North Eastern USA participated in this study. Data were collected in the fall (T1) and spring (T2) semesters. At T1, 253 of them (60% girls) provided popularity nominations. Participants were also asked "Are there any students in your grade who hang around together a lot?" at T1 in order to identify a target individual’s affiliation with popular peers. Both at T1 and T2, physical aggression and pro-social behavior was measured by peer nominations. Results show that: (1) Popular peers influence a target adolescent’s physical aggression, which is moderated by the target’s initial level of physical aggression, the affiliation with popular peers, gender similarity and racial similarity between the target adolescent and popular peers, (2) popular peers influence a target adolescent’s pro-social behaviour, which is moderated by the target’s initial level of pro-social behaviour and racial similarity between the target individual and popular peers. These findings have important implications in preventing physical aggression and promoting pro-social behaviour.

The developmental trend of peer respect and the prospective effect of sociability-leadership: A three-year longitudinal study
Zongkui Zhou Central China Normal University, China; Fan Gouying; You Zhai
The present research held a three-year follow-up investigation on 285 students of grades 3 and 4 in elementary school. It analyzed the trend and individual differences of children’s peer respect development, and discussed the effects of sociability-leadership on children’s peer respect development. By using the Revised Class Play procedure, we measured peer respect nomination and sociability-leadership. Hierarchical Linear Model (HLM) was employed to analyze the longitudinal data. The result demonstrated that getting and giving respect had grown steadily over the three years. According to the initially tested data, we found that getting respect has no significant difference between girls and boys, but girls tend to increase faster than boys in the growth rate of getting respect. With regard to the giving respect, we saw a gender advantage on it in the early stage (7 to 8 years old) such as girls’ scores are higher than boys’, but the growth rates of giving respect had no significant difference between them. More importantly, sociability-leadership is a significant predictor of the developmental trend of respect of children.

Children’s understanding of emotions under different circumstances
Shuangzhu Zhou Beijing Normal University, China; Meng Zhang; Yinghe Chen
This study investigated 4, 5, and 7-year-olds’ predictions of emotions in rule situations. Rules were stated by different rule sources (adult authority, peer authority, no supervisor) in personal and prudential domain. We found that even 4-year-olds showed early insights of sensitivity to different rule sources and different rule domains, and the evidence from 7-year-olds were most robust. In personal and prudential domain, children predicted more "transgression feel good" and more "compliance feel bad" with age increasing. Adult authority was a prominent rule source for young children; they predicted more "transgression feel good" and "compliance feel bad" for adult authority trails than for peer authority and no supervisor. Children’s prediction patterns were similar for peer authority and no supervisor. This suggests that children may not appreciate the importance of peer authority till they are 7-year-olds.

Autonomy priming and its effects on Chinese high school students’ text learning
Xuelian Chen Art and Law Department, China; Zhao Zhang; Zongkui Zhou
Based on positive psychology, self-determination theory (SDT) asserts and has proved, that autonomy is one of the fundamental psychological needs of human beings; it is considered to represent self-determination, which in turn is assumed to predict optimal functioning in social, academic and other domains. To gauge the effects of autonomy priming on their text learning, a designed experiment: 2 (verbal priming vs.nonverbal priming) ×3 (autonomous condition, controlled conditions and non-directed group) ×2 (non-directed learning vs. conceptual learning), was conducted among 268 Chinese high school students. The results indicated that interactions among all the constructs were not significant. Students tested in the group that was given autonomy priming scored higher in text learning than the controlled group and the non-directed group. As for non-directed learning, the non-verbal autonomy priming group and the non-directed group got higher scores than the controlled group did. Regarding conceptual learning, the verbal autonomy priming group scored higher than the other two groups. Girls had significantly higher scores than boys in text learning. Students in the group who given oral directions performed significantly better than those in the other two groups. The scores of the non-directed text learning group were significantly lower than those of conceptual text learning group.

Children’s performance of conflict detection
Chu Chiao-Ling Fo Guang University, Taiwan, R.O.C.; Wen-ying Lin; Jenn-wu Wang
In the present study, two experiments were designed to examine the elementary school children’s ability and the strategies in detecting conflicting information presented in different story types. In experiment 1, second-(n=30) and fifth-graders(n=30) were individually read two short narrative stories and each story contained either an implicit or an explicit conflict. Results indicated that the children’s ability in detecting conflicts increased with age. In experiment 2, 30 second- and 30 fifth-grade children were asked to detect either structure conflicts or
The Big Five Model represents the most widely accepted taxonomy of basic personality traits (McCrae & Costa, 1997). Many empirical studies prove that this approach can be taken as universal and stable across different ages (McCrae & Costa, 2003). Searching for the structure of personality in self-descriptive data obtained from children is a particularly intriguing challenge. Children as respondents often find it difficult to complete word-based questionnaires. Measures for children should consider aspects of their cognitive development. Such a measure was recently proposed by Mackiewicz and Cieciuch (2011): the Picture Based Personality Survey (PBPS) for children. The inventory consists of 25 behaviour-oriented items. Extraversion, Neuroticism, Agreeableness, Conscientiousness, and Openness are measured by 5 items each. In each item, 2 pictures are presented that describe the two polar ends of the respective dimensions. The leading character is in the same situation, but behaves completely differently. The behaviour in the first picture indicates a high intensity of the factor, whereas the behaviour in the second picture indicates a low intensity of the same factor. Children choose the picture that is most indicative of their own behaviour. The presented study was carried out in Poland, Germany and Italy. Results of confirmatory factor analysis (CFA) as well as of exploratory structural equation modeling (ESEM) will be presented and discussed in terms of the development of personality structures.

The recognition of non-verbal messages expressing emotion by children aged 4 to 8
Ewa Czapolawska University of Gdańsk, Poland; Sonia Czapolawska University of Gdańsk, Poland

Researchers have been discussing which behaviour (verbal and non-verbal) can be called pragmatic. Most agree, however, with the statement that we may include among them the giving and understanding (receiving) of communicative intentions (acts of speech). While data concerning the understanding of verbal messages by children are available in subject literature, there is much less information on the subject of their understanding of non-verbally expressed communicative intentions, or their reception of contradictory messages. The two main factors of non-verbal expression are voice and facial expression. The purpose of this study was to determine: (1) If and to what extent pre-school aged children (4.0-7.11 years) recognize facial signs of emotion. (2) If and to what extent pre-school aged children recognize vocal signs of emotion. (3) If, in the case of contradiction between the verbal and non-verbal message, preschool children emphasise the content or the intonation of speech. This research involved the participation of 113 children attending pre-school in the Tri-City in Poland. Analysis of the study results allowed us to state that as children mature there is also an increase in their ability to decipher emotion from facial expressions, while their ability to recognize emotion expressed by voice manipulation decreases. Moreover, it appears that in the case of ambiguous messages, younger children place more emphasis on voice intonation than their older peers, whereas older children prefer message content as the main indicator of information.

Fostering prosocial behaviours in Mexican and European-American adolescents: Parenting and gender roles considered
Alexandra Davis University of Missouri, United States of America; Cara Streit; George Knight; Gustavo Carlo

Research demonstrates that parents influence the prosocial development of their children (Carlo & De Guzman, 2006). Parents engage in a number of practices that socialise and shape their children’s prosocial and moral tendencies. Particular styles of parenting have been the focus of prior scholarly research, namely responsive and demanding parenting (Maccoby & Martin, 1993). Furthermore, there is research that suggests that parenting styles might be associated to prosocial behaviours in different ways across distinct ethnic groups (Carlo & DeGuzman, 2006), such that cultural values might mediate the relations between parenting styles and prosocial behaviours (Carlo & DeGuzman, 2006), and that parenting styles might be differentially related to different forms of helping (Carlo et al., in press). The current study will examine the relation between parenting and prosocial behaviours and the moderating role of gender roles. Participants included 314 Mexican American and European American adolescents (206 Mexican Americans, 50% girls, mean age = 10.97 years). Participants completed measures of parental responsiveness and demandingness, traditional gender roles, and prosocial behaviors. Preliminary structural equation modelling (models had adequate fit, CFI > .95, RMSEA < .08) indicated that responsive parenting negatively predicted traditional gender roles. Traditional gender roles were positively associated with public and anonymous prosocial behaviours and negatively associated with altruistic prosocial behaviours. Further analyses will examine the moderating effects of gender and ethnicity. Discussion will focus on the role of parenting styles and cultural values in moral development among Latino youth, and the importance of studying different forms of helping behaviours.

Adoption project
Silvia De Medeiros University of Erecchim, Brazil; Simone Krah; Jacqueline Meneghati

Adoption, understood as a legitimate form of family constitution, which meets the desire of many couples who want to perform the function of parents and many children and teenagers who yearn to be reintegrated into a new family in which they can grow up with health and integrity. Estimates suggest the existence of 80 thousand youngsters in Brazil scattered in shelters waiting for adoption. The Adoption Project is part of a University Extension Program, developed through the course of Psychology at URI – Campus Erecchim, located in Brazil, in partnership with the Children and Juvenile Court and Public Ministry. The Project was implemented in 2006 with the purpose of strengthening and expanding culture in favour of adoption. Adoptive families and ones qualified to adopt are given a space where they can express their feelings and reflections, and also information on the adoption issue. During its implementation emerged other tasks prospective, such as: open lectures to the community, public awareness about adoption through conducted dynamics in schools, fomentation of affective sponsorship programs and fostering families – as an alternative shelter – also spreading the culture of late adoption. We understand that the Adoption Project became more than a support group for adoptive families and ones qualified to adopt, serving an average of 100 families every year, and now a days is consolidated in the city of Erecchim and Region as a reference center of studies on the subject, and as a partner of the community and the entities who care about children and adolescents in situations of social vulnerability.

A day in the life of siblings who take care of younger siblings
Letícia Delaazama UFRGS, Brazil; Lia Freitas

Siblings play influential roles as caregivers, friends and sources of support throughout life. In addition to helping to socialise their younger siblings, older siblings may take on the role of being their formal caregivers. Some anthropologists have highlighted the fact that in different cultures children and adolescents routinely take on the role of caring for younger siblings. The objective of this paper is to describe the daily routines of low-income adolescents, focusing particularly on those who look after their siblings. The description is based on a study conducted with 20 12- to 16-year-old Brazilian adolescents. The instruments were: A record of socio-demographic data, a family genogram, and a semi-structured interview about a typical day. The activities described were organised into: Personal care, sibling care, domestic tasks, school tasks, and leisure. The participants were divided into three groups based on the type of care: Those responsible for sibling care, those who helped their mothers with sibling care, and those without such responsibilities. Whether siblings have formal care responsibilities is related to socio-economic status, family configuration and the culture in which the family is located. It was observed that the number of children, single-parent family configuration and sex of the eldest child are also important factors related to formal sibling care. Adolescents of both sexes took care of siblings, but females were more likely to take on domestic chores. School and leisure activities of adolescents were negatively impacted when they were responsible for care.

Children’s perceptions of peer and student-teacher conflicts in the school-setting
Megha Dhillon Mann Delhi University, India

This qualitative investigation explored Indian children’s perceptions of conflicts with peers and teachers in the school setting. Forty girls and boys...
Developmental

The development of 5- to 11-olds' ability of time reproduction

Ge Fang Institute of Psychology, CAS, Afghanistan

The purpose of present study was to investigate the developmental process and the effects of task conditions on time prospective reproduction with the duration of 6s and 12s in 5, 7, 9 and 11 year olds. Two conditions were carried out in the study: (a) Single-tasks on time reproduction, (b) dual-tasks on time reproduction with easy and difficult non-temporal tasks. The results showed that (1) children's ability for reproducing a short time-duration was improved increasingly with age, specially improved rapidly from 7 to 9 olds, (2) in single tasks on time reproduction 5 and 7 year olds overestimated the duration of 6s and underestimated the duration of 12s. However, the lengths of such duration had no effects on 9 and 11 year olds' accuracy of time reproduction, (3) the non-temporal tasks had more effects on 5 and 7 olds' accuracy of time reproduction than 9 and 11 year olds' one of those, (4) counting was one of the most efficient strategies for the problem solving of time reproduction. Even 5 olds had already showed the ability of regarding time as a quantitative dimension.

How do Chinese children come to think of themselves and others as a girl or a boy?

Fuxi Fang Institute of Psychology, CAS, China; Zhen- tao Fan

How do children develop their beliefs that the gender of their own selves and others is unchangeable? The findings of prior studies in Western societies indicated that the understanding of gender constancy followed a developmental sequence. In this study we addressed the question of how Chinese children, who live in an Eastern society, come to think of themselves and others as a girl or a boy. This was done by interviewing 120 Chinese children grouped by the ages of 3, 4, 5 and 6 individually, in Beijing, using a questionnaire with pictures of figures attached. The subjects had to make judgements about their own and others' gender, with justification. The results showed: an understanding of gender constancy went through a developmental sequence from gender identity (in 3 to 4 olds) to gender stability (in 4 to 5 olds) and finally to gender consistency (in 5 to 6 olds); that 3 olds identified themselves with gender earlier than they identified others' gender; with regard to gender stability, children first came to understand that one's gender can not be changed in the near future, or in the past nor in the foreseeable future, and finally not in distant future; Concerning gender consistency, children first come to believe that one's gender can not be changed by willing it, neither can it be altered by adopting the clothes or hairstyles of the opposite sex, and finally, nor can it be transformed using a combination of the clothes and hairstyles of the other gender. Thus, the development of gender constancy in Chinese children is largely universal.

Social risk, vulnerability and resilience in Brazilian teenagers' autobiographies

Liciane Felix Federal University of Ceara, Brazil; Idílvia Germano

This work discusses social risk and resilience processes based on narrative interviews with 21 Brazilian teenagers, and youth who attend public schools, and who live under low socioeconomic conditions. The aim of the study was to analyse how vulnerable individuals told their life stories, particularly how they dealt with adversities, navigating their way to health-sustaining resources, including material support and social relations, leading to experience of well-being in family, community and cultural environments. The qualitative design of the study is expected to provide a more comprehensive picture of lives lived under adversity and addresses youth's own perspective on their culturally embedded pathways to resilience. Using Michael Ungar’s concept of resilience, and Fritz Schutz’s contributions on biography and narrative theories, the study discusses the various “tensions” negotiated by those young tellers in their life course, how they perceive social risks, manage to seek help (personal agency) and overcome painful adversities such as poverty and violence. Considering that the concept of resilience, as navigation, also refers to the availability of the help sought, special attention was directed to their perception of their families’ and communities’ capacity to provide health resources and experiences in meaningful ways. A result that stands out is their perception of public politics and services, as ineffective or absent. Facing the decline of the public sphere, youth tend to take refuge in the family and in their own personal resources as means to stand up to their future and resist risky unhealthy choices.

Families: influences in child development and behaviour, from parent and teacher point of view

Claudia Figueiredo ISPA-IU, Portugal; Filomena Dias ISPA-IU, Portugal

Family plays a very important role in an child’s development and behaviour, and a divorce can be a very stressful experience. This is an exploratory, comparative study that aims at identifying the differences in children’s behaviour with divorced (or separated) parents and with married parents (or parents who are living together), based on parents’ and teachers’ perceptions. We recruited a convenience sample of 62 children (30 with single parents, and 32 children with married parents) between 6 and 9 years old. To evaluate the parents’ perceptions about their children’s behaviour the Portuguese version of the Child Behaviour Checklist

Dating and sexual behaviour of undergraduates in Obafemi Awolowo University, Ile-Ife, Nigeria

Opeyemi Ekundayo Obafemi Awolowo University, Ile-Ife, Nigeria; Ayobami Oyedeji

Wanting to have a romantic partner is a natural, anticipated part of adolescence. However, involvement in a serious or exclusive romantic relationship at this stage of development can be problematic. This study assessed the influence of dating on the sexual behaviour of the undergraduate students of Obafemi Awolowo University, Ile-Ife, with a particular focus on gender, dating pattern, age and their family type. Two hundred subjects were sampled, comprising of 105 (52.2%) males and 95 (47.5%) females. Their age range was between 17 and 30 years. A self-developed questionnaire was used to gather data. It is established by this study that dating and sexual behaviour, especially sexual activities, have a very strong relationship; dating influences sexual behaviour. Results revealed that older undergraduates engage more in sexual activities than younger ones. It was also found that the sexual behaviour of undergraduates is being affected or in young children reported lower frequencies of peer conflict, older children perceived such events to be a regular occurrence. Moreover, younger children reported conflicts to be short-lived while older children believed that the duration of conflicts depended on their ‘seriousness.’ Anger was frequently mentioned in relation to conflicts. Sadness was associated with conflicts with friends but not with non-friends. Boys believed that controlling anger was essential for ending conflicts while girls felt that feelings of sadness and regret motivated them to resolve conflicts. Children reported settling disputes through various strategies like apologizing and negotiation. Intense conflicts were perceived to entail negative consequences and were thus considered best avoided. Yet, factors like anger and impulsivity were believed to push children into fights. Regarding conflicts with teachers, children reported feeling upset when teachers mis-understood them or sided with another child. The most common response to conflicts with teachers was reported to be submission. However many older children believed that parents or the school principal could be asked to intervene in certain cases. Implications of findings and areas for future research have been identified.

How do Chinese pupils know the clock time?

Ge Fang Institute of Psychology, CAS, Afghanistan; Xiuhua Zhu

Knowing of the clock time significantly depends on the transferable abilities from digital time to clock time and vice versa. How are these two kinds of abilities developed in the individual? Do they develop synchronously? What kinds of strategies do the pupils use to construct the clock time? We addressed these questions by testing 72 pupils in Beijing grouped in ages of 6, 8 and 10, using both time-setting and time-telling procedures. Furthermore 11 children of 8 years old with ADHD were tested in comparison with the normal children. The results showed that (1) the performances of knowing clock time grew rapidly from 6 to 8 years old. The 8 to 10 year olds could recognise the clock time based on hours, half an hour and 5 minutes but not on minute, (2) the performances of telling-time were better than the time-setting. The development of two kinds of transferable abilities were not synchronous, (3) the strategies used for time-setting were changed from drawing clock face clockwise or anticlockwise (in 6 and 8 year olds) to setting digits of 3, 6, 9 and 12 as anchoring coordinate, while drawing the clock (8 and 10 year olds), and (4) there were significant differences in the performances of difficult tasks but not of easy tasks, between normal children and children with ADHD at age 8.

from grades 1 and 5 (average ages 6.4 years and 10.5 years respectively) were interviewed. The data was analysed using Interpretative Phenomenological Analysis. Children reported having conflicts with peers over issues such as physical and verbal provocation and the use of objects and spaces. While younger children reported lower frequencies of peer conflict, older children perceived such events to be a regular occurrence. Moreover, younger children reported conflicts to be short-lived while older children believed that the duration of conflicts depended on their ‘seriousness.’ Anger was frequently mentioned in relation to conflicts. Sadness was associated with conflicts with friends but not with non-friends. Boys believed that controlling anger was essential for ending conflicts while girls felt that feelings of sadness and regret motivated them to resolve conflicts. Children reported settling disputes through various strategies like apologizing and negotiation. Intense conflicts were perceived to entail negative consequences and were thus considered best avoided. Yet, factors like anger and impulsivity were believed to push children into fights. Regarding conflicts with teachers, children reported feeling upset when teachers mis-understood them or sided with another child. The most common response to conflicts with teachers was reported to be submission. However many older children believed that parents or the school principal could be asked to intervene in certain cases. Implications of findings and areas for future research have been identified.

Opeyemi Ekundayo Obafemi Awolowo University, Ile, Nigeria; Ayobami Oyedeji

Wanting to have a romantic partner is a natural, anticipated part of adolescence. However, involvement in a serious or exclusive romantic relationship at this stage of development can be problematic. This study assessed the influence of dating on the sexual behaviour of the undergraduate students of Obafemi Awolowo University, Ile-Ife, with a particular focus on gender, dating pattern, age and their family type. It is established by this study that dating and sexual behaviour, especially sexual activities, have a very strong relationship; dating influences sexual behaviour. Results revealed that older undergraduates engage more in sexual activities than younger ones. It was also found that the sexual behaviour of undergraduates is being affected or influenced by their family type and that undergraduates who possess the adequate social skills to date the opposite sex reported high rates of sexual activities.

How do Chinese pupils know the clock time?

Ge Fang Institute of Psychology, CAS, Afghanistan; Xiuhua Zhu

Knowing of the clock time significantly depends on the transferable abilities from digital time to clock time and vice versa. How are these two kinds of abilities developed in the individual? Do they develop synchronously? What kinds of strategies do the
of young Taiwanese children were established. In these interactions with more mature members of the cultural group, the developmental pathways and affectively participating in the routine of daily life are more spaced the father’s visits, in single parents’ children, the more behavioural problems they have, according to the mothers. Therefore, based on our results, teachers and parents indicate that divorce has a negative impact in children’s behaviour.

Brenda Fassie: A psycho-biographical study
Paul Fouche University of the Free State, South Africa; Roelf Van Niekerk; Odwa Gogo

The aim of the psycho-biographical life history study was to uncover the lifestyle of the musician Brenda Fassie, known as the "Madonna of the Township". Psycho-biography is the use of psychological theory to uncover and reconstruct the development of a significant personality. The Psycho-biographical model by Alexander (1988), was used to identify which biographical data were salient. The Neo-Adlerian theory of Witmer and Sweeney (1992) was used to re-interpret her lifestyle in terms of holistic wellness. Brenda Fassie’s life was explored and described in terms of the life tasks of spirituality, self-regulation, work and friendship. The findings revealed an emerging pattern of wellness and a lesser degree of wellness in certain historical phases of her life.

Taiwanese parent-child conversations for moral guidance: Uncovering the ubiquitous but enigmatic process
Heidi Fung Academia Sinica, Taiwan, R.O.C.; Eva Chen; Jin Li

Building upon our efforts in the past years, in this poster we illustrate how examining parent-child conversations opens a window onto the actual process of how children gradually become full-fledged moral beings. We discuss our research findings on three distinct, yet inter-related, types of communicative activities, the socialisation of 'knowing shame', personal storytelling about past transgressions, as well as talks about learning and achievements. By adopting an ethnographic approach, we observed spontaneous interaction between mother and child. The ages of participating children ranged from toddlerhood (in the first two sets of data) to school ages (in the third set of data). In these interactive processes, the flow of socio-moral messages was relentless. Through actively and affectively participating in these routinely occurring communicative activities with more mature members in the cultural group, the developmental pathways of young Taiwanese children were established.

Hedonic matching of faces and odours: already effective in 5- and 7-month old infants?
Ornella Godard Center of Taste Sciences, France; Jean-Yves Baudouin; Sylvaine Martin; Benoist Schaal; Karine Durand

Understanding facial expressions of emotion is an important aspect of social and cognitive development. Past research has shown that infants differentially treat emotional expressions from the first half-year of life. They also show abilities to process the hedonic meaning of odours, in particular by displaying differentiable facial patterns. In addition, at all ages, odours that are pleasant vs. unpleasant elicit typical patterns of facial expressions. Here, we investigate whether infants can associate a pleasant/ unpleasant odour with a facial expression of happiness/disgust? In this study, 5- and 7-month-old infants were presented with a video of faces while exposed to either a pleasant or unpleasant odour condition, or to a no odour control condition. The video consisted of a 32-s visual presentation of a woman expressing happiness and disgust [composed of 8 4-s sequences of 1/ 4 neutral to expressive to neutral face, the expressive phase lasting 1.5 s]. The results reveal an effect of odour in 7-month-olds, with no effect of expression and no odour by expression interaction. In contrast, in 5-month-old infants, we noted a significant odour by expression interaction. This study highlights: 1/ that olfaction can modulate an infant’s responsiveness to an adult’s face expressing an emotion, and 2/ that this odour-based modulation changes between the ages of 5 and 7 months.

Effect of temperament and external award on social creativity of Chinese adolescents
Chuanghai Gu Central China Normal University, China; Sen Yang

Social creativity is a special sort of creativity in the process of finding and solving social problems which is prevalent in daily life, and has been one of the focuses of creativity research recently. The self-developed open Social Problem Situations (Gu, 2010) and Temperament Scale for Chinese Adolescents (Zhang & Chen, 1985) were administered to 265 Chinese adolescents (117 junior high school adolescents and 148 senior high school adolescents) selected by group sampling to investigate the effect of the temperament (melancholic temperament, choleric temperament, sanguine temperament, phlegm temperament) and external award (having external award of a fine gift vs. no external award of a fine gift) and their interactions on adolescents’ social creativity. The findings indicated that adolescents’ social creativity was significantly correlated with the level of melancholic temperament, choleric temperament, sanguine temperament, and phlegm temperament. The main effect of external award was found on social creativity, and the group with external award scored higher on social creativity than the group without external award. Meanwhile, adolescents’ social creativity had significant interaction with the level of melancholic temperament and phlegm temperament. It could be concluded that external award could improve adolescents’ social creativity, and the actual effect of external award in the process of promoting the development of social creativity might depend on adolescents’ temperament, and the related intervention should consider the temperament of adolescents.

The revised Achievement Motivation Scale (Ye & Hegytvet, 1992), and the Self-developed Open Social Problem Situations (Gu, 2010), were administered to a sample of one hundred and eighty-seven Chinese adolescents, (100 junior high school adolescents and 87 senior school adolescents), who were selected by group sampling to investigate the effects of different types of achievement motivation: namely, pursuing success vs. avoiding failure; having external evaluation vs. no external evaluation, on the social creativity of adolescents. The findings indicated that external evaluation had a significant interaction with the type of achievement motivation on the dimension of fluency of social creativity rather than on the four dimensions of originality, appropriateness, validness, and flexibility of social creativity. Furthermore, under conditions of external evaluation, the adolescents who were apt to avoid failure scored higher on fluency than those pursuing success. No difference existed in the fluency of social creativity between the adolescents avoiding failure and those pursuing success under the condition of no external evaluation. It could be concluded that with external evaluation, those adolescents avoiding failure tended to give more solutions to social problems which indicated fluency rather than originality, appropriateness, validness and flexibility of social creativity.

Effect of coping skill training with stress on emotional intelligence among female high school students
Mohammad Hikami Islamic Azad University, Karaj, B, Islamic Republic of Iran

The purpose of the present study was to investigate the impact of stress coping skill training on EQ increment, its sub scales include stress tolerance, impulse control, problem solving and emotional self-awareness, in female high school students. The statistical population were all female 2nd standard high school students who were studying in 3 majors includes maths sciences, experimental sciences and humanity sciences in the school year 2010-11. From the population 90 girls were selected randomly in multi stage. Then the sample was divided into 6 groups (3 Major Studies: Maths sciences, experimental sciences and humanity sciences and each one divided into 2 groups of control and experimental, each group 15 individuals), each consisted of 3 control groups and 3 experimental groups. All the sample members were examined by Bar-On EQ questionnaire before teaching how to cope with stress, as a pre-test. Then the experimental group were trained by the skill of stress coping in 12 meetings. The results showed that the coping stress training had a positive significant effect on emotional intelligence; and about the sub scales, there were differences between the effects of training on the 3 sample educational fields. Emotional intelligence had been increased statistical- ly in humanity, mathematics and experimental fields, respectively. Additionally, the sorted decrease of stress in mathematics, humanities and experimental fields are concluded to be significant.

Primitive reflex retention and its influence on learning behaviour
Caroll Hermann University of Zululand, South Africa

All humans are born with a set of primitive reflexes that aid survival during the early developmental
years. Over time, these reflexes are inhibited, and replaced with more mature reflexes. If the reflexes are retained, for whatever reason, this can lead to interference in activities of daily living, of which learning behaviour is the most important. The aim of the study was not to integrate the reflexes, but to evaluate the effect of a simple step intervention on learning potential. No other factors that could influence learning behaviour were taken into account.

The work reported here is part of a large qualitative PhD study entitled “Perspectives on children’s participation in custody decision making and children’s reported experiences with participation of custody decision making”. The work reported here sought to investigate children’s experiences with parental verbal arguments using two projective techniques, the human figure drawings (HFD) and the kinetic family drawings (KFD), with 30 conveniently sampled children attending a rural primary school in Zimbabwe. The children lived with either parent or two guardians (grandparents, uncle and aunt). The children were aged between 10 and 12 years of age (Mean = 11years; Standard Deviation = 0.37). There were of 15 male and 15 female participants. The data were thematically analysed. The following five superordinate themes emanated from the study: causes of parental verbal arguments; time of occurrence; effects of parental verbal arguments on children; repressed memories about parental verbal arguments; and gesticulation and parental verbal arguments. The findings of the study revealed that children expressed through drawings, their perceived causes of, experiences of parental verbal arguments and the effects that these verbal arguments have on the family and children. The study highlighted the usefulness of drawings as a non-threatening way of investigating and incorporating children’s views of adult interaction and family dynamics.

The psychological implications of retained Moro Reflex in the classroom
Caroll Hermann University of Zululand, South Africa

This study investigated the psychological effect of the retained Moro Reflex on the behaviour of the client in the classroom. Participants in a preschool setting were assessed for the Moro primitive reflex retention. Structured questionnaires were distributed to the teacher and parents, and time was spent within the classroom by the researcher. Areas of focus were birth delivery method and lifestyle of the participants. Behaviour in the classroom and at home was graded according to a separate questionnaire and compared to academic performance. A significant number of the participants who had retained various primitive reflexes presented with the Moro Reflex. High levels of hypersensitivity, hyper-reactivity, poor impulse control, anxiety (particularly anticipation anxiety), labile emotions and emotional and social immaturity were reported. The results were compared to the DSM-IV-TR criteria of ADHD and a relationship between the retained Moro reflex and ADHD were investigated. This study supported the view that retained Moro Reflex impacted negatively on learning behaviour of the participants in the classroom. The author proposed that an intervention of simple structured movement programmes at school level can assist in integrating these retained reflexes.

Developmental changes in young children’s self-assertion: Observation in free play situations
Shohei Hirose Japan; Yuko Yato

This study investigated young children’s self-assertion in free play situations, focusing on developmental changes in self-assertion and response to assertion from other children. Forty-four 3- to 6-year-old children were observed in free play situations. Results indicated that frequently used types of self-assertion differ by age group. The low-age group used the “request” type more frequently than other groups. On the other hand, the middle- and high-age groups often used “proposition” and “report”. Children in the middle-age group advocated for other children most frequently among other age groups. In contrast, no difference relating to frequency was observed between the low- and high-age groups. Furthermore, various responses to assertion from other children were observed in the high-age group, and children in this group responded to the other children’s assertion more frequently than other age groups. By contrast, children in the low-age group responded the least frequently to assertion from other children. These results indicated that response to assertion from other children increased as children grow older. Moreover, in the high-age group, the frequency of self-assertion decreased and the frequency of response to assertion from other children increased. Children in this group were able to not only assert their opinion to other children but also to respond appropriately. These results were discussed in terms of development of self-inhibition.

Perceived parental attitude and aggression amongst adults: A correlational study
Samuil Hossain Scottish Livingstone Hospital, Bangladesh; Mahbuba Keya

The purpose of the present study was to find the correlation between perceived parental attitude and aggression. The sample was randomly selected from different faculties of Rajshahi University. It comprised 100 participants, 64 were male and 36 were female. The Perceived Parental Attitude (PPS) scale was used to measure perceived parental attitude and a Bengali version of the Edwards Personal Preference Schedule (EPPS) was used to measure aggression. The result showed that there is a significant co-relation between Perceived Parental Attitude and aggression in the sample.

Experimental research on judgement and attribution of moral emotion of children with different self-supporting levels
Xi-Ting Huang Southwest University; Ching-Hsi Wu Ling

The judgement and attribution of moral emotion of children with low support, high support and self-supporting levels in three moral story situations (the lying situation, the stealing situation, and the body injury situation) was assessed through clinical interview. The results showed that children were more likely to judge themselves as the actor of the story. The two groups showed no significant difference on moral judgement tasks. The two groups showed no significant difference in attributing emotions, mothers tended to respond with positive expressions, that is, by facial match. By contrast, when infants expressed negative emotions, mothers tended to respond with mind-related comments, accompanied by positive facial expressions, that is, avoidant mothers were more avoidant attachment were less likely to respond to their infant’s negative emotion with mind-related comments, accompanied by positive facial expressions, that is, avoidant mothers didn’t respond by way of attunement. These findings suggest that this kind of attuned response might be important for infants to develop their empathic abilities.

The observation of maternally attuned responses to infants’ emotional expressions: The normative style and the individual differences of the attuned responses
Shinsuke Kaboya The University of Tokyo, Japan

It has been suggested that a mother’s ability to match the infant’s mental states by attuned responses contributes to the infant’s capacity to develop a concept of its own mind, and the minds of others (Fonagy et al., 2002; Galles, Eagle, Migeone, 2007). This study investigated how mothers of pre-speech infants actually responded in a manner of attunement to the emotional expressions of their own infants. In addition, this study examined the associations among mothers’ attachment style and the frequency of mothers’ attuned responses. 38 pairs of mothers and their infants, at the age of between 5 and 9 months, were observed in free play interactions. To assess mothers’ attachment styles the ECR-GO (Nakao and Kato, 2004) was used. The overall analysis showed that (1) when infants expressed positive emotions, most of mothers responded with positive facial expressions, that is, by facial matching. By contrast, (2) when infants expressed negative emotions, mothers tended to respond with “comments on their infants’ mental states” (Meins et al., 2003), rather than facial matching. More focused analyses showed that mothers rated as having a more avoidant attachment were less likely to respond to their infants’ negative emotion with mind-related comments, accompanied by positive facial expressions, that is, avoidant mothers didn’t respond by way of attunement. These findings suggest that this kind of attuned response might be important for infants to develop their empathic abilities.
Sensitive interactional behaviour and arrangement of learning environments in family homes

Miriam Kachler; Universitätsklinikum Heidelberg, Germany; Andreas Eckhorst

The concept and design of the new project, FILU, and its contribution to the area of early learning in nurseries and day-care centers will be presented. This project started in the autumn of 2011 with the aim to encourage the parental competencies in accompanying and supporting the child within parent-child-interactions in learning environments. Parental competencies should be trained in the areas of (1) functional interactions with the child (cf. Cierpka, 2009) and (2) the arrangement of adequate learning situations and environments in the family homes (e.g. Son & Morrison, 2010). There are two phases scheduled for the project: (1) Training studies in encouraging the parental supporting behavior towards the child and (2) development and implementation of a training program for nursery nurses in teaching consulting competence in the area of parental supporting behavior towards the child and functional parent-child-interaction. After that an effectiveness test concerning the changes will be initiated. Therefore a study with a quasi experimental design is planned with a randomised allocation of the parent-child-dyads respectively the nurses-child-dyads. This is a project of the IDEA center in Frankfurt (Center for Research on Individual Development and Adaptive Education of Children at Risk) in cooperation with the Institute for Psychosomatic Cooperation Research and Family Therapy at the University Hospital Heidelberg. It is funded with a grant from an initiative for scientific excellence (LOEWE), of the government of the state of Hessen/Germany.

The Czech longitudinal study of optimal development

Vladimír Kebza; Nat. Inst. of Publ. Health, Czech Republic; Iva Solcova; Miloslav Koldi; Vera Kernessa

The joint project of the Institute of Psychology, Brno, and of the National Institute of Public Health, Prague aims to explore the paths to optimal development using empirical data of the longitudinal studies following individuals since 1956 (Prague) and 1961 (Brno). We considered the state of present well-being and its circumstances as the manifestation of optimal development in a current sample of 98 individuals (Prague) and 56 individuals (Brno) surveyed by the same set of methods. The variables expressing different aspects of well-being (feeling good, life satisfaction vs. frustration, tension, life events etc.), as well as selected health and behavioural variables have been monitored over the long term, and further constructs (resilience, human strengths) are included in the new project for the 2010 – 2014 period. In current survey we found mostly positive correlations with former findings, e.g. low level of neuroticism (correlation 0.62, but higher in women), higher level of life events (0.43), higher in women, higher level of tension (0.44), higher in men, but better evaluation of self-rated health in men, etc. We hope to gain a better understanding of adaptive functioning of personality during the life course.

Self-esteem, stigmatisation and coping strategies among children with nocturnal enuresis

Simon Klitzo; Stellenbosch University, South Africa

The purpose of the study was to investigate whether nocturnal enuresis affects stigmatisation, self-esteem, and coping strategies of the child. The sample comprised 200 pupils between the ages of seven and thirteen years in primary boarding school. One hundred respondents with nocturnal enuresis were selected using a purposive sampling technique, while one hundred respondents without nocturnal enuresis were selected using quota sampling. The study used a causal-comparative study design. Data on self-esteem was collected using the Rosenberg Self-Esteem Inventory, while data on stigmatisation and coping strategies was collected using an interview guide. The hypothesis on self-esteem and nocturnal enuresis was tested using an Independent Sample T-test, while data on stigmatisation and coping strategies were analysed using case-ordered descriptive Meta matrices. An event dynamics matrix and a cross-case causal network were designed to explain stigmatisation and coping strategies. Results indicated that there was a significant difference between children with nocturnal enuresis and those without nocturnal enuresis as far as self-esteem was concerned. The results indicated that children with nocturnal enuresis had a lower level of self-esteem than those without. Results also indicated that children with nocturnal enuresis were stigmatised by significant others. Children with nocturnal enuresis used both functional and dysfunctional coping strategies in order to cope, as well as using more problem focused coping strategies than emotional focused coping strategies.

Mu rhythm modulation during observation of an occluded grasping action in 14-month-old infants

Jennifer Landt; University of Cambridge, United Kingdom; Maren Grigutsch; Vincent Reid; Tricia Striano

The electro-encephalographic mu rhythm has been shown to be suppressed in adults and in infants during the observation of a precision grip. This has been related to the activation of cortical neurons that are linked to action coding, known as mirror neurons. The current study was designed to determine whether a modulation of the mu rhythm in relation to the mirror neuron system could be observed in 14-month-old infants under conditions similar to those in the original mirror neuron studies involving monkeys (Umiltà et al., 2001). In that study Umiltà and her colleagues presented macaque monkeys with an experimenter grasping for an object in a visible and an occluded condition. When the final part of an action movement is invisible, it can only be inferred, indicating an internal representation of that movement. A frequency analysis of EEG data resulting from the passive observation of an object-directed precision grip in a visible and in a hidden condition indicated a significant enhancement of mu power during the hidden condition when compared with a baseline condition. These results indicate that infants at the age of 14 months discriminate the hidden condition from the baseline condition.

The development of children’s expressive drawings: From literal to metaphorical expression

Samuel Lebaz; University of Toulouse, France; Christopher Gauthier; Delphine Picard

The way children express emotions in their drawings of human and non-human topics is assumed to reflect their artistic, emotional, and cognitive development. This study was designed to investigate the development of expressive drawings during childhood up to adolescence, using a large age range (5 to 15 years) and sample size (N = 480), so as to provide a precise and complete view of the age-related changes in children’s ability to produce expressive drawings. Specifically, we focused on children’s developing ability to use literal and metaphorical expressive techniques, either alone or in combination. We also examined gender-related effects, and the role played by the drawn topics (house, tree, person), and the depicted emotions (happiness, sadness) on the use of each expressive technique. The collected data describe the normal developmental curves of expressive drawing abilities, showing a significant shift during childhood from literal to metaphorical expression techniques. The use of metaphorical expression techniques was also found to vary according to gender and topic, being more frequent in drawings produced by girls than by boys and more frequent in expressive drawings of non-human (house, tree) than human topics (person).

The moderating role of alexithymia on adolescents’ stress and depressive symptoms

Yu Ling; Hunan Agriculture University, China; Ming Zhong; Jin Yi; Shu Yao

The objective of this study is to explore the predicition effect of adolescents’ alexithymia and stress on their depressive symptoms. The current study examined whether the association between the occurrence of negative events and increased depressive symptoms is moderated by alexithymia. At the time 618 adolescents (ages 14–18) completed self-report measures assessing alexithymia, depressive symptoms, and the occurrence of negative events. Every three months for the subsequent 12 months, adolescents completed measures assessing depressive symptoms and the occurrence of negative events. Results of hierarchical linear modeling analyses indicated that adolescents possessing high levels of alexithymia reported greater somatic symptoms following the occurrence of negative events than adolescents possessing low levels. The association between the occurrence of negative events and increased psychological symptoms was not moderated by alexithymia. It follows that adolescents’ alexithymia can predict their depressive symptoms, and that adolescents’ alexithymia and stress can predict their somatic symptoms together.

Behavioural problems in a high risk sample of children born preterm

Maria Beatriz Linhares; University of Sao Paulo, Brazil; Fabiola Andrade; Claudia Gaspardo; Rafae- la Cassiano

Prematurity birth is a risk for developmental problems. Moreover, the mental health preventive strategies recommend the detection of these problems at early ages, especially in vulnerable infants. The aim of the present study was to estimate the prevalence of behavioural problems in a sample of children born preterm and with a low birth weight, in their first five years. The sample comprised 295 children (50% boys) with mean chronological age of 34 months (+ 12m; 18-60), who were born with
The effects of event-control and self-control on children’s mental-time-travel ability
Yan Liu Liaoing Normal University, China; Li-Zhu Yang

Mental time travel comprises the mental reconstruction of personal events from the past (episodic memory) and the mental construction of possible events in the future (forsight) (Suddendorf and Corballis, 1997). The current study examines whether event-control and self-control can affect children’s mental time travel ability. Fifty-seven 4-year-olds were randomly assigned to one of two conditions: Remembering past experiences or simulating future events. Adapted from the paradigm by Quon and Atance (2010), children were asked questions about the same ten events, phrased in past or future tense. Half of these events were ones for which parents rated their children as having a high level of control over how the event unfolds, whereas others were rated as “low control”. Children were further divided into two groups (high self-control or low self-control) according to the waiting time in delay-of-gratification test. Results revealed that (a) Children with low self-control ability remembered more specific past experiences for high-control events compared with low-control events, (b) children generated more specific and accurate future imagination for high-control events compared with low-control events. These findings offer new insights into the dynamic relations between environmental and genetic factors and their influences on mental time travel.

The characteristics of peer conflict resolution strategy of Chinese 4 to 6 year old children
Wen Liu Liaoing Normal University, China; Xuewen Yuan

This study explores peer conflict resolution strategy and the characteristics of children themselves. It chooses temperament and multiple intelligence level of children as an indicator. Family parenting styles is selected as an indicator of the factor of family. The mixed-age education of Montessori is selected as compared with normal age class. Subjects in this study consist of 126 children aged four to six; male and female in equal ratio. It uses the methods of a questionnaire and story interview to measure the peer conflict resolution strategy among 4-6 years old children. The conclusions are as follows: (1) There are significant differences among 4 to 6-year-old children in the maturity of peer conflict resolution strategy; the overall trend is that maturity comes with increasing age. There are still significant age differences in the frequency of strategies of problem solving, seeking help and ignoring. The frequency of problem-solving strategies shows an upward trend with age; and ignoring strategy and help-seeking strategies show a downward trend with age. (2) There are close relationships between peer conflict resolution strategy and temperament, multiple intelligence level and family parenting styles. Linguistic intelligence; interpersonal intelligence of multiple intelligence; activity of the temperament; and a democratic type of parenting styles can predict the development of peer conflict resolution strategies. (3) The mixed-age education gives a promotional power to the maturity of peer conflict resolution strategies.

Conceptions of adulthood in Cameroon: Emerging adult voices from four major ethnicities
Joseph Lah Lo-Oh University of Buea, Cameroon

Research on emerging adulthood has indicated comparative and contrastive definitions of adulthood across cultures and ethnic backgrounds. Such studies have sought to understand the criteria that are most important in signifying adult status; and whether there are universally held conceptions regarding adulthood or if these conceptions are cultural or context bound. The absence or scarcity of such studies from Africa is also evident to the extent that a lot of questions have not been asked and answered about how young people not only develop but also perceive the future of their tomorrow. With a multi-methods approach-interview and questionnaire data, this study explored cultural and ethnic differences as well as score comparisons in the criteria emerging adults hold for becoming adult in Cameroon. Specifically, it compared and contrasted responses from young people in four major ethnic groupings in Cameroon – the highlanders, the coastal peoples, the forest peoples, and the predominantly Islamic peoples, concerning whether they believed they have reached adulthood; examined if conceptions of adulthood could fit a common statistical model for all ethnicities considered; and compared the importance of such conceptions for Cameroonian emerging adults. Using Multiple Response Score comparisons, the findings showed comparative conceptions of adulthood across all four ethnic groups; however, there was also evidence of differential views with respect to specific indicators of components. Also, Cameroonian emerging adults share differing importance to their definitions of adulthood, being the reason why the influence of culture in the transition to adulthood was discussed.

Age 3 lying: is it related to mind, parenting behaviour or intelligence?
Fengling Ma Zhejiang Sci-Tech University, China; Fen Xu

This research examined 3-year-olds’ ability to tell lies, and its relationship with socio-cognitive factors, such as children’s theory of mind ability, general cognitive ability (intelligence) and parenting behaviours. Seventy-six Chinese three-year-olds and their parents participated in the investigation. The results indicated that 82 percent of these children peaked at the toy in the temptation resistance paradigm, and forty children covered up their transgression by lying. Among the transgressors, the occurrence of lie-telling was closely related with children’s theory of mind ability, rather than the general cognitive ability, especially 3-year-olds who performed better on knowledge-ignorance understanding, were more likely to tell lies. The parenting behaviour questionnaire, including emotional-warmth, rigorous and control dimensions, was self-rated by the children’s parents. The results revealed that the control dimension was negatively related to the tendency to lie. The mediation analysis proved that control parenting not only directly affected 3-year-olds’ lying but also had an indirect effect on the child’s theory-of-mind ability. Overall, the present investigation reveals that lie-telling is widespread in 3-year-olds, and identified two socio-cognitive factors related with children’s ability to tell a lie.

Adolescent temperament as a moderator between maternal control and adolescent problematic behaviour in Taiwan
Hsu Ming-Yu National Chiao Tung University, Taiwan; R.O.C.; Liu Yih-Lan

Research has indicated that adolescent problematic behaviours are related to maternal control and their temperament (Shih, 1998; Lai, 1999; Emily et al. 2011). This study examined whether adolescent temperaments (e.g. aggression, inhibitory control and activation control) have moderating effects on the relationship between maternal control (e.g. psychological control and behaviour control) and adolescent problematic behaviours in Taiwan. Participants were 455 adolescents (215 tenth grade and 240 seventh grade students, 221 girls and 234 boys) from northern Taiwan. Multiple Linear Regressions (SPSS 12.0) was conducted to examine the moderating relationships based on Baron and Kenny’s (1986) suggestion of moderation analysis. The result showed main effects of aggression (β = .24, p<.000) and maternal behaviour control (β = -.16, p<.000), and interaction effects of psychological control and aggression (β = .15, p <.001), and interaction effect of behavioural control and inhibitory control (β = .15, p <.001), when controlling gender and grade. This study found that high maternal behavioural control and low adolescent aggression temperament were related to lower adolescent problematic behaviours. Results of moderation.
indicated that adolescents with higher aggression showed a stronger and positive relationship between maternal psychological control and problematic behavior than adolescents with lower aggression. Adolescents with higher inhibitory control displayed a stronger and negative relationship between maternal behavioral control and problematic behavior than ones with lower activation control.

A meta-analysis of studies on gender differences in the prevalence of ADHD in Iran
Azam Moradi Payame Noor University, Islamic Republic of Iran; Soghra Taheri
The purpose of this research was to meta-analyse research on gender differences in the prevalence of ADHD in Iran. Nine studies on gender differences in the prevalence of ADHD, which were completed throughout Iran were selected for meta-analysis. Based on the results of this study, the effect size of the rate of gender differences in the prevalence ADHD was found to be 0.096. This shows that the effect size of gender differences in the prevalence ADHD is low in Iran, based on Cohen’s criteria for interpreting effect size.

Parents perceptions of the most significant change in their autistic spectrum children’s social skills as learnt in a group programme
Divan Mouton Midrand Graduate Institute, South Africa; Lynn Hendricks
There are few programmes in South Africa that deliver social skills interventions for children with autistic spectrum disorders, and of those that are, services are inaccessible to most due to financial constraints. The perceptions of parents are important to the sustainability of such programmes and an exploration of parents perceptions serve as rich sources of data in the investigation of the generalisation of their children’s social skills development beyond the context of the group programme. The objectives of the study were to collect written or verbal stories from each parent to illustrate the individual and collective perception of parents regarding the most significant change in their child’s social skills development since attending a group programme. All parents whose child had attended the programme for more than twelve months were invited to participate in this study (N=9). Four parents submitted their individual stories after which two of the four parents participated in a discussion. Each story was submitted as a narrative and expressed the parent’s perception of social skill challenges their children faced before entering the programme, the most significant changes in their children’s social skills, and how the group programme addressed their children’s initial challenges. An in-depth analysis of the qualitative results illustrate that parents individually and collectively perceived their children to improve in their academic skills, peer relationships, sharing and turn-taking, self-confidence, and their self-management skills.

Secure and disorganised attachment in the relational interactions in shelter for abandoned children
Mbiya Muadi UC Louvain, Belgium
The abandonment of children in Kinshasa and some of its psychological effects, such as the attachment strategies and cognitive impairments, are examined in this study. The aim is to provide a suitable care needs device for not only physical, but also psychological needs of abandoned children. A sample of 50 abandoned children aged from 3 to 7 years, collected in an institutional setting in Kinshasa/DRC, compared to 50 children aged from 3 to 7 years living in families, all explored with ASCI (Attachment Story Completion Task), Raven Matrices (cognition) and a drawing of the family. The Disturbances of Attachment Interview (DAI) and Semi-structured interviews of parents and caregivers were realised. In subjects living in institutions, disorganised and secure attachment strategies are the most frequently observed with respectively 38% and 36%, followed by insecurity 22% and a special category "unclassified" 4%. For the control group, attachment strategies are as follows: 60% secure attachment, 22% insecure attachment and 18% for disorganised attachment. The Raven Matrices showed a higher score than the average for all tested patients in the control group. In a population of abandoned children living in residential institutions in Kinshasa, caregivers-child interactions do not always give the possibility to develop a secure attachment.

Patrimonial traditions in consciousness structure of nations of the world
Valentia Mukhina Moscow Pedagogical State University, Russian Federation
Mentality as a historically formed individual and collective consciousness of ethnic groups, organises typical life dominants, behavioural patterns, and perception of the world. The results of the research (Mukhina, 1985–2011) demonstrate the heritage safety of patrimonial mentality. It is expressed in steady stereotypes, traditions and myths which dominate in the consciousness of present representatives of ethnic groups. The components of the data about Russian and ethnic groups, living in the Far North – Chukchi, Eskimos, Khanty, Mansi and Angolans – is a way to understand general phenomenological features of the consciousness of world nations. The author’s photo archive, analysed by means of the scientific photo method, illustrates the mental features of individual attitudes to life and death. The remaining traditions connected with a birth of a child and name-giving prove that a child is viewed as having great value: the ancestors come back through the child, the patrimonial name carries, for the child, the role of defender, defining his/her personal qualities and destiny as a whole. The attitude to death, oral and visual representations of the Netherworld, life transition into another form (death) are analysed on an example of the traditions connected with funeral rituals. The general phenomenological feature, unique identity of patrimonial consciousness, its fixation on the accepted set of knowledge and rules, interdictions and permissions, myths, and cultural codes reflecting the mental model (the person – human kin – the person) are shown in the article.

Mental models of attachment in middle childhood and self-esteem of adolescents
Tatsuya Murakami University of Tsukuba, Japan; Shigeo Sakurai
The purpose of this study was to examine the influence of attachment mental model in middle childhood on self-esteem at adolescence, by retrospective reporting. Given recent evidence for multiple attachment models, we also examined the structure of attachment mental model. We compared three models: Hierarchy model, Independence model, and Integration model. In Hierarchy model, the mental model for the first attachment person influenced mental model for other attachment persons, and the mental model of the first person strongly influenced the dependent variable. In Independence model, mental models for specific persons were separated, and independently influenced dependent variable. In Integration model, mental models for specific persons were integrated by general model, and it influenced the dependent variable. Respondents were 368 university students. First, we identified the Attachment Figure in middle childhood. Attachment figures were assessed by 3 important nominated people, in proximity seeking function, secure haven function, separation protest function, and secure base function. Secondly, we measured children’s attachment mental models for each these attachment figures. Mental models were assessed in two dimensions: avoidance and anxiety of abandoned model. Thirdly, we measured self-esteem. SEM analysis was conducted in the three models, Hierarchy, Independent and Integrated model. The results showed that Integration model indicated a better fit index than other two models. In integration model, general avoidance mental model (β = -24) and general abandoned mental model (β = -13) significantly influenced self-esteem. Therefore, we suggest that attachment mental model in middle childhood influenced self-esteem in adolescence.

Elder/grandparent caregiving and its implications for emerging adult development
Faheemah Mustafaa University of Michigan, United States of America
As a consequence of greater life expectancy and other modern trends (e.g., families living farther apart), fewer elderly adults rely on spouses and adult children as caregivers (Fruhauf, Jarrott, and Allen, 2006). In 2000, approximately eight percent of caregivers to the elderly in industrialised nations were grandparents (Fruhauf, et al., 2006). The percentage of emerging adult caregivers (EACs) is expected to increase as the “baby boomer” generation ages, and middle-aged, female caregivers become less available due to work and other role responsibilities (Dellmann-Jenkins, Blankemeyer, and Pinkard, 2001). Thus, while “premature” EACs desire to explore identities, establish autonomy, and indulge in “relative independence from social roles and from normative expectations” (Arnett, 2000, p. 469), they sometimes express feelings of frustration, stress, and regret over perceptions of delayed or lost opportunities. At the same time, EACs report stronger family bonding, preparation for future caregiving (e.g., of their own children), increased self-esteem, and positive identity characteristics (e.g. a sense of maturity). This poster addresses questions of interest to the international community regarding the psychological, social, and emotional consequences of elder caregiving for young adult development. Questions such as: What are the strengths and limitations of the current literature? What can nations and cultures where EAC roles are normative teach us? What practical interventions might support both elders and EACs as they adapt to changing social roles and relationships?
What factors experienced during pre- and post-delivery stimulate development of motherhood?
Shuza Oh! Gifu University, Japan; Hitomi Kodama
Some mothers cannot feel that their babies are cute. The case of child abuse by parents has also increased in Japan. But, research on animal mothering behaviour (e.g. Klopfner, J. L., 1971) suggests to us that various marvelous experiences in the perinatal period may drive the mother during motherhood. To support this mothering our purpose is to identify the facilitators to motherhood in the perinatal period. 191 pregnant mothers joined the workshop for late pregnant mothers in obstetrics hospital and participated in this research. They were asked to respond to questionnaires 4 times: Before Delivery (D) (BD), Puerperal Term (PT: within 7 days after D), One Month (1MAD) and 3 Months After D (3MAD), although inquiry items were different among research times. In all, Affection Scale for Babies (ASB) was asked. In addition, the BD questionnaire participant’s base information (age, sex, delivery frequency etc.) were asked. In PT, information on delivery (labor, baby’s weight, baby’s sex, delivery impression scale (18 items) etc.). In 1MAD and 3MAD, mother’s condition, contents of nursing, supportive circumstance, etc. (ASB were constructed by 20 items and 4 factors: positive feeling, appearance, vitality, troublnessomeness. These results were used as dependent variables). The longer labour was, the higher positive feeling for baby, appearance and vitality was in 1MAD and 3MAD, but troublnessomeness was not affected by labour length. Labour also did not affect any factors in PT.

Social support and family status as predictors of adolescents’ life satisfaction
Samuel Oladipo Tai Solarin University of Educa, Nigeria; Sonia Ogunronbo; Olamakinde Olapega
The study examined social support and family status as predictors of adolescent satisfaction with life in a local government area of Ogun State, using an existing descriptive survey research design. Participants in the study were 200 randomly selected secondary school students (100 males and 100 females). The age range was between 16–20 years, with a mean age of 27.3 and SD of 15.5. Validated scales were used for data collection and the three hypotheses stated were tested using the Pearson Product Moment Correlation and t-test statistics. Result of analysis showed that the three hypotheses stated were accepted, thus there was significant correlation between social support, family status and adolescents’ satisfaction with life. Social support and family status significantly predicted life satisfaction among adolescents, but there was no significant difference between male and female adolescents in their life satisfaction. Attention should therefore be focused on providing adolescents with adequate social support as well as keeping intact families that can foster satisfaction with life for the adolescents. School counsellors and psychologists should pay attention to these variables in attending to students who are dissatisfied or less satisfied with their lives.

Viva Mais: A programme for retirement preparation
Marina Pedralho Universidade de Brasilia, Brazil; Thayana Pastor; Sheila Neres; Joao Negreiros;

Sheila Murta; Samia Abreu Universidade de Brasilia, Brazil; Cristineide Franco; Juliane Rosa
Retirement is often a difficult experience for workers, often also associated with health issues. A public University in Brazil implemented a retirement preparation programme, called “Viva Mais!”! The programme aims at promoting wellness, health and quality of life for workers, mobilising them to face the common vulnerabilities before retirement. The implementation occurred in six steps: (1) assessment of needs, (2) creation of visual identity, (3) elaboration of a guide for participants, (4) sensitisation and marketing, (5) launch and (6) groups intervention. The last step consists of two types of interventions: multi-modal and brief. The first one is structured into twelve informational and experiential modules in a psycho-educational format, lasting three hours weekly. The brief intervention occurs in a single session, in groups, lasting 180 minutes, and is based in the “FRAMES” model (Feedback, Responsibility, Advice, Menu Option, Empathy, Self-efficacy). After three sessions of intervention, 43 workers participated of the multi-modal intervention and 108 of the brief intervention. Both interventions show improvements in planning for retirement, greater coping skills and positive changes in mental and physical health. These results, seen as positive, indicate that the content, having been learnt and put into practice by the participants was consistent with what was offered during the intervention. These findings corroborate studies about available resources as relevant to increase quality of life in retirement and aging, showing itself as an important indicator of prevention and health promotion.

The development of children’s expressive drawings: From literal to metaphorical expression
Delphine Picard University of Toulouse II, France; Christophe Gauthier; Samuel Lebaz
The way children express emotions in their drawings of human and non-human topics is assumed to reflect their artistic, emotional, and cognitive development. This study was designed to investigate the development of expressive drawings during childhood up to adolescence, using a large age range (5 to 15 years) and sample size (N = 480), so as to provide a precise and complete view of the age-related changes in children’s ability to produce expressive drawings. Specifically, we focused on children’s developing ability to use literal and metaphorical expressive techniques, either alone or in combination. We also examined gender-related effects, and the role played by the drawn topics (house, tree, person), and the depicted emotions (happiness, sadness) on the use of each expressive technique. The collected data describe the normal developmental curves of expressive drawing abilities, showing a significant shift during childhood from literal to metaphorical expression techniques. The use of metaphorical expression techniques was also found to vary according to gender and topic, being more frequent in drawings produced by girls than by boys and more frequent in expressive drawings of non-human (house, tree) than human topics (person).

Psycho-biographical study of John Wayne Gacy
Juazel Pieterse NMMU, South Africa
This is a psycho-biographical study, aiming to explore and describe the life of John Wayne Gacy. He was respected in his community, but there was a dark side to his nature which he kept hidden. This dark side was exposed, when police found twenty-seven dead bodies ranging from boys of nine to young men twenty years of age, hidden in his basement. The study utilises Erikson’s psychosocial developmental theory in examining Gacy’s lifespan development, in a qualitative single case approach, and the subject was selected through purposive sampling. Archival data was collected from secondary sources. Data were analysed by first organising and reducing information obtained, then displaying it for discussion. Gacy’s life was reconstructed from birth to adulthood and his death. The findings suggest that the theoretical approach considered the psychosocial as well as cultural influences of situations and experiences in Gacy’s development. The main themes of discussion centre around the abuse he experienced, and its influence on his development, the lack of crisis resolution, Gacy’s lack of difficulty in establishing attachment, and the resulting narcissism and lack of self-abandon, as well his homosexuality, sadism and the murders he ultimately committed. The study highlights the importance of psycho-biographical studies and the value of Erikson’s theory in understanding development. Recommendations for future research in this field was made in the hope of further uncovering and understanding personality development.
The role of social and non-social stimuli in shifts of attention in early infancy
Francesca Simion University of Padova, Italy; Valentina Ghirardi; Elisa Di Giorgio

To orient to and detect social objects in the environment is critical to survive from birth. Orienting towards face-like patterns have been demonstrated in newborns and in adults. Given the special status of faces in biasing orienting of attention, a still open question concerns whether or not the mechanisms of orienting are affected by the biological significance of the stimuli. The present study is aimed at testing the role of the central stimulus and of the peripheral target in determining shifts of attention in functional context, by using socially relevant or non-relevant stimuli. The overlap paradigm (Posner & Petersen, 1990) with social and non-social stimuli have been administered to adult subjects (N = 40), 4-month-old (N = 18) and 7-month-old infants (N = 18).

In Experiment 1 and 2, the social stimuli comprised static upright faces whereas non-social stimuli were static inverted and noise faces. In Experiment 3 and 4 the social stimuli were emotional dynamic faces, (i.e. fearful and happy faces) whereas non-social stimuli were noise dynamic faces. Both social and non-social stimuli appeared as central stimuli and peripheral target. Saccade latencies have been recorded by an eye tracker system (ASL) in free viewing conditions. Together, the results demonstrated that the social nature of the stimuli affects the capacity to shift and to disengage attention both in adults and in infants and that the main role is played by the central stimulus rather than the peripheral one.

Newborns’ sensitivity to biological motion: Critical factors inducing spontaneous preference at birth
Francesca Simion University of Padova, Italy; Lucia Regolin; Lara Bardi

Many adaptive responses to natural objects depend on the way these objects are moving and this is particularly true for the movement of biological creatures. Detecting and interpreting the movements of other living beings is critical for social interaction. Recently, studies on newborn babies provided evidence that sensitivity to biological motion is present in humans, as well as in other animals, prior to any visual experience. In a series of experiments, we tested for the specificity of the biological motion preference in humans at birth. Two-day-old babies were tested by comparing a point-light biological motion stimulus with a structured non-biological sequence (an animation depicting a rotating cylinder, exp.1), a non-structured biological motion sequence (a spatially-scrambled stimulus, exp.2) and a biological animation violating the natural direction of the gravity force (an upright stimulus in which each point underwent an inverted trajectory, exp.3).

Results revealed that newborns’ spontaneous preference is specific for the gravity-dependent dynamic of the biological movement. Interestingly, sensitivity to this motion pattern at birth does not depend on configurational information but extends to non-coherent patterns, which maintains the dynamic of biological motion. These fascinating results support the idea that inborn system for detecting the motion of living creatures is present in humans from birth and paves the way to a better understanding of the mechanisms that drive the human system to process socially-relevant signals in their environment.
The effect of leisure activities as a coping strategy on depressive symptoms among adolescents

Zuzana Sykorova Masaryk University, Czech Republic; Aimee Ferreira

Stressful life events are commonly associated with the occurrence of depressive symptoms in adolescence. A number of studies have shown that certain forms of leisure-time activities play a buffering role in moderating the negative effects of stress on physical and mental health. In this study, 300 high school students (age 15 and 17) participated in the study. The European Longitudinal Study of Pregnancy and Childhood – in the Czech Republic. The data were gathered using Coping Style Inventory (Kohoutek et al, 2008), Depressivity (Masopustová, et al, 2008) and Semi-structured Interview (interests and leisure-time activities). Results suggest that leisure activities mediate the negative effects of stress and moderate the depressive symptoms. Adolescents engaged in structured leisure activities (e.g. sport, art, outdoor activity) have experienced less depressive symptoms than adolescents engaged in unstructured leisure activities (e.g. watching TV, playing on PC, hanging out with peers). Results will be discussed in the light of practical implications.

Research on friendship quality and mental health of Chinese disadvantaged middle school students

Yuan Tian Central China Normal University, China; Jing Li Central China Normal University, China; Xiaojun Li; Xiaoyong Hu; Zongkui Zhou; Cuiying Fan

The goal of this study is to investigate the relationship between the friendship and mental health of different levels of academically and economically disadvantaged Chinese students. This study involves students from three disadvantaged situations to examine the interaction effect of disadvantaged situations on middle school students’ friendship. 197 Chinese middle school students were examined by Peer nomination, Friendship Quality Questionnaire, and Mental Health Test. This paper explores the effect of friendship on the relationship between disadvantaged situations and mental health. Conclusions reveal that middle school students’ friendship quality differs among different levels of economic, social and academic situations. Friendship quality has a moderating effect on the relationship between disadvantaged situations and mental health. Positive friendship has a positive effect, while negative friendship does not have a significant moderating effect.

Young children have difficulty inhibiting external facial features: Revisiting the developmental difference of matching unfamiliar faces

Sugimura Tomoko Fukuoka University of Education, Japan

Recent studies have shown that both children and adults are better at identifying or recognising unfamiliar faces from external features (e.g. hairstyle) than from internal features. However, these studies used matching tasks in which internal features were presented only in the absence of external features and vice versa. Here, we examined the developmental difference of internal or external advantages using a new face-matching task, where the two features interact. Sixty 5- to 6-year-old children and 62 adults were presented with two facial images and asked to decide whether the images showed the same or two different persons, not being misled by external hairstyles. Four types of stimuli were prepared: SS, in which the two faces were identical with the same hairstyle; SD, in which the two faces were identical with different hairstyles; DS, in which the two faces were different but had the same hairstyle; and DD, in which the two faces were different and had different hairstyles. We found that the identification accuracy of children was lower than that of adults for every type of stimulus, and that adults exhibited a ceiling effect. Children’s performances with SD and DS stimuli were considerably lower than with SS and DD. This indicates that adults exhibit an internal advantage, while children exhibit a robust external advantage, even when asked to attend to internal features. These results suggest that, unlike adults, young children have difficulty in matching internal features while inhibiting information from external features.

The concept and reference to art and visual objects in children

Carmen Torres Universidad de la República, Uruguay

This paper intends to show some peculiarities concerning the concept of art and visual objects in children. In current times, the concept of art has been shown to follow a very different itinerary, in academic discussions, that have formulated its perception. The search for the concept, in the case of children, poses different questions because it can neither be considered in isolation of the context, nor the complex development of such a concept. This paper tries to follow how children understand the concept and categorise visual objects, based on data obtained from interviews with children of different school levels conducted through a micro-longitudinal design which involved different operations within language.

Violence and gender role depiction in children’s magazines: An examination of Ben Ten and Barbie

Ayca Ulker Karabuk University, Turkey; Ebrar Yenice Kanik

For the child who begins to acquire social roles through the socialisation process, each of the parents, peers, teachers and the others around him are accepted as being important role models. In addition to those agents of socialisation, the increasing number of products of mass media has affected the children in terms of social roles in the last decades. A great number of different magazines are presented for consumption by children in various age groups. Therefore, it is important to examine the quality of publications addressing the children. Most of the literature argues that cartoons and advertisements or games have an effect on the child’s development. This research aims to analyse the depiction of gender roles and the use of violence in two international magazines; Ben Ten and Barbie. Considering the circulation rates taken from two main distribution companies in Turkey, Barbie and Ben Ten were chosen as the main subject of this research. In the current study, all issues published between 2011 and 2012 were examined and content analysis was used to examine the use of violence and depiction of gender roles in the last issues (February, 2012) of those magazines. Three main criteria were defined for the content analysis by the researcher: Depiction of boys, depiction of girls (names of the characters, descriptive features of male/female characters, reference to adult relationship style, reference to the characters’ daily life) and story plot.

Intellectual development of Estonian children during 15 years: A longitudinal study

Marika Veission University of Tallinn, Estonia; Kristina Nugin University of Tallinn, Estonia

This is a 15-year longitudinal study of the intellectual development of children in Estonia. 130 children participated in the first study group. Children were tested with Bayley Scales of Infant Development (BSID-II, 1993) once a year from 1 to 3 years of age. Further, children aged 3 to 6-years were tested once a year with Wechsler Preschool and Primary Scale of Intelligence – Revised (WPPSI, 1990). When the research group children were 3 years old, two control groups of children (one from Step by Step and another from mainstream kindergarten) were invited to the study, and all children were tested with BSID-II and WPPSI. Correlation of the results of both tests was .84, meaning that the tests gave similar results. At the end of basic school, cognitive skills of the same children were tested with the Raven progressive matrices test and, in addition, results of their achievement in native language and mathematics were included. Results show that girls performed better at age 3, but there was no difference in general IQ at the age of 6. In Step by Step kindergartens, it was possible to see a significant growth of IQ compared with mainstream kindergartens. Most of the children who had good results in the early years, also received good results when graduating from basic school. However, there are some different examples.

Verbal definitions of familiar objects in blind children reflect their peculiar perceptual experience

Annie Vinter University of Dijon, LEAD-CNRS, France; Pascal Morgan; Viviane Fernandes; Oriana Orlandi

The aim of the study was to examine to what extent the verbal definitions of familiar objects produced by blind children reflect their peculiar perceptual experience, diverging accordingly from those of sighted children. 96 visually impaired children, aged between 6 and 14 years, and 32 age-matched sighted children had to define 10 familiar words denoting concrete animate or inanimate objects. The blind children evoked the tactile and auditory characteristics of objects and expressed personal
periences in their definitions. The sighted children relied on visual perception, and referred to color, brightness and transparency properties. By contrast, no differences were observed between children in their propensity to include functional attributes in their definitions. The results are discussed in line with embodied views of cognition that postulate mandatory perceptuomotor processing of words when accessing to their meaning.

How Brazilian children evaluate their parents’ marital relationship
Adriana Wagner UFRRGS, Brazil; Viviane Goulart; Luciana Gryzbowski; Nauro Mittmann
This study investigated 200 children and adolescents aged between 8 and 16 years, to ascertain their perceptions of their parents’ marital relationship. Participants completed a demographic data sheet and answered individually an interpersonal conflict scale. Analysis of the items that assessed the frequency, intensity, resolution and content of marital conflict, showed that from the children’s appraisal their parents get along well or very well (91.7%), like each other a lot (75%) and never attack each other (94%). However, children pointed out the existence of marital conflict, which content involves issues such as money, relationship, sex, housework, personality characteristics of each spouse, work, family, time available, their children and “platitudes”. Furthermore, the results revealed that children are exposed to episodes of marital conflict, since the parents fight in front of them (50%) and allow them to witness their conflicts (70%). Parents also pursue coalition with children and ask their opinion about the discussion (85%) and talking down the spouse to them (81%). These findings show that children have a realistic view of marital relationship, which is characterised by the coexistence of love and conflict. On the other hand, results reinforcing the need for psychoeducative interventions with families to assist them in constructing clear boundaries between family subsystems so that the children are protected from marital strife and families have improved health.

How culture, age and manual dominance affect directionality in drawing side view objects
Annie Vinter University of Dijon, LEAD-CNRS, France; Hana Kebbe
The aim of the present experiment was to investigate the extent to which the orientation of objects drawn in side view is a function of culture, age and manual dominance. Right-handed French and Syrian children aged between 6 and 10 years and right-handed adults from the same cultural groups were asked to produce side views of faces, vehicles (car and airplane), self-centered tools with a handle (mug and toothbrush), object-centered tools with a handle (jag and hammer) and animals (dog and fish) using their dominant and non-dominant hands. The French participants exhibited a leftward directional bias whereas their Syrian counterparts displayed a rightward bias. However, no differences between the two cultural groups were observed in the 6-year-olds, who did not present any systematic directional bias in their drawings. Furthermore, regardless of culture, the children did not modify the orientation of the objects in their drawings as a function of the hand used, whereas the hand effect was strong in adults. Finally, despite their directional bias toward the right, the Syrian participants tended to draw the self- and object-centered tools facing leftward. These results are discussed with reference to the current literature on this topic.

A study on the relationship between attachment, self-esteem and interpersonal safety among peasant workers’ children
Hongqiao Wang Central China Normal University, China; Bin Zuo Central China Normal University, China; Min Hu Central China Normal University, China; Feixiang Hou; Wen Jiang Central China Normal University, China
In this research, we explored the distribution of peasant-workers’ children’s attachment type and the relations between the interpersonal safety and self-esteem and interpersonal trust. 1896 peasant-worker’s children in Guangdong province, aged from 12-18 years old participated, and completed the Self-Esteem Scale (SES) as well as the Inventory of Parent and Peer Attachment (IPPA) and Interpersonal Trust Scale (ITS). The results indicate that there is a certain development tendency with attachment. Peer attachment is remarkably higher than mother attachment and father attachment. There are remarkable correlations between attachment and interpersonal trust. Peer attachment is a better predictor than the other two attachments. Peasant-workers’ children’s self-esteem has a partly intermediary role in the attachment on the impact of interpersonal trust. Results are discussed in terms of the educational implications for the social development of peasant workers’ children.

Developmental experiences of mental time travel in 5–10 year old children
Lin Yu Research center of mental health, China
Mental time travel refers to the faculty that allows humans to mentally project themselves backwards in time to relive, or forwards to pre-live events. Mentally reliving past events is also known as episodic memory (i.e., mental time travel into the past). By contrast, mental construction of potential future episodes is also known as episodic future thinking (i.e., mental time travel into the future). As a cognitive ability, mental time travel research is
The effect of external scaffolding on other-regarding preference in young children

Zhen Zhang Institute of Psychology, CAS, China

The effect of external scaffolding (asking children to decide the reward consequences before they made a choice) on young children’s concern for the welfare of others in an anonymous context was investigated. We presented 61 (4- to 5-year-old) children with a two-alternative choice task adapted from research on chimpanzees. Each child was paired with a photograph of a sex-matched child stranger and could choose to merely benefit their own, or to benefit both their own and the recipient. Before the child made a choice, the experimenter either kept silent after baiting all four reward locations, or the experimenter asked the child the consequences of each choice after baiting. As a control, the same choices were presented with no other child’s photograph appearing. Results showed that there was a significant main effect of condition: children were more likely to choose the option that benefited both sides, when they were asked the consequences of each choice before making a choice, than when either the experimenter kept silent after baiting, or when in the control condition. There was no difference between the experimenter’s silent condition and the control condition. Results suggest that young children can take the welfare of an anonymous stranger into account, but that this depends on external scaffolding, i.e. asking children the reward consequences before they make a choice, which may induce children to process the recipient’s desire and thereby facilitate their demonstration of other-regarding preferences.

Session Type: Invited Addresses

Perspectives on cognitive development in adulthood

Adam Niemczynski Katowice School of Economics, Poland

Four sets of data on cognitive functioning in adolescence and adulthood were obtained from both cross-sectional and longitudinal studies with participation of more than 600 women and men at different age levels, from 15 years to 85 years of age. They represented at least the completed high school level of education. The data were analysed to test the developmental hypothesis of growth, plateau, and regression with age. Psychometric data has been derived from application of Thurstone’s Primary Mental Abilities Test and all the partial measures formed the predicted pattern. The same was found with Piagetian measure of operational intelligence as determined by Hornemann and Llongoet’s ‘Test of Fornal Operations’. In the third domain, the social-moral reasoning was studied with Kohlberg’s Moral Judgment Interview on six developmental stages scale. Here again the data support the hypothesis of growth, plateau, and regression in performance of the Kohlbergian tasks. In contrast to findings in the above three domains, a different pattern of continuous growth was found in the domain of biographical thinking development. Niemczynski’s Biographical Dilemmas Interview was used to measure development in this domain. It is argued that biographical dilemmas’ resolution seems to be best suited to study cognitive functioning and development from adolescence to old age.

One language or two? First steps in infancy toward language acquisition

Janet Werker University of British Columbia, Canada

In this talk, I will describe recent research linking speech perception to language acquisition in both monolingual and bilingual learning infants. I will provide data indicating that bilingual acquisition is as natural as monolingual acquisition. Research on the cues infants use to recognise the native language or languages, to segment and represent words, and to link sound to meaning will be presented.

Session Type: Invited Symposia

Symposium title: Behavioral genetics: Looking back and looking forward
Convener: Sergey Malykh

Behavioral genetics: Looking back and looking forward
Sergey Malykh Psychological Institute of RAE, Russian Federation; Yulia Kovas

The symposium gathers scholars who work in the field of behavior genetics from Russian and Great Britain scientific groups. The papers cover a wide range of psychological phenotypes – cognitive development, temperamental and personality traits, IQ, emotional and behavioral problems, and depression. The main methodology employed by the participants is based on the classical twin method, including the cross-cultural behavioural genetics study.

Symposium title: Bullying and cyberbullying among children and young people
Convener: Peter Smith

Bullying and cyberbullying among children and young people
Peter Smith Goldsmiths University of London, United Kingdom

Bullying of pupils in school has been an area of concern for several decades, however the majority of the research has been on mainstream pupils, and in western societies. More recently, cyberbullying has become a new form of bullying with distinctive characteristics. This symposium brings together five...
contributions that take this area forward in various ways. The opening paper by Lee, Smith and Monks (Terminology of bullying–like behaviours in South Korea: a life-span perspective) provides a perspective on bullying from preschool through to school age and into the workplace. This paper focuses on the words used to describe types of bullying (in Korean) and points out the importance of cultural and historical context in our study of these phenomena. The next paper, by Monks and Mahdavi (Cyberbullying among primary school-aged pupils) uses focus groups to identify the earliest forms of cyberbullying. A second study describes the development of measuring instruments for use at these young ages, and some characteristics such as incidence, awareness and impact. The paper by Olenik-Shemesh and Heiman (Cyberbullying victimization: Linkages with depression, loneliness and interpersonal relationships) presents findings on cyberbullying from adolescents in Israel. Besides reporting incidence figures, the authors discuss gender differences, emotional responses, and social correlates of victimisation, and greater risks attached to children with learning disabilities. The paper by Naylor, Dawson, Emerson, Tantam and Lara (Bullying of secondary school pupils with and without Special Educational Needs) reports on a large-scale survey in England. Pupils with SENs are generally much more at risk of victimisation, but interestingly, this does vary considerably with the type of disability or special educational need.

Finally, the contribution by Ortega and del Rey (CON-RED, a Preventive Program to Stop Cyber bullying in the frame of the School Convivencia) describes practical measures to reduce bullying in schools, and especially (in this program) cyberbullying. The program impacts on pupils, teachers and families, and some evaluation of the program will be presented.

Syposium title: Presidential symposium: Acculturation of diaspora migrants
Convenor:

Spouses’ language proficiency gaps in the host country: Longitudinal effects on marital satisfaction
Yaniv Kanot-Maymon IDC, Israel; Orly Sarid; Julia Mirsky; Vered Slonim-Nevo

The current study explored whether gaps in second language acquisition predict marital satisfaction among married immigrant couples in their first years in the host country. Data were drawn from a three-wave longitudinal study of 316 married couples who immigrated from the former Soviet Union (FSU) to Germany and Israel. An Actor-Partner Interdependence Model analysis was employed while controlling for gender, age, working status and host country. Results indicate that gaps in second language acquisition predicted the marital satisfaction two and three years following migration. Simple slopes indicate that gaps between partners in their second language proficiency were related to decreased marital satisfaction. The findings are discussed in the light of the social exchange theory and of theories of stress and adaptation.

Relational aspects of ‘return’ emigration: A South African case study
Maria Marchetti-Mercer South Africa

During the apartheid years emigration from South Africa was often linked to particular political events. In the nineties many exiles returned to find that the country they had considered “home” had changed. Many experienced practical and psychological problems as they often did not receive the expected welcome and in many instances faced criticism and resentment from those left behind who had had to bear the brunt of the “struggle”. Post 1994 emigration has been characterised by a “brain drain” deeply impacting the social core of our society. However, most recently it appears that many are choosing to return to South Africa. The reasons for this return are often speculated upon and may involve difficulties in adapting to very different lifestyles and a longing for relationships left behind. Within this historical context I will present the case study of a family who returned to South Africa from New Zealand so as to illustrate some of the psychological implications of “return” migration. Emphasis will be placed on how interpersonal dynamics and imbalances in marital relationships may impact on families’ decision to return and subsequent adaptation.

Perceived discrimination against immigrant youth living in Greece: How does group discrimination translate into personal discrimination?
Frosso Motti University of Athens, Greece; Jens Asendorf; Frosso Motti-Stefandifi

The purpose of this study was to examine whether and how individual differences contribute to the translation of perceived group discrimination into perceived personal discrimination. 145 Pontic Greek and 269 Albanian students (mean age 12.9 years) enrolled in Greek urban public schools were assessed in grade 1 of high school. Albanians reported higher discrimination against their ethnic group, but not higher discrimination against themselves personally, than Pontic Greeks. Personal discrimination could be predicted by perceived group discrimination, as well as from individual differences between immigrant students, independently of their ethnicity. Furthermore, when students reported high, but not low, group discrimination, their individual characteristics were shown to buffer against translating perceived group discrimination into experiences of personal discrimination. These results highlight the importance of individual differences, in addition to perceptions of group discrimination, for feelings of being discriminated as an individual and suggest that high group discrimination of immigrants, independently of ethnic background, does not necessarily result in high personal discrimination, if individual protective factors are present.

Presidential Symposium: Acculturation of Diaspora Migrants
Peter F. Titzmann Friedrich-Schiller-University, Germany; Peter Titzmann; Rainer Silbereisen

Research in recent years started to investigate Diaspora migration (also referred to as return migration) in greater detail. Diaspora migration is characterised by the immigration of individuals who, for generations or even centuries, have lived away from their ancestral territories and, due to pressing political, social, economic, or cultural reasons, return to what they deem their traditional home. Diaspora migration is a growing phenomenon worldwide and especially some Asian, African, and European countries receive substantial numbers of return migrants. These migrants face a very specific situation, marked on the one hand by identification with the receiving society (even before immigration) and often by an official welcome in the country they return to. On the other hand, however, Diaspora migrants experience acculturation processes similar to those of other immigrant groups, as they had to adjust to the language and cultural practices of the heritage culture. Due to these circumstances Diaspora migrants frequently report that they did neither perceive themselves as member of the heritage culture, nor as member of the receiving society. The aim of this symposium is to bring together various research perspectives from diverse countries and to draw attention to the specific situation of Diaspora migrants in various parts of the world. This will allow us to identify similarities and differences in the psychological and socio-cultural adaptation of Diaspora migrants, to discuss
factors relating to a better or a less optimal adaptation of these groups, and to compare the adaptation of Diaspora migrants with that of other immigrant groups.

**Acculturation or development? Autonomy expectations among ethnic German immigrant adolescents and their native German age-mates**

Peter F. Thoemmes, Friedrich-Schiller-University, Germany; Rainer Silbereisen, CIIPME - CONICET, Argentina

This longitudinal study compared immigrant and native adolescents’ expectations concerning the timing of conventional and oppositional forms of autonomy. Based on normative development and a collectivist background among immigrants, both developmental and acculturative change was expected. The study was conducted in Germany, and 523 ethnic German Diaspora immigrants from the former Soviet Union and 475 native German adolescents participated. Both ethnic groups were divided into an early (age 12.5 years) and a late (age 16 years) adolescent group in order to enable age-group comparisons. All adolescents were viewed annually over four years about when they expected to reach what we defined as conventional and oppositional autonomy variables. Conventional autonomy refers to socially acceptable behaviours, such as expectations of falling in love or being able to go out without having to always tell one’s parents where one is going. Oppositional autonomy refers to socially less-accepted behaviours, such as being drunk or smoking, which can be hidden and more easily elude parental control. Results revealed more developmental than acculturative change, as immigrants and natives mostly showed a similar rate of change in autonomy expectations. Unexpectedly, only immigrants and natives in the older adolescent group differed in their autonomy expectations, whereas young immigrant and native adolescents did not. Acculturative change was found only for oppositional autonomy among late adolescent immigrants, whose later expectations approached those of their native age-mates over time. The findings help to understand when and how autonomy expectations are formed and changed by normative development, enculturation, and acculturation.

**Symposium title: Social and moral development in children and adolescents**

**Convenor: Jose Moreno**

**Expected parental reactions, empathy-related traits and prosocial behaviors among Argentinian and European American adolescents**

Gustavo Carlo, University of Missouri-Columbia, United States of America

Parents who employ an authoritative style, characterized by firm demandingness and support, have children and adolescents who demonstrate more prosocial behaviors. However, youth must be open and accepting of parental moral messages. The more appropriate youth judge parental reactions to their prosocial and antisocial behaviors, the more likely youth accept parental moral messages. Although there is supportive evidence for this model, tests of the generalizability of the model in non-European American youth is lacking. We directly examined the relations between expected parental reactions and youth prosocial behaviors in adolescents from Argentina and the United States. We investigated whether these relations were mediated via empathy-related variables. The participants were adolescents from public high schools in the United States (N = 233) and from Buenos Aires, Argentina (N = 196). Participants completed measures of expected parental reactions to their own prosocial and antisocial behaviors, empathy and perspective taking traits and six types of prosocial behaviors. Across both samples, preliminary analyses show significant relations among expected parental reactions to prosocial behaviors and sympathy, perspective taking, and several prosocial behaviors. However, there were some culture-specific relations to specific types of prosocial behaviors. Further analyses will be conducted to directly compare model fits in each culture and across cultures. Discussion will focus on the roles of expected parental reactions and empathy-related variables in predicting prosocial behaviors in Latino and Euro-American adolescents.

**Adolescents’ empathy, parental expectation and flow in prosocial behaviour**

Belén Mesurado, CIIPME - CONICET, Argentina

The optimal experience or flow is a concept developed by Csikszentmihalyi (2000), who defines it as the mental state of operation in which the person is fully immersed in what he or she is doing, characterized by a feeling of energized focus, full involvement, and success in the process of the activity. Although the concept of flow has been applied to the study of subjective experience in work, sport, leisure, daily life, and study (Rathunde & Csikszentmihalyi, 2005), the existing evidence for the subjective quality of prosocial activities (behaviors intended to benefit others) in adolescence is quite scarce. Several researchers have demonstrated that empathy is associated with prosocial behavior (Carlo & Randall, 2002). On the other hand, recent reports have demonstrated that adolescents who expected more appropriate reactions from parents for prosocial behaviors reported higher levels of prosocial behaviors (Wyatt & Carlo, 2002). The purpose of this research was to study if adolescents’ empathy would have an influence on parental expectation on adolescents’ prosocial behaviors, and if these both variables - adolescents’ empathy and parental expectation- would have an influence on flow experience in prosocial behavior. The sample included 430 participants, both sexes, aged 10 to 15 (M = 12.19; SD = 1.74); of middle socioeconomic level, from Argentina. Structural equation modeling was run to test the model proposed. The results showed that the theoretical model fit the data very well, χ2 (6) = 4. p = n.s.; GFI = .99; AGFI = .99, NFI = .99, RMR = .007.

**Social and moral development in children and adolescents**

Jose Moreno, CIIPME - CONICET, Argentina

In this symposium we will consider different views of social and moral development, especially in childhood and adolescence. The importance of bonding with parents, socialisation of the developing child and adolescent within the family and school context, and the contribution of peer relationships to social and moral development will be discussed in the symposium. We present some interesting findings on peer interaction and parental styles, empathy and prosocial behaviour, moral development and emotions, and the effects of an intervention programme with children and adolescents. Family is the main group for handing down socially acceptable values and rules. The fact of feeling oneself accepted, valued, and loved by our parents influences positively in peer relationships, allowing us to establish better friendship and partnerships. As well as this, it also improves moral development, social skills and competences in general. There is a critical need to increase the availability of quality infant and adolescent care. Parents, caregivers, and policymakers must understand that the development of attachment, parental styles and family circumstances may contribute to overcome insecurity, poor performance in school, and lack of interest in playing with friends. In the past twenty years researchers have shown increasing interest in demonstrating empirically the relationships between empathy and a wide range of socio-emotional variables of children-adolescents’ personality, such as social behaviour, peer acceptance or self-concept. Dispositional empathy has provided the focus for numerous studies, as a crucial variable of prosocial behaviour, and several correlational studies have found positive significant associations between empathy and prosocial behaviour in children and adolescents. On the other hand, significant negative correlations have been found between empathy and antisocial behaviour, interpersonal violence, and all types of aggression in children and adolescents. Statistically significant gender differences were found in capacity for empathy, with girls scoring higher at all ages. It can be assumed that girls, to a greater extent than boys, have been socialised in a way that favours the development of skills oriented towards warmth in interpersonal relationships. The main objective of another presentation was to evaluate the influence of the Values System and Ethical Positions (absolutism and relativism) on Prosocial Behaviour. It was determined by regression analyses the values and ethical positions that influence positively and negatively, or not, on prosocialness, helpfulness, sharing, consoling, supportiveness, and cooperativeness. Besides, the values profiles of relativistic and absolutistic adolescents were compared. One important theme in the papers in this symposium is that adolescence is the foundation for adulthood, that adult moral character is given some shape in adolescence. In other words, by understanding and eventually controlling the influences acting on the adolescent, adult moral character development can be set on the correct path. Primarily because of the contributions of cognitive developmental and moral socialisation theories, the bulk of research on the influences of morality has focused on moral cognitions and socialisation agents (such as parents). The study of adolescence reminds us, however, that other agents of change are important to study. This symposium will go through these different issues from a theoretical and empirical point of view, summarising several years of research on the subject.
Efforts to provide tests for Botswana students

Thomas Oakland  University of Florida, United States of America; Elias Mpofu

Approximately 2000 key informants (e.g., teachers, officers, parents and students) from across Botswana provided information on the need for psychometric tests at the primary and secondary education levels.

Conditions favourable to the introduction of psychometric tests in schools include an institutionalised school guidance and counselling programme. A framework to deliver psychometric tests in Botswana schools developed from this project. Data from this study are summarised and discussed with regard to how the results can be used in the guidance and counselling programmes in Botswana together with the nature of resources that will be needed to meet the needs of the project. Relevant stakeholders are enthusiastic about the prospects for psychological tests to be introduced in Botswana schools.

Maternal nutritional knowledge and practices with children 0–8 years in Cameroon

Therese Tchombe  CRCFDE/University of Buea, Cameroon

In many African settings, cultural and religious beliefs, hygiene issues and lack of knowledge about nutrition influence maternal feeding practices of infants and children. This study presents an evaluation of mothers’ knowledge and practices as they affect child development. 300 households were purposely sampled from five communities (rural = 107, and urban = 193) in Adamawa region of Cameroon. Participants included pregnant women (n=142), nursing mothers (n=108), family relations who are caregivers (n=35), medical personnel (n=8) and other community stakeholders (n=7). The region is dominantly Muslim. Data were collected through interviews and observational study. Thematic analysis of the qualitative data was used to identify major influences on child development, and to explore perceived mothers’ knowledge and practices relating to nutrition. Findings suggest that most respondents (80%) report  at least one advantage of a balanced and varied diet. Just over half of the women surveyed (57.3%) are aware of the dangers for pregnant women of consuming alcohol, tobacco or kaolin. Several women surveyed (about 72.0%) know at least one value of the prevention of anaemia during pregnancy. A majority of the women (89.7%) know at least one benefit associated with immediate breast feeding of the newborn baby and the dangers of early weaning (84.7%). Knowledge of the value of breast milk for the newborn and of the importance of other foods for the growth and benefits of the child appears to be widely distributed among community dwelling women in this Cameroonian district.

Session Type: Symposia

Symposium title: Applications of psychology to human service development in Africa
Convenor: Robert Serpell

Applications of psychology to human service development in Africa
Robert Serpell  University of Zambia, Zambia; Elias Mpofu

This symposium brings together four teams of investigators, each active in research in an African country. South Africa, Nigeria, Tanzania and Zambia. Each of the papers will present the results of a substantial research project or programme that has not already been published elsewhere, highlighting its rootedness in the African country where the research was conducted, and emphasising positive psychology concepts with the potential for hope rather dwelling mostly on deficits. Tchombe and Fonkeng report on a study of maternal beliefs and practices in rural and urban areas of Cameroon. Oguntuase and Akinsola report on a follow-up study of young people who received crisis psychosocial counselling in the wake of a massive explosion that occurred in a civilian residential area of Nigeria’s capital city of Lagos, ten years ago. Lyytinen et al report preliminary findings from an ongoing intervention project designed to support the initial acquisition of literacy by children enrolled in a representative sample of government schools in the city of Lusaka. And Mpofu et al report on a survey designed to evaluate the relative worth of competing mechanisms of delivery for psychosocial services to school learners in Botswana. Discussion will consider how the studies address the complementary challenges of practical relevance and theoretical coherence, and the complementary benefits of qualitative and quantitative methods in attaining their goals.

Symposium title: Test use in sub-Sahara Africa
Convenor: Thomas Oakland

Accessible tests for Zimbabwean allied health practitioners
Elias Mpofu  University of Sydney-Cumberland, Australia; Alice Mayo  University of Sydney-Cumberland, Australia

Tests in their use for intervention are selected for the incremental knowledge they contribute to intervention design, monitoring and evaluation. Test users seek to identify and unlock resources in the participant and environment important for enabling real world solutions for clients. In the Zimbabwean content, dynamic assessments or those that allow for in-use tailoring to participant responses appear to hold great promise to deliver solutions that participants have ownership, and which they understand for guiding their choices. Tasks for such tests typically are sampled and selected from the activities that take users engage in their daily activities. As such, they address strengths, needs, and potentialities to support sort-after or desired outcomes by participants. Illustrative examples are discussed from test use in education and health in the Zimbabwean setting.

Assessment within Namibia’s primary health care setting

Drienie Naude  United States of America

In Namibia, patients presenting with mental status change and/or focal signs are routinely screened by nurse practitioners and Physicians at hand of the Glasgow Coma Scale, then Mini Mental Status Exam and the NIH-scale as patients enter the health care system at primary care level. However, these scales are not contextualised for the Namibian region and often produce false positives. However, patients need to be accurately screened to ensure that they are accurately referred to secondary or tertiary levels of health care. Namibian psychologists are currently contextualising these scales and replacing items to improve screening and referral at the first point of entry into the health system. This paper compares the results derived from non-contextualised and contextualised scales for use with the country’s prominent cultural groups to ascertain whether contextualised tests render more accurate screening and consequently more effective referral within the health system.

Test development and use in four African countries

Thomas Oakland  University of Florida, United States of America

Test development and use constitute the flagship activity of applied psychology. Test development and use is context dependent and occurs uniquely within various cultural contexts. This symposium examines test development and use in four Sub-Saharan African countries: Botswana, Namibia, South Africa, and Zimbabwe. These four countries, like others in the region, are attempting to determine the relevance of methods used commonly in the West in light of contextual conditions. New models and methods may be needed to help advance test development and use in this important region.

Symposium title: Attachment assessment, classifications and intervention in a South African population
Convenor: Renate Gercke

Representations of attachment in children in care during middle childhood
Danielle Douglas  University of the Witwatersrand, South Africa
Douglas then assesses attachment patterns in children in care in a South African children’s home using the ASCT and Kinetic Family Drawing. High concordance between attachment classifications from the ASCT and the combined attachment classification resulting from the Kaplan and Main (1986) scoring system and the Family Drawing Global Rating Scale (Fury et al., 1997) was found, further validating the use of the ASCT in a South African population. Furthermore, use of the ASCT (Granot & Mayseless, 2001; Kerns et al., 2008) provided a more simple and effective attachment based measure. 69.60% of the children were classified with an insecure avoidant attachment pattern while 23.70% were classified as insecure ambivalent. The mental health implications of these findings are considered.

A comparison of attachment story completion test inter-rater reliability and history based attachment classifications
Renate Gerike University of the Witwatersrand, South Africa; Katherine Bain
This symposium will explore attachment assessment, classification and intervention in a South African population. The first paper (Gerike & Bain: presenter – Gerike) investigates use of the Attachment Story Completion Test (ASCT) (Granot & Mayseless, 2001; Kerns et al., 2007) in a South African population by comparing ASCT inter-rater reliability with history based attachment classifications. The sample comprised 35 eight to twelve-year-old children attending an outpatient psychology and psychiatry clinic attached to a government hospital in Johannesburg, South Africa. This age cohort was chosen as middle childhood is under-researched as it pertains to children’s development and attachment (Graham & Easterbrooks, 2000; Kerns et al., 2007). To arrive at history based attachment classifications the authors reviewed the initial intake history questionnaires, psychiatric evaluations, psychological assessments, therapist notes and general case notes. The importance of this study is two-fold, (a) it will help to validate the use of the ASCT on a SA population and (b) examine the validity of basing attachment classifications on history rather than using a standardised attachment assessment tool. Findings reflect on the importance of inter-rater reliability and use of a standardised attachment assessment tool across clinicians, history based attachment classifications. Implications for clinical practice and research will be discussed.

Redefining disorganised attachment: Exploration of subcategories of disorganisation in middle childhood
Alexa Plit Wits, South Africa
However, disorganised attachment is the only attachment category that is not considered an adaptive or functional strategy for maintaining the caregiver-child dyad and is often a result of having abusive or neglectful caregiving relationships. Children with disorganised attachment are at higher risk for developing severe emotional and psychological problems. The study by Plit analysed disorganised attachment in children presenting at a hospital psychiatry clinic, who are also in care, a unique context with a high rate of youth at risk. Using the ASCT, 17 disorganised children between the ages of 8-12 were selected and their story stems were analysed using a thematic content analysis. Results indicated clear subcategories of disorganised attachment ranging on a spectrum of severity. This study has possible implications for the classification and treatment of disorganised attachment as well as moves towards predicting the possibility and severity of future pathology.

Symposium title: Bullying and cyberbullying among children and young people
Convenor: Peter Smith

Cyberbullying among primary school-aged pupils
Claire Monks University of Greenwich, United Kingdom; Jess Mahdavi
A growing body of research has described the nature and extent of cyberbullying among school-aged children, with the majority of this focusing on children of secondary school age (11 years and older). However, children younger than this have access to the internet and mobile phones (e.g. Eurobarometer, 2006). Research has also suggested that cyberbullying may be on the increase (Rivers & Noret, 2010). It is therefore important that we focus on the experiences of younger children. We describe two studies exploring the nature of cyberbullying among primary school-aged pupils. The first is a qualitative study using focus groups to identify the forms of cyberbullying that participants (teachers, parents/guardians and pupils) were aware of occurring among primary aged pupils, and the youngest ages at which they thought that this occurred. The findings suggest that cyberbullying does occur among children of primary school-age and that this is viewed as being at least as upsetting for the victims as more traditional forms of bullying. The second is a quantitative study, which describes the development of age-appropriate measures to find out about cyberbullying, for use with children aged 7–11 years, their teachers and parents/guardians.

Findings from a survey with 200 pupils, their parents/guardians and teachers are reported, including description of the nature and extent of cyberbullying among this age group, and participants awareness of cyberbullying occurring among this age group and among younger children. The implications of the findings are discussed in relation to intervention/prevention work and future directions for research.

Bullying of secondary school pupils with and without special educational needs
Paul Naylor The Open University (UK), United Kingdom
Bullying of pupils with Special Educational Needs (SEN) has so far not been much studied. We analysed self-reports of 15770 pupils in England who were 13-14 years old in 2004. We classed a pupil with SEN as one who is at School Action Plus or who has a Statement of SEN. Depending on the speciﬁc disability, SEN is deﬁned as deliberate, aggressive, or threatening behavior in which the pupil is harmed or in which the pupil is subjected to destruction or degradation of something of importance to the pupil. We report the extent of cyberbullying and bullying among this age group, and pupils with SEN as one who is at School Action Plus or who has a Statement of SEN. The likelihoods of pupils with specific SEN compared with those with no identiﬁed SEN of being bullied, vary by speciﬁc disability, but pupils with a Sensory Impairment SEN are less likely to be bullied; and bullied pupils are unhappier at and have less commitment to school than pupils who are not bullied. These responses to school are also true of pupils with SEN, which may, in part at least, be because they are more likely to be bullied than pupils with no identiﬁed SEN. We also report data using the criterion of being bullied at least once a month and the outcomes of longitudinal analyses of data for annual waves 2004-2008 of the UK National South Anna study. We discuss the implications for educational policy-makers, teachers, parents, and researchers involved with pupils.

Cyberbullying victimisation: Linkages with depression, loneliness and interpersonal relationships
Dorit Olenik Shemesh The Open University Of Israel, Israel; Tal Heiman
Cyberbullying (CB) is defined as deliberate, aggressive activity aimed at hurting another person through digital communication. Recent studies reported on the unique features of CB as anonymity, easy accessibility, and potential of huge number of bystanders. CB may be related to negative psychosocial outcomes, such as feelings of sadness, depression and loneliness (Patchin & Hinduja, 2006), as well as disrupting interpersonal relationships, while social support may play a role as a protective factor. The purpose of the study is to describe the CB phenomenon among middle-school Israeli students and to examine the association of CB, social-emotional aspects and academic functioning. 1058 adolescents (54% boys, 46% girls), aged 12-16 completed questionnaires regarding CB, traditional bullying and psychological-social measures. The finding revealed that 15.8% of the participants were victims to CB; 20.4% reported decrease in grades, 41.8% reported reduced concentration in school; 31% reported absence from school after being a CB victim and 20.4% reported having fewer friends as a result CB involvement. Regarding emotions towards CB victimisation, 67% felt highly angry, 22-44% felt moody and sad, frustrated, having appetite loss and sleep difficulties. Results showed that CB was related to lower social and emotional competence, increased loneliness, and decreased social support. Stepwise regression analysis showed that loneliness and lower personal competence can predict cyber-victimisation; girls tend to be more often victims than boys. The results may be useful as a basis for developing prevention and intervention programmes in order to cope with this new phenomenon.

Con-red, preventive programme to stop cyber bullying in the school convivencia
Rosario Ortega University of Cordoba, Spain; Rosario Del Rey
The existence of cyberbullying in secondary education schools in Spain has been shown by several studies, in Andalusia, and with representative samples across the country. However, it remains to be explored whether certain educational implications arise from such studies, as in Spain, resources and guidelines offered by the public administrations to teachers, pupils and families are scarce. In the frame of the European Project Daphne: Cyber bullying in adolescence: investigation and intervention in six European countries, a psycho-educational programme
about the use of Information and Communications Technology (ICT) and social networks has been designed with the aim of providing some tools to intervene in the case of cyberbullying. CON-RED is a programme focused on Acknowledging, Building and Convivir within the Internet and being involved in social networks with safety. CON-RED has three lines of intervention: (i) pupils, (ii) teachers, and (iii) families; and, depending on the level of use of ICT, it has four fields of action: (a) awareness of social networks and privacy issues, (b) healthy and safe use of communication on these social networks, (c) prevention of risks from social network use, and (d) coping with and preventing cyberbullying. The impact of the programme was evaluated in three secondary schools, with pupils aged 12 to 16 years. The evaluation was developed with a pretest-posttest and control/experimental design using a bank of instruments about school climate, cyber bullying and prosociality. We present our evaluation results and analysis of the strengths and weaknesses of the intervention programme.

Terminology of bullying-like behaviours in South Korea

Peter Smith Goldsmiths University of London, United Kingdom; Claire Monks

Most studies of bullying-like phenomena have been made in Western cultures; it is rarely studied whether the definition and behavioural characteristics of bullying are similar in Eastern cultures. We focused on terms for bullying-like phenomena in South Korea, where there are several terms which correspond to bullying behaviour. One term predominantly used is wang-ta, a relatively recent and colloquial term. We studied what terms South Korean people used across different age ranges and different contexts: from early childhood to adulthood, and school to workplace. 113 participants, from young children to adults, were group-interviewed in Seoul. They were shown cartoons or descriptions in which several types of negative and harmful behaviour were described, and asked what they would call them, and what they thought about the terms they generated. Different terms for the behaviours were elicited, depending on the type of aggression, and age of respondent. No single Korean term appeared to aggregate typical Western bullying behaviours, but wang-ta was widely reported to indicate social exclusion or physical attacks by a group of people, reflecting a collectivistic aspect of bullying in South Korea. In conclusion, wang-ta is a term used to broadly describe a socially excluded person; but historical change in usage of wang-ta and the elaborated levels of exclusion found, indicate that the phenomenon has been evolving in South Korea and point to some differences between Eastern and Western cultures.

Peer-victimisation in preschools in Europe and Latin America

Claire Monks University of Greenwich, United Kingdom; Rosario Ortega; Gamal Cera

This paper describes peer-victimisation among preschoolers in different countries. We present data examining the nature and extent of peer-victimisation among preschoolers (aged between 4 and 6 years) in a Latin American country (Chile). Data from Chile is compared with earlier data from European countries (Spain, England and Italy). An individual interview technique was used to obtain peer-nominations for the roles of aggressor, victim and defender. Findings suggest that peer-victimisation can be identified during the preschool period in Chile and it is possible to identify children as behaving aggressively towards others, being targeted for victimisation and defending others from victimisation. Young children in Chile use a variety of different forms of direct aggression against their peers, including social, physical and verbal. However, they are less likely to use indirect forms of aggression (such as rumour spreading). The findings with preschoolers in Chile will be discussed in relation to findings in three European countries. Similarities and differences will be explored and implications for intervention and prevention work will be discussed.

The development of children’s fair behaviour and its relationship with theory of mind

Liqi Zhu Institute of Psychology, CAS, China; Liqi Zhu; Jing Yu

Fair behaviour is an important prosocial behaviour. A few studies have examined developmental trends in the dictator game (DG) and ultimatum game (UG). Previous studies found an age effect that children offered less as they became older. (Harbaugh, Krause, & Lidy 2000; Harbaugh & Krause, 2000; Bettinger & Slomn, 2006), while Zhu et al. (2010) found that Chinese children showed a different trajectory. The current study investigated even younger children and also examined the relationship between theory of mind and children’s fair behaviour. The subjects were 3 to 9 year old preschoolers and school-age children. In the first study, two players were good friends from the same class (in-group members) versus strange partners from different schools (out-group members). Dictator games were conducted to study the fair behaviour of children as proposers. In the second study, four simplified ultimatum games (Mini-UG) were adopted to study the rejection behaviour of young responders to unfair offers and different intentions. The theory of mind of all the participants was measured by means of false belief tasks. The main findings are as follows: (1) Children became more fair and altruistic with age in DG. Children showed an in-group bias in DG no later than 5–6 years old. Young children who passed false-belief tasks were more likely to treat others fairly and altruistically. (2) Older children rejected unequal allocation more often than preschoolers do. 5–9 year old children could adjust their rejections towards unfair offers based on the intentions of the proposers, but the rejection behaviour of 3–4 year old children was independent of intention conditions.

Early intervention for autism: The Early Start Denver model in South Africa

Michelle Hoogenhout University of Cape Town, South Africa

Early intensive intervention has been shown to be effective in reducing the severity of autism. However, such intensive intervention is currently limited to high-income families, and is not readily available in resource-poor countries. We investigated whether one-hour-a-week therapy using the Early Start Denver Model approach could reduce the severity of autism and increase developmental skills. Twelve families (average participant age = 47.5 months, Autism Diagnostic Observation Schedule (ADOS) severity rating = 8.6, developmental quotient = 48.8) participated in 12 weeks of one-on-one therapy for one hour per week. Families were referred from the non-governmental organisation Autism Western Cape. Before and after the intervention, children were assessed on the ADOS, the Griffiths Mental Development Scales – Revised Edition, and the Vineland Adaptive Behaviour Scales, second edition. Parents completed the Social Communication Questionnaire and the Measure of Processes of Care – South African edition, a measure of satisfaction with service delivery. Parents noted improvement in multiple domains (e.g., socialisation and behaviour), and indicated that their behaviour towards their child had changed as a result of the intervention. Formal measures of developmental partially supported the parent reports. These results suggest that low-intensity intervention can be effective. The main barriers to service delivery were language and non-attendance due to financial constraints. For greater impact, future
interventions should use easily-accessible community centres to host intervention sessions, provide language training for therapists, and train parents in aspects of therapy delivery.

The absence of cradling bias in autism spectrum disorders

Lee Ann Pileggi University of Cape Town, South Africa

Deficits in empathy are considered a defining characteristic of autism spectrum disorders (ASDs). The fundamental difficulty these individuals experience is that of relating to others. Research focussing on the more basic difficulties with social reciprocity exhibited by ASD individuals has, however, been lacking. A well-established social phenomenon, namely cradling bias (the preference to cradle an infant to the left of the body midline) is argued to be facilitated by a capacity for empathy. Previous studies suggest that this phenomenon taps into an individual’s innate ability to relate to another. Direct systematic observation was employed to investigate the occurrence of cradling bias in children diagnosed with autism spectrum disorders. This study was a cross-sectional comparison of two groups: an ASD, and a Control group (including typically developing and mentally handicapped children). Fifty-three ASD and 40 Control children, aged 6–15 years, were asked to cradle a doll as if it were an infant he/she wanted to soothe or put to sleep. Cradling was observed on four separate occasions. As hypothesised, the leftward bias was absent in ASD children. In contrast, the leftward bias was present in Control children. This is the first human population in which the universal leftward cradling bias has been found absent. The absence of cradling bias in ASDs reflects these individuals’ impairments in social and emotional reciprocity. Focused investigation of basic difficulties experienced in relating has implications for the management and treatment of affected individuals.

Symposium title: Ethical and methodological issues of research with at risk children and youth

Convenor: Silvia Koller

Sexual exploitation on the roads of South America: Learning more about clients

Elder Cerqueira-Santos Universidade Federal de Sergipe, Brazil

This study aimed to compare two different groups of Brazilian truck drivers: Group I was submitted to a psychosocial intervention called “On the Right Road”, focused on better health habits and against C&A sexual abuse and exploitation (94.0% that group II (p<0.001), regarding toll free phone against C&A sexual abuse and exploitation (94.0% X 56.2%). The intervention program seems to educate relatively well truck drivers about issues related to health problems and C&A sexual exploitation.

Street children in Brazil: Health, risk and protection

Normanda Morais Universidade de Fortaleza, Brazil; Silvia Koller

This study aimed to investigate the perceptions of homeless adolescents, health professionals and social workers in regard to the health conditions of homeless adolescents. The research took place in two Brazilian institutions that offer services to homeless children and adolescents (e.g., health services and daytime shelter). Participants were twelve adolescents, five health professionals and four social workers. Two qualitative studies were conducted to examine each group in regard to their perceptions of health and illness, their perception of the influence of street-living upon the adolescent’s health, the main health issues, the health care strategies and the support network. The analysis of the interviews suggests that a dynamical analysis between risk and protective factors is needed. Some risk factors are emphasised: Inappropriate life conditions, use of drugs and violence. The protective factors mentioned were: The search for the street as a “healthy strategy” towards a violent family environment, the existence of an assistance network, as well as the “resistance” created by the adolescents to some illnesses. The analysis of the binomial risk/protection allows a more realistic view of the homelessness situation upon health and the overcoming of a static, a-historical, and one-dimensional health and illness view. Finally, the validity of the Biocultural Approach of the Human Development is emphasised and its relation to resilience and Positive Psychology.

Symposium title: Exploring everyday life: human development within a cultural psychology perspective

Convenor: Anne Jansen

The child as a shared enterprise: Same gendered couples constructing family life

Agnes Andenas University of Oslo, Norway

In Norway and other western countries an increasing number of children grow up in families with same-gendered parents. The main message from studies on these families is that children raised in same-gendered families do just as fine as other children, or even better. However, the research methods used have not offered much insight into how same-gendered couples actually do their parenting, and how they share tasks, responsibility and understandings. Actually, the lack of interest characterises developmental psychology’s approach to opposite-gendered parents. The aim of this paper is to get closer to what characterises the developmental conditions for young children living in families with same-gendered parents by exploring everyday life, as accounted for by the parents themselves. The study is based on detailed interviews about everyday life in same-gendered (all female) families with young children. According to the analysis both partners in the six families are committed to a joint project of developing a balanced relationship, each of them having the overview and responsibility for the total composition of the day as well as deep knowledge about details. The argument is that exploring families that deviate from the heteronormative arrangement is helpful because taken-for-granted and naturalised understandings of modern family life with young children are made explicit. Moreover, the analysis points out how children may profit from equality between their parents, and thereby offers psychological knowledge of use to improve children’s developmental conditions.

Child-headed households under watchful adult eyes: Support or surveillance?

Jeanne Haley University of KwaZulu Natal, South Africa; Jill Bradbury

This paper focuses on the relationship between children in Childheaded-households and adults in the wider community. The paper is based on a narrative study of the lives of six adolescent heads of households and their siblings, from an informal township settlement and a rural village in KwaZulu-Natal, South Africa. The study aimed to gain insight into the experiential lives of these adolescents and how they construct their sense of self and family. Child-headed households challenge conventional conceptions of the “borders” between childhood and adulthood and suggest new contested forms of family structure. However, although the categories of “child” and “adult” may be socially constructed, they are perceived as real. Children or adolescents may be taking on adult responsibilities and running households but they are all too familiar with the power differentials that accord them inferior status to that of adults, restricting their access to resources and making them vulnerable to exploitation in a variety of forms. While adults in the wider community do offer some supportive engagement with these young people, perceptions of hostile adult surveillance emerged as a surprisingly dominant theme. This surveillance seems an anxious response to the absence of adult regulation in these households and is particularly gendered, with girls positioned as “whores” and boys as “thugs”.

Symposium description

Anne Jansen HiOA, Norway

Understanding development within a cultural psychology perspective means to see development not only as a cultural product, but as a part of culture itself. It means paying attention to how the growing person engages in developmental processes and how this engagement is embedded in specific cultural contexts. The papers in this symposium have a joint interest in cultural psychology and developmental psychology and each of them will address questions of importance for understanding development as culturally embedded and sensemaking processes. The approach to exploring such issues is
through interviews about activities and relationships of everyday life, as experienced by the participants. Each of the papers contributes to theoretical and empirical knowledge of developmental processes. By connecting context and development they provide tools for understanding and for acting in ways that may improve children and young people’s lives.

Narrative engagement and subjectivation among young people in residential care
Anne Jansen
HiOA, Norway

This paper explores developmental processes among young people who live in residential care provided by child protection services. It is based on repeated interviews with twelve adolescents living in residential homes nearby Oslo, conducted over a period of 15 months. By investigating their personal narratives, the significance of the young persons’ narrative engagement and upon subjectivation is put into focus. Subjectivation is understood as the process through which a person makes him or herself into a subject and is argued that we can understand development as ongoing processes of subjectivation where the growing person’s narrative engagement plays a central role. For young people who live in residential care, prevailing discourses of what out-of-home care means and who residential youths are, constitute part of the context in which they have to figure out who to be and who to become. The paper illuminates how such discourses are made relevant at a personal level and how the context of living provides opportunities and restrictions for narrative engagement, processes of subjectivation and thus for development.

Development of child and family as reciprocal and culturally embedded processes
Anita Sundnes
United States of America

The sociocultural context of a person’s development is not a fixed analytical entity. It consists of individuals, groups and institutions that are also developing. Therefore, when analysing children’s developmental conditions, it is necessary to take the developments in their social environment into account. The notion of citizenship, highlighting social participation and including both psychological an economical dimensions, may theoretically compose an age-transcending developmental goal. It will be applied as a tool for simultaneously exploring the reciprocal developmental relation between child and parents, and between parents and society. The paper draws on life mode interviews with parents of children up to the age of three in Norway, with various backgrounds regarding ethnicity and class. Due to a one-year maternity leave, most infants in Norway are taken care of in their own home by one of their parents, mostly the mother, during their first year of life. Thus, the everyday lives of infants are structured in generally similar ways across social groups and seems to provide all children with a most favourable start in life. Nevertheless, what it means for a child’s developmental path to have a parent at home during this year must be analysed in a broader perspective, for instance, it depends on whether or not the mother continues to stay at home, and on the economical situation of the family. The family’s development is put forward as a central concept for exploring the relations between individual life chances and social structures on a macro level.

Symposium title: Family and children’s emotions
Convenor: Victoria Del Barrio

Emotions and socialisation as aggressiveness predictors
Maria Vicenta Mestre, Spain; Paula Sanmoer

In the last years aggressiveness has risen in prevalence, and adolescents are assuming an increasing protagonism in these behaviours. Investigations, in the last few years, have focused on analysing risk and protection factors in aggressive behaviour. Recent investigations show that empathy (Garaigordobil, 2009a; Mestre, Mestre, Samper y Frías, 2002; Carlo, Mestre, Samper, Tur, and Armenta, 2010) is a protector factor of aggressiveness and a process which is of benefit to help with adaptation and social integration. The study we present assesses to what extent do empathy and emotional self-control, considered as positive emotionality variables, interact with upbringing styles, in the prediction of aggressiveness in childhood and adolescence. Populations samples consist of 1222 participants between 10-12 years old and of 731 adolescents between 14-18 years old. The results show that absence of positive emotions (empathy), emotional regulation and impulsivity control, together with socialisation processes, in which parent upbringing styles take part, predict aggressive behaviour during childhood and adolescence. Besides these, personal variables such as sex and age have an influence on some of the evaluated processes. There is significant empirical evidence that supports the significance of affection and familial communication to achieve a correct adjustment in adolescence. The results obtained should be considered in the design of programmes directed towards prosocial development and inhibition of aggressiveness in childhood and adolescence.

Parental styles and prosocial behavior in children 9–12 year old
Maria Richaud
Argentina

Eisenberg et al. (1999) asserts that prosocial behavior is a voluntary behavior intended to benefit others. There is considerable evidence that prosocial behavior begins as early as 6 years old (Persson, 2005; Scourfield, John, Martin, & McGuffin, 2004). Although both individual and environmental factors affect children’s prosocial behavior (Knaflo & Plomin, 2006), it is possible to increase it using improving programs. In this work we hypothesize that parental styles of relationships with their children and attachment modulate the results of intervention programs in prosocial behavior. This study included a sample of 50 middle-low socioeconomic status children, aged 10 -11 years, from primary schools in Paraná, Argentina. Measures included were: 1) Prosocial Behavior Scale (Caprara & Pastorelli, 1993) translated and adapted into Spanish by Del Barrio, Moreno & López (2001); 2) Richaud Argentine Scale of Perception of Relationships with Parents for 8 to 12-year-old children, and 3) Kersh Attachment Security, translated and adapted to Argentina children by Richard, Sacchi, and Moreno (2003). We developed an intervention program that included various activities to encourage prosocial behavior: helping physically and verbally, giving and sharing, providing comfort, positive value of other, and cooperation. These activities were carried out during two school years following both: a specific program and activities integrated in the school curriculum content. To test the hypothesis we conducted a repeated measure ANOVA corresponding to pre and post intervention program in prosocial behavior, with parental styles and attachment as covariate variables.

Symposium title: Focal symposium – Toward Africentric theories of developmental education
Convenor: Bame Nsamenang

Yoruba epistemology as one facet of Africa’s educational foundations
Bame Nsamenang
University of Bamenda, Cameroon

Before Africa was colonized Africans had their own indigenous theory of knowledge, their traditional ways of socializing and educating their young. The African indigenous educational practices derived from African epistemology are driven by oral traditions and the African philosophy of self-actualization and social competence. The method of learning is participatory, collectivist and cooperative, and is savoured with parental, sibling, peer and communal inputs. African traditional education addresses the intellectual, moral, emotional, physical, spiritual, artistic, and skills acquisition aspects of child development, thereby making it a comprehensive and well-rounded educational approach for training African children. In this paper an attempt is made to showcase African traditional education by presenting Yoruba epistemology as a model of African epistemology, and to emphasize the need to incorporate its precepts into the education of African children. This is because part of the law of learning claims that learning becomes easier when it proceeds from the familiar to the unfamiliar. Due to the fact that the training of the African child starts from the womb as portrayed in Yoruba epistemology, African children are familiar with these educational methods and incorporating them into Education in Africa would lay a foundational springboard from which African children can attain a more robust development and blossom both within and outside their cultural domain. Yoruba epistemology is thus a facet of Africa’s educational foundation.

North African children’s development through play and toy cultures
Bame Nsamenang
University of Bamenda, Cameroon

Sociocultural anthropology research on North African children lies at the basis of my paper (www.sanatoyplay.org). After a brief introduction to Moroccan children’s play and toy making activities, topics such as observation and experience, socialization, child-child and adult-child relations, gender, change and the influence of globalization will be analyzed. I will stress cultural and social aspects but also refer to some specificities of the individual development and identity formation of Arabic or
Amazigh (Berber) speaking children. The paper will also reveal the pedagogical and sociocultural applications of this research on North African children’s play and toy making activities for individual development, interpersonal socialization and school curricula in diverse contexts. Resourcing and integrating local knowledge and practices into “westernized” African education is of great importance, as international organizations have claimed since the 1980s, but with little evidence of applications in Africa. Using African children’s cultural heritages for pedagogical, sociocultural and therapeutic purposes within an African context but also within a Western context certainly is an adequate way to promote children’s individual and sociocultural development in the age of globalization. Is it not a basic necessity that development and learning must start from the child itself and therefore from its own experience in the community in which it grows up? This is not a favour but part of Children’s Rights.

South Africa’s inclusive education precepts 

Bame Nsamenang University of Bamenda, Cameroon

The demands for teacher education to sensitize teachers in inclusive educational practices cannot be overemphasized as schools in South Africa and elsewhere are increasingly becoming diverse in terms of learner populations. Teachers are challenged to respond sensitively to learner differences – ability, religion, culture, language, health, socioeconomic status, class and gender. Inclusive education, an educational practice which affords all learners the rights to equal and quality education and support, is undoubtedly an important vehicle which could equip teacher trainees and even practicing teachers with necessary skills and attitudes to work in diverse classrooms. However, if we continue to interpret such a practice in terms of Euro-Western perspectives and ignoring understandings which validate and address the experiences of the local people, we might find ourselves repeating the exclusionary practices of the past.

Towards Africentric theories of developmental education: Thematic abstract

Bame Nsamenang University of Bamenda, Cameroon

Africa’s ways of thinking about children and their developmental learning are largely short-chained into irrelevance and extinction by governing Western theories and models. In fact, ever since Western ideologies, especially social Darwinian motives, penetrated Africa, Africa’s developmental knowledge and educational theories began to wilt and increasingly ceased to be rooted in African soil. Western theories and narratives censor African developmental knowledge and educational ideas and practices, as conclusions on their research are progressively draped in Western theories and ideological perspectives. For instance, the few African scholars and policy developers who have the onerous task to research or plan African child development and education make a priori decisions within Western epistemologies, logic systems, and research evidence. They are forced by overly Western research and publication norms to address the universalizing Anglo-American image of the child that drives developmental and educative sciences in stead of researching, within leading-edge scientific methodologies, African children who have always been active and productive agents of their own development and learning. They lamentably persist in this intellectual mindset and research thrust in spite of evidence from a Kenyan Gusii infant study that alternative modes of early childcare and education based on Africentric moral and practical considerations have constituted normal patterns of development that had not been imagined in Westernized developmental and educational theories (LeVine, 2004). In this Focal Symposium panelists who have researched in Eastern, Northern, Southern and Western African regions will share Africentric perspectives on selected facets.

Bamileke (Cameroon) cultural strategies for cognitive enrichment of early learning

Therese Thombé CRCFDE/University of Buea, Cameroon

A fundamental characteristic of human civilisation is the education of the next generation (Reagan, 1996) whereby cultural communities pass on traditional values and norms. The process of formal education as it has been conceived and taught has focused almost entirely on the ways in which Western educational traditions emerged, developed, and spread. Regrettably this is to the loss of all other educational ideas and practices. This paper highlights selected cultural cognitive strategies and practices use by the Bamileké of the west region of Cameroon for children’s cognitive enrichment. The strategies employ participative processes that utilise needs and interest-driven (piifik wen) principles and the mediated mutual reciprocity principle for generative learning (faksi zhi’i-é-hi). As active agents in their families and communities, Bamileké children are introduced very early in life to age-graded and sex-appropriate cultural activities within a holistic framework. Education is developmental, enabling children to live intensively across family chores, symbolic situations and rituals with the objectives of experiencing and learning. The socio-emotional and cognitive influences through oral traditions are of prime importance. The expected end profile is the development of a socially competent person with an open spirit who thinks creatively. Having an open spirit implies a theory of mind that is governed by solidarity, tolerance and team work. Learning is interactional and action-based. The Bamileké cultural teaching for cognitive enrichment is the “how” rather than “what”.

Emotional closeness between parents and children: The role of family structure

Bernhard Nauck Germany; Oliver Arranz Becker; Veronica Zalbarger; Nadia Rost

Previous studies have shown that parents report less involvement and closeness and provide less financial support to stepchildren than to their biological children. The “stepgap” is hypothesised that the size of the stepgap depends on both family-related parental values (e.g., normative solidarity) and on the quality of social ties within the family (parental relationship quality, frequency of parent-child contact, parent-child co-residence). The “German Family Panel” (pairfam) provides a unique data structure for addressing the research question, including reports from both parent relations on relations with both biological and stepchildren. The sample comprises N=584 parent-child dyads from families with at least one biological and one stepchild. Using multilevel modelling techniques, we examine the stepgap (within-subjects model) from the maternal and paternal perspectives (between-subjects model) within the same families. We find evidence of a considerable stepgap in terms of emotional closeness, which is particularly pronounced among mothers. Furthermore, the size of the stepgap varies as a function of family values and family structure: First, parents’ normative solidarity narrows the stepgap. Second, (higher) parental age and a high-quality parent relationship reduce the stepgap. The findings are discussed in the context of the hardship many stepfamilies face after parental separation.
Intergenerational relationships in diverse family settings
Sabine Walper LMU Munich, Germany

Intergenerational relationships are of primary importance across the life span. Numerous findings point to the salience and developmental significance of parent-child relationships from infancy to adulthood. Grandparents may provide an important resource by sharing parents’ tasks in child rearing, but also by providing unique experiences in the grandparent-child relationship. This set of four papers addresses issues of parent-offspring relations highlighting the role of the interparental relationship and family structure, and follows up on similar issues when looking at grandparent-grandchild relationships. The first paper by Werneck et al provides a broad view on longitudinal predictors of parent-offspring relations in young adulthood pointing to the salience of interparental solidarity and earlier parenting quality in addition to personality factors. The second paper by Nauk et al. focuses on differences between young adult-parent-child relations and stepparent-stepchild relationships adopting a unique approach which uses within family comparisons for biological as well as stepchildren. The third paper by Buchanan offers a broad view on grandparent-grandchild relationships. Among other factors, the role of family adversity - be it due to family discord or break-up of the parental relationship, is addressed. The fourth paper by Langmeyer et al. takes a closer look at differences due to family structure as well as family dynamics and investigates issues of gate-keeping as well as gendered patterns of grandparent involvement. The final discussion seeks to integrate the findings on intergenerational relationships from a systemic and life-course perspective.

Symposium title: Longitudinal studies of family functioning and child development
Convenor: Oscar Barbarin
Symposium overview
Oscar Barbarin Tulane University, United States of America

Poor families are vulnerable to a host of stressful life events which lead to high levels of psychological strain that have the potential for impairing family functioning and compromising the development of children. Psychological strain is associated with poor outcomes but the likelihood of poor outcomes is moderated by how well the family adapts and responds to those stressors. This symposium presents the results of four longitudinal studies that explore the effects of poverty on children’s development and examines the ways outcomes are moderated by family functioning. The studies focus on outcomes as diverse as language competence, aggression, self-regulation of attention, behaviour and emotions, substance abuse, risky sexual behavior and HIV. As a group studies illuminate ways the context of family life particularly support and control processes, religiosity, and parental psychological functioning contribute to optimal development of children from infancy to adolescence. The results suggest that family life can buffer or offset protections against the effects of stress and adversity by imbuing children with positive coping strategies. However, the studies also suggest that the effects of family life are not always positive. Certain parental practices such as high intrusiveness and coercion can themselves constitute an adverse environment that lead to poor outcomes for children’s development. These findings offer insights that may lead to the development of preventive and clinical interventions with families to foster more positive development of children and adolescents.

Relationships between young adults and their parents from a longitudinal perspective
Harald Werneck University of Vienna, Austria; B ripe Rollett; Christina Majovsky

This paper analyses longitudinally influences on the relationships between 18-years-olds and their parents. It is based on data of the long-term intensive longitudinal research project "Family Development in the Course of Life (FIL)", which followed 175 Austrian families across time with seven assessments: At 6th month of pregnancy, when the child was 3 months, 3 years, 8 years, 11 years, 15 years and 18 years of age (51-7). A large number of instruments was used to assess family life and family relations, e.g. the Questionnaire of the Quality of Partnership (Hahlweg, 1979), the Family Schedules (Cierpka & Frevert, 1994), the Inventory of Parent and Peer Attachment (IPPA; adapted from Arnsden & Greenberg, 1987), as well as socio-economic variables. The quality of parent-offspring relations proves rather stable between age 15 and 18, reaching on average rather high levels of quality, with no pertinent gender-specific differences and no differences between the relationships to the mothers and to the fathers. Three factors emerge as relevant predictors for parent-offspring relations at age 18: The quality of the inter-parental relationship, earlier maternal parenting, and offspring personality (e.g. neuroticism). In line with other findings, increased strain between parents and parenting problems undermine parent-offspring relationships. As positive relationships to parents are in turn associated with young adults’ higher well-being, better relationships to their friends, and a more positive view of the future, intergenerational relationships seem to provide an important resource for young adults’ future.

The experiences of a family living with autism in Macao
Ng¢ Teng Lao University of Macau, Macao

Research regarding psychological issues and mental health of children and their families has always been scarce in Macao. Since the dominant culture of Macao is Chinese, taboos often forbid discussions of mental health or developmental disorders, particularly when a child is diagnosed with Autism Spectrum Disorder (ASD). People in Macao have very few opportunities to get in touch with or even see children with developmental challenges. The purpose of this project was to explore the issues of living and coping with autism in Macao focusing on the experiences and perceptions of families and individuals living with ASD. Adopting a qualitative case study approach that allows a more in-depth understanding, the researchers used the Collage Life-Story Elicitation Technique (CLET) to collect rich narratives from a Macao family including the parents, siblings and the child diagnosed with ASD. An interpretive phenomenological analysis was used to examine the data for narrative performance of themes related to the (a) stressors and challenges, (b) positive experiences, and (c) community interactions of the family living with autism. The researchers conclude with a discussion of the support systems in the local context, and ways to raise awareness and give voice to the “invisible” people in society.

Symposium overview
Oscar Barbarin Tulane University, United States of America

Poor families are vulnerable to a host of stressful life events which lead to high levels of psychological strain that have the potential for impairing family functioning and compromising the development of children. Psychological strain is associated with poor outcomes but the likelihood of poor outcomes is moderated by how well the family adapts and responds to those stressors. This symposium presents the results of four longitudinal studies that explore the effects of poverty on children’s development and examines the ways outcomes are moderated by family functioning. The studies focus on outcomes as diverse as language competence, aggression, self-regulation of attention, behaviour and emotions, substance abuse, risky sexual behavior and HIV. As a group studies illuminate ways the context of family life particularly support and control processes, religiosity, and parental psychological functioning contribute to optimal development of children from infancy to adolescence. The results suggest that family life can buffer or offset protections against the effects of stress and adversity by imbuing children with positive coping strategies. However, the studies also suggest that the effects of family life are not always positive. Certain parental practices such as high intrusiveness and coercion can themselves constitute an adverse environment that lead to poor outcomes for children’s development. These findings offer insights that may lead to the development of preventive and clinical interventions with families to foster more positive development of children and adolescents.

Symposium title: Perspectives on human development in non-traditional societies
Convenor: Gertina Van Schalkwyk
Symposium overview
Ng¢ Teng Lao University of Macau, Macao

Understanding gender-related discourse in Chinese society
Holly Sit Macao

Gender-related discourses include varieties of speech and phrases associated with a particular gender – male or female. It expresses the social norms for gendered language use and the construction of gender-related behaviour patterns. On the other hand, it also forms the discursive construction of self as a product of social interaction. In this paper, I apply an analysis of existing literature and contemporary media to explore the psychological impact of gender-related discourses in Chinese societies and how these are related to gender identity development of Chinese people. I review both traditional and modern developments of gender-related language used in Chinese societies. Furthermore, I explore how the gender role discourse is constituted and affected by the changing realities of modern Chinese society; the discursive construction of gender in traditional and contemporary society. The
Utility of the collage life-story elicitation technique: An ethnographic study
Gertina Van Schalkwyk University of Macau, Macau

Autobiographical memories and narrative meaning making of life events transforms knowing into telling. Art therapy and collage making are techniques to scaffold autobiographical memories when verbal communication is not forthcoming. In this paper, the author explores the utility of the Collage Life-Story Elicitation Technique (CLET) to elicit narrative representations and autobiographical memories from adults in the middle adulthood phase of life. As an innovative and collaborative technique, the CLET aims to elicit self-defining memories using collage making as a form of narrative performance, storytelling, positioning of the dialogical self, juxtaposing dynamic conflicts, and reflection. The present study employed interpretive phenomenological analysis to the CLET data collected from 31 Chinese adults living in Macao. Preliminary findings suggest that the CLET is effective eliciting life and volunteering, social networks and relationships, retirement, and family life. The project provided greater understanding of the lived experiences and coping styles that adults employed when adjusting to different contexts. Justification for the utility of the CLET in different settings, including clinical settings, will be discussed.

An exploration of the factors affecting Chinese college students’ life satisfaction
Fan Wu University of Houston, China

Emerging adulthood is a distinct period with a focus on ages 18–25. Similar to young people in developed countries, college students in urban China are likely to experience emerging adulthood due to late marriages and more education. The purpose of this study was to investigate the psychological factors influencing Chinese emerging adults’ life satisfaction. Data from 192 Mainland China and Macau college students (21 to 25 years old) were collected. These participants were studying at universities in major cities in China, namely, Shanghai, Shenzhen, Wuhan, and Macau. They came from 21 different provinces and special administrative regions. It was hypothesised that Chinese college students’ optimism, self-efficacy, and acceptance of Chinese values would be positively correlated with their perceived life satisfaction. Differences between Mainland China and Macau college students were also explored. The hypotheses were analysed by correlations, t-tests, and multiple regressions. Results supported the hypotheses that Chinese college students’ acceptance of Chinese values, optimism, and self-efficacy were positively correlated with their perceived life satisfaction. It was also found that Mainland college students scored higher in life satisfaction and Chinese values than Macau peers. In addition, students who were unemployed scored higher in life satisfaction and lower in Chinese values than students who have part-time jobs. In order to increase subjective well-being of college students, resources, workshops, and courses related to positive psychology, self-efficacy enhancement, and Chinese values and culture should be available at Chinese universities.

Psychology contribution to care for children with handicaps in the Czech Republic
Jaroslav Strurna Czech-Moravian Psych. Society, Czech Republic

The care for handicapped children in Czechoslovakia under the totalitarian regime was characterised (in accord with the regime of terror) by a high degree of segregation and a strong tendency to deprive children of their own families, putting them into a collective institution of social care without school education. After the democratic revolution in 1989, the first step was to humanise the care and base it on the up-to-date knowledge of child psychology. Also, new options were introduced, e.g., traditional full-time institutional care was substituted by day centres and expert guidance to primarily develop a deep personal relation between the child and the primary caring person; parents were encouraged to unconditionally accept their children, children were helped to develop a safe attachment and encouraged to instigate any small remainder of their available abilities. Simultaneously, the children were guaranteed the right to school attendance; whenever necessary, in the form of an individual instruction and tuition. Such a complex care was carried out by interdisciplinary teams of specialists, often coordinated by a psychologist. Maturing children have been offered new, advanced opportunities of continuing care, in early adulthood in the form of sheltered living provisions and sheltered workshops. This paper presents a selection of concrete methods of psychological intervention and strategies for cultivating of our society. Special attention is paid to the process of transition of state care to private services.

Insights from the resilience questionnaire for middle-adolescent learners in township schools
Motlapule Mampane University of Pretoria, South Africa

Research on resilience among black South African youth, especially in township contexts, is critical, yet a dearth of studies exist that consider the unique developmental and contextual conditions of township adolescents. Black South Africans often use assessment instruments of Western orientation, mostly developed for white populations. Consequently, there is urgent need for development of ecologically valid assessment instruments for diverse black South African populations. This paper outlines the empirical process in the development of a Resilience Questionnaire for Middle-adolescents in Township Schools (R-MATS), administered to 291 Grade 9 respondents from two Mamelodi township schools. The instrument contains two sections. Section A identified contextual resources, social and economic risk factors frequently found in social and home environments in South African townships. Section B considered youth assets, personal/psychological characteristics related to positive adaptation (e.g., locus of control, commitment/persistence). Factor analyses and reliability and validity analyses of items indicated four factors that revealed how township middle-adolescent learners characterised their resilience. The four identified factors reflected resilience characteristics defined in existing resilience literatures but also raised questions about conceptions of resilience that may be unique to youth in particular South African contexts. Findings raised developmental and contextual questions regarding how the respondents thought about and understood the resilience items. Finally, analyses indicated differences in how resilient and less-resilient youth defined themselves, including how they interacted with their environments. The study is an initial step in identifying both individual and contextual-level factors related to positive adjustment and adaptation among black township youth.

Neural correlates of processing own-age versus other-age emotional faces
Natalie Ebner University of Florida, United States of America; Anna Rieckmann; Matthew Johnson; Marcia Johnson; Fischer Hakan

Age constitutes a salient feature of a face and signals social group membership. There is evidence of greater attention to and better memory for own-age than other-age faces. However, little is known about the underlying neural processing differences for own-age versus other-age faces, and how own-age effects may or may not interact with the emotion expressed in faces. Prior work suggests a role of amygdala, fusiform gyrus, insula, and medial prefrontal cortex in processing social in-group versus out-group faces. Using functional magnetic resonance imaging, we examined young and older adults’ brain activation while viewing and identifying facial expressions of neutral, happy, and angry young and older faces. Across expressions, left amygdala and fusiform gyrus, bilateral insula, and subregions in ventral and dorsal medial prefrontal cortex showed greater activation in response to own-age than other-age faces in both young and older adults. Examining neutral, happy, and angry faces separately showed that differences in brain activation between own-age and other-age faces in these areas were largely driven by neutral faces (and for insula and medial prefrontal cortex also by happy faces) but did not hold for angry faces, suggesting that processing of (particularly negative) facial emotions reduces age-of-face effects. Interestingly, for young adults,
greater self-reported frequency of contact with own-age as opposed to other-age individuals was related to greater activation to own-age than other-age faces in left amygdala. The results are discussed in the context of affective evaluation and familiarity effects in young and older adults.

Aging affects the encoding of emotional experiences  
Natalie Ebner  
University of Florida, United States of America

Emotion influences every phase of memory: it affects where we direct our attention and how we initially experience an event, it influences how the event becomes solidified in our memories over sleep-filled delays, and it molds the ways in which the event is later retrieved (reviewed in Kensinger, 2009). In this talk, I will focus on how an adult’s age influences the initial encoding of emotional information. I will present evidence that older adults recruit the ventromedial prefrontal cortex more than young adults when processing positive information, and older adults also show an enhancement in connectivity between the ventromedial prefrontal cortex, the hippocampus, and the amygdala during the encoding of positive information. Evidence will be presented to suggest that this shift toward more prefrontal-mediated processing of positive information may be connected to older adults’ enhanced self-referential processing of positive information.

Congruent brain activation during encoding and retrieval of emotional scenes in younger and older adults  
Hakan Fischer  
Stockholm University, Sweden

It has been demonstrated that memory is better for emotional than neutral information in both younger and older individuals, and the neural correlates of emotional memory enhancement has been investigated in several recent functional imaging studies. These studies have focused on either encoding or retrieval processes and demonstrated an important role for amygdala, hippocampus and entorhinal cortex in emotional memory processes in younger adults. In older adults better memory for emotional information has been associated with more cortical activation. No study has investigated age similarities and differences in the overlap between brain activation during encoding and retrieval. In the current fMRI study brain activation in twenty young (20-30 years) and 20 older (65-75 years) adults was investigated. Brain and behavioral data were collected during both encoding and retrieval of negative and neutral emotional scenes (immediately after, one week after, and three weeks after encoding). An event-related design was used to enable isolation of brain activation related to successful encoding and retrieval. The hypothesis was that: (1) Amygdala and hippocampus will show congruent brain activation in younger but not older adults during emotional encoding and retrieval and that (2) modality-based brain areas (e.g. occipital cortex) and process-based brain areas involved in executive-like functions (e.g. fronto-parietal cortices) will show overlapping brain activation during emotional encoding and retrieval in both younger and older adults, potentially in a dose-response fashion. Data will be presented and discussed at the conference.

Effect of aging on the neural correlates of social evaluation  
Angela Gutchess  
Brandeis University, United States of America

Age-related cognitive decline occurs across many domains, although little research has assessed the extent to which this characterizes social processes and the corresponding neural substrates. Recent work suggests that some neural mechanisms underlying social information processing may be relatively spared with age. In this study, we assessed how young and older adults engaged these regions in personally and socially meaningful task contexts. In an fMRI study, participants viewed faces paired with sentences inferring a trait, and formed an impression of each person. They also responded to a prompt that was personally meaningful, social but personally irrelevant, or non-social. Conjunction analyses revealed that both young and older adults recruited neural regions implicated in social cognition when making social relative to non-social evaluation, including dorsal and ventral medial prefrontal cortex, precuneus, temporal parietal junction, and temporal pole. Additionally, older adults had enhanced activation relative to young in the right temporal pole when making social relative to non-social evaluations, suggesting more reliance on stored social concepts based on experience, when forming impressions of others. Interestingly, young, but not older adults, had greater activation in bilateral posterior cingulate gyrus, potentially reflecting an overall focus on evaluating ambiguous social stimuli for later use. The findings demonstrate the preservation of the neural correlates underlying social evaluation and impression formation with age, and suggest that the function in these regions might be mediated by age-related changes in socio-emotional goals.

Positive health message framing promotes increased walking behaviour in older adults  
Anna Nottkeff  
Stanford University, United States of America

Most people do not meet the recommendations for physical activity, and older adults are the most sedentary segment of the population. It is possible that health information may not be communicated to them effectively. In two behavioural experiments, we found that emphasising the benefits of walking (positive framing) was more effective than emphasising the negative outcomes of not walking (negative framing) for promoting physical activity among older adults (assessed with a pedometer). The health messages were rated by an independent group of older adults, and the messages rated as more helpful were more successful in increasing physical activity. This suggests that positive framing may be a more effective way to recruit and encourage physical activity among healthy older adults.

Symposium title: Social and moral development in children and adolescents  
Convenor: Jose Moreno

Parental styles and roles attributed by teenage schoolmates  
Gustavo Carlo  
University of Missouri-Columbia, United States of America

In this presentation we will show the results of our research on teenagers from 12 to 15 years old regarding the existing relationship between parental styles and roles attributed by teenage schoolmates. We especially focused on agressor and victim roles. The sample comprised 420 teenagers from both sexes. We used the Children’s Report of Parental Behavior Inventory (CRPBI, teenager Spanish version by Klimkiewicz & Richaud) to measure parental styles, which has three scales (control, acceptance, and autonomy); and a sociogram based on the Revised Class Play (Ann S. Masten) to evaluate the roles given by schoolmates, and to obtain the aggressor and the victim samples. We carried out a multivariate analysis of variance (MANOVA) and we found significant differences (p < .001) between aggressors (M= 1.71) and victims (M= 1.91) in the mother control scale, but not in the case of mother acceptance and autonomy scales, as well as in father scales. The teenagers who took on the victim role considered themselves highly controlled by their mother, but not by their
father. Finally, we will show the results of our previous research on children regarding the existing relationship between parental styles and roles attributed by classmates and we will compare and discuss the differences.

Differences in prosocial practices in adolescents: Influence of parental warmth and control
Maria Vicenta Mestre Spain
Several authors such as M. Hoffman (1983, 2002), J. E. Grucec, J.J. Goodnow (1997, 2000), N. Eisenberg (2000, 2006), have highlighted the importance of parenting styles (warmth and control) in the social and moral development of children. In this study we propose the relationship of parental warmth and control to adolescents’ prosocial behaviour by specifying the types of prosocial behaviour (physical, emotional, altruistic, emergency, obedience, anonymous). The aim is to relate the different types of prosocial behaviour and the expectations of the children on prosocial behaviour of parents of adolescent self-report about their own prosocial behaviour and how to modulate parental warmth and control these relations. In the study 731 adolescents (male and female) participated with a mean age of 16.15 years, and attending public schools in the Valencian community. The subjects completed the adapted questionnaire of the Child’s Report of Parent Behavior Inventory CRPBI (Schaefer, 1965; Samper, Cortes, Mestre, Turkey, and Nacher, 2006), the Interpersonal Reactivity Index (Davis, 1980; Mestre, Frias, and Samper, 2004), the Prosocial Behavior Scale, the Scale of Physical and Verbal Aggression and Emotional Instability Scale (Caprara and Pastorelli, 1993; Del Barrio, Moreno and Lopez., 2001), the Expectations Questionnaire / kids about the reaction of parents to their behaviour (Wyatt, J.M. & Carlo, G., 2002) and the Prosocial Tendencies Questionnaire Revised (Carlo, Hausmann, Christansen, and Randall, 2003). The questionnaires were completed in a 50-minute session. The results show a significant influence of parental styles on the socio-moral development of children.

The changing role of adults
Amos Aloa Covenant University, Nigeria
Adults today are facing a much more complex world than the adults in the past. The globalisation and IT revolution have made the world smaller and flatter. Changes do not happen once in a decade, or yearly, or monthly; they happen every day or even in every minute. Adults in the year of 1960s have been prepared to cope with the more stable world by their parents who lived during World War II, whereas adults today were raised by parents of the lucrative “baby-booming” era, who were not aware of the possibility of future ever-changing world. Adults today have also to face the reality that they cannot understand their offspring, who are born in the IT world. They “speak” native IT language that is alien to the ears of the adults. Some of the adults today cannot cope with the current situation, and they become maladjusted, mentally ill people, while the rest of them can still handle the situation by adapting an ever learning and open attitude. How they do it in developing and developed countries, in the West and the East, will be discussed.

The Madrid international plan of action on elder adult ageing: A modern comprehensive agenda
Florence Denmark United States of America
All too often older persons are ignored or excluded from any decisions concerning them. This is true despite the growing number of older persons internationally. As world populations are ageing at a rapid pace, many challenges stand in the way of global sustainability. This segment of the presentation will examine and discuss the relevance and influence of the Madrid Plan of Action as it relates to ageing older adults in our modern society. The Madrid Plan of Action was developed in 2002 by representatives from around the world. This comprehensive plan included reconceptualizing the role played by older persons in society and methods to improve their quality of life. This presentation will provide information on the growing ageing population in modern society, an overview of the Madrid Plan, and an update on what has happened since the plan was formulated. A comprehensive agenda for a proposed plan of action will be discussed.

Symposium title: The state of psychology in Zimbabwe
Convenor: Gwatiirera Javangwe
Developmental psychology in Zimbabwe Gwatiirera Javangwe University of Zimbabwe, Zimbabwe
The paper focuses on how developmental psychology has contributed to the understanding of human behaviour, diagnosis of problems and how it has brought about remediation in different facets of human development. The paper concludes by focusing on how developmental psychology can partner with other fields in an attempt to serve humanity.

Symposium title: Challenges and advances in developmental psychopathology
Michael Rutter United Kingdom
These will be considered in relation to five main issues. First, the continuity between childhood and adult life is greater than previously realised. Second, there is substantial overlap among supposedly different diagnostic categories. Third, most factors and most diagnoses operate dimensionally rather than categorically. Fourth, major environmental influences operate in adult life and not just in childhood. Fifth, there is a biological embedding of environmental influences that have enduring effects.

Symposium title: When age matters: Developmental perspectives on processing and regulating emotions
Convenor: Michaela Riediger
Age and emotion affect how we look at a face and what emotion we see
Natalie Ebner University of Florida, United States of America; Yi He; Marcia K Johnson
Two of the most salient facial features are the age of faces and the emotion expressed in faces. Both are extracted rapidly and affect whether faces are attended to and later remembered. However, little is known about how age and emotion may or may not interact in influencing young and older adults’ visual inspection of faces and reading of facial expressions. Using eye tracking, we examined young and older adults’ looking patterns while viewing young and older faces and judging their expressions (neutral, happy, angry, sad, disgusted, or fearful). Overall, reading of expressions was better for young than older faces, suggesting that interpreting expressions in young faces was easier than in older faces, even for older participants. Moreover, there were age-group differences in misattributions of expressions: Young participants were more likely to label disgusted faces as angry, whereas older adults were more likely to label angry faces as disgusted. For both age groups, misattributions of disgusted faces as angry were more likely for older than young faces. In addition, there were age
effects on visual inspection of faces. Both young and older participants spent more time looking at own-age than other-age faces, with longer looking at own-age faces predicting better own-age expression ide–identification. Thus, cues used in expression identification may shift as a function of age and emotion of faces, in interaction with the age of the perceiver. We discuss implications of these findings for everyday social interactions in young and older adults.

Too positive to be true: Visual attention toward positive images of aging
Helene Fung Chinese University of Hong Kong, Hong Kong; Xin Zhang; Tianyuan Li; Derek M Isaacowitz
This study examined whether older adults, relative to their younger counterparts, looked more at positive images of aging, even when the images were too positive to be true. Negative, neutral, positive and overly (i.e. unrealistically) positive images of aging were presented to 50 young (27 female, 18–35 years old), 49 middle-aged (24 female, 36–59 years old), and 50 older Chinese (25 female, 60–77 years old). An eye tracker was used to record gaze time towards these images. Findings revealed that: (1) younger, middle-aged and older adults gazed more at overly positive images than either positive or negative images; (2) gazing more at overly positive images (as opposed to images of any other valence) was positively related to greater persistence among older adults, but not among middle-aged and younger adults; (3) there were individual differences in attention toward overly positive images. Gaze time towards overly positive images was moderated by participants’ realistic ratings of them, such that the more unrealistic an image was perceived to be, the more younger and middle-aged participants gazed at it while the less older participants gazed at it. These results suggested that older adults might selectively ignore unrealistically positive images of aging.

Aging and the role of context: From emotional social perception to emotion regulation
Derek Isaacowitz Brandeis University, United States of America; Daniel Rovenpor; Nikolaus Skogsberg; Soo Noh
Cognitive psychologists have argued that aging brings an increased reliance on context, perhaps as a way of compensating for age-related perceptual/cognitive losses. We consider the role of context in age differences in various aspects of emotional processing. In terms of social perception, recent work on younger adults has suggested that context may affect judgments of facial expressions of emotion. We tested whether older adults differed in the influence of context on these social perception judgments. Consistent with the idea of age-related increases in reliance on context, older adults showed larger context effects on social perception judgments than did younger adults. Context may also be used by older adults to regulate their emotions. However, in a typical lab-based emotion regulation task, the context is one in which emotional stimuli are presented and participants cannot choose what to interact with and what not to. To make the lab-based study of age differences in emotion regulation more ecological and closer to real-world regulation, we designed a context in which participants could select what sorts of affective stimuli to interact with. Contrary to findings that older adults may show positivity in their attention and memory when instructed to view negative stimuli, when given the choice of what stimuli to view, no significant age differences emerged in choice or duration measures. Thus, context may be important for understanding age differences (or lack thereof) in the perception of emotional stimuli, as well as in how emotional stimuli are used in the ongoing regulation of emotion.

Happy or to be unhappy? Pro- and contra-hedonic orientations from adolescence to old age
Michaela Riediger MPI for Human Development, Germany; Ulman Lindenberger; Cornelia Wutz; Gert Wagner
Hedonism, or wanting to feel good, is central to human motivation. At times, however, people also seek to maintain or enhance negative affect or to dampen positive affect. Here, we investigate age-related differences in the prevalences and functions of pro- and contra-hedonic orientations from adolescence to old age, using a longitudinal design. Four hundred participants ranging in age from 12 to 85+ years participated in two experience-sampling phases about three years apart. Participants were provided with mobile phones that they carried with them for three weeks while pursuing their daily routines. The phones prompted participants at least 54 times to report, among other things, their momentary affect and affect-regulation orientations. At the second measurement wave, participants additionally completed Implicit Association Tests (IAT) assessing the implicit valence of the “happy – unhappy” concept. As expected, self-reported contra-hedonic orientation in daily life was substantially less prevalent than pro-hedonic orientation. There were, however, pronounced age-related differences. Contra-hedonic orientation was most prevalent in adolescence, whereas pro-hedonic orientation was most prevalent in old age. The implicit measure showed a convergent pattern of findings indicating that the association strength between the concepts “happy and pleasant” and “unhappy and unpleasant” increased with age. Longitudinal analyses investigated predictors of change in participants’ propensity to report pro- and contra-hedonic orientations in daily life as well as associations with short-term affect-regulation effectiveness and longer-term emotional adjustment. Implications of these findings for theoretical conceptualisations of emotional development in different phases of the lifespan are discussed.

Emotion regulation in recurrent unpleasant situations: Mood recovery in the old and mood adjustment in the young
Manuel Voelkle Max Planck Institute Berlin, Germany; Michaela Riediger; Natalie Ebner; Ulman Lindenberger
Do adults from different age groups differ in how they regulate their mood in the face of unpleasant tasks that are recurring and cannot be easily avoided or changed? We propose that in order to address this question it is important to distinguish between mood regulation prior to, and mood regulation during the task. For this purpose, we assessed pre- and post-task mood in 154 men and women aged 20 to 81 years across twenty 100-minute sessions during which participants rated posed facial expressions on a total of 2,052 photographs. While older participants tended to maximise positive affect inbetween sessions (mood recovery), younger adults tended to attain their pre-task mood to the upcoming task (mood adjustment). We argue that while in a given situation both “strategies” are typically employed simultaneously, there exists a continuous shift across the adult life span, away from emphasising homeostatic mood towards the maximisation of positive affect. Regarding mood regulation within tasks, we follow up on recent evidence suggesting that particularly older adults attempt to enhance their mood by selectively attending to positive stimuli (attention deployment). In the present study this should not only be reflected in an increased perception of positively valenced (happy) facial expressions, but also in a differential effect on pre- to post-task changes in participants’ mood. In contrast to nonrecurring situations, our results suggest that this effect is dominated by between-tasks mood regulation. Results are discussed in the context of theories and recent evidence on emotion regulation in young and older adults.

Symposium title: Women in psychology in the 21st century: Perspectives from different nations
Convenor: Yuwanna Mivany
Workspaces and women’s psychological health: Implications for leadership
Remi Ayoko Australia
In this presentation, I discuss the connection between workspaces, territoriality and women’s psychological wellbeing (e.g. stress and belongingness) as well as their implications for leadership. Although studies in work stress, empowerment and occupational health have received little attention (Nelson & Burke, 2000a) and more so, research connecting workspaces, territorialism and women’s psychological wellbeing are wanting. Moreover, we know that organisations are moving towards working in open plan offices. Nevertheless, prior studies suggest that open plan offices can be beneficial but burdensome. For example, while open space offices reduce costs, improve communication and foster relationships, such offices and their features reduce privacy and employees satisfaction. Similarly, workspaces drive employees’ territoriality of marking and defending. While control for territory leads to identity, security and stimulation (increasing productivity), territoriality also holds potential to increase conflict, aggression, frustration, turnover, noise, and loss of privacy leading to inefficiency. Overall, studies show the negative effects of open plan offices (e.g. noise, distraction) on work performance, wellbeing and health (Lee & Brand, 2005). Therefore, in this paper, I propose that women (in particular) will be affected by the features of physical workspaces and territoriality and that these, in turn, will influence their exposure to physical workplace-related stress and put constraints on their place and organisational identity. My proposition is based on existing literature which shows that
women have different occupational stress and health issues than men (LanganFox, 1998). For example, Collins and colleagues (1997) report that women are uniquely affected by work conditions such as exposure to chemicals and reproductive health, affected disproportionately by the need for work/family balance and differ with handling workplace stress. Overall, I argue that while open plan office can lead to more collaboration, it will likely reduce women’s psychological wellbeing – increasing stress and reducing place attachment, low employee identification and belongingness (Albert et al. 2000). Given the above, I discuss two critical questions: (1) what are the likely effects of physical workspaces and territorialism on women’s choices of work/family balance programs (2) How can organisational leaders (e.g. women) manage the physical environment to promote women’s wellbeing and reduce work/family conflict? Results hold potential to further our understanding of the role of physical workspaces and territoriality on women’s psychological wellbeing and its implications for leadership. This review expands the literature on workspaces; territoriality and women’s wellbeing by proposing that leaders (especially women leaders) can maximize the benefit and minimize the burdens of open plan offices on women’s psychological wellbeing.

Multi-stakeholder model for empowerment and poverty eradication in rural African women
Judy Kuriansky Columbia University Teachers Co, United States of America

Girls and women in the developing world need support to bolster their sense of empowerment and to rise out of poverty both of which are United Nations Millennium Developing Goals (MDGs). This is particularly important in countries in Africa, also suffering from high rates of HIV/AIDS, combating which is another MDG. This presentation describes a model camp programme in Africa that teaches young girls entrepreneurship and life skills. The project represents a unique multi-stakeholder approach, as many partners were involved, including the government of Lesotho through the Office of the First Lady and several ministries, UN agencies and civil society through the collaboration of several NGOs, including the International Association of Applied Psychology which is accredited at the UN and Global Camps Africa. The project was also unique in that an extensive assessment protocol was carried out to evaluate the participants functioning before and after the camp. The results indicated significant improvement in various target areas. Videos will be shown and the merits and limitations, of doing such work will be described. Also presented will be ongoing promising efforts to expand the programme to other countries.

Women in psychology in the 21st century: A Nigerian perspective
Yuwanna Mivany Kaduna Polytechnic, Nigeria; Hafsat Kontagora; Rosemary Kato

Women in psychology and women in formal education at all, in Nigeria, may not be farfetched from each other since formal education is foreign in source. Talking about women in psychology must involve discussing their participation in Western education, which has cultural differences. Mivanyi, Pelemo, Kontagora and Okafor, (2010), in their paper on "Development of Psychological tests in Nigeria", showed that males and females differ in a variety of tests. A composite state of affairs of women in psychology includes number, level of growth in and outside academics, professional leadership, ambition, and other factors. This research involved a national survey on women in psychology and included documentary interviews, in collecting data. Data were analysed based on a hypothesis. Conclusion/Recommendations. From the results conclusions project recommendations useful for women within and without Nigeria and for students in psychology.

The changing role of women in psychology in South Africa
Fatima Seedat PsySSA, South Africa

Since the fall of apartheid, there appears to have been a change in the role of women in general, and more particularly within the domain of psychology. The South African constitution promulgated in 1996 has empowered women to take on stereotypically male roles or roles previously occupied by a statistically higher proportion of males. This paper examines 10 case studies undertaken with women located within the discipline of psychology who have recently excelled in their careers. The paper will consider the enabling and facilitative conditions that account for their positive career trajectories. Notwithstanding the successes of the women interviewed, the extent to which the career growth pathways of women in psychology have changed evenly and significantly remains a question.

Women in psychology: Obstacles to their contributions – the case of Cameroon
Therese Tchombe CRCGDE/UNIVERSITY OF BUEA, Cameroon

Psychology as a young discipline struggled to detach itself from philosophy to gain its identity. Historically, women in psychology were few yet their contributions were great. In Cameroon’s only university at the time, students had to enrol for a combine degree; philosophy and psychology. Women’s interests in psychology per se were greatly reduced as only a few women registered for the programme. When qualified Cameroonians, especially women who studied in English-speaking universities from abroad returned home, a conflict emerged because of the bicultural nature (English and French) of the country. The misconceptions that only those trained in France were psychologists deterred engagements and development. This absence of recognition led to the creation of an environment that was not enabling for involvement of women in psychological activities even in the creation of an association. The absence of women is glaring and their contributions are very invisible on this account. Globalisation has greatly influenced the African social and cultural landscape in a variety of ways that are theoretical and conceptual. Women psychologists are not motivated to address these issues in context on account of mis-education. Today many young women are entering the field but they lack leadership from senior colleagues who should act as role models. Postgraduate students seem to be restricted to benefit from the activities and contributions of women in psychology. The issues of equality and access that was greatly addressed in Beijing in 1995 still persist and must address deculturalisation in the case of Cameroon to change mindsets. The field for intervention for women in psychology is enormous. This paper draws from statistics in the six state universities in terms of women psychologists who are lecturers, numbers of under-graduate and postgraduate women students, and from literature to illustrate the significance of women in psychology in this era of globalisation.
Personalized treatment of parental depression in the ongoing research area: Diagnosis

Session Type: Papers

The impact of parental depression and remission on child psychopathology: Data from two studies
Lisa Batten University of Ottawa IMHR, Canada
Children of depressed parents have an increased risk of mood, anxiety, and behavioural disorders. Possible mechanisms underlying this risk include: genetic heritability, neuroregulatory mechanisms during development, stress, and negative parental affect and behaviours. Previous research has shown that effective treatment of maternal depression results in a significant reduction of psychiatric symptoms in the child followed by improved overall functioning. To examine incidence of psychopathology in children of depressed parents and to test whether remission of parental depression is associated with a decrease of offspring psychiatric symptoms, data from a completed (N=151) and an ongoing study (N=163) were used. Children were assessed for psychiatric diagnoses and a symptoms count using the K-SADS-PL and overall functioning with the C-GAS at baseline (before parents began treatment). Parental remission status was assessed using HAMD17 scores. Baseline data was compared across both studies. Demographic data, diagnoses, and the symptoms count showed no significant differences across both studies. Rates of psychopathology were significantly elevated: nearly half of the children in the completed and ongoing dataset (45%, 43% respectively) had a current or lifetime psychiatric diagnosis and the symptoms count showed no significant differences between fluent and non-fluent speakers. The aim of this paper is to present the results of the Self Statements during Public Speaking Scale (SSPS) in a sample of 25 adults who stutter. The SSPS is a self-assessment instrument designed by Hofmann and DiBartolo (2000), translated and adapted for Brazilian Portuguese by Osório, Crippa, & Loureiro (2008). It consists in two-5 itens subscales, positive (SSPS-P) and negative (SSPS-N). Participants (n=25) are patients at the Laboratory of Voice, Speech and Fluency at Universidade Federal de Sergipe, with graduation of stuttering. Most of them (80%) are men, 18 to 64 years old (M: 29.76, SD: 11.43), without diagnosis for social anxiety. All of them were asked to fill out the SSPS, before the therapy programme. Analysis showed a mean of 17.80 (SD: 4.69) and 8.64 (SD: 6.02) for SSPS-P and SSPS-N, respectively. Comparing the results with other published researches, involving general population, reveals significant differences at SSPS-N. Experiences of stuttering seems to increase public speaking anxiety and decrease expectations of success in communication situations.

Stuttering and the fear of public speaking
Susana Carvalho Universidade Federal de Sergipe, Brazil; Ivana Oliveira; Fabrício Souza; Elaine Santos
The fear of public speaking is one of the most frequent in social situations. It may be considered a subtype of social anxiety disorder and causes negative effects in academic and professional activities. For those who stutter, communication situations are considered threatening, causing anxiety and avoidance. However, there are few studies that measure the fear of public speaking and establish differences between fluent and non-fluent speakers. The aim of this paper is to present the results of the Self Statements during Public Speaking Scale (SSPS) in a sample of 25 adults who stutter. The SSPS is a self-assessment instrument designed by Hofmann and DiBartolo (2000), translated and adapted for Brazilian Portuguese by Osório, Crippa, & Loureiro (2008). It consists in two-5 itens subscales, positive (SSPS-P) and negative (SSPS-N). Participants (n=25) are patients at the Laboratory of Voice, Speech and Fluency at Universidade Federal de Sergipe, with graduation of stuttering. Most of them (80%) are men, 18 to 64 years old (M: 29.76, SD: 11.43), without diagnosis for social anxiety. All of them were asked to fill out the SSPS, before the therapy programme. Analysis showed a mean of 17.80 (SD: 4.69) and 8.64 (SD: 6.02) for SSPS-P and SSPS-N, respectively. Comparing the results with other published researches, involving general population, reveals significant differences at SSPS-N. Experiences of stuttering seems to increase public speaking anxiety and decrease expectations of success in communication situations.

Personality pathology in adolescence
Melissa Card University of Johannesburg, South Africa
Over the past twenty years there seems to have been an increased interest on the topic of adolescent personality pathology among researchers and clinicians in the field of psychiatry and clinical psychology. There have been many contentious debates on the topic, the most prominent being around the possibility of diagnosing a personality disorder or variant thereof in adolescence. With this in mind, the researcher attempted to understand some of the most pertinent debates as well as investigate some of the hypotheses proposed in the arguments. The main focus of the study was on the possibility of diagnosing personality pathology in adolescence and whether or not this was being achieved on an inpatient psychiatric ward. The study quantitatively investigated the prevalence of personality pathology as well as the extent to which healthcare professionals in South Africa are diagnosing various personality pathology among adolescents admitted to an inpatient psychiatric ward. The data collected was further analysed using the statistical measures in order to assess whether there were positive correlations between genders, Axis I and Axis II disorders. The results reveal that clinicians are cautiously diagnosing personality pathology in an inpatient adolescent psychiatric ward, with the borderline personality pathology being the most prevalent.

Differential outcomes from traumatic head and cerebrovascular injuries
Theophilus Lazarus South Africa
A 16-year-old patient who was involved in a motor vehicle accident whilst riding his motor cycle had his right, dominant hand (above elbow) amputated. His Glasgow Coma Scale was 6/15 on admission and a brain magnetic resonance angiography (MRA) revealed a watershed area of injury, four days post-accident. Initially, his head injury was classified as severe, based on his admission GCS. He recovered without neurological residuum and completed school. Four years post-accident, the 20-year-old patient evidenced average to above scores on the WAIS III, and on a comprehensive battery of cognitive tests. He completed a programme leading to a career as a draughtsman, retraining his left (non-dominant) hand to use a computer mouse. Pre-accident intellectual scores that were obtained in late childhood suggested comparative findings to those

Open letter to DSM-5: History and update
Sarah Kamens Fordham University, United States of America
This presentation will provide an overview of psychologists' efforts to reform the upcoming Diagnostic and Statistical Manual of Mental Disorders, fifth edition (DSM-5), with particular focus given to the Open Letter effort of the Society for Humanistic Psychology, Division 32 of the American Psychological Association (APA). In October 2011, APA's Division 32, in alliance with Divisions 27 and 49, posted an Open Letter to the DSM-5 Task Force and the American Psychiatric Association on a petition website, inviting mental health professionals to sign. The petition took off "like wildfire," as one blogger put it, amassing support from organisations, professionals, and others who were concerned about proposals for the diagnostic manual. As of today (November 29, 2011), the petition has been endorsed by over 30 mental health organisations, including 14 Divisions of the APA, and signed by almost 7,500 individual mental health professionals and others. The purpose of this presentation is to provide an overview of the main points in the open letter, and an update on DSM-5 reform efforts. Additionally, the Open Letter will be compared to other critiques of DSM-5, including those by the British Psychological Society, American Counseling Association, and the "Stop DSM" manifestos of Barcelona, Buenos Aires, and São João del Rei. The presentation will be followed by audience Q & A with the presenter, who is a co-author of the Open Letter and student representative of APA Division 32.
obtained in young adulthood (post accident). An MRI brain scan was re-ordered and the findings interpreted in light of the impact of peripheral vascular injury on cerebral perfusion. The case is discussed in light of the known profiles and outcomes of cerebrovascular and head injured patients, respectively, illustrating the transient and reversible brain ischaemic changes that occur after a peripheral artery injury associated with blood loss. The diagnostic category of reversible ischaemic neurological deficits (RIND) is revisited. The test findings obtained from this patient are contrasted with those of a similarly-aged stroke patient, highlighting commonalities and differences, making reference to the anatomical pathways underlying cognitive function.

Who is WHO, what is the ICD-11, and why should global psychologists care?

Geoffrey M. Reed Switzerland

Switzerland

Mental disorders account for 13% of the global disease burden, and up to one-third of all disabilities in low- and middle-income countries. Yet, mental disorders are drastically undertreated, with more than 75% of people with serious mental disorders in developing countries, and up to 50% in high-income countries, receiving no treatment at all. The International Classification of Diseases (ICD) is used by the World Health Organization’s 193 Member States as the basic unit of clinical information for purposes, including treatment selection and eligibility, reimbursement, outcomes and health service evaluation, health policy and priorities, and resource allocation. Therefore, the ICD has a profound impact on the professional lives of psychologists around the world. WHO is currently revising the ICD, with publication of the ICD-11 planned for 2015. WHO’s key goal, in developing the ICD-11 classification of mental and behavioural disorders, is to reduce the global disease burden through more effective treatment, of people with mental health needs at the point where they are most likely to come into contact with the health care system. The current ICD revision is the first in which psychologists have been integrally involved, reflecting WHO’s belief that its goals can only be achieved through a truly multidisciplinary process. This presentation will explore how psychological research, psychological treatments, and psychologists around the world are making a difference in how mental health and mental disorders are defined and operationalised, in ways that promise to benefit global public health as well as research and practice in psychology.

Predicting resilient adolescents and youths: Validation of a screening test in Colombia

Alexandra Restrepo

University of Antioquia, Colombia; Luis Duque; Alexandra Henao; Nilton Montoya

This article presents the validation of the Child and Youth Resilience Measure-58 (CYRM-58) in the Colombian context in Spanish. CYRM-58 has 58 questions and was developed by an international team of researchers coordinated by the Resilience Research Centre (Dalhousie University, Canada). Simplified CYRM Colombia is a test that uses 7 questions of CYRM-58. For its validation we tested reproducibility in 22 persons aged 14 to 23 years. We validated content and internal consistency in 39 resilient, 43 youth with deviant behaviours, and 66 controls matched by age and sex. We estimated internal consistency by non-parametric factorial analysis, and we assessed content validity by means of the Mann-Whitney test, boot strap regression and logistic regression. The reproducibility was found to be in the range of 75–86%. Correlation between measurements was 75%. The best predictive model or Simplified CYRM Colombia was found to have seven questions (sensitivity = 96%, specificity =76%, power = 80%).

Implications for psychiatric nomenclature in latent DSM-IV-TR Borderline Personality Disorder

Ching-Man Lai

Chinese University of Hong Kong, Hong Kong; Ching Man Lai

Past studies of latent class analysis (LCA) on Borderline Personality Disorder (BPD) obtained inconsistent findings regarding the number of classes identified. The objective of this study was to evaluate the latent structure of DSM-IV-TR BPD diagnostic category, by means of LCA in Chinese psychiatric patients. Psychiatric patients (n = 1419; 58.6% male) aged between 18 and 45 years, were recruited from ten psychiatric hospitals in mainland China, and two psychiatric clinics in Hong Kong. Clinicians at the designated participating hospitals performed the initial screening, and conducted the standard diagnostic interviews. The Chinese Personality Assessment Inventory-2 and the Chinese Personality Disorder Inventory were administered to participants. A simulated diagnostic assessment was generated to assess the presence of each DSM-IV-TR BPD criterion. The 4-class LCA model with gender and age as covariates, fitted the data best: (a) the “Severe BPD” class (5.99%) characterised by high conditional probabilities for almost all BPD criteria, (b) the “Non-BPD” class (54.90%) characterised by low conditional probabilities for all BPD criteria, (c) the “Impulsive” class (16.84%) outlined by high conditional probabilities for anger dyscontrol, marked impulsivity, unstable relationship and fear of abandonment, and (d) the “Psychotic” class (22.72%) outlined by high conditional probabilities for identity disturbance, chronic emptiness and paranoid ideation. Results of LCA supported that BPD is a discrete category featured by high conditional probabilities for almost all BPD criteria, and that LCA can be used to develop a diagnostic system based on Bayesian network. The present study, using structural equation modelling, tried to understand the overlap between anxiety and depression symptoms in 1,200 Mexican adolescents. Data were interpreted in terms of the tripartite model of anxiety and depression originally proposed by Clark and Watson.

Diagnostic system of cerebrovascular diseases based on bayesian network

Sun Yan

Liaoning Normal University, China

The cerebrovascular diseases (named as CVD) have been a major cause of morbidity and mortality worldwide. Therefore, it is a very important topic to diagnose the CVD as accurately as possible. In this study, we adopt common and important demographic and physiological indicators mainly including age, sex, hypertension, diabetes mellitus, coronary heart disease, hyperlipemia as risk factors to diagnose the CVD as accurately as possible. In this study, we adopt common and important demographic and physiological indicators mainly including age, sex, hypertension, diabetes mellitus, coronary heart disease, hyperlipemia as risk factors to develop a diagnostic system based on Bayesian network. Bayesian network supports the nonparametric representation of multivariate nonlinear probabilistic associations. We obtain the diagnostic system and it can analyze the probabilistic dependencies among the CVD and risk factors and further to diagnose and prevent the CVD on the base of risk factors. In addition, we test the diagnostic system on the real application. The experienced CVD doctors assess the system and confirm that it is benefit to the current medical diagnosis.

Session Type: Invited Symposiums

Current thinking and future challenges on changing impairment prevalent in ASD

Mallika Banerjee

University of Calcutta, India

The objective of the present symposium is to provide current and background information on autism and ASD, some current but conceptual issues surrounding diagnosis of autism, and to present and discuss current thinking and future challenges on changing prevalence of ASD. Autism the word was first used by Bleuler (1906) as a characteristic to describe schizophrenia and first described as a separate entity by Kanner (1943) and Asperger (1944). Autism is characterised by social and non-social features. Social features are regarded as a triad of impairments (Wing & Gould, 1979) in socialisation, imagination and communication. Non-social features are seen as a narrow range of interests, repetitive behaviour, good performance on visuospatial tasks, savant skills. Current thinking aims to explain autism mostly with sensory disintegration, initiated by Jean Ayers (1972) which affects sensory awareness, perception, body-attitude directly and socialisation, communication, cognition and other behaviours manifested indirectly of a person with autism. Autistic spectrum disorder (ASD) as described by Wing and Gould (1979) which includes Autism, Asperger Syndrome, Atypical autism & PDD—not otherwise specified (plus Retts syndrome & Fragile X). Current research thinking is trying to
exclude Retts from ASD and to include it within Locomotor disability. Individuals who gain a diagnosis of ASD (PDD-NOS) may have greater symptomology in some areas than others, mild impairments in several areas, or late onset.

Executive functioning and theory of mind of autism
Malliko Banerjee University of Calcutta, India; Anindita Chatterjee University of Calcutta, India; Sravasti De
The present study focus on the variables of Executive Functioning (EF) such as working memory, inhibitory control, planning and mental set shifting for assessment, training and transfer as well as on training of the affective part of Theory of mind (ToM) of individuals with ASD. TOM is described as the ability to understand or speculate about the way others think and believe, including the ability to anticipate others behavior, intentions and emotions. Frith et al advanced the hypothesis that the central symptoms of autism could be explained by a specific deficit of TOM. So, from this point, it can also be inferred that since the mentally challenged individuals have the developmental years delayed, they probably lacks in TOM. But how far this notion is true the probable explanation regarding it calls for a planned research. An experimental work was conducted in the University of Calcutta, India, by providing a training of TOM and EF to the persons with autism. 10 high functioning children with autism were taken. Software were prepared for training of TOM and standardized. Standardized tools for assessing and training EF were taken. Result shows a horizontal (social, communication and cognitive) gain of autistic children after training on TOM. But though EF training showed cognitive improvement but not revealed any significant gain in other areas of impairment particularly, socialization and communication. Interestingly, EF training demanded a good effect on motivation which was not measured quantitatively. Result was discussed on the basic principles of Theory of Mind.

Dance/movement therapy on autism
Kakoli Chakrabartty Manovikas Kendra, India; Malliko Banerjee Manovikas Kendra, India; Mital Sengupta
The body is an instrument which helps to express languages. For autistic children the pervasiveness of the problem includes not only in verbal communication but also in body expressions, in both encoding and decoding system. Dance/Movement Therapy (DMT) is a process which introduces a freedom of experiencing movements which helps to establish coordination in developing the skills in socializing and communication in a rhythmic process. DMT can be characterised as Expressive, Developmental and Physically Integrative and Inclusive. The various techniques to be used in DMT are Laban movement analysis which is based on Sensory awareness, Space effort, and Intensity of Movement and Barteniiff Fundamentals which is based on Body Attitude, Body Awareness, Body Coordination, Body Reflex, Effort, Gestalt, Interational Synchrony, Kinesphere, Kinesthetic Memory, Movement vocabulary, Phrasing, Spatial Awareness, Expressional aspect. The present study is an attempt to investigate the effect of DMT on body attitude of autistic children. Socialisation and Body Attitude of 16 autistic children (8 Experimental and 8 control) were assessed. Eight sessions of DMT twice a week with a session of 40 minutes for each child followed by post therapy assessment were done for experimental group. The same pre and post assessment were obtained from the control group who were devoid of DMT intervention. A significant effect of DMT on socialisation and body attitude of the children was evident. The discussion of the study throws light on the number and extensity of therapy sessions and the worthiness of DMT to combat autism.

Sensory disintegration and ASD
Anindita Chatterjee Manovikas Kendra, India; Malliko Banerjee Manovikas Kendra, India; Santosh Kumar
The term sensory integration (SI) has been used to describe a neural process (occurring at cellular or nervous system level), a behavioural process (observable behaviours that result from this process), and a frame of reference useful for assessment and intervention. Sensory integration theory assumes that the brain is immature at birth and also is immature (or dysfunctional) in some individuals. SI theory is based on plasticity and hierarchical organisation of the central nervous system. First proponent of SI believes that CNS has the capacity for change or remediation called neuroplasticity. Second proponent believes that the CNS is functionally organised both hierarchically (motor function and motor system output), and heterarchically (cognitive processes, motivation and others). To prove this to proponents 40 children with autism of both sexes between age group of 4 to 16.5 years were taken for experiment purpose. They were divided into two groups in matched pair techniques on the basis of age, level of autism and sex as Experimental and Control group. Dependent variables were (1) Sensory Profile for Autism (self constructed); (2) Perceptual Motor Coordination (self constructed); (3) Vineland Social Maturity Scale (VSMS) for socialisation; (4) Problem Behaviour Checklist (only for autism). After twenty sessions of intensive therapy, experimental group showed a significant gain in both hierarchical and heterarchical functions in terms of neuroplasticity. Moreover, male and older children gain and sustain their gain (as shown in post observation) in a better way than that of their female and younger children counterparts.

Health and sex education for persons with ASD
Amrita Panda Calcutta University, India; Pragya Roy; Malliko Banerjee Calcutta University, India
The tool was developed on Sex and Health Education curriculum for the adolescents having ASD. Following are the domains (1) Biology and Personal appearance: people with autism have a lack of idea about self, self identity i.e. in which sex he belongs, unless he is not aware about body parts of the same and opposite sex. (2) Privacy/modesty (about sexual expression): It has been observed that people with autism are lacking in the issues related to private and public so they have a tendency to touch body parts inappropriately or undress publicly etc. (3) Health/Hygiene/Personal care: People with autism are less concerned with self care or cleanliness during bathing, menstruation, ejaculation, masturbation etc. For example, if they know about handling of menses prior to the onset cycles they would get less confused after menstruation. (4) Emotion: Due to social impairment people with autism are unable to understand and express emotion appropriately. (5) Social behaviour: Social impairment is one of the major characteristics for ASD. Keeping in view different studies and observation and to develop, few social skills in this area have been included. Based on the above domains, statements were constructed. Initially 28 statements and 57 materials were constructed, including 5 domains of sex education curriculum. All the steps of scale construction were followed and finally 28 statements and 56 materials totalling 84 items were retained. The positive effect of health and sex education via the help of this module on problem behaviour, odd sexual behaviour of adolescents with autism, and attitude toward disability of parents was evident by an experiment with 15 young autistic adolescents with their parents.

Animal models of autism and related disorders: Implications for treatment
Petrus Devries University of Cape Town, South Africa
Recently, a flurry of animal models of autism have been developed based on genetic syndromes associated with the disorder. These models involve measurement of behaviours typically associated with autism, such as social approach and social behaviours, communication (vocalisations), and repetitive actions. Even more recently, based on inferences about the neural pathways affected by the genetic patterns, new medical treatments have been proposed and begun to be tested, first with mouse models and now even with persons. The paper will discuss some of these recent findings and the implications for our understanding of the symptoms of autism and possible mechanisms for treatment.

Animal models of autism and related disorders: Implications for treatment
Petrus Devries University of Cape Town, South Africa
Recently, a flurry of animal models of autism have been developed based on genetic syndromes associated with the disorder. These models involve measurement of behaviours typically associated with autism, such as social approach and social behaviours, communication (vocalisations), and repetitive actions. Even more recently, based on inferences about the neural pathways affected by the genetic patterns, new medical treatments have been proposed and begun to be tested, first with mouse models and now even with persons. Advances in treatment of adults with ASD: What is still needed
Vanessa Hus University of Michigan, United States of America
There has been a rising awareness of the need to increase services available to adults with autism spectrum disorders (ASD). Current treatments with evidence demonstrating effectiveness in groups of adults with ASD span a wide range of foci, from improving social skills to promoting independence in daily life. Further research is needed to enhance our understanding of the strengths and difficulties of adults with ASD and the most effective approaches with which to target areas of need.

Implementing evidence-based intervention for young children with autism
Nanclares Nogues Valeria Pediatric Developmental Center, United States of America
For the past two decades, research has focused on early identification of autism symptoms in infants
and toddlers with autism. The early symptoms of autism spectrum disorders suggest that the brain systems that support language and social development are developing in an atypical manner. The rapid learning capacity of infants suggests that intervention experiences may contribute to brain changes, in turn contributing to changes in behaviour. We will discuss the key components of these types of intervention experiences as well as lessons learned during the implementation process.

Early detection of ASD in young Zulu-speaking children in KwaZulu-Natal
Amy Wetherby Florida State University, United States of America; Nola Chambers; Aimee Ferreira
The paper will describe a project using standardised measures of parent report to promote early detection of children with autism spectrum disorders in KwaZulu-Natal, South Africa. The work builds on the Early Autism Indicators and coding of red flags for autism developed by Amy Wetherby at Florida State University.

Symposium title: Psychology’s role in developing the World Health Organization’s ICD-11: Perspectives, progress, and prospects
Convenor: Ann Watts
Voices from Arab region: Proposals for classification of mental disorders in ICD-11
Brigitte Khoury American University of Beirut, Lebanon
The ICD profoundly affects mental health programmes and services, but has historically been dominated by Western perspectives. The Arab region, with its unique cultural patterns and concepts of mental health and mental illness, has been under-represented. In collaboration with WHO, the Arab Regional Centre for Research, Training, and Policy Making on Mental Health is leading the development of proposals for changes to the ICD in diagnostic areas of concern to Arab mental health in terms of cultural relevance and applicability. Issues related to culture, family, gender, religion, and the region’s political tensions affect Arab conceptualisations of mental disorders, and in turn will influence the use and utility of the ICD-11. For example, the ICD-11 conceptualisation of stress-related disorders should be strongly influenced by Arab experience due to our long history of political instability and violence. Relevant considerations include whether the trauma relates to a single event or is chronic, whether it is experienced individually or as part of a group, and prolonged exposure to traumatic events among children. With respect to mood disorders, the classification must consider the importance of predominantly somatic presentations of depression and emotional distress, which may also affect course and management. Classifications of sexual disorders risk over-pathologising problems related to sexual activity that are common, and even normal, among individuals in traditional Arab cultures. How Arab psychologists take up these issues will shape their roles as opinion leaders within their own communities and also affect future generations of professionals and mental health programmes throughout the region.

Trauma and stress-related disorders: Developments for ICD-11
Andreas Maercker Switzerland
As a part of the development of ICD-11, WHO has appointed a globally representative and multidisciplinary group to consider critical questions regarding mental and behavioural disorders, categories related to trauma and severe stress or adversity. WHO’s major goals for ICD-11 include improving the clinical utility and global applicability of the classification of mental and behavioural disorders, and for the ICD-11 to serve as a more effective tool for WHO member countries in reducing the disease burden associated with these conditions. The Working Group has made a series of recommendations for stress-related disorders based on literature reviews, group discussions and consultations with leading professionals. Key questions include: How should the stressor or trauma criterion for Post-Traumatic Stress Disorder and Acute Stress Reaction be revised? Should other proposed syndromes (Complex PTSD and Prolonged Grief) be included? Can Adjustment Disorder be conceptualised as a stress-response syndrome based on positive symptoms? Should the diagnosis Enduring Personality Change after Catastrophic Experience be preserved? Proposals for the candidate disorder entities related to trauma and severe stress or adversity have been developed, including Post-Traumatic Stress Disorders, Prolonged Grief Disorder, Adjustment Disorders, and Complex PTSD. The main features of these proposals will be presented. Current drafts of the definitions and clinical guidelines for these diagnoses would allow us to view these diagnoses as expressions of a stress- and trauma-reaction continuum. Future timelines and prospects of the working group will be discussed. Proposals are subject to further consultation and field testing.

Sexual disorders and gender identity in ICD-11: Preliminary recommendations
Adele Marois University of Cape Town, South Africa
During the more than 20 years since the approval of ICD-10, there have been major advances in research and social understanding related to sexual disorders and gender identity that must be considered in the development of ICD-11. For example, some categories in the paraphilias section of ICD-10 have little basis other than social rejection of certain sexual practices, while others relate to behaviours that, if enacted, are considered serious crimes in which an identifiable victim has either not consented or is not considered capable of doing so. With regard to sexual orientation, although WHO adopted the policy in 1990 that sexual orientation by itself is not to be regarded as a mental disorder, there are continuing controversies regarding categories that can be specifically applied to individuals of homosexual or bisexual orientation. With regard to gender identity, current global advocacy related to the removal of categories related to transgender identity from the mental disorders section of the ICD is based partly on strong objections to the stigmatisation that accompanies the designation of a condition as a mental disorder. A solution must be developed that is responsive to these concerns but also preserves access to health services. This presentation will describe the initial recommendations of the WHO Working Group on Sexual Disorders and Sexual Health. These recommendations must be based on the principles of clinical utility, global applicability, and human rights, within the context of WHO’s mission of the attainment by all peoples of the highest possible level of health.

Towards ICD-11: WHO field studies on clinicians’ conceptualisations of mental disorders
Michael Roberts University of Kansas, United States of America
The World Health Organisation Department of Mental Health and Substance Abuse has been conducting an active programme of field studies and international surveys as a part of developing the ICD-11 classification of mental and behavioural disorders. A key priority for WHO is that the ICD-11 serve as a more effective tool for reducing the global disease burden of mental and behavioural disorders. In support of this objective, a major goal of the revision is to improve the classifications clinical utility. To provide relevant information on clinical utility, WHO has worked to assess the perspectives of practising clinicians throughout the world. Two global field studies have been conducted regarding how clinicians conceptualise the relationships among mental disorders based on their clinical experience. The first study included 1371 psychiatrists and psychologists from 64 countries, and used a paired comparisons methodology. The second study used a folk taxonomy method, and was administered with 517 psychiatrists and psychologists in Brazil, China, India, Japan, Mexico, Nigeria, Spain, and the USA. Highly similar results were obtained across two large international studies using different methodologies. Clinicians’ conceptualisations are rational and highly stable, regardless of country, language, profession, and country income level. Differences between clinicians’ judgments and classification system are not due to idiosyncratic clinician error, but rather to systematic differences. The presentation will discuss how empirical data on clinician judgments are contributing to the development of a new and more clinically useful classification of mental disorders, without sacrificing validity.

Psychology’s role in developing the World Health Organisation: Perspectives, progress, and prospects
Ann Watts Entabeni Hospital, South Africa
The World Health Organisation has unique authority to establish global standards and secure international agreements on health. Among WHO’s core functions are responsibility for international definitions and nomenclatures of disease, and the standardisation of diagnostic procedures. WHO’s 193 member states use the International Classification of Diseases (ICD) as a basis for reporting health information that is usable and comparable across countries. The World Health Assembly comprising the health ministers of all member states has directed WHO to revise the ICD-10, and publication of the ICD-11 is planned for 2015. The ICD has a profound impact on government health policies, the structure of mental health services, and the professional activities of psychologists and other health professionals around the world. The ICD-11 represents the first time that psychologists have been integrally involved in the development of the new classification system, reflecting WHO’s commitment to a multidisciplinary and international process, with the goal of improving the clinical utility
and global applicability of the ICD-11. This invited symposium will describe the activities of psychologists across a range of areas related to the ICD-11 development. These include global surveys of psychologists’ experiences and attitudes, field studies, regional efforts to improve local usefulness and cultural applicability, and the development of specific proposals for ICD-11 in two examplar areas: (1) stress-related disorders and (2) sexual disorders and gender identity. The programme will provide a rich overview not only of the ICD revision, but also of the scope and depth of psychology’s involvement.

**IUPsyS-WHO global survey of psychologists’ attitudes towards classification of mental disorders**

*Ann Watts* Entabeni Hospital, South Africa

The World Health Organisation (WHO), the International Union of Psychological Science (IUPsyS), and IUPsyS Member national psychological associations have conducted an international, multilingual survey of psychologists’ views and experiences with the classification of mental and behavioural disorders, including the ICD-10 and the DSM-IV, and psychologists’ priorities for an improved classification. WHO is using the survey results in the development of the mental and behavioural disorders chapter of ICD-11, planned for publication in 2015. More than 2000 psychologists from 22 countries across all global regions participated in the survey, which was conducted in five languages. This is the largest and most international survey of psychologists’ views on diagnosis and classification ever conducted. The survey was conducted via the internet, with minimal difficulty even in developing countries. The survey was intended to assess the perspectives of rank and file practitioner psychologists, as one of WHO’s main goals for ICD-11 is to improve the classifications clinical utility. The survey focused on key practical and conceptual issues, such as the most important purpose of a classification, desired number of categories, desirability of a strict criteria-based approach as compared to a more flexible one, how to incorporate severity and disability, and cultural applicability. Respondents provided ratings of ease of use and goodness of fit for each diagnostic category they reported using regularly. International data from the survey will be presented, including differences by global region and by country income level. Implications of the results for the developing ICD-11 classification system will be discussed.

Session Type: Papers

Engaging delinquent adolescents to learn through mediation
Fauziah Abdul Rahim Universiti Utara Malaysia, Malaysia; Zemira Meverech

The objective of this paper is to answer a general question, ‘How can learning through mediation help teachers to engage delinquent adolescents to learn?’ and focuses on a teacher and his learners’ processes of transformation when mediation becomes central in his learning and teaching approaches. Delinquent learners in this study refer to disengaged students who show less or no interest in schooling, play truant and demonstrate antisocial behaviours. This study follows an intervention-interpretive paradigm and uses a qualitative strategy. Data were gathered using classroom interaction, observations and interviews on a group of 14 to 16-year-old students learning Physical Education, specifically when playing softball games in a secondary school in the north of Malaysia. Data were analysed based on a model of mediation (Abdul Rahim, 2007). Findings suggested two emerging themes, i.e. a learner-centred learning focus and a transformation of teachers and learners’ learning experiences. Understanding the students’ interest; challenges and aspirations was vital in involving the students in the learning activities, hence focusing on learner-centred learning. The softball game and rules as an environmental mediation assisted the teacher in mediating the students’ understanding of the importance of obeying rules in schools. The teacher also provides cognitive and affective mediation to stimulate learning thus enabling learners to go through a process of transformation which then changes the teacher’s perception of his learners’ learning capacity. It is recommended that teachers understand the importance of learning through mediation and teacher training programmes introduce models of mediation in helping learners, especially delinquent ones, to learn.

The impact of using Fink’s active learning model on grade 10th Omani female students’ self-regulated learning strategies
Nawar Alrawahi Ministry of Education, Oman

Cumulative research shows that an important means to life-long learning is to help students develop self-regulated learning (SRL) strategies. In SRL, students become aware of their own thinking, are strategic, and are able to direct their motivation toward valuable goals. Based on previous research, SRL can be developed if effective learning environments are established. The current study investigated the impact of using Fink’s Model of active learning in developing SRL strategies. Fink’s model is a learner-centred model where both experience (doing and observing) and reflective dialogue are recognised. The sample consisted of (62) grade 10th female students in Al-Dhakhila school district. The sample was randomly divided into two groups: An experimental (N= 32), which was taught by the Fink’s Model of active learning and a control group (N= 30) which was taught using the traditional method. The teaching process has a frequentcy of seven lessons per week and lasted for eight weeks in the academic year 2010/2011. The researcher administered the Motivated Strategies for Learning Questionnaire (MSLQ, Pintrich, et al., 1991) to measure SRL strategies. The MSLQ scores showed a reliability value of (0.88). The results revealed statistically significant differences at (α=0.05) in (MSLQ) favouring the experimental group. The current study contributes to the educational practices by designing a program of active learning (based on Fink’s Model) to promote students’ SRL. The researcher recommends the use of this program to promote SRL strategies.

Empathy and the personal experiences of trainees in a persona doll training programme in South Africa
Zaytoon Amod Wits University, South Africa; Nikki Barnfather

Many devastating problems face South Africa’s young children that can hamper their emotional and social development. The Persona Doll programme (Buchanan, 2007) attempts to intervene in the young child’s emotional development. Persona Dolls are used to encourage emotional expression and management in young children. Previous research has indicated the positive effects of the Persona Dolls and Emotional Literacy programmes with children. Buchanan (2007) demonstrated that the Persona Doll sessions elicited emotional material that could be used in developing emotional literacy in children. Irish (2009) indicated that preschool children’s ability to perceive and label emotions increased after the programme. Furthermore, the teachers involved with the Persona Doll programme perceived that there was an improvement in emotional expression with their children, and that the children appreciated working with the Persona Dolls, which helped to facilitate speaking about emotions and feelings (Irish, 2009). However, the development in the trainees and practitioners who use these dolls has yet to be researched. This research study assesses the development of empathy, and the personal experiences of trainees who undergo the emotional literacy and Persona Doll training programme in South Africa. Participants include social workers, psychologists, and preschool and foundation phase teachers. Participants’ empathy is assessed before the first training session, and at the end of the training through the Davis Inter-personal Reactivity Index (1980). Participants also document their feelings, experiences, and thoughts while undergoing the training, in a journal. This research is still being conducted.

Ghanaian students’ attitude toward the use of the internet as a learning tool
Lebbeaus Asamani University of Cape Coast, Ghana; Stephen Fia

The internet has become an indispensable tool in the world. Its usage has increasingly become common in many spheres of our daily life. It is in this regard that the researcher sought to find out about the University of Cape Coast (Ghana) undergraduate students’ attitude towards the use of the internet as a learning tool. The design employed was a descriptive survey. The extent to which students used the internet to learn effectively and their perceptions about the academic environment in the University of Cape Coast (UCC) in relation to the extent to which it facilitates the use of the internet for learning were investigated. The self-perception theory, the functionalist theory and the cognitive dissonance theory were the foundation for the study. The study was conducted using a random sample of 341 undergraduate students from the 15,026 students from all Faculties in the university who had registered for the second semester of the 2010/2011 academic year. This number was derived from a sample size determination table provided by Krejcie, Robert, Morgan, and Daryle (1970). The findings indicated that students use the internet to learn effectively and perceived that the academic environment in UCC facilitated the use of the internet for learning. In general, the findings indicated that UCC students had a favourable attitude towards the use of the internet for learning. The age and gender of the student did not have any significant effect on the extent to which they used the internet to learn effectively.

Teaching is exhausting: Examining the role of discrete emotions and emotional dissonance in the classroom
Eva Becker University of Konstanz, Germany; Anne Frenzel; Thomas Goetz; Melanie Keller

Compared with other professions, teachers experience higher levels of emotional exhaustion than other professionals, and the emotional exhaustion, in turn, influences their job satisfaction and emotional dissonance (Chang, 2010), yet empirical evidence is lacking. As teachers spend approximately 40% of their total working time in class, the present study focuses on emotional experiences while teaching, and their relationship to emotional exhaustion. Drawing on the regulatory resource model (Baumeister, Bratslavsky, Muraven, & Tice, 1998) we hypothesise that experiences of negative emotions and emotional dissonance (displaying emotions not genuinely felt) deplete resources and result in emotional exhaustion. A paper-pencil questionnaire was administered to 36 secondary education teachers (56.2% female). They reported on their discrete emotions (anger, anxiety, boredom and shame) and emotional dissonance (suppressing feelings / faking emotions) in class, as experienced “in general” (beliefs about emotions, trait-emotions), and their emotional exhaustion. To compensate for bias in retrospective self-reports on emotions, teachers also reported their momentary emotional experiences and emotional dissonance in class (state-emotions) via computerised experience-sampling. Multilevel analyses revealed that emotionally exhausted teachers experience higher levels of state-anger, -shame and -emotional dissonance (suppressing feeling) in class. Moreover, emotionally exhausted teachers have a greater discrepancy between their trait- and state-reports, resulting from an over-estimation of trait-anger, -anger and -suppression of feelings. This indicates that emotionally exhausted teachers have stronger dysfunctional beliefs about their emotional lives. The study provides important new insights into the role of emotional experiences for teachers’ burnout, which can prove beneficial in designing future studies or treatments.
The relationship between spatial awareness with mathematic disorders in elementary school students
Monir Behruz; Islamic Republic of Iran; Ahmad Yarmohammadi; Ahmad Abdi
This research was designed to study the relationship between spatial awareness with mathematic disorders in elementary school students at grade three in Isfahan city. A sample of 60 students was selected from elementary schools. Spatial Awareness Questionnaire and Raven Intelligence Test were administered to the subjects. The results of stepwise regression analysis showed that the correlation between spatial awareness, IQ and classification of students with mathematic ability were significant (P < 0.05). The results of this study support the claim that stimulus of child in environment and pre-school programs, especially in spatial awareness, can progress the mathematic ability of students in elementary school. The most important finding from these analyses is that mathematic ability of children is influenced both by intelligence and by spatial awareness.

"Graduateness" a contested idea
Colleen Bernstein; University of the Witwatersrand, South Africa; Dick Ettema; Haruna Suzuki; SAToshi Fujii; SAToshi Fujii; Rukhsana Osman
Navigating expectations between higher education, employers and graduates, the notion of "graduateness" is a highly contested idea amongst multiple stakeholders. Higher education institutions (HEI), employers and students continue to grapple with the meaning of the construct. Allocation of the responsibility to ensure that "graduateness" is instilled in students when they move out of the confines of the university environment, prepared to enter the professional working world is further contested. Consequently, the aim of the present paper is to explore the contested nature of "graduateness" and the contested expectations as to whose responsibility it is to instil "graduateness" within students. The paper will also endeavour to explore the meaning of "graduateness" from a South African perspective with an emphasis on "graduateness" being more than just 'employability attributes'. Instead "graduateness" will be discussed as embracing critical competencies such as global citizenship, moral leadership, social responsibility and a theoretical and practical understanding of ethics and their importance within communities of practice. Finally, the paper will attempt to outline strategies that need to be undertaken by institutions of higher learning and employers to transcend the gap between university 'outputs' and employer 'demands' so as to enable a seamless and continuous learning flow for graduates as they leave the safe confines of higher learning and enter the diverse and highly complex world of work.

Effect of leadership training in sport learning on middle school students
Wang Bin; School of Physical Education, China
This research first guides leadership training to sports to investigate the effect of leadership training used in the sport learning of middle school students by a cautious teaching experiment. The pre-post-test/control group design was used in the study. Subjects, 102 experimental and 95 controls, were selected in Guanshang middle school. Leadership skills were measured three times (pre-test, post-test and a time-lapse determination) and sports performances were tested twice (before and after training) among the subjects. Only the experimental groups of subjects (31 were junior students, and 71 were high school students of which 31 were in a basketball elective class as a group event and 40 were in an aerobics elective class as an individual event) were exposed to a 15-week leadership training intervention in sport learning in which subjects met for 45 minutes a day twice weekly. Repetitive measure analysis of variance was used to analyze the data. Results show that the subjects of the experimental group score significantly higher in total leadership, working with groups, understanding self, communicating, making decisions (no statistically significant difference is found in the aerobics elective class) and leadership, and thus reveal that it is effective to train leadership in sport learning. Students' sport performances show no significant differences between the two groups, indicating that leadership training has no influence on students' sport learning. Also, the data of the time-lapse determination reflects that the effect of leadership training can be retained to a certain degree. The results have shown the feasibility, applicability and validity of involving leadership training in sport learning in middle schools.

Creativity and talent development in ethnolinguistic diverse nations of South America
Sheyla Blumen Pontificia Universidad Catolica, Peru
The importance of creativity as an expression of mental health in human development is established, as well as its development in contexts of ethnolinguistic diversity, from empirical data. The social construction of the talent concept in Peru, Chile, and Colombia under the influence of Positive Psychology in its actual conception is analysed, as the need to promote its development from individual and group efforts towards the improvement of well-being. The relationship between creativity and talent concepts is discussed, considering empirical studies, and a case study, in order to understand the particular contributions of those who used their talent to improve the living conditions. Emphasis is put on the important role of opportunities and complementary services for the talented children and youths living under poverty conditions. Finally, the need to sensitize the professionals of health and education on the needs of the talented children and youths living under ethnolinguistic diversity, and poverty conditions is imperative. Most of them are exposed to a lack of opportunities to develop their abilities. Recommendations involve formal lineaments for talent development, as well as the advocacy of the different agents of civil society, as well as universities and enterprises, in order to build-up a communal, social, and working space, supporting their development towards a positive social transformation.

Teachers' conceptualisation of their professional relationships as a factor of educational effectiveness
Alexandra Bochaver MSUPE, Russian Federation; Vladimir Kasatkin
To explore how the teachers conceptualise their role position in their relationships with students, what metaphors they consider as relevant to their experience, and how these metaphors are linked with their professional activities, 15 semi-structured interviews with Russian primary and secondary school teachers were performed. Content-analysis techniques and expert assessment were used. The stories about conflict situations within the educational process were collected, and teachers' metaphors of relationships, weaknesses, resources to restore psychological balance, and new knowledge obtained from the conflict experience were discovered and analysed. Experts also analysing texts of the interviews assessed teachers' levels of competence, constructiveness in conflict solving, tendency to burnout/self-realisation, and to ego-centrism/decentration. Surprisingly, most common metaphors used by respondents are not of knowledge transfer but of people management. Teachers' constructs of professional relationships describe predominantly distribution of power, where the teacher is a representative of authority ('commander', 'orchestral conductor', 'guide' etc.), and students are represented as his or her followers ('soldiers', 'musicians', 'inexperienced travellers', etc.). Teachers' weaknesses are often related with the lack of power. The links between their metaphors, weaknesses, resources, and competence according to experts' opinion were evaluated. Teachers in Russia tend to conceptualise the process of teaching as people management, and their role as power representative. Links between teachers' type of power position, stress-resistance, psychological ability to self-project, competence, and quality of relationships with students are discussed.

Communicative strategies in education: Theoretical review
Victorija Boguslavskaya Southern Federal University, Russia
Despite numerous research studies into the nature, mechanisms and properties of senses translation as an interdisciplinary problem, in psychology, there is practically no sense-creating research, even in the educational context, as a field of common senses in which their directed transference from the teacher to the pupil is realised. The vector of influence from the teacher to the pupil can be considered to be communicative strategies. Interaction of the teacher and the pupil, considered as the intention of sense-creation, has a certain steady orientation, however the logic of realisation of the given process can be varied. Communicative strategies in the educational process can be differentiated on the grounds of the way that transmission of senses (which are presented in informational constructs) are subjected to assimilation. As a basic strategy, it is possible to distinguish manipulating and conventional strategies. In the process of realisation of manipulating strategies, the sense is generated and transformed before the process of its transmission. In this case, actions of the "teacher-pupil" parties are unequal, and one party (the manufacturer of the sense) controls the other party (addressee). In the process of realisation of conventional strategies, the sense is generated, and transmitted within the communication process where actions of the parties are equal in rights. In conventional communications, control of the audience is open and equivalent.
Under-graduate students’ self-directedness and employability attributes in open distance learning
Jo-Anne Botha UNISA, South Africa; Melinde Coetzee
Adults enroll as distance learning students at tertiary institutions to further their qualifications and improve their employability. Research shows that the psychological constructs of self-directedness and employability attributes influence adult learners’ study performance and motivation. These constructs are under-researched in the South African distance learning context. The objective of this study was to explore the relationship between under-graduate adult learners’ self-directedness (measured by the Student Self-directedness Scale) and employability attributes (measured by the Employability Attributes Scale). A quantitative survey approach was followed. A stratified proportional random sample drawn from a total population of N = 10 398 undergraduate distance learning adult students in the economic and management sciences field - Final sample (N =1 102). The sample comprised 88% between 18 and 40 years (early career stage); 63% females; 92% blacks; 57% employed. Exploratory factor analysis was conducted on the newly developed Student Self-directedness Scale. Descriptive statistics (means, standard deviations, reliability statistics), and correlational analyses were performed. Acceptable internal consistency reliabilities for the two instruments were obtained. Significant relationships were observed between the participants’ self-directedness and employability attributes, pointing to the importance of developing these psychological attributes in adult students. In conclusion, new knowledge was gained which can be used to inform teaching and learning design for adult learners ensuring their success as students and employability. The results are limited to the demographic confines of the study. Recommendations for future research and practice are made.

Exploring the value of employing metacognitive procedures into teaching
Alexandra Butterfield University of Stellenbosch, South Africa; Louise Botha; Marietjie Oswald
This paper reports on a study that explored the value of employing a range of metacognitive teaching procedures in a high school classroom, during a time when education, both in South Africa and internationally, experiences a number of challenges with regards to the need for improved teaching and learning. The study employed a social constructivist theoretical framework that views learning as a unique, internalised construction of knowledge from a social interaction, such as teaching. The study was embedded within a paradigm of praxis and employed an action research design. Purposeful sampling was used to select nine learners as participants. Data were collected in the form of learner reflections, an open-ended questionnaire, a focus-group interview, and a research journal. Furthermore, the data was analysed, using a theoretically founded coding scheme in order to identify and interpret significant themes. The findings will be presented under the themes learners’ metacognitive development (knowledge and regulation of cognition), metacognition and the ideal learner, and the development of teaching practice, with the intention of revealing the value of metacognitive teaching procedures. The main findings of this study indicated that the employed metacognitively orientated teaching procedures enhanced learners’ metacognition. Their metacognitive awareness and reflection abilities improved, as well as their knowledge and regulation of cognition. The research process proved to enhance my teaching practice with the teaching procedures demonstrating the potential to facilitate the development of my learners’ conscious thinking, self-discipline, responsibility and active participation in learning - all characteristics envisaged for the ideal South African learner.

Self-regulation, working memory and attention: Effects and interactions
Eduardo Cascallar Katholieke Universiteit Leuven, Belgium; Monique Boekaerts; Mariel Mussa Katholieke Universiteit Leuven, Belgium
The capacity of human beings to self-regulate has been an important topic of study in psychology. It has resulted in significant findings regarding human cognition, problem solving, decision making, metacognition, motivation and volition. This study investigates the interactions between basic cognitive processes (working memory [WM] and attentional networks [ATN]), and their effects on self-regulation (SR) factors. The sample consisted of 900 entering university students, with equal representation of both genders, ages between 18 and 25, from various disciplines (humanities, psychology, business, and accounting). The instruments used were: The Attentional Networks Test, the AOSPAN (an automated test measuring WM capacity), and an online SR/motivation questionnaire (OMQ91). Participating students were divided into four cognitive groups (high and low levels of each cognitive resource). ANOVAs compared levels of SR factors between the four cognitive groups. In addition re-gression analyses examined the relative contribution of cognitive and SR factors on general academic outcomes. Results showed the functional independence of the three attentional networks, and a significant correlation between executive attention and working memory capacity. Significant interactions were found between the SR factor levels and the levels of the cognitive resources studied in the four cognitive groups, demonstrating interesting patterns of effects of the cognitive processes on the components of the self-regulation construct. These results have important implications for the understanding of the functional distinctions of SR components and of the effects of basic cognitive processes on SR, important for cognitive theory and the understanding of SR in learning.

Impact of remedial intervention on mental health issues associated with learning disabled students
Kakoli Chakrabarty Manovikas Kendra, India; Anindita Chattree in Manovikas Kendra, India
Learning disabilities are problems that make it difficult for a student to learn in spite of having normal intelligence. They lack in fluid intelligence and fail to keep up with academics and tend to fall behind. This leads to social rejection and develops criticism, and gives rise to mental health symptoms like low self esteem, truancy, aggression, delinquency and low self confidence. The present study has been done on a very small sample with action research approach. Twenty first-generation learners, aged 10-12 yrs, have been selected on the basis of their behavioral and scholastic difficulties. They were initially assessed by Standard Progressive Matrices, Aggression Scale and Self confidence Inventory and also by observational method, which is an informal way of assessment. Each child was found to have normal intelligence but low self confidence and with aggression trend. An Individualized Remedial Education Plan (IREP) was made for each child on the basis of their difficulty level and training was imparted for three months. After the training, they were assessed in school performance and showed improvement in academics. This was followed by reassessment by the Inventory Scales which also showed significant changes. This small study affirmed that scientific intervention can have a positive effect on mental health symptoms among children with learning disabilities.

Debate on kinesiology and pedagogy
Lu Changfen The P.E. Institute, China; Xiaobing Luo
Kinesiology has been listed as one of the the first level disciplines of pedagogy and its study has been recognised as a degree qualification since postgraduates was recruited for further study in the field in the 1980’s. During the course of the creation and development of kinesiology, the impact of the broad field of pedagogy in determining the field kinesiology has been obvious. This results in pedagogy being closely related to the discipline of kinesiology. The relationship of kinesiology and pedagogy is the most important of all the relationships determining the nature of the discipline, which deeply reflects the mechanism of traditional pedagogy and this is a particular and operative problem that effects the development of kinesiology. Therefore, the research on the relationship of kinesiology and pedagogy has important academic consequences as well as practical value. Through the use of literature consultation, mathematical statistics, comparison and analysis, this paper analysed the mechanism operative in kinesiology that relates it to pedagogy. In particular it investigates the promotion and localisation of pedagogy and its effects on kinesiology in terms of the trend determining the close relationship of kinesiology and pedagogy. The result shows that pedagogy has in some ways been promoting the development of kinesiology, while restricting it in some ways at the same time. Kinesiology will depend on pedagogy and gradually develop into an independent discipline in the future.

Which cognitive levels do students use when solving the maths problems? Students’ and teachers’ perspectives
Natalija Curkovic NCEEE, Croatia
When constructing knowledge tests, cognitive level is usually one of the dimensions comprising the test specifications with each item assigned to measure a particular level. The aim of this paper is to investigate: (I) Can the Math teachers recognise which cognitive level is measured by each item?; and (II) What cognitive levels do students really use when solving the Math items? For the purpose of this research, a Croatian final high-school Math test was used. Subject-matter specialists who constructed the test classified the items into the three categories based on the cognitive level that they supposed to
measure: knowledge, comprehension, and application. High-school Math teachers (N = 105) were asked to classify the items from the math test into three cognitive level categories. In addition, 16 senior high-school students individually took the Math test and after each solved item, they were asked to explain the cognitive processes used to reach their solution. Teachers’ judgments and cognitive interviews with the students revealed differences in the cognitive classifications of the items designed by the test makers. The cognitive levels were not efficient descriptors of the items and so improvements are needed in describing the cognitive skills measured by items.

Stress, coping and support in first and final year students at the University of the Witwatersrand, Johannesburg

Stephanie Da Costa Leite The University of the Witwatersrand, South Africa; Nicky Israel Stellenbosch University, South Africa

University is considered to be highly stressful and there is an alarming increase in the number of stressed university students. Effective coping strategies and support are associated with decreased levels of stress. The current study was aimed at exploring the sources of stress, coping strategies and sources of support for first and final year students, as well as exploring whether a difference exists between first and final year students regarding sources of stress. 251 students (152 first year and 96 final year students) from the University of the Witwatersrand answered a self-developed questionnaire comprised of four sections: demographic information, sources of stress, coping strategies and sources of support. Analysis indicated that there were no differences between first and final year students with regards to sources of stress. Academic stress and family stress were substantial sources of stress for all the students. The majority of the students coped using problem-focused and avoidance strategies. Friends were the biggest social support agents, followed by family. The results of the study contribute to a better understanding of the sources of stress facing first and final year students, the coping strategies they employ as well as the support structures they used. These findings may lead to more effective stress management programs to assist students in coping with stress and reducing their stress.

Researching the adolescent living with a physical disability: Collaging as an alternative form of qualitative data collecting

Doria Daniels Stellenbosch University, South Africa

The use of visual-based methods within qualitative research provide a creative space for participants to express views that are often submerged by textual representations. Creating a drawing, compiling a collage or taking photographs are described by many researchers (Daniels, 2006; Rogers, 1997; Betensky, 1995) as natural activities that children and adolescents use to explore their world as well as comment on it. The textual representations of participants’ realities have been criticised for the ways in which it can appropriate the voices and stories of participants (Denzin, 1997). We argue that reliance on only text-based knowledge to report on human experience could be at the expense of silencing voices and submerging data. Though there have been investigations into drawings and photo interviewing as visual-based research methods to empower marginalised adult participants, there is a dearth of research on the value of collaging as a tool in educational research, specifically in understanding the experiences of adolescents. In this narrative inquiry the researchers made use of semi-structured interviews, a focus group interview and collages to afford adolescent participants who were living with a physical disability, the opportunity to tell their stories. We explored how these symbols and metaphors in the collages of five adolescents provided insights into their experiences and the social worlds that they navigate as teenagers. We found that the visual data disrupted and challenged the validity of some of the textual data.

Longitudinal predictive validity patterns: A case study spanning five years

Marie De Beer UNISA, South Africa; Catherine Otto

A longitudinal predictive validity study was conducted over a 5-year period within a secondary school context (n=371). All learners in the school were assessed with a learning potential measure, as well as both an English and calculations aptitude test respectively before entry to the school at a junior secondary level. Ongoing academic marks for all learners from grade 7 to grade 12 were gathered and used as criterion measure to evaluate the predictive validity of these measures for predicting Mathematics, English and general academic performance of learners in the years following the initial assessment – spanning between one and five years for the different grade groups. Patterns of statistically significant correlations between the predictor variables and academic performance results showed consistent statistically highly significant predictive validity results for all predictor measures in the first four years. However, the statistical significance and magnitude of correlations were lower after criterion results obtained five years after the initial assessment. The results seem to indicate that prediction beyond a 4-year period could be less accurate than during an initial more solidly supported window period of between one and four years.

The meeting of two worlds: Multi-disciplinary approach to the training and education of OT students

Marianne De Beer University of Pretoria, South Africa; Henk Swanepoel

The training and education of occupational therapists is extensive and involves a broad spectrum of techniques and activities. One facet of the training and education for the future career of the occupational therapist is exposure to and eventual facilitation of group treatment. As part of their curriculum the third year occupational students at the University of Pretoria have since 2007 been exposed to an adjusted socio-emotional group experience the main purpose of which is not only to facilitate experiential learning, but also to demonstrate the effectiveness of the multi-disciplinary interaction between occupational therapy and psychology. The group-process training, facilitated by a senior occupational therapist and a senior clinical psychologist, extends over three days and is based primarily on the psychotherapeutic principles devised by Irving Yalom. The group generally consists of between 8 to 10 third year occupational therapy students. Each group is exposed to an art activity on the first day, followed by a discussion of each one’s art creation on the second day, and finally, formal closing of the group on the last day. After closing the group the leaders facilitate insight into the group processes by merging the students’ experiences and the theoretical concepts that were taught.

Investigating teachers’ experiences of workplace bullying: Health effects and strategic interventions

Jaqueline De Vos North-west University, South Africa; Tiaan Kirsten

There has been a growing multi-disciplinary interest in the phenomenon of bullying. The evolving research on this topic indicates that this phenomenon can also occur in various work contexts. Recent research studies identified teachers as an occupational group that is often physically and psychologically bullied by learners, colleagues and education managers. The aim of the study was to investigate how teachers’ physical, psychological and social health is affected by their experiences of workplace bullying, using the Biopsychosocial model as the theoretical foundation. Victimized teachers were recruited through the use of print media and voluntarily participated in the research study. The research was conducted using a qualitative research design and methods. Data was gathered by means of telephonic semi-structured, phenomenological interviews. These interviews were transcribed verbatim and analysed by means of thematic content analysis. Findings indicated that victimized teachers were affected physically (e.g. hypertension, sleep problems), psychologically (e.g. anxiety, depression) and socially (e.g. withdrawal from personal and work relationships, distrust). It was further recognized that these teachers’ ill-health experiences also severely affected their families and work performance. It is suggested that various strategic interventions are conducted to psycho-educate teachers regarding the phenomenon of bullying and further create awareness in the school community and broader society.

How to increase teachers’ accuracy in detecting dishonesty

Oliver Dickhauerser University of Mannheim, Germany; Tamara Marksteiner; Marc-Andre Reinhard

Teachers’ accuracy at distinguishing students’ lies and truth is often only at chance. We investigated whether person-oriented or situation-oriented approaches can enhance teachers’ detection accuracy. Experiment 1 (N = 75) used a person-oriented approach by instructing half of teachers not to use wrong stereotypical nonverbal cues when judging students’ dishonesty. Teachers received videotapes of students’ true and false messages about school aggression (i.e. students were innocent) and untrue denial messages (i.e. students were actually involved in aggression). Teachers receiving correctional instruction did not achieve a higher overall accuracy than those without instruction, however the former judged more messages as truth than the latter. In Experiment 2 N = 123 teachers judged the credibility of videotaped students’ true or untrue denial messages about having cheated. To test the
effects of characteristics of the interviewing situation, half of the students had the opportunity to plan their message before being interviewed, while the other half had not. Detection accuracy was higher for messages without preparation time. The other half had the opportunity to plan their message before being interviewed, while the other half had no opportunity.

Findings are discussed in terms of counselling theory and recommendations are made for the professional preparation of Educational Psychologists.

Emotional intelligence and burnout among high school teachers
Iram Feroz Aligarh Muslim University, India; Asma Parveen
The aim of this study is to determine the relationship between emotional intelligence and burnout among high school teachers. The present study comprised 50 male and 50 female teachers selected randomly from the High School of Aligarh Muslim University. To measure emotional intelligence Trait Emotional Intelligence Scale developed by Law, et al. (2004) was used and for the measurement of teachers’ burnout, Teacher Burnout Questionnaire devised by Friedman (1999) was used. The obtained data were statistically analysed by means of ‘t’ test and the correlation analysis method was applied, which shows a relationship between emotional intelligence and burnout among male and female teachers. It was evident from Table ‘A’ that male and female teachers differ significantly from each other on emotional intelligence scale. The higher mean score of male teachers showed that they were more emotionally intelligent compared to female teachers. Table ‘B’ showed male teachers significantly differ from female teachers on the burnout questionnaire, the significant value of ‘t’ indicate that both have different levels of burnout.

The higher mean score of female teachers showed that they faced more burnout situations. Table ‘C’ showed that there were a negative relationship between emotional intelligence and burnout among both groups of teachers. The findings of the present study depict the structured relationship between the dimensions of emotional intelligence and burnout and it is suggested that the cultivation of emotional intelligence can be an effective strategy for reducing burnout and enhancing the professional efficacy among teachers.

Using participatory action research in schools: Collaborating with teachers to develop an HIV/AIDS school plan
Ronel Ferreira University of Pretoria, South Africa; Maesela Thabe; Ayob Ayob; Melanie Joubert; Liesel Ebersohn; Willie Pietersen; Deliwe Khumalo; Liz-Marie Basson University of Pretoria, South Africa
In exploring the feasibility of peer-facilitation during dissemination research, we investigated teachers’ (n=7, female) experiences as facilitators and other teachers’ (n=11, female) experiences as recipients during the dissemination phase of a prospective intervention study. The findings of the present study relate to the experiences of teachers, assets and resilience in three schools in the Eastern Cape Province, South Africa. In two concurrent Participatory Reflection and Action studies, peer-to-peer facilitation denotes teacher-facilitators from one school, facilitating an intervention with teachers of two neighbouring schools. Data included transcriptions of focus groups, field notes and visual data of observations, as well as research journals. Thematic analysis indicated that, as facilitators, teachers enjoyed sharing knowledge and enabling peers; and experienced feelings of self-worth, self-confidence, personal development, affirmed commitment and motivation. Furthermore, they experienced a collective voice in the community; and managed their new role with peers by overcoming feelings of uncertainty, working as a team, relying on creative problem solving, and looking forward to future facilitation. As recipients, teachers highlighted the importance of social cohesion in terms of social support, peer consultation and interdependency. They appreciated feelings of mutuality regarding care and compassion, respect and empowerment; and were motivated to claim ownership and deliver results. Based on the findings of the two studies we conclude that peer-facilitation in dissemination research reaps benefits for both facilitators and recipients, for personal as well as professional development. In addition, peer-facilitation in the STAR intervention lead to a sense of belonging, and culminated in renewed dedication to support the respective communities.

Pseudo-families support adolescents in secondary South African schools
Jean Fourie University of Johannesburg, South Africa; Lisa Andersen
Supporting the emotional well-being of secondary school pupils in many South African schools is
challenging. In an action research design, data was collected over two years through semi-structured, in-depth interviews with five teachers and eighty pupils in a highly diverse school. The adolescents experienced problems such as parental alcoholism; prolonged divorce; single parent households and parental illness due to HIV/AIDS. This family breakdown influenced pupil development: dropout rates increased; engaged in deviant peer behaviour; had lower academic achievement and exhibited disruptive classroom behaviour. The school implemented therapeutic groups forming ‘pseudo-families’ to establish deeper relationships and promote adolescent wellbeing. Pupils were assigned to a group, with a teacher as the ‘parental’ figure. They discussed pertinent issues relating to their personal life stressors in a supportive, safe and caring environment. The groups offered a regular space and time to talk and think about worries and difficulties; to explore feelings and solutions to these problems.

As a totality the group produced a powerful therapeutic experience in holding each individual and creating a sense of common identity. The adolescents took responsibility for their own behaviour and learning. Educators were better able to identify pupil’s emotional challenges and learning problems were supported. Senior pupils acted as mentors to the juniors encouraging them to participate in the school’s sporting, cultural and academic extra-murals. Management perceived the holistic development of each pupil. Such pseudo-family groups could greatly benefit schools with limited resources to employ school psychologists.

Trans-disciplinary team support for a severely intellectually impaired Tswana boy

Jean Fourie University of Johannesburg, South Africa

Children who present with intellectual impairment pose many challenges for inclusive schools as they exhibit a range of functioning difficulties with learning, communication, socialisation, sport and leisure which South African schools are generally ill-equipped to manage. This case study describes five years of holistic trans-disciplinary team support for Sipho, a 10 year old, Tswana speaker with severe intellectual impairment. Qualitative data such as referral forms, therapist and school reports were collected. Semi-structured interviews with the psychologist, speech, occupational and remedial therapists, teacher, Sipho and his parents were conducted. Data was systematically organised into a comprehensive database for content analysis. A detailed case history revealed multiple delayed milestones. Sipho’s limited English hampered his learning resulting in a poor self-esteem. His low muscle tone and co-ordination difficulties limited sport involvement. He needed constant encouragement to perform daily school activities and to interact with his peers. His level of functioning was interdependent on the intensity of the team support which provided varied opportunities for developing functional skills and a range of appropriate activities for Sipho to construct applicable knowledge at his own pace. The team designed an individualised support plan with clear, attainable goals and social learning in his mother language, Tswana, as the basis of all learning to imbue a sense of ownership and accomplishment. As an integral part of the team, Sipho’s parents implemented strategies to improve his daily home functioning. The team support was most successful with constant collaboration, continual monitoring; information and resource sharing, and goal orientated team work.

Exploring the emphasis of academic success amongst Asian families with kindergarten-aged children

Amie Frewen James Cook University, Singapore

Research into academic emphasis has revealed that Asian school children spend significantly more time on academic than non-academic activities compared with children of a western background (Larson, Richards, Sims, & Dworkin, 1998). Singapore, an educational hub for Asia has a reputation for demanding academic excellence from children (Chung et al., 1993), but do these high expectations come at any cost to the child’s overall development? The objective of this study is to investigate parental beliefs and parental involvement in kindergarten-aged children living in Singapore to better understand a) the amount of time students are spending in academic versus non academic activities in a typical week, and b) to explore ethnic diversity within the Asian cultures in regards to beliefs and expectations about academic success. Approximately 300 parents will complete an online survey including the Child Rearing Beliefs Scale (Okagaki & Stemberg, 1993), rating of Parental Involvement (Reynolds, 1992), and will complete a diary of a typical week for the child’s academic and non academic activities. This study is surveying responses between November 2011 and January 2012. Results are expected to show that children in the Singaporean kindergarten system are spending the majority of their day engaging in school based activities (including homework, tutoring and enrichment activities). Additionally, it is expected that families of a Chinese background will have beliefs and greater involvement in their child’s academic success than families from other Asian countries. Implications for an emphasis on academic excellence will be discussed.

Playing into gender stereotyping in a pre-school theatre production

Elette Fritz University of Johannesburg, South Africa

This paper reports on a critical analysis of a nursery school play and is informed by previous research (Fritz, Swart & Henning, 2008) conducted on how school plays can be at risk of serving the needs of adults, versus addressing the developmental needs of the children involved. Vygotskian theory was used as the organising framework with which to discuss the stages of childhood development. Vygotsky (in John-Steiner & Mahn, 1996, p. 192) proposed that development could be regarded as the transformation of “… socially shared activities into internalized processes.” The purpose of this presentation is therefore to provide a critical analysis, in which lyrics and enactment set the stage for gender stereotyping and sexualised behaviour of pre-school children involved in a school play. A case study design was used, in which a school play captured on DVD was analysed through critical discourse analysis, considering the lyrics and observations. Only the DVD recording, publicly distributed, was used for analysis and as such ethical clearance entailed using the video for analysis and not directly engaging with the children who participated in the concert. Limitations to this research will therefore be discussed, pertaining to a using a single case study. The findings of this research alludes to how the social engagement in a concert can influence gender stereotyping of pre-school children and also predispose them to sexualised behavior. I propose that a school play, as a cultural ritual, should be employed as therapeutic tool to the aid of childhood development.

Qualitative research about the effects of interpersonal relationship network on career development

Anguo Fu Hainan University, China; Jianzhong Zheng

Based on the in-depth interview with seven excellent graduates (3 males, 4 females; age range between 24-27. Among them 3 Company Clerks, 2 public servants and 2 office-bearers), the method of interpretive phenomenological analysis (IPA) was used to study the effects of interpersonal relationships on career development. The result showed: (1) The weaving of interpersonal relationship network is one of the key ways to obtain important information and resources in the current Chinese social context that has imperfect competition. (2) Weaving and managing interpersonal relationship network and seizing the opportunities contribute greatly to career development and success.

Relation between identity styles and spiritual intelligence in college students

Bagher Ghobar Bonab University of Tehran, Islamic Republic of Iran; Shahrazad Manavi

The aim of the current study was to study the relation between identity styles of college students with quality and magnitude of their spiritual intelligence. To accomplish the stated goal, 388 college students were selected by means of cluster sampling from the colleges of Islamic Azad University of Tehran. The following scales were administered on them. The spiritual intelligence self report inventory (King, 2008) was used to measure spiritual intelligence and Identity styles inventory (Berzovsky, 1998) was used to measure identity styles of students. The results of multiple correlation analysis demonstrated that the total score of spiritual intelligence and its aspects had a meaningful positive correlation with informational, normative domains of identity styles and commitment. Multiple regression analysis showed that around 17% of change variance in the normative identity style is predictable using total score of spiritual intelligence. Moreover, about 12% of change variance in the normative identity style was predictable by "personal meaning production" and "transcendental consciousness" domains. Moreover, 15% of the commitment of the students was predictable by "personal meaning production" of spiritual intelligence report inventory. According to the findings of the present research, it can be concluded that spiritual intelligence and its domains are fundamental variables in determining the quality of students’ identity styles. Implications of the current study for the theoretical understanding of the identity formation, and its practical significance for clinicians have been illustrated in the paper.
Results suggest that although girls may report higher math anxiety on retrospective measures, they do not experience greater math anxiety than boys during mathematics classes or tests.

Teachers’ emotion regulation goals and strategies: Evidence from China
Shaoying Gong; Central China Normal University, China; Liu Zhong; Yongqing Jiao; Ting Duan; Xiaoyun Chai
This study aimed to explore Chinese teachers’ emotion regulation goals by employing strategies used before, both in and after classroom teaching. 34 teachers from elementary, middle and high schools in central China were interviewed. The semi-interview included three questions: (1) Which emotions do you experience in classroom? (2) Do you ever try to regulate/control/disguise your emotions? (3) Why do you regulate your emotions? Teachers’ motivation for regulating their emotions included achieving instructional goals, keeping positive emotional images, maintaining teachers’ and students’ mental health, and nurturing good teacher-student relationships. Teachers used various antecedent-focused and response-focused strategies to control their emotions, especially negative emotions before, in, and after class. In general, Chinese teachers used response-modulation most frequently, followed by cognitive changes. Compared to American teachers (Sutton, 2004), Chinese teachers used response modulation more often, which could be the result of culture difference.

Teachers’ emotional work strategies and job burnout: The moderation effect of professional identity
Shaoying Gong; Central China Normal University, China; Fei Zhao; Eun Yeon
The study aimed to explore the relationships among teachers’ professional identity, emotional work strategies and job burnout. The participants were 391 teachers from Hunan, Hubei and Jiangsu provinces, including 57 elementary teachers, 115 middle school teachers and 219 high school teachers. 47 percent of them were male teachers. All teachers were assessed with Teachers’ professional identity scale, Teachers’ emotional labour strategies questionnaire, and Teacher’s Job Burnout scale. The findings were that teachers’ professional identity significantly positively correlated with active deep acting, passive deep acting and personal accomplishment and significantly negatively correlated with emotional exhaustion, depersonalisation, and intellectual burnout. There existed significant positive correlations between surface acting and emotional exhaustion, depersonalisation and intellectual burnout. The regression analysis showed that role values in professional identity negatively predicted emotional exhaustion, depersonalisation, and intellectual burnout best, and predicted surface acting positively, secondly best. Professional behaviour inclination in professional identity positively predicted personal accomplishment most strongly. After controlling the effects of personal backgrounds and school, teachers’ professional identity moderated the prediction effect of surface acting on depersonalisation, personal accomplishment and intellectual burnout. These findings indicated that increasing teachers’ professional identity could decrease the negative effect of surface acting on job burnout.

Bullying in middle school: A worldwide perspective and comparison
Haigen Gu; Shanghai Normal University, China
Using the latest international educational database, TIMSS, this study investigates eighth-grade students’ five types of bullying (something was stolen; was hit or hurt; was made to do things; was made fun of or called names; was left out of activities) in fifteen countries. For each country, the study also compares the bullying rates in middle and elementary schools, explores the relationships of bullying to school backgrounds, and reveals the influences of bullying on students’ associations, attitudes, addictions, academic interests, pressures, and achievement. Finally, a longitudinal study analyzed changes and developments of bullying in middle school using data collected in 1995, 1999, 2003, and 2007 by using the data from the four regular cycles of TIMSS. The results find that although the rates of bullying show great differences among the countries, the orders of the percentage levels of types are similar; elementary students’ perceptions of bullying are more serious than those in middle schools; male students experience some types of bullying in school more than female students; school backgrounds do not play a key role in bullying levels; bullying strongly affects students’ attitudes toward school and their associations but has less impact on students’ academic interests and pressures; and bullying is positively correlated with students’ addictions but is negatively correlated with their academic achievement. These findings provide worldwide outlooks and meaningful references for intensive research of school reformation, reduction of bullying behaviors, improvement of school environment, and perfection of students’ development.

Using latent class analysis to examine adolescents’ perceptions of autonomy support from parents, teachers and friends
Frederic Guay; Laval University, Canada; Senecal Caroline
Research showed that adolescents perceiving others as autonomy supportive (others as acknowledging their feelings, providing them with choice, and minimizing control) are better adjusted at school (Guay et al., 2008). However, most studies investigating perceptions of autonomy support used a variable-centred approach in which each source of autonomy support (e.g., parents, friends) is related to outcomes (e.g., Vallerand et al., 1997). Such a way of examining the role of perceptions of autonomy support does not offer the possibility of identifying groups of individuals that perceive different levels of support among various sources. The goal of this study was to examine adolescents’ perceptions of autonomy support regarding five sources (mother, father, French and maths teachers, and friends) using latent class analysis. Participants were 1,406 high school students (47% boys, 52% girls). Analyses revealed four groups: Group 1 was constituted of students (69.4%) reporting that the five sources supported their autonomy; Group 2 was made up of students (16.6%) reporting that the five sources were unsupportive; Group 3 was made of students (8.5%) reporting that only their fathers
were unsupportive; Group 4 was made of students (5.5%) reporting that only their friends were unsupportive. Analysis revealed that students from Group 1 achieved better in French and in maths than students from the other three groups. There were no significant differences on achievement among Groups 2, 3, and 4. These results suggest that all sources of autonomy support are important to foster academic achievement.

Relationship between boredom proneness and mindfulness of Chinese college students

Lu Guo; Beijing Sport University, China; Sabine Hammond; Jillian Bull

The term boredom refers to an aversive subjective state of dissatisfaction attributed to an inadequately stimulating environment. The experience of boredom has both situational and individual determinants. So, as a personality characteristic, trait boredom is referred to as boredom proneness and is operationalised as an individual’s susceptibility to experiencing boredom. According to the attentional theory of boredom proneness, boredom results from a deficit in attention. The current study investigated the relationship between boredom proneness and mindfulness which is defined as the ability to attend to the immediate environment. 252 college students participated in this study. They completed the Boredom Proneness Scale and Mindfulness Scale.

Bivariate Pearson correlations were conducted in order to investigate the relationships between mindfulness, boredom proneness and the subdimension of boredom proneness. Results indicated significant negative correlations between mindfulness and boredom proneness (r = -.558). Furthermore, significant negative correlations were found between mindfulness and monotonousness, loneliness, lack of self-control ability, nervousness and sense of restriction (r = .453, .539, .359, -.273, -.333). However, mindfulness did not relate significantly with creativity deficiency (r = -.053).

The status of educational psychology as a field of study in Iran

Mansoor A. Hameedy Alzahra University, Islamic Republic of Iran; Mahdieh Paaknehad

The higher education system in Iran, despite the anti-American rhetoric in the post-revolutionary era, is still, after 33 years, strongly influenced by the American system of higher education. The field of educational psychology could be the very epitome of such influence, as its curriculum has remained the same as when it was first imported. Recent talks of re-"islamization" of the curricula have alarmed many practitioners as to the future of their fields. One constructivist approach to the problem would be an overall evaluation and reconstruction of the curricula to make them relevant and up-to-date, and hence, immune from any ideological intrusion. To this end, the curriculum in educational psychology was evaluated at three levels of intended, applied, and achieved. The official and centrally approved curriculum was content analyzed from a constructivist perspective. The participants in the in-progress study are three groups of students, professors, and graduates in and from the master’s degree programs in educational psychology at different universities who responded to questionnaires on the quality of the curriculum. The preliminary data indicate that the very foundations of the program, as well as its different components, are in need of serious overhaul and renovation if it is to be spared from any ideology driven socio-political intrusion.

The design and trial of a constructivist course aimed at improving self-regulation in learning among Iranian high school students

Mansoor A. Hameedy Alzahra University, Islamic Republic of Iran; Masoomeh Jafary

Looking at the quality of public education in Iran, from a constructivist perspective, one would notice the absence of emphasis on self-regulating skills in the curricula, leading to many educational shortcomings such as low achievement. With the objective of helping with the remediation of this problem, a constructivist course aimed at helping the high school students in developing and utilizing such skills was designed and experimentally implemented. The course consists of 10 weekly 2 hour sessions in which the following skills are introduced and practiced: self-monitoring, use of cognitive and metacognitive strategies, time and resource-management, and self-motivation. The teaching method is constructivist in nature, emphasizing on critical thinking, reading, writing, dialogue, and role-playing. To evaluate the course, with the help of two groups of first-year female high school students, an experimental trial was undertaken in the subject of Chemistry. The instruments used included a skills questionnaire with a reliability of .87 and internal consistency of .78, and an achievement test in Chemistry with reliability of .74. The two groups were similar in intelligence, achievement, and initial self-regulating skills. The post-tests in targeted skills showed a significant improvement in the experimental group which persisted in the ten-weeks later follow up as well. Although the achievement scores of the two groups did not show a statistically significant difference, the results are indicative of the course effectiveness in improving the targeted skills. Hence, it is suggested that the course be imbedded in other subjects’ curricula.

Looking at, and talking about, teaching methods in Iranian universities

Mansoor A. Hameedy Alzahra University, Islamic Republic of Iran; Elham Fakhari; Mahsheed Tajrobehkar; Masoomeh Barandak

Improvement of teaching methods is the primary goal of all educational institutions. However, any improvements require a critical look at currently used methods. To help the Iranian educational system reach this goal, the research reported herein was conducted from a constructivist perspective. 47 classrooms were selected from among all current classrooms across Tehran universities, using a cluster sampling method. The instruments were an observation list emphasizing all aspects of teaching methods, and a questionnaire used to interview the 47 professors of the selected classrooms. The questions covered the philosophical/theoretical, affective, and practical aspects of teaching methods. The validity and reliability of both instruments were assessed to be adequate and acceptable. The results show that most university professors interviewed did not have an adequate grasp of the philosophical and theoretical underpinnings of the methods they use. The methods observed and claimed to be used did not seem to be that constructivist in nature, or foundation, as they mostly emphasized lecturing on the part of the teacher and rote memorizing, on the part of the student. The findings are in corroborating with those of the previous studies, despite their theoretical/methodological differences or shortcomings. Given the fact that the current approach to teaching in Iran is more traditional than scientific, and university professors simply practice what they have experienced during their years of schooling, it is suggested that all potential university teaching staff be required to take a course in teaching methods conducted by Education Psychologists.

Journeying unmapped routes to an educational niche for our son with pervasive developmental delay

Pauline Hanekom University of Stellenbosch, South Africa; Doria Daniels

At birth every human being is at the starting point of many different journeys, journeys of discovery and change and journeys of mental and physical growth. Most children follow a similar path of physical and mental growth into adulthood, achieving predetermined milestones at approximately the same age. But what happens to the parents of a child who cannot follow this path, a child born without a map? Parents who, although not disabled in the normal sense of the word, find themselves disabled in their experiences of parenthood and life. This presentation reports on an autoethnographic study that was undertaken to reflect on two parents’ journey to find an educational niche for their son, diagnosed with Pervasive Developmental Delay – Not Otherwise Specified (PDD-NOS), an Autism Spectrum Disorder. Ellis (2007, p. 13) argues that “autoethnography starts with personal experiences and studies ‘us’ in relationships and situations”. In this study evocative autoethnographic co-constructed narratives (Ellis & Bochner, 2006) were married with analytic autoethnography (Anderson, 2006) in an attempt to engage and involve the non-academic audience, while at the same time addressing the analytical needs of the researcher audience. The process of data collection involved both parents narrating stories of how they experienced the journey, followed by sessions of sharing of, and reacting to, their stories. Through dialogue and co-construction, a parental-narrative was created. A reflexive layer, stating the researcher’s positioning and analysis of the narratives, artefacts and field notes of the dialogue and co-construction sessions, was also provided.

The conceptual impact of variation in semantic mediation in schools: An activity theory perspective

Joanne Hardman UCT, South Africa

The foundation of Vygotskian thought is captured in his "general genetic law", which states that higher cognitive function-thinking, reasoning and problem-solving begin as real relations between people, intersubjectively, before being internalised intrapsychologically. Dialogical interaction is thus posited as a crucial means of cognitive and pedagogical change. This idea, that communicative interchange can be said to provide a 'basis for thinking', is of clear importance for any communi-
cational strategy with a properly transformative agenda. Vital in this respect is Vygotsky’s notion of mediation, namely, the utilisation of cultural artefacts as a means of attaining higher mental functions. Vygotsky extends the concept of mediation with the pedagogical idea of the Zone of Proximal Development (ZPD). The ZPD refers to the gap that exists between the skills a given subject or audience has already acquired, and those tasks or abilities that require outside assistance. We are thus provided with an innovative means of assessing the efficacy of dialogical interactions in classrooms. Given the importance of semiotic mediation in the development of higher cognitive functions, this paper asks what happens when there is variation in semiotic mediation across contexts; in this case between face-to-face mathematics lessons and computer-based mathematics lessons. Four teachers and 179 students participated in the small scale exploratory case study. Findings indicate that there is significant variation in semiotic mediation across contexts, calling into question the developmental impact with will have on children.

The situation and relationship among gratitude, intrapersonal emotional intelligence and burnout of teachers
Anming He School of Education Science, China; Qinyuan Hui; Qiping Hui; Qiping Hui School of Education Science, China
In order to explore the situation and relationship between gratitude, intrapersonal emotional intelligence and burnout of central teachers in rural middle schools, data were collected from a sample of 103 central teachers in rural middle school using the Gratitude Questionnaire-6 (GQ-6), our own Intrapersonal Emotional Intelligence Scale (Intra-EIS) and Maslach Burnout Inventory-Educators survey (MBI-ES). Based on descriptive statistics, multivariate analysis of variance and multiple regression analysis, the results showed that: (1) Levels of gratitude and intrapersonal emotional intelligence of central teachers is higher, and degree of burnout is not very serious, (2) there are significant main effects and only two interactions on a handful of demography variables, the factors of gender, class teacher and health on burnout have significant main effects, gender on gratitude has significant main effects, class teachers on intrapersonal emotional intelligence has significant main effects. Moreover, the age and the class of the teacher on three factors have significantly two interactions, namely, gender and health on gratitude and burnout have significant two interactions, (3) gratitude and intrapersonal emotional intelligence of central teachers have significant negative effects upon burnout.

Examination of ‘self-handicapping’ in a structural model for prediction of academic achievement
Mahmood Hozar Shahid Beheshti University, Islamic Republic of Iran
The main objectives of this study are the examination of the mediating role of self-handicapping (SH) in the relationship between the above-mentioned factors and academic achievement, and the evaluation of SH variables in structural modeling in prediction of academic achievement. The statistical population of the current study consists of all Sha-hid Beheshti University undergraduate students during the second semester of one academic year (1387-88 IR colander, 2008-2009). Based on the number of instrument items, number of variables, and paths brought to the model, a sample of 1,010 subjects were selected randomly through a cluster sampling method. A battery of questionnaires including the SH scale, Self Esteem Inventory, Procrastination Questionnaire, Perfectionism Inventory, Goal Orientation Scale, and Five Factor Personality Inventory were completed. Data were analyzed by a series of statistical methods including correlation, partial correlation, exploratory and confirmatory factor analysis, path analysis and SEM. Results indicated that SH shows a mediating role between personal factors and academic achievement. The structural model developed for students’ academic achievement was supported. These results indicated that SH as a behavioural reflection of psychological constructs such as self-esteem, procrastination, perfectionism, goal orientation, and personality factors may play an important role in academic failures. SH demands professional attention in order to manage the problem since a majority of afflicted students can easily survive this damaging characteristic if professional care is provided to them.

Attention and perception in ADHD
Roche Herbst Human Capital Solutions Inc., Canada
Inconsistencies in concentration and attention abilities seen with Attention Deficit Hyperactivity Disorder (ADHD) are shown to correlate with perceptual problems often seen with learning disabilities. Difficulties in determining an individual’s learning profile often result in inappropriate academic accommodations and other interventions that support successful learning in an academic setting. This analysis explores cognitive and behavioural aspects related to ADHD and its co-morbidity with learning disabilities. Diagnostic interviews, standardised measurements and questionnaires/behaviour ratings i.e. Amen Brain System checklist, were used. The population comprised Canadian students within a formal academic setting. A sample of 45 case studies from elementary to high-school students with reported learning difficulties are reviewed. The examination of individual summary reports were seen as goal-directed action, exploratory, qualitative and non-experimental. In summary, practical accommodations for interpreting/processing stimuli in an academic setting are discussed where conclusions reveal a co-morbidity of atypical cognitive perceptual development and ADHD.

Preparing pre-service teachers for dealing with students’ diversity related to learning: An intervention study
Silke Hertel DIFF / IDEA Research Centre, Germany; Sanne-Kristina Djakovic; Katja Afi Amin; Ina Rieger; Lena Handerich; Susanne Marnel; Simone Bruder
The competent handling of students’ individual learning needs plays an important role in everyday school life. Teachers are faced with the challenge to adapt their teaching methods to individual learning abilities, needs, and preconditions of their students, everyday. Teachers with high adaptive teaching competencies succeed in meeting the demands of subject knowledge, in taking diverse pre-conditions and learning processes of students as well as situational aspects of topical themes into account, in making benefits of diverse teaching methods fruitful for learning, and in supporting students and the class in the regulation of learning processes. The present study investigates the effectiveness of a university course on dealing with students’ diversity related to learning in the classroom as compared to a control-group (N=74). Data on competence beliefs, beliefs about teachers’ role and content knowledge were analysed conducting ANOVAs with and without repeated measures. The results that we gained within the scope of our quasi-experimental study, support our main hypotheses: Student teachers gain knowledge and competence in dealing with students’ diversity regarding learning by attending a regular university course on that content. The findings support the conclusion that it is worthwhile to include courses on dealing with students’ differences related to learning in the classroom in the early stages of teacher education, already.

Mathematics and statistics performance and anxiety: An online cognitive behavioural intervention
Elizabeth Howe James Cook University, Australia; Anne Swinbourne; Deborah Graham
Prior research shows a complex relationship between mathematics and statistics anxiety, self-efficacy and performance. The interaction of these factors is thought to be counterproductive to mathematics and statistics learning. Methodological problems and conflicting results are evident in intervention research, the majority of which have focused on performance deficits within the classroom. While performance is an important factor, anxiety is a greater determinant of future enrolment and avoidance of maths and stats in university and the workforce. Anxiety also has a negative effect on memory which can further compromise performance. Therefore, Cognitive Behavioural therapies are recommended to combat anxiety. Attrition, time and cost are common deterrents to this approach however. Online Cognitive Behavioural Therapy (OCBT) can address these issues and has been effective in combating a number of anxiety related disorders. The current research developed an OCBT program using short multimedia clips to combat mathematics and statistics anxiety and improve approach behaviours in Psychology students. Initial usability data provided positive feedback about the content, accessibility, and ease of use for this program from participants of different ages and educational backgrounds. Data is currently being collected in a randomised controlled trial of the OCBT program. An improvement in anxiety and reduction of avoidance behaviour for OCBT participants compared to controls is predicted. Preliminary findings will be presented. The program provides a flexible tool for targeting anxiety while reducing time constraints for staff and students.

Violence in higher education institutions as correlate of negative psychosocial and emotional well-being of students
Eucharia Igbeafue University of Pretoria, South Africa
Worldwide, higher education institutions are seen as an excellent instrument for effective and efficient
development of an individual and the nation. Universities, as higher education institutions, make the best contribution to national and international development through strengthening and diversification of their programmes. The university environment is expected to be violence-free, equipping students with the capacity to live in unity and harmony as one indivisible, indissoluble and democratic community practicing principles of freedom, equality and fairness. The recent increase in the diversity and escalation of violence, as well as the increase in technology used for violence in Nigerian universities has become a great concern to the society. Violence has become a significant negative tool that students utilize in addressing issues among themselves, with lecturers and university management. The main purpose of this study is to explore violence in Nigerian universities to ascertain if it is an indicator of students’ negative state of mental well-being. The Mental Health Continuum Short Form (MHC-SF) was used for data collection. Three universities were purposively selected. Six hundred students enrolled in the universities responded to the questionnaire. Based on categorization of languishing, moderate, flourishing, the Mental Health Continuum-Short Form (MHC-SF) scoring was used. The finding indicates that violence is significantly related to students’ negative state of mental well-being. The university management consequently needs to address the issue and stop dismissing violence in universities as actions of reckless students. Psychologists need to design an intervention approach aiming at the promotion of positive mental well-being of students in Nigerian universities.

Intercultural understanding concerning child care and education in Japan and China Tomoyoshi Inoue Doshisha University, Japan; Yuko Yamamoto

There are a variety of cultural differences between any two countries. This study aims to reveal the differences in child care and education between Japan and China. The third author (an expert of visual anthropology) videotaped and edited two versions of 20 minute long films that mainly focused on children’s activities in the respective kindergartens (for three to five year old children) both in Japan and China. The distinctive difference between the two countries is that the children in the Japanese kindergarten mostly played spontaneously with some assistance by their teachers while those in the Chinese kindergarten were intentionally instructed by their counterparts. These two films were presented to both Japanese and Chinese university students (12 participants respectively). The participants were interviewed concerning the following questions: (1) What the child care and education was like when the participant was a child, (2) if the participant thought the film of their own country generally represented the children’s activities in the kindergarten or not, (3) what the participants thought of the differences between the two films. The results indicated that the two films roughly, but symbolically, reflected the real situations in the kindergartens of the two countries. It was also shown that Chinese participants underestimated the significance of early childhood education that emphasized care through play-centered instruction in the Japanese kindergarten.

Motivation and social relationships in secondary school: Four different types of learners Danila Igenow Free University Berlin, Germany; Diana Raufelder; Frances Gottwald

Although much is known about the relationships between teacher and peer support and motivational outcomes (i.e., Radel, Sarrazin, Legrain, & Wild, 2010; Ventzel, Battle, Russell, & Looney, 2010) much less is known about students with relatively constant levels of academic achievement and motivation independent of teacher or peer support. Based on three theoretical perspectives, namely Bandura’s social-cognitive theory, self-determination theory, and achievement goal theory the purpose of the present study was to address this gap in the literature by examining the individual differences in the roles played by peers and teachers in students’ academic motivation and several aspects of academic achievement. Students of 8th grade (N=1089) with a mean age of 13.71 years (SD = .527) from secondary schools in Brandenburg (Germany) completed measures on achievement motivation, achievement goals, school related self-efficacy, and self-regulation as well as measures on relationship and motivation. Latent class analysis revealed four different types of learner: (1) teacher-dependent learner (2) peer-dependent learner, (3) teacher- and peer-dependent learner and (4) teacher- and peer-independent learner. Furthermore, these types differ on several aspects of motivation and achievement. Differences between the four identified types of learners on several aspects of academic achievement and learning motivation suggest their relevance and highlight the need to exercise caution in promoting or accepting generalisations in academic settings. Results from the study can help to foster and support each student individually within the school setting.

The application and effectiveness of knowledge management systems within Malaysian private higher education Raymond Jambaya HELP University Graduate School, Malaysia; Zahra Izadihkah

The Altbach paradox (2004) of the world class university, is as poignant as it is ironic, succinctly stating “everyone wants one, no one knows what it is, and no one knows how to get one.” Knowledge management in higher education has evolved into an effective approach, that has bridged much theoretical rhetoric into a practical application through organisational and workplace learning. This paper examines how two local private universities have invested in knowledge management capabilities, whilst exploring the perception of end users (academic staff) on the effectiveness of these processes. Utilising multi-variate analysis on a random stratified sample of 150 respondents drawn from multiple departments, the study affirms, in three key constructs: knowledge management systems, knowledge sharing, and workplace learning, that university staff are aware of these processes but their application and perception of their effectiveness is low, due to a number of institutional and personal limitations. Challenges revolve around organisational structure and individual inertia, to apply adaptive and experiential methods of ICTs. Universities counter-intuitively run tangentially to their own knowledge management agenda, resulting in an internal rise of work conflicts, stress, and recalcitrant attitudes which mitigate the effective exploitation of individual and organisational performance. The study highlights a culture of knowledge hoarding by academics, reinforced by a lack of proper incentives to encourage knowledge-sharing beyond the norm. Further implications and recommendations are alluded to in this paper.

Multi-sensory environment enhancing learning: Higher efficiency of working memory, better information utilization Weili Jiang Peking University, China; Chen Zhao; Si Wang; Jing Zhao; Yanjie Su

Researchers pay much attention to e-learning with the development of computer science, which creates a multi-sensory environment. However, multi-sensory learning’s functional mechanism and the optimal condition in which to apply it are still not clear. In the current study, we tested the learning process of efficient learners (EL) and ordinary learners (OL), and the impact of multi-sensory learning. ELs were defined as students who were admitted to Peking University after the college entrance examination, whereas OLs were those students who failed the examination. In Experiment one, 29 ELs and 31 OLs described six acquired scientific concepts. According to exploratory factor analysis, the number of scientific terms, sentences and tables/diagrams in their descriptions showed a significant difference. In Experiment two, 21 ELs and 29 OLs learned three new scientific concepts and then described them. The primary difference between them was the number of terms they described, which correlated with their capacity of working memory. In Experiment 3, 21 ELs and 29 OLs also learned three new scientific concepts. However, these concepts were separately presented on paper, via videos or both. The results showed ELs’ learning efficiency was highest and correlated with their working memory in multi-sensory conditions. Together, these findings suggested that multi-sensory learning could enhance the efficiency of working memory, so that ordinary learners would have better access to information, which in turn enhances their learning.

Knowledge and attitudes towards attention deficit hyperactivity disorder among primary school teachers Morayo Jimoh University of South Africa, Nigeria

Attention-Deficit/Hyperactivity Disorder (ADHD) has been described as a common childhood disorder affecting approximately 5% of primary school-aged children all over the world. This has led to studies on the knowledge of and attitudes of teachers towards Attention-Deficit/Hyperactivity Disorder (ADHD) in various countries among which are Australia and Unites States (Kos, 2004; DuPaul & Stoner, 2003; Kos, Richdale, & Jackson, 2004). On the contrary, there seems to be a dearth of research on the knowledge of and attitudes of teachers towards Attention Deficit Hyperactivity Disorder (ADHD) among children in Nigeria. To this end, the study investigated primary school teachers’ knowledge of and attitudes towards ADHD using two social psychological theories: Theories of Reasoned Action (TRA) and Theories of Planned Behaviour (TPB). Data were collected using a researcher developed questionnaire administered on...
two hundred and fifty (250) primary school teachers (125 males and 125 females) drawn from 10 inclusive primary schools in Lagos State of Nigeria. The analysis of data was done using the t-test and ANOVA. Findings revealed a deficiency in teachers’ knowledge of as well as negative attitudes to ADHD among primary school pupils. It was also found that teachers’ level of education, length of service and exposure to training on ADHD all have significant influence on the perceived knowledge of and attitudes to pupils with ADHD. Based on the findings, it was recommended that ADHD education should be made a compulsory part of teacher education curriculum in Nigeria.

Fostering resilience amongst youth:
The development of a community-based programme
Bridget Johnson The JEDA Foundation, South Africa

The interest in resilience research has grown exponentially over the past few years as researchers and practitioners have come to realise the shortcomings of a deficit and pathology approach to assisting at-risk youth to overcome adversity and lead successful lives. Resilience research proposes that all human beings possess an innate drive towards growth and success. This innate drive is enhanced when there is a focus on innate strengths and support within an eco-systemic framework. A research study in the Western Cape found that the youth are engaging extensively in a variety of risk behaviours that threaten their well-being. Results from the resilience component of the study indicated that internal assets such as co-operation and communication, self-efficacy, empathy, problem solving, self-awareness and goals and aspirations need to be enhanced. External assets such as caring relationships, high expectations and meaningful participation need to be further developed within the domains of school, home, family and peer relationships. Furthermore, school connectedness and recognising the value of indigenous knowledge systems are important aspects to secure positive outcomes. Recommendations of this study included the development of a resiliency training program that focuses on empowering teachers, social workers, psychologists, counsellors and other helping professionals to strengthen resilience in the wake of adversity. To this end, the paper focuses on the development and piloting of a community-based programme to foster resilience amongst youth.

Implications of teachers’ efficacy and self-esteem on teachers’ burnout: A correlational study
Mohita Junnarkar IIT Bombay, India; Raj Kumar Pandit; Devendra Singh

Self-efficacy is the “beliefs in one’s capabilities to organise and execute the courses of action required to produce given attainments.” It is a cognitive process where people construct beliefs about their capacity to perform at a given level of attainment (Bandura, 1977). Teacher’s self-efficacy is assumed to be affected by self-esteem and influences teachers’ burnout. Efficacious (rather than non-efficacious) teachers appear to exert a greater positive influence upon students due to their attitude and behaviour. That is, efficacious teachers tend to be less judgmental with students’ mistakes. Self-esteem is considered to be a trait reflecting an individual’s characteristic affective evaluation of self (Gist & Mitchell, 1992). The present research examines the relationship between teacher’s self-efficacy, burnout and self-esteem degree. In the current study 315 teachers participated from various public schools in India. Correlational and regression analysis were employed to understand the effect of self-esteem and self-efficacy on teacher’s burnout. The results indicated significant relationship between teacher’s efficacy and burnout, self esteem, self-efficacy. The results are consistent with existing literature.

Problem solving, attention, and working memory: Longitudinal study of lower secondary school children
Devaraj Kalaimathi Ladywilldingdon Institute of Advanced Study in Education, India

The role of problem-solving in students’ growth in working memory (WM) was examined in a longitudinal study of children (N = 90). A battery of tests was administered that assessed WM, problem-solving, achievement, and cognitive restructuring in Grade 8 children, with follow-up testing in Grades 9 and 10. The results were that (a) Grade 8 predictors that contributed unique variance to Grade 10 problem-solving performance were WM, and restructuring and (b) growth in the executive component of problem-solving was significantly related to growth in WM. The results support the notion that growth in the executive system of WM is an important predictor of growth in children’s problem-solving beyond the contribution of cognitive restructuring as well as achievement measures related to.

Perception of ICT by administrators of the French National Education (research project “Digital Culture”)
Olga Kasatkina Moscow State University of Psychology, Russian Federation

The purpose of this research project on the digital culture of administrators is to determine the representations, attitudes, values and practices of senior administrators in French national education. In relation to “digital culture” among individuals, it is both about the technological environment that surrounds them, and their place in that environment (their practices, skills, attitudes and values) (Cerisier, J-F. 2010). As part of this project, an analysis of the representations of administrators on ICT was performed. The sample consisted of 104 administrators of the French national education. We applied the method of unfinished sentences, which allowed a connotative meaning of representations of ICT among administrators. The results were analysed. Our results show that 61.5% of administrators describe ICT- essential. Distribution of qualifiers according to the emotional pole: Neutral - 55.9%, positive - 28.8%, negative - 15.3%. Examples of adjectives: positive - “evolutionary,” “facilitators,” “approaches,” “a good tool,” “motivating,” “practical,” “effective” negative - “invasive,” “inadequate,” “time consuming,” “sometimes dangerous”. We believe that the positive or neutral representations of ICT are the source of achievement is experimentally manipulated and assess each student’s performance after a period of time. Cognitive abilities were measured with the “Advanced Progressive Matrices” in Study 1 and the subscale “Figure Analogies” from the “Cognitive Abilities Test” in Study 2. In Study 1 we found a moderate correlation between cognitive and diagnostic abilities drawing on a sample of N = 44 teacher students: A higher cognitive ability was associated to a higher judgment accuracy. The second study, with N = 133 teacher students, replicated the results. Both studies suggest that there is a relation between cognitive and diagnostic abilities. These findings need to be validated by the use of field studies.

Teachers’ efficacy as a function of self-esteem and burnout: A correlational study
Mohita Junnarkar IIT Bombay, India; Raj Kumar Pandit; Devendra Singh

Self-efficacy is the “beliefs in one’s capabilities to organise and execute the courses of action required to produce given attainments.” It is a cognitive process where people construct beliefs about their capacity to perform at a given level of attainment (Bandura, 1977). Teacher’s self-efficacy is assumed to be affected by self-esteem and influences teachers’ burnout. Efficacious (rather than non-efficacious) teachers appear to exert a greater positive influence upon students due to their attitude and behaviour. That is, efficacious teachers tend to be less judgmental with students’ mistakes. Self-esteem is considered to be a trait reflecting an individual’s characteristic affective evaluation of self (Gist & Mitchell, 1992). The present research examines the relationship between teacher’s self-efficacy, burnout and self-esteem degree. In the current study 315 teachers participated from various public schools in India. Correlational and regression analysis were employed to understand the effect of self-esteem and self-efficacy on teacher’s burnout. The results indicated significant relationship between teacher’s efficacy and burnout, self esteem, self-efficacy. The results are consistent with existing literature.

Teachers’ cognitive abilities related to the accuracy of teachers’ perceptions of students’ performance
Johanna Kaiser University of Kiel, Germany; Jan Retelidof; Friederike Helm; Anna Suedkamp; Jens Moeller

Teachers’ judgments affect students’ academic careers and should therefore be quite accurate. Research on teachers’ judgment accuracy has revealed large interindividual differences in teachers’ ability to judge student performance accurately. There is still a lack of research on the question of which individual teacher characteristics are related to teachers’ judgment accuracy. During classroom instruction, teachers are confronted with a lot of diagnostic information, and therefore high cognitive abilities should be necessary to be able to judge students’ performance accurately. Two experimental studies were conducted aiming to investigate the relationship between teachers’ diagnostic and cognitive abilities. Teachers’ judgment accuracy was measured by using a computer simulation of a class setting, where the user is instructed to interact with a class of students whose
integration of ICT in professional and personal practice of administrators.

Evaluation of a school-based self motivation training programme

Marie-Christine Kees University of Trier, Germany; Nicola Baumann

Self-motivation is one of the most important core competencies in the context of school. It refers to a person’s ability to independently overcome motivational deficits and to remain capable of acting regardless of particular situational factors. A promotion of this competency is eligible, but only few of the existing training programmes are theory based and have undergone a standardised evaluation process. The aim of the present study was to evaluate a newly developed theory based training program for grammar school students aged 10 to 12 years. To provide a meaningful summative evaluation, multiple measures from 50 participants, who were randomly assigned to the training and the waiting group, were collected. Self-report data (which are susceptible towards social desirability) were supplemented by parent ratings and two different kinds of behavioural data. First of all, a newly developed computer-based measure was applied to assess self-motivation competencies non-reactively. It is based on the classical Stroop task. Removal of Stroop interference indicates high self-motivation competencies (i.e., high abilities to smoothly translate difficult intentions into action). Secondly, information about academic improvement was collected to assess self-motivation outcomes on a broader level. The results are discussed within the framework of an integrative personality theory.

A relationship-focused approach to the co-construction of enabling school communities

Ansie Kitching North-West University, South Africa; Vera Ras

Schools across the globe are facing serious challenges as human behaviour demands are becoming more complex and problematic due to the social ills besetting society. The objective of this presentation is to propose a relationship-focused approach to the co-construction of enabling school communities since the traditional modernist approaches that focus mainly on the control and cure of individual behaviour seem ineffective to enhance mental health and well-being in schools. The proposed relationship-focused approach is based on complex responsive process theory and was conceptualised following a qualitative study in three phases. In the first phase a baseline study was conducted by obtaining the experiences of learners, parents and educators of enabling and disengaging ways of relating and interacting through written assignments. In the second phase, an instrumental case study design was applied to conduct an in-depth exploration of relationships in a school community by using visual research methods and focus group discussions. The thematically analysed qualitative data provided an understanding of how relationships might be nurtured and restrained in school communities. In the third phase a relationship-focused approach that encompasses continuous conversations focusing on six facets of interrelatedness was conceptualised to facilitate a meta-level understanding of being together in school communities.

Cyber-bullies: Who is behind the screens?

Constantinos Kokkino Democritus University of Thrace, Greece; Nausika Antonidou

The aim of the present study was to investigate the psychological profile of University students involved in cyber-bullying. Four hundred and thirty students from four University departments in Greece, aged between 18 to 35 (M= 20.3), completed a self report questionnaire, measuring cyberbullying, and various personal characteristics such as big five dimensions, attachment style, empathy, psychopathy, and psychopathology symptoms such as anxiety, depression, hostility, and interpersonal sensitivity. Results indicated that 58.4% of the sample had participated in a cyber-bullying incident assuming any role, with only a low percentage of high frequency participation. Bully/victims, the most common participant role, scored significantly higher on anxiety, depression, hostility and interpersonal sensitivity, whereas bullies had significantly higher scores on boredom susceptibility. Both cyber bullying and cyber-victimisation were significantly predicted by gender, depression, grandiosity and callousness-unemotionality, in addition with attachment for cyber-bullying only. Overall, results confirm that cyber-bullying is correlated to psychopathology symptoms, while the presence of psychopathic personality characteristics is indicated in all involved, especially bully/victims. It is possible that manipulative, impulsive and callous students, who are susceptible to boredom, exploit the anonymity of the Internet to entice themselves and express their hostility. Intervention could promote mediating factors such as cognitive empathy in students with high psychopathic tendencies.

The perceived effect of school environment on the retention of nomadic Fulani pupils in primary school, Kaduna State, Nigeria

Hafsat Kontagora Kaduna Polytechnic, Nigeria

The nomadic education programme (NEP) has been providing education opportunities to children of the nomadic people in Nigeria for almost a century. Recent studies show an increase in enrolment rate but a very low retention rate. Statistics on enrolment/retention indicate a mere 2.3% retention rate in 2002. To this end, a 37 questions instrument was developed and administered to a total of 240 nomadic pupils as respondents across 9 nomadic primary schools in three identified LGAs in one State (Kaduna State). 60 respondents were from each of the three different school environments and 60 from those that have dropped out of school. The survey questions dealt with the perceived effect of the nomadic school environments: permanent, semi-permanent and the temporary school environment on retention. A hundred percent response rate was obtained. Results indicate that: (1) The permanent school environment does not promote retention as the nomadic children found the permanent school environment strange and thus it became difficult for them to adapt to the school environment, thereby dropping out eventually. (2) Home environment and the community play a major role in the extent of participation of children in schooling. (3) Peers have a large influence in retention in school of nomadic pupils. (4) The Nomadic Education Program should give more emphasis to enriching the temporary school environment to improve retention and participation. Further research efforts should broaden this preliminary effort by including nomadic parents and teachers as part of the respondents.

Psychology serving humanity: Exploring intercultural sensitivity and experiential foundations of the human condition

Paul Kriese Indiana University East, United States of America; Randall Osborne

This work is built upon the theoretical framework of: (1) exposing students to issues surrounding the human condition, (2) requiring students to explore their own reactions to those elements of the human condition, and (3) requiring students to then connect their reactions to the reactions of others. We outline assignments enhancing active learning, intercultural sensitivity, and multicultural effectiveness. We utilize a 4-step model - (1) recitation (what does the student know?), (2) exploration (how does the student know this?), (3) understanding (how do these views differ from others?), and (4) appreciation (how do others views add value to our own understanding?) - for exploring this self-other dynamic in an Internet course on ‘Hatred’. By exploring these issues, students in the course look at hatred from an international perspective and begin to see “social justice” in a broader perspective. This presentation will describe this model, outline assignments we use to foster the development of intercultural sensitivity and present collected data documenting this approach’s effectiveness. Our research shows use of this model facilitates changes in students making them more (1) open minded, (2) tolerant of ambiguity, and (3) stronger in interpersonal skills. Efforts to get students to connect to and understand the broader world must START with directed and repeated efforts to get students to explore their own assumptions, biases, opinions and values BEFORE exploring those of others.

Bullying in secondary schools: Teachers’ perspectives and experiences

Retha Kruger Stellenbosch University, South Africa; Estelle Swart

Bullying is a pervasive problem in most secondary schools. Teachers are tasked with unravelling complex dynamics of bullying in a context that is often not conducive to addressing bullying. In South Africa, unique contextual factors such as community violence overflowing into the school, increased administrative load and limited support from school management, parents and education authorities impact on teachers’ management of bullying. This paper reports the findings of a study that aimed to explore and describe teachers’ perspectives on, and experiences of, bullying in a secondary school in the Western Cape and to generate recommendations for the intervention and prevention of bullying in similar contexts. The theoretical framework which informed the study was the social context perspective which draws on social constructionism and the bio-ecological approach. A qualitative, interpretivist research approach was used. Data was generated through semi-structured individual and focus group interviews and analysed using the constant comparative method. The research findings indicated that the teachers experienced and perceived a wide variety of bullying behaviours which occurred
Comparing reading and spelling test scores and frequency of phonic errors in a remedial and mainstream high school

Michal Kruger University of the Witwatersrand, South Africa; Charles Potter

Identifying students with learning difficulties is vital in the South African context, especially with respect to the inclusive education system. This study aimed to determine if students with learning difficulties make significantly different errors from mainstream learners on reading and spelling tests at a high school level. This research compared the errors made on the Phonic Inventories (Level 1, 2 and 3), the Schonell Spelling test (one word) and the Stanford Reading test (Brown level) by two samples of mainstream (56) and remedial (37) government high school learners who were from grade 8, 9 and 10, from the East Rand, near Johannesburg. The results indicated high positive correlations between all of the tests. There were also significant differences between the scores of learners in the mainstream and remedial school environments on all three tests, indicating phonics, spelling and reading abilities were highly correlated at high school level among both mainstream and remedial school learners. Anova and Kruskal Wallis results indicated the impact that gender, grade and school had on the scores obtained. It was also evident from the discriminant function analysis that the Phonic Inventories had potential for use in identifying learners with learning difficulties at high school level.

Revealing life-sense strategies of students in educational process

Ludmila Krutleva Southern Federal University, Russian Federation

In Russian tradition there is a distinction between meaning and sense. Meaning refers to a total social-historical experience of a community and reflects objective characteristics and relations of objects and phenomena. Sense is a result of individual-specific experience and represents an attitude of the subject to these objects and phenomena. Each person has got a complex hierarchical sense system of his/her personality which consists of such structures as personal meanings and sense attitudes (level 1); motives, sense dispositions and sense constructs (level 2), supreme senses which include common humanitarian and cultural values (level 3). Each of the levels has got a sense-creation potential which displays in life-sense strategies of the person by means of which the person perceives, cognises and responds to the world around. The objectives of our research are to reveal specific life-sense strategies used by students during education. We applied both specially developed questionnaires and valid procedures (the Rotchek Value Survey, modified Purpose-in-Life Test, etc.). We found out that students absorb the educating materials according to their sense preferences which can be distinguished and described as life-sense strategies. These strategies are utilitarian-pragmatic, communicative, self-actualisation, independent judgments, and variability. Among them students have different cognitive orientations, essential differences in sense self-regulation that display in emotional, cognitive and behavioural components. Students of one and the same strategy have common stable sense-motive characteristic features which influence their success in education. Materials oriented at life-sense strategies of the students promote their efficiency in education.

An animal-assisted reading programme: results from a South African study

Mariëanna Le Roux Stellenbosch University, South Africa; Leslie Swartz; Estelle Swartz

Animal-assisted therapy (AAT) has been widely used with children, elderly and other groups of people. This study is the first known investigation into the impact of AAT on children’s reading, employing an experimental pre-test/post-test control group design. The reading ability of all the third graders in an Afrikaans primary school in a low socio-economic community in the Western Cape were assessed with the ESSI Reading and Spelling Test and the Neale Analysis of Reading Ability. Those scholars struggling with reading were asked to participate further (N=138). They were then randomly assigned to three experimental groups and one control group. Twenty seven learners read to a dog in the presence of an assistant, 26 learners read to a teddy bear in the presence of an assistant while 24 learners read directly to an assistant while 24 learners read directly to an assistant. Data collection took place at the end of the first term (Time 1), directly after completion of the 10-week reading programme (Time 2) and 8 weeks after the completion of the programme (Time 3). Mixed-method analysis of variance revealed significant interaction effect between group(s) and time on the ESSI Reading Test. Significant interaction between group and time on the Neale Analysis of Reading Ability scores were also found. The animal-assisted reading programme had an impact on the reading skills of the scholars who read to a dog.

The influence of yoga on learners with attention deficit hyperactivity disorder

Ansie Lessing University of South Africa, South Africa; Karena Beart

The study explored the influence of yoga on learners with ADHD. Particular phenomena such as concentration, anxiety, self-esteem and aggression...
were highlighted. A qualitative study was conducted, looking at the influence of yoga on ten learners who manifested attention ADHD. Semi-structured interviews with parents, teachers, learners and the yoga instructor were used. Valuable data was also collected about the learners’ concentration, aggression, anxiety and self-esteem, by using a projection test and a self-esteem questionnaire. Interviews and assessments were conducted once during the situation analysis and again after the yoga intervention. Based on the data collected and analysed a trend was found that yoga had to an extent a positive influence on learners with ADHD with regard to concentration, anxiety, self-esteem and aggression. Due to the qualitative nature of the investigation, only ten learners were involved, no control group was required and the results of the study can therefore not be generalised. Although no long term influence of yoga is determined in this investigation there is sufficient evidence to suggest that the use of yoga to support learners with ADHD regarding concentration, aggression, anxiety and the improvement of their self-esteem might be of value. Decreasing the manifestation of ADHD behaviour may contribute to the improvement of learners’ academic achievement.

The relationship between expectancy divide and loneliness in freshmen: The mediating role of self-esteem

Yuhui Li Renmin University of China, China; Weizhen XIE; Fengmei HOU

Loneliness appears to become more and more widespread in modern society, arousing people’s concern and consideration frequently. This study aimed to reveal the existence of feelings of loneliness among Chinese freshmen, and explore the latent relationships between expectancy divide, self-esteem and loneliness, with in-depth discussion on whether self-esteem serves as a mediator between expectancy divide and feelings of loneliness in Chinese freshmen. 623 freshmen (average age = 18.32 ± 0.41) from different majors (popular and unpopular) were tested by means of the loneliness scale (Schmidt & Sermat, 1983), Rosenberg’s self-esteem scale(SES) and expectancy questionnaires. The results showed that (a) there was a significant difference between males’ and females’ feelings of loneliness, especially in unpopular majors, (b) the positive relationship between expectancy divide and loneliness is significant (p < .01), and self-esteem partially mediated the relationship. These findings can facilitate in explaining why students in different majors experienced more expectancy divide and loneliness, and give us some suggestions as to how to advance freshmen’s adjustment in the first year.

An empirical study of the impact of teacher and student factors on students’ performance: A multilevel analysis

Meijuan Li Beijing Academy of Educational Sciences, China; Yanchun Wang; Yongmei Zhang; Yi Hao; Yi Tian

This study examines the impact of teacher factors (i.e., background and work) and student factors (i.e., background and study) on students’ performance, based on an analysis of large-scale test data of 27,331 three-graders taught by 941 teachers in Beijing’s compulsory education. A multilevel analysis led to five findings. (1) There exists a significant inter-class difference. (2) In terms of teachers’ background, gender, years of teaching, and speciality consistency significantly influence the students’ performance. Specifically, students taught by female teachers perform better. Students of teachers with more than 10 years of teaching experience perform better than those with less than 10 years experience. Additionally, students taught by teachers who majored in Mathematics perform better than those taught by teachers in other disciplines. (3) As to teachers’ work, teacher’s involvement in other subjects has a significant impact on the students’ performance. Specifically, classes of teachers who focus on a single subject have much better performance. (4) In terms of students’ background, gender and whether they are the only-child or not have a significant impact on students’ performance. Specifically, male students, only-child students have much better performance. (5) As to students’ study, their self educational expectation, learning habits, ways of finishing homework, and amount of after-class readings all have a significant impact on their performance. Specifically, the higher the educational expectation is, the better the study habits they will have. In addition, the more readings they do after class the better results they achieve.

A research on harmonious personality and its cultivation for college students

Che Liping USST, China; Che Liping

The cultivation of harmonious personality for deepening education reform should be by promoting quality-oriented education to strengthen students’ ideological and moral construction, and to improve the students’ psychological health level. In this paper, from China’s actual conditions, we discuss the development of a harmonious personality and education in the cultivation of young college students. On the basis of the literature, research proposes and defines the concept of harmonious personality, and points out that self-confidence is based on a harmonious personality. Mental health is a prerequisite for developing a harmonious personality. Questionnaire investigation, experimental method and interviews were all used as research methods. From a psychological point of view the present situation of university students’ harmonious personality, the investigation and analysis determining the specific form and education content, are put forward. Corresponding teaching methods and measures, and expanding education and training are also suggested. There are two ways put forward to develop a harmonious personality of college students: One is that the creation of a harmonious personality, education and specialised training courses, the harmonious personality education as a course into the university curricula education system is recommended. Systematic knowledge of teaching students to carry out the appropriate cultivating and training, and setting a special class, teaching programs and assessment and evaluation standards. The other way is to integrate a harmonious character education in the existing departments, in line with the existing education and purposefully training students’ harmonious personality. Whether by open special courses, or by putting the harmonious personality into existing education of teaching, are available depends on the following aspects to the culture: Give full play to the psychological education in the role of individual growth, develop interpersonal harmonious education, strengthen the construction of campus culture, cultivating and training of self-confidence, reinforce healthy lifestyle education and moderate setback education.

Research on the status quo of youth’s affective quality in Shanghai, China

Jianmei Lu Shanghai Normal University, China; Junshan Wang

This study developed an original investigative tool with good reliability and validity. The ‘Questionnaire on Youth’s Affective Quality’ was made up of six sub-questionnaires, composed of two aspects with six categories (moral affection, rational affection, aesthetic affection, interpersonal affection, life affection and emotional intelligence) containing 29 types of affection. This questionnaire was used to investigate 4076 students (aged from 10 to 18) from 15 schools (elementary, junior and high) in Shanghai. The results showed that 1) As a whole, the affective quality of youth in China was positive, but still has room for improvement. 2) Structural differences existed between boys and girls. 3) From the elementary, junior to high school, affective quality does not improve, but shows a downward trend especially in the affection of happy learning and self-confidence. 4) Affective quality correlated positively with students’ self-evaluation of learning performance and their parents’ educational background. 5) Good teacher-student rapport and teachers’ expression of affection to optimize teaching directly facilitated the development of students’ affective quality. 6) The results in Shanghai were generally consistent with those of similar surveys conducted nationwide, but subtle differences were indicated in specific aspects.

The development and validation of a competency model for Chinese primary and secondary school teachers

Hongyu Ma Central China Normal University, China

The aim of this study was to develop and validate a competency model of Chinese primary and secondary school teachers. 127 items of competency of primary and secondary school teachers were collected from the previous studies. The number of items was reduced from 127 to 67 by item analysis of 36 excellent Chinese teachers. The 67 items formed the Chinese Primary and Secondary School Teacher Competency Questionnaire (CPSTSCQ). 287 primary and secondary school teachers completed CPSTSCQ. With exploratory factor analysis the results indicated that the Chinese primary and secondary school teacher competency model was constructed by interpersonal manner, teaching ability, student-oriented view, professional identity, personality trait and positive attitude on learning. These factors explained 71.92% of the total variance. Results of confirmatory factor analysis showed that the model was well-verified by both teacher-perception (537 teachers) and student-perception (303 students) data. The Cronbach α of each factor was higher than 0.85. In addition, regression analysis showed that the model could effectively predict teachers’ performance, job satisfaction and teaching efficacy. As a teacher, no matter from which country, one plays similar roles, such as
disseminator of human experience, promoter of student’s growth and life-long learner, and the different demands of those roles could be reflected by this six-factor model. Therefore, the model may not be specific to Chinese teachers only. However, whether this model could really be applied across cultures still needs follow-up studies’ verification.

The psycho-social experiences of immigrant children at a South African primary school

Mercy Mahembe Stellenbosch University, South Africa; Lynette Collair

South Africa attracts a significant number of refugees and immigrants from poverty stricken and war-ravaged African nations who come in search of greener pastures. As this population continues to grow, its children have begun to experience South African schools in an array of uniquely challenging ways (Vandeyar, 2010). This influx of foreigners has increased the diversity in South African classrooms and presents challenges both for the foreign learner as well as for schools. While several studies examined educational factors relating to the education of foreign learners in South Africa, the psycho-social experiences of these learners have not received research attention. This paper will report on a study which sought to understand the psycho-social experiences of immigrant learners in South Africa. Within the framework of Erickson’s psycho-social theory (Pessar & Smith, 2008; Plotnik, 1993), psychological factors such as self-esteem, self-identity, self-efficacy and confidence as well as social factors such as language, culture and peer relations were explored in an attempt to understand their adjustment to learning in a culturally different environment. A basic qualitative research design was utilised. Participants were voluntarily recruited at a primary school in the Western Cape. Data were collected through visual, image-making, interview- ing and observations and analysed by means of thematic content analysis. The findings of the study will be revealed in the presentation as it is still in progress. It is anticipated that the findings of the study will contribute to the development of meaningful support strategies for immigrant learners.

Predicting professional development in the sciences

Debra Felton Old Dominion University, United States of America; Valerie Morganson; Karin Orvis

Retention in science, technology, engineering and math (STEM) is a cross-national priority. Research suggests that capitalization (i.e., engaging voluntary professional development activities) helps anchor students to STEM majors. This study examined supports, barriers, and proactive personality as predictors of capitalisation variables, including capitalisation actions (i.e., engaging in voluntary professional development activities), capitalisation intentions (i.e., plans to engage in professional development in the future), and outcome expectations (i.e., beliefs about anticipated results of capitalization). Supports are the encouragement and assistance provided by peers, faculty and advisors in the STEM major environment. Two types of barriers were considered, including discouragement from peers, faculty, advisors, and family members, and students’ time constraints. Of particular interest, was the extent to which proactive personality might mitigate the influence of supports and barriers on capitalisation outcomes. Data were collected from computer science and engineering majors at two universities (N = 170). A web-based survey measuring proactive personality, supports and barriers was administered at the beginning of Fall 2010; the survey assessing capitalisation outcomes was administered at the end of the semester. Regression analyses revealed that proactive personality was related to all three outcomes. Supports, time barriers, and discouragement were also related to some outcomes. In addition, for both capitalisation intentions and outcome expectations, proactive personality interacted with discouragement in a manner that mitigated the negative influence of discouragement. Results show that both individual differences and contextual supports and barriers are linked to capitalization. Moreover, individuals high in proactive personality are resilient in the face of discouragement.

Schooling experiences of Saora children in Odisha

Sakshi Manocha Jawaharlal Nehru University, India; Minati Panda

India and many countries around the globe present a gloomy story of schooling experiences of children belonging to minority groups, who are forced to leave their language and culture at the school door and are compelled to study in an unfamiliar language. This paper examines the schooling experiences of Saora (tribal) children studying in Multilingual Education Plus (MLE Plus) and Odia medium schools (non-MLE) in Odisha. The Cultural Historical Activity Theory (CHAT) provides the theoretical framework for the study. The study was carried out in two schools- one MLE Plus and one non-MLE school in the Gajapati district of Odisha. The data includes classroom observations, interviews and focus group discussions with children. The content analysis of the data revealed that the inclusion of cultural artefacts like Saora children’s language, games, songs, and other everyday activities changed the schooling experiences of Saora children in MLE Plus schools. The children not only enjoyed coming to school but also found learning experiences with teachers and peers very meaningful. In contrast, children in non-MLE schools could not comprehend the language in which their teacher was teaching and depended heavily on the black board and rote memorization of texts. The students in MLE Plus schools shared a very strong bond with their teachers and were not afraid of expressing their thoughts and views in front of the teachers. On the other hand, experiences of Saora children in non-MLE school were marked by passive learning patterns with a poor relationship between the students and teachers.
authority, or they may rely on naïve criteria. This study aims to extend current research by focusing on the effectiveness of an instructional intervention on how to evaluate the reliability of online sources. Participants were 154 ninth graders (F=72), randomly assigned to the instruction or no-instruction group. The instruction group received information about critical aspects to be considered when evaluating the reliability of a website. In both groups, the same Internet sources on two controversial topics (mobile phones and genetically modified food) were provided, varying for authoritativeness and stance. Data were collected from various tasks for quantitative and qualitative analyses. The quantitative analyses revealed that the instruction group outperformed the other group in the reliability ranking of the sites, as well as in inquiry learning. The qualitative analyses showed that in the instruction group, students with more availing epistemic beliefs appealed to more sophisticated criteria in source evaluation. In addition, the instruction group produced better arguments about the transfer topic. The study documents that the crucial ability of source evaluation for the new literacy in today’s information-saturated contexts can be significantly improved by appropriate instructional interventions.

Self fulfilling prophecy, teacher attribution and expectations as determinants of student performance
Shradha Mathur University of Delhi, India
Expectations have the capacity to alter human potential and destiny. This view has been tested and researched in the field of educational psychology and in the classroom settings. The paper highlights the concept of Self Fulfilling Prophecy, which proposes that an expectation gets confirmed because it has been expected by behaving in a manner that will make it happen. This transaction is maintained by the expectations of the perceiver (teacher) and the behaviour of the target (student). The focus is on understanding the dynamics of the relationship between teacher expectations/attributions and student academic achievement. The paper is based on a critical review of literature. It deals with the social bias popularly known as the ‘Fundamental Attribution Error’ in which teachers have high expectations of academic success from high achievers and vice versa. They further attribute success of high achievers to internal causes (intrinsic motivation, individual efforts and ability) and failure to external causes (task difficulty, chance errors). The opposite has been observed to be true in case of low achievers. An attempt is also made to appreciate the “Cup Half Empty” philosophy over the “Cup Half Full” deterministic view. The later segment provides suggestions to both teachers and parents, for the creation of a field for young minds to grow to their full and unexplored potential. The paper aims to provide necessary insights into the vastness of human potential, by citing several examples, which can form the basis for future empirical studies.

A tale of three stakeholders in a historically Black university: The lecturers’ story
Michelle May University of South Africa, South Africa
This project started when I, who was a lecturer at a historically Black university (HBU), was confronted by violent interactions between lecturers and students, and a perceived passivity on the part of management when lecturers were threatened by students with violence in social and academic settings. Based on socio-historical factors and personal experiences, I explored the experiences of lecturers at an HBU, i.e. their relationship with students and management, to form an understanding about how the lecturers’ experiences influenced the unconscious dynamic processes of the intergroup transactions amongst the three stakeholders. A qualitative research method was chosen. Hermeneutic phenomenology, using the systems psychodynamic perspective, allowed for the in-depth description and interpretation of the lecturers’ experiences. Data collection entailed hermeneutic conversations with the nine lecturers from an HBU. The analysis and interpretation entailed a collaborative dimension - the analysed data was sent to the lecturers and experts in the systems psychodynamic perspective to ascertain whether the interpretations were plausible. The relationship between the stakeholders was contradictory, because it was marked by hope for an effective relationship and by continuing conflict and violence - resulting in the (k)not of relationship between the stakeholders. The intergroup transactions between students, lecturers and management were marked by a reign of terror as threats of violence, or actual physical violence, were directed at lecturers by students with little or no intervention by management. However, the hope for an effective relationship gave rise to a new story developing as part of the tale of the three stakeholders.

Carol McGuinness Queen’s University, United Kingdom; Angela Eskin; Brendan Bunting
This paper presents findings from a classroom-based study that evaluated the effects a metacognitively-rich pedagogy on children’s thinking skills in primary classrooms. ACTS (Activating Children’s Thinking Skills) adopted an infusion methodology where a curriculum topic and a specific pattern of thinking were taught together. The theoretical perspective with regard to children’s learning, focused on the development of their metacognitive capacities; their ability to become proactive about their learning in terms of planning, monitoring and appraising their thinking. Comparisons were made between a group of control children (N=548, 25 classes) and two groups of children who participated in the intervention for different lengths of time: ACTS 1/2 Years (N=412, 17 classes) and ACTS 3 Years (N=292, 12 classes). The main finding was that participating in ACTS had a statistically significant positive effect on how children rated themselves with regard to their use of cognitive and metacognitive strategies, their willingness to work harder and to put in more effort. The pattern was characterised as a pro-active learning effect. However, the changes took time to build and were not evenly distributed across all learners. The implications of the findings for policy, and for classroom practices for teaching thinking, are discussed.

Making minds: Analysing metacognition through classroom talk and interaction
Carol McGuinness Queen’s University, United Kingdom; Carol Curry
This paper draws on the findings of the ACTS (Activating Children’s Thinking Skills) project in Northern Ireland. It reports a framework for analysing metacognitive features of teacher-pupil dialogue in classroom interactions. The theoretical perspective with regard to children’s learning focused on their metacognitive capacities. Analyses of the video recording of 21 ACTS teachers who were teaching 8-9 year old children showed that they arranged their classrooms in ways that supported opportunities for children’s talk and created conditions for mediating metacognition. For example, they engaged children in cognitively demanding tasks, developed a vocabulary for talking about thinking and modelling thinking in more concrete situations. What made good thinking lessons distinctive was that, through their talk, learners were able to jointly construct meaning, to evaluate their thinking and to make connections to contexts both within and outside the curriculum. The evidence from the video recordings was corroborated by a larger sample of 94 teachers’ questionnaire reports about changes in their classroom practices. They reported changes to both the quantity and quality of group work, increases in children’s talking and listening, increase in the quality of questioning and more pupil involvement and independence. They also reported significant changes in their images of themselves as teachers, such as being more open to alternative approaches and allowing children to be more independent in their learning.

The nature and impact of psychological violence on staff members’ health in FET college campuses
Helen Meyer North West University, South Africa; Tiaan Kirsten
Psychological violence is currently emerging as a priority concern in all workplaces due to its serious negative consequences on victims’ health. This mixed methods study aimed to investigate the nature, prevalence, severity, sources and experience of psychological violence and its impact on staff members’ health in FET (Further Education and Training) Colleges and how they cope with it. Survey instruments included psychological violence scale and symptom checklists which were distributed simultaneously to a large FET College with five campuses. From the population of 262 staff members, 174 instruments were completed and returned. 29 respondents were individually interviewed for the qualitative part of the study. The nature of psychological violence was experienced as a hostile organisation culture, unfair demands, excessive pressure and unmanageable workload, structural violence, verbal abuse, public humiliation and lack of recognition. Holistic health impacts included depression, distress, anxiety, thoughts of violence, suicidal thoughts, chronic fatigue, insomnia, life threatening diseases, bitterness, resentment, negative effect on social and interpersonal relationships, reduced motivation, increased absenteeism from work, experience working in an environment of ‘survival of the fittest’, racism and experiencing the implementation of Affirmative action negatively, amongst others. Findings of both datasets suggested
that staff members in FET Colleges experience psychological violence in all its complexity, that it has an impact on their health and that they lack effective strategies to cope with it. Multi-level strategies are suggested to ameliorate psychological violence.

Effects of psychological violence on staff members’ health in a South African FET college

Helen Meyer North West University, South Africa

Psychological violence as a constant stressor results in cumulative injury to a victim’s health (Field, 2002). As part of a larger study, this qualitative study aimed to investigate the physical and psychological effects of psychological violence on staff members’ health in a multi-campus FET (Further Education and Training) College. A purposive sample was utilized to select participants for the study based on their experiences of the central phenomenon, namely psychological violence. Twenty-nine willing participants were individually interviewed to collect data for this study. Findings revealed that staff members experienced the physical health effects of psychological violence as life-threatening diseases including heart disease, hypertension and worsening of existing diseases. Psychological health effects included suicidal thoughts, thoughts of violence, distress, frustration, anger and personality changes. A range of diagnosable psychological injuries was also noted, such as anxiety disorders and depression (The American Psychiatric Association in DSM-IV-TR, 2000). Staff members also indicated that psychological violence affected their relationships with family, colleagues and students. It also affected the quality of their instruction negatively in addition to diminishing productivity, creativity and motivation, thus increasing absenteeism and higher staff turnover in the workplace. It can be concluded that psychological violence severely affects the physical and psychological health of victims, including their relationships and the entire workplace where it occurs. Multi-level strategies are suggested to ameliorate the effects of psychological violence effectively.

Thinking in the classroom: Mobile eye-tracking of novice and experienced teachers

Kevin Miller University of Michigan, United States of America

Teacher attention to students serves multiple purposes informing student engagement and understanding but also showing students that they are attended to. We used mobile eye-tracking methodologies to collect real-time eye fixation data from teachers (25 student teachers and 25 supervisors, teaching the same students). This allowed us to look at how beginning and experienced teachers monitor students as they teach. We summarised the distribution of teacher attention to students using the Gini coefficient, often used to measure income inequality in nations. This indexes how much a distribution differs from perfect equality (Gini index = 0) to one person receiving all the money or attention (a Gini index = 1). Experienced teachers showed a lower overall Gini (i.e., a more equal distribution of attention across students) than did novices (a one-tailed paired sample t-test t(24) = -2.06, p = .05). Novice teachers also showed substantially more attention to what we termed “other objects”, objects not directly related to instruction (e.g., litter on the floor) (one-tailed paired sample t-test t(25) = 3.16, p < .01). Our results suggest that there are substantial differences in the ability of new and experienced teachers to monitor their students.

The relation of Shahed students perception of their campus environment and individual and familial characteristics with social adjustment

Khodayarifard Mohammad University of Tehran, Islamic Republic of Iran; Golrokh Fard Azar; Mohsen Paknejad; Alfred Pritz

The present study was carried out to observe the Shahed students in the campus environment and study their individual and familial characteristics in correlation to their social adjustment. Students were Shahed students - students whose fathers were martyred during the imposed War of Iran-Iraq - and other students namely non-Shahed students. The research subjects were 315 female and male college students; they were selected through the proportionate stratified sampling method from Tehran universities’ students. The instrument used for data collection was the California Personality inventory and a researcher-made inventory to measure Shahed students’ perceptions of the campus environment and demographic characteristics. The data were analysed by using hierarchical regression analysis. The findings showed that the students’ satisfaction of the Shahed quota in the university entrance exam, the professors’ reaction and other students’ positive attitude towards them, as well as their marriage status were the most predictive factors for their social adjustment. There was no significant correlation between the family variables such as the mother’s re-marriage with Shahed students’ social adjustment. Possible causes of a non-significant relation between family variables and social adjustment have been discussed.

Early school dropout: Psychosocial and psycho-clinical approach, the case of secondary school children

Marie Noelle Monpble UPJV, France

Our research so far on has focused on early school dropout and its consequences on teenagers’ development from social, educational and emotional perspective. We have laid emphasis in psychological factors that may lead to a child dropping out of the educational system without qualification. We have observed that whereas some children fail to attend school, other children with similar background or problems are able to remain within formal education. Our research attempt to pin point certain behaviours in and out of school which can affect whether a child stays in education. The factors highlighted so far include frequent absenteeism, lack of school behaviour, behavioural problems etc. Although some intervention strategies are currently in place within the French education system which aims to reduce the number of school children leaving school prematurely, we realise that more could be done. Further exploration of differences in psychological factors, such as coping styles, sense of belonging and self esteem may also help to explain why French children are more likely to leave education system with few or no academic qualifications. In order to understand and prevent early school drop, we have built a questionnaire coupled with a projective test that takes account self image, self esteem, sense of belonging and engagement in family, school and community. This communication aims at presenting the first results of our research.

An analysis of a pre-schooler’s family and school influences on the social outcome of schooling

Vuyisile Msila University of South Africa, South Africa; Angeline Sethhako

Many parents register their children in various schools every year. There are many aspects that have an impact on these learners’ school progress. Housing, socio-economic status, abuse and neglect are some of the factors that have an impact on any child’s life. The family and the society in general, play a huge role on the learning child from an early age. The product we see at the end of a schooling career is a consequence of various influences. This article explores the findings of a qualitative study performed at three black African pre-schools in a South African township. It shows how the family’s social and cultural capital is crucial to the growing child. Oftentimes teachers would not understand the learners in their classrooms until they are familiar with the children’s family background or the children’s cultural contexts. Aspects such as language acquisition and learning in general can be fully understood if the child’s habits is well understood. Moreover, the study’s findings also explicate that for pre-school teachers to be effective, they need to comprehend the dynamics involved in family-school relationships.

Construct of giftedness as a means of inclusion/exclusion in the Czech educational system

Jiri Mudrak Charles University in Prague, Czech Republic

Contemporary developmental and educational psychology offers various explanations of what giftedness is, how it should be identified and what the optimal ways of its development are. Psychological concepts of giftedness in many ways transcend psychological theory and influence educational practices and policies of educational institutions. In the present paper, we analyse the ways in which the concept of giftedness is construed within the Czech educational system and what the recommended methods of identification and development of gifted students are. As the main method we use critical text analysis inspired by critical discursive psychology. We analyse contemporary Czech psychological and educational texts (scientific as well as popular) in order to understand how they construct the giftedness in Czech students. Therefore, we do not approach giftedness as an objective fact (as it is common in the field) but as a discursive phenomenon which is established, reproduced and transformed through language, discourse and cultural practices. We show how the concept of giftedness is used in the Czech educational system as a means of inclusion or exclusion of different groups of students.
The effects of cognitive processes, learning strategies and social context on academic performance

Mariel Musso Katholieke Univ Leuven - UADE, Argentina; Eduardo Cascallar

It has been shown that general academic performance is an important predictor of future academic performance, job performance, and future income level (Kuncel, Crede, & Thomas, 2005). Previous research has also shown that working memory (WM) and attentional networks (ATN) are extremely good predictors of performance on various cognitive tasks and of academic performance in particular, even when estimating long-term learning outcomes. The goal of this research is to study the interaction of basic cognitive resources (WM and ATN) with learning strategies, social context, self-concept, and individual background variables, as well as specifically the use of internet resources, and their impact on general academic performance. The sample of subjects was 700 entering university students of both genders, 18 to 25 years old, from various business and humanities programmes. The cognitive measures used were the Attentional Networks Test, and the AOSPAN (an automated test measuring working memory capacity). In addition, the LASSI (a validated learning strategies questionnaire) was used, together with a general questionnaire collecting basic background information, family system, socio-economic data, level of education of parents, occupation of parents, and internet use, of each student. Results show a very interesting pattern of interaction effects between the cognitive variables and background variables as well as with the LASSI subscales, highlighting the importance of certain levels of cognitive resources in combination with other variables for the prediction of levels of academic performance. These results have significant relevance for cognitive theory, learning, and self-regulation models, as well as applications in higher education practice.

Four decades professing psychology: Lessons I have learned

David Myers United States of America

Drawing from the experiences of celebrated teachers across North America, and from my own teaching and writing about psychological science, I offer some practical strategies for professional development, effective teaching and student learning. Attenders will, I hope, feel encouraged in their teaching and be reminded (if not newly informed) of tips for engaging students, using new media, and finding satisfaction in professing psychology. A social psychologist, I am a communicator of psychological science to college students and the general public. My research and writings, enabled by National Science Foundation grants and fellowships, have appeared in three dozen academic periodicals, four dozen magazines, and seventeen books.

Inclusion of socio-cultural context in education and its impact on concept formation

Shivani Nag Jawaharlal Nehru University, India; Minati Panda

Every child is located in a socio-cultural context that provides her with certain mediating tools such as language and other cultural artefacts, which are carried to the classroom. However, the contribution of these tools towards academic development depends on the space created for them in the school and classroom practices. This paper is based on a study conducted in an NGO run school in Rajasthan, called ‘Diganantar’. The study aimed to examine how inclusion of socio-cultural resources of children in the pedagogic practices of a classroom facilitates concept formation. The sample consisted of one of the three multi-grade classes of the school comprising of 30 students in the age group 5-9½ years. The theoretical framework was based on the Goytskian concepts of mediation, zone of proximal development, and every day and scientific concepts. Using focused ethnography method, data were gathered in the form of classroom observations, interviews with teachers and parents, and the documents and textbooks prepared by Diganantar. Content analysis of the data showed that the pedagogic practices of Diganantar were based on the premise that learning can be built on a child’s experiences and already developed skills. The multi-grade teaching, spiral curriculum and active interaction between the school and community enabled the teachers’ to use children’s socio-cultural resources as mediating tools and help the children progress from their spontaneous ways of reacting to their everyday world towards a higher level of mental functioning.

Maths anxiety and locus of control as predictors of cheating behaviours among middle school students

Raysa Nasroen Gadjah Mada University, Indonesia; Devi Lim

The aim of the study is to investigate maths anxiety and locus of control as predictors of cheating behaviours among secondary school students. Maths anxiety has been found to be one predictor of low mathematics achievement, whereas locus of control serves as an important variable of attitudes and behaviours in academic achievement. This study used a quasi-experimental design and participants were selected by an accidental sampling method which consisted of 100 private secondary school students, and 100 state secondary school students. Two scales administered were the Mathematics Anxiety Rating Scale-Revised, the Nowicki-Strickland Locus of Control Scale and a cheating behaviours observation list. All measures were translated and adapted into Indonesian norm. Six students were assigned in each class as incognito observers of peer students’ cheating behaviours in a disguised experimental maths examination. Results and discussion have not yet been conclusive as the study is still ongoing.

Design, application and impacts of an educative model to train socially responsible professionals

Gracia Navarro Universidad de Concepción, Chile

Understanding the need to train professionals in the service of humanity and that educational psychology can make a contribution to this through the design and validation of models of education, the University of Concepcion and other Chilean universities apply a model of education to train socially responsible professionals, people that, in the exercise of their profession contribute to generate equity for the development and assess the impact of their decisions, opting for those that serve the common good. The aim is to identify whether a relationship exists between achieved learning, attitudes toward social responsibility (SR), self-attribution of socially responsible behaviour, valoric type, professional behaviour observed and participation in a specific model to be socially responsible professionals. We applied to 500 students and graduates, divided into experimental and control groups (trained and untrained in the educational model) the Achieved Learning Questionnaire, attitudes toward social responsibility, Schwartz Values, Inventory questionnaire and self-attribution of socially responsible behaviour and we conducted interviews with employers to identify the professional behaviour of the graduate. Students and graduates perceive cognitive, affective and behavioural learning, with significant differences in their attitudes toward SR and self-attribution of socially responsible behaviour, between experimental and control groups. There are also differences in employers’ perceptions of the professional practice of those who agreed to the model and those who didn’t. The educational model impacts on the learning of SR and it’s necessary to identify mediating variables of the model effect.

The effects of female parliamentary representation and gender quotas on the scholastic empowerment of girls in sub-Saharan Africa: A test on the effects of in-group bias.

Jo Nel University of Limpopo, South Africa; Steyn Renier University of Limpopo, South Africa

This study focuses on the number of women in parliament and the tenure of girls at school. Tenure at school is related to employability, and the employment of women, as suggested by some studies, is related to the number of women in parliament. Theories on in-group bias suggest that groups tend to promote their own agenda. This is also true for women, and literature suggests that women are best at improving their own circumstances. As more women become members of parliaments all over Africa, it can be expected that the feminist agenda will be advanced in this way. It is, however, not evident if the legislative affirmation of women at a political level affects the well-being of, in this specific case, girls at school. In this paper two questions are posed and resolved. Do legislative quotas result in more women being elected to parliament? Do more women in parliament correlate with the average number of years girls spend in school? Data were collected from 47 sub-Saharan countries. The results indicate that countries that apply legislative quotas have more women in parliament (r=2.889; p<0.006; d=0.8) and that there is a relationship between the percentage of women in parliament and the years girls spend in school (r=1.483; n=45; p=0.003). Although this relationship is not necessarily causal, the results seem to affirm the effects of in-group bias. The results also suggest a strong imperative to adopt legislation to ensure that more women become parliamentary representatives.

Exploring academic identity and its meanings for high performing women students

Pinkie Nkadimeng University of the Witwatersrand, South Africa; Jill Bradbury

This research explored the perceptions, experiences and meanings of academic identity for high
performing undergraduate women students. We explored the intersections of academic identity with other key identities and explored how young women negotiate a sense of who they are within personal, historical and situational spaces. The context of this focus is the increasingly utilitarian value placed on university education both in South Africa and internationally. The project adopted a qualitative approach, conducting individual in-depth interviews with a small group of high performing women students in their final year of study in the Humanities at the University of the Witwatersrand. Key findings indicate that these young women understand their achievements to be the result of hard work rather than luck, special ability or social advantages. All participants reflected positively on their schooling experiences regardless of whether the schools that they attended were well-resourced or not. Family support was very salient. In some instances, this support was directly educational evidence-supplementing schooling but all women identified emotional support from parents as most critical to their success. The participants’ reflections on their university experiences point to an appreciation of the increased diversity of their social world but in the main, close relationships and friendships seem to remain racialized. All students expressed a strong orientation towards issues of social justice and a view that there are social responsibilities attached to high academic performance.

Parenting styles, goal orientation and maths anxiety in high school students
Zohre Nouri
Shahid Beheshty University, Islamic Republic of Iran
Mahmood Heidari
This study investigates the relationship between maths anxiety, goal orientations and parenting style. In order to identify the main predictors of maths anxiety the following variables were investigated using t-tests, correlation and regression analysis: perceived parenting styles, goal orientation dimensions and maths anxiety. The responses of 424 subjects (204 females and 220 males) for the instruments were used for measuring the above-mentioned variables. The results showed that maths anxiety and goal orientation correlated with perceived parenting styles. Avoidance-performance and approach-mastery orientations were also positively related to authoritarian and neglectful parenting styles. Avoidance-mastery and approach-mastery orientations were also positively related to authoritative and indulgent parenting styles. Also, goal orientation and perceived parenting styles were predictive of math anxiety.

The national strategy on screening, identification, assessment and support in South African schools
Maria Nthoba
Gauteng Department of Education, South Africa; Sithembile Mkhiize
The aim of this paper is to empower educational psychologists on Screening, Identification, Assessment and Support (SIAS) of learners experiencing barriers to learning and development in schools. The South African Education Department gazetted a White Paper 6: "Building an Inclusive Education and Training System" in 2001. Inclusive Education Policy focuses on overcoming barriers in the system that prevent it from meeting the full range of learning needs. There are two Key Strategies to implement Inclusive Education Strategy on SIAS: How do we identify the learners who have additional support needs as well as barriers that are preventing them to reach their full potential. Guidelines on Inclusive Learning programmes will involve addressing the question: How do we address barriers in the classroom and in the curriculum through the way in which we teach. SIAS emphasises the Support Needs/Aspirations Analysis of learners and its process consists of: Learner Profile and Diagnostic Profile. Teacher reflection, problem solving, parent consultation, identifying contextual barriers and curriculum differentiation. Institution Level Support Team consultation by the teacher, review of support by SBST and community, and application for support from the District Based Support Team (DBST). DBST action planning, consultation, intervention, tracking and monitoring. The DBSTs are mandated to promote and protect human rights of persons with disabilities by ensuring that they are not discriminated against educationally.

How ‘soft touch’ is ‘high tech’: New approaches to improve the prevention and control of chronic conditions
Brian Oldenburg
Monash University, Australia
Follow up and support are critical in maintenance of lifestyle change and self-management for diabetes and many other chronic conditions that are becoming increasingly common in all of our countries. Fifty years of research has clearly demonstrated that long maintenance of behaviours such as abstinence from smoking or diabetes self management are best predicted by ongoing monitoring, support and encouragement, and assistance in solving problems and addressing barriers to more desirable behaviour patterns. However, the provision of ongoing follow-up and support is a big challenge in all of our countries and health systems are generally very poor at delivering and supporting such programmes. Compared to the decades over which people need to manage conditions such as diabetes or risk factors such as overweight or high blood lipids, very few of our intervention trials even follow-up people for more than a year or two. More high tech interventions using smartphones and the internet now offer new approaches to monitoring self management and clinical status indicators relevant to diabetes management and progression. This links individuals to needed care, assisting in problem solving, and, even, providing long term social support and encouragement (“soft touch”). These methods can also be combined with new evidence-based approaches that utilise peer support and other soft touch approaches, as well. This presentation will consider some of our recently conducted complex real world intervention trials of telehealth and more soft touch interventions conducted in both developed and developing countries over the past 10 years.

Phobic and anxiety disorders in children and adolescents: Where to now?
Thomas Ollendick
Virginia Tech, United States of America
Although CBT has been found to be effective with phobic and anxiety disorders of youth and enjoys evidence-based status, as many as 25% to 40% of youth with these disorders do not respond to these interventions. In this address, new and exciting developments will be reviewed that show promise for addressing some of these treatment non-responders. Innovations including computer-assisted interventions, virtual reality interventions, attention retraining strategies, and intensive treatment modalities will be highlighted. In addition, it will be argued that some non-responders or difficult-to-treat youth will require interventions that benefit from an idiographic approach to case formulation and treatment. In many respects, this approach invites us to return to our roots in behaviour therapy and clinical science. This idiographic approach will be illustrated in the treatment of non-responders to evidence-based treatments using controlled single case design methodologies. Implications for these findings and intervention science will be highlighted.

Inclusive policies in higher education: Challenges to Brazilian psychology
Miriam Pan
Federal University of Paraná, Brazil
Norma Ferrari; Patrícia Somers; Jardel Machado
The impact of higher education on the identity of young people from a humble background is a recent research theme in Brazilian psychology. Brazil has kept up with the worldwide trend of creating more places in higher learning institutions, and as a result faces a double challenge: More equitable access and, consequently, a more diverse body of students. This study analyses the effects of inclusive policies to help young people complete higher education. By researching the database, websites, official documents and previous studies of the Federal University of Parana, we were able to map the courses that identify these students. They are recognised by their class identity: Young people from a humble background and young people who are financially fragile. In addition to showing their financial situation, the practices proposed by these programs symbolically mark their identities and set them apart from the other students and other types of scholarships provided. This fragility brings in different meanings and interpretations. In addition to their financial condition, the students’ fragile academic background prior to coming to the university and their fragile links with the university, they also have to juggle with the demands of work and study and still overcome the discrepancies that result from this situation. This results in a contradiction: What a different policy does to identify and benefit a student, also affects him/her by its counterpart concerning work and study, reproducing the same logic of inequality that has marked the student’s life story.

Experiences of learners from child-headed households in a vulnerable school that makes a difference: Lessons for school psychologists
Jace Pillay
University of Johannesburg, South Africa
Helen Dunbar-Krige; Ezzette Fritz
The purpose of this study was to explore and describe the experiences of vulnerable learners from child-headed households through an ecological systems model. Special emphasis was given to the role of school psychologists as change agents within the context of schools. This qualitative study included a sample of 98 5th to 7th grade learners in a vulnerable
mixed self-perceptions. 649 students of public elementary schools in central Greece participated in the study. The mean age of children was 10 years old. A mixed self-perceptions inventory was developed to measure 8 domains of self-perceptions: academic, literacy, maths, social, emotional, socio-emotional, physical and general self-perceptions. The study revealed that students do experience mixed self-perceptions. They have lower levels of mixed self-perceptions regarding the social, literacy and mathematics domains, and higher levels of mixed self-perceptions in the academic, physical, general and especially the emotional and socio-emotional domains. Girls had lower mixed self-perceptions than boys, mixed self-perceptions decreased with age, and mixed self-perceptions were related to school performance in literacy and maths. The acknowledgment of students’ mixed self-perceptions provides an important tool for teachers, psychologists and administrators to better understand their students, and consider whether the child might have contrary or mixed views about himself/herself, before they make limited attributions of children’s self-perceptions.

Adjustment to university and its psychological impact on disabled students

Anlia Pretorius University of the Witwatersrand, South Africa; Nita Lawton-Misra

For all students starting university is a time of great transition, often accompanied by many challenges. Change, although exciting, is often very challenging as new students navigate their way around the many facets of campus life. For students with disabilities, adjusting to university is an even bigger challenge. Although much work has been carried out in the last few years to increase access for and improve services to students with disabilities, there are still many barriers to overcome. Students with disabilities still experience many difficulties including: Physical issues - barriers in terms of size of institution when compared to special schools, orientation to relevant physical spaces, such as lecture halls, offices, libraries, food outlets, residences, etc. and concomitant emotional stress; Psychological adjustment - social integration with people without disabilities, high number of and changes in lecturing staff, living away from home or familiar environments, dangers associated with big city lifestyle, creating support networks, allure of social life (parties, independence, dating), etc.; Access issues - programmatic and physical access, access to learning material, access to multi-media, etc.; and Attitudinal barriers. Disability support units, student counsellors, and other university staff need understand the unique and widespread barriers disabled students encounter daily in order to provide effective support that will lead to better functioning, improved wellbeing and improved throughput rates of students with disabilities. A case study will be presented to illustrate the difficulties disabled students experience, and how important appropriate support is to positive adjustment.

The association between parenting practices and the goals and aspirations of learners at secondary schools in the Western Cape

Nicolette Roman University of the Western Cape, South Africa; Willy Lens; Alice Moyo

According to Self-Determination Theory the environment plays an important role in either hindering or enhancing the need satisfaction, well-being and self-determined behaviour of individuals. Parents are central as part of the environment in which children and adolescents grow up. As such, parenting may influence the motivational choices which individuals make and their self-determined behaviour. Goals and aspirations are key in future planning and decision-making. Thus, the aim of this study is to investigate if there is an association between parenting styles and practices, the importance learners in secondary schools attach to intrinsic versus extrinsic goals and aspirations and the degree in which they could achieve these goals. A quantitative research approach with a cross-sectional correlational design will be used to conduct the study. The participants will be Grade 11 learners from the schools in the Metro South district of the Western Cape Education Department. The sample will consist of about 800 learners in Grade 11. The data will be collected by means of self-reported questionnaires, which are the Parenting Style and Dimensions Questionnaire (PSDQ: Robinson, Mandleco, Olsen, & Hart 2001) and the Aspiration Index (Kasser & Ryan, 1996). The questionnaires will also contain a section containing items to include biographical data of the participants. The findings will be discussed within the context of Self-Determination Theory.
The influence of basic psychological needs on the goals and aspirations of grade 11 learners at secondary schools in the Western Cape Nicolette Roman University of the Western Cape, South Africa; Lauren Schilder; Willy Lens

In South Africa, learners in Grade 11 are nearing the end of their secondary school life. The new, but also difficult, transition into (early) adulthood now begins. This critical period of development brings forth an array of new challenges, exercising free will, becoming more independent, an increased focus on the self, and the decision of what path is to be taken after high school (e.g. continuing in higher education, starting professional life). With these challenges comes the act of setting particular future goals and aspirations. The question is thus what exactly motivates the South African Grade 11 learner, and why are they motivated to set and aspire to certain future goals. This study aims to investigate the associations between basic psychological need satisfaction (i.e., the need for autonomy, for competence and for relatedness), the importance attached to intrinsic and extrinsic goals and aspirations and the degree in which these goals are already achieved in the present among Grade 11 learners at Secondary schools in the Western Cape. The study will be quantitative with a cross-sectional design. A sample of about 900 Grade 11 learners will participate in the study. The participants attend secondary schools in the Metro North Western Cape Education District. The Balanced Measure of Psychological Needs (BMPN, Sheldon, Niemiec, 2006) and the Aspiration Index (Kaasser & Ryan, 1996) will be used to collect the data. Results will be discussed in the context of Self-Determination Theory and the implications for the education sector.

Cognitive effects of two opposed teaching styles: expositive and guided-participative Nestor Roselli CONICET, Argentina

Using Vygotsky’s theory as framework, the objective of this research is to compare the cognitive effects on learners of two teaching styles: expositive and guided-participative. The hypothetical assumption was that each of these different systems of activity, produces differences in learning. The interest was focused on non-explicit, or hidden, effects of each one. These cognitive effects were related to the transfer of knowledge (extended learning), the cognitive (in)dependence from the teacher, the permanence on time of learned knowledge and, finally, the efficacy of peer inter-individual support. Four teachers in biology were invited to teach, to their own secondary students, an extra-curricular subject, the same for all. Two of them were using an expositive style, while the two others were employing a participative style. Data were processed by SPSS, using “t” to test differences (in quantitative variables) between the means of both conditions. Differences in the permanence on time of learned knowledge were tested with “chi-square.” Individual post-tests of learning results, show that the participative style produces more extended learning, that is, the transfer of the learned knowledge to new situations is stronger. The participative style promotes the independence of the student from the teacher. Also these students use peer inter-individual support more efficiently.

The effect of training problem solving skills on the emotional intelligence of self-supervisory women Mohammad Sadeghi Payam Nour University in Tehran, Islamic Republic of Iran; Mohammad Mohsen Elahi; Fereshteh Afsar; Leila Esmaeili; Ali Sadeghi; Asefheh Ariyan

The aim of this study is to determine the efficacy of problem solving training (self-consciousness, making decisions and problem solving, stress coping strategies, interpersonal relationships, controlling anger) on the emotional intelligence of self-supervisory women. This study employed a pretest-posttest, experimental method, using a control group. The statistical population of the study consisted of women who were under the supervision of Imam Khomeini Relief Committee in Isfahan. Referring to the muster of the population, a sample of 60 women were selected and then were assigned randomly into two experimental and control groups (each consisting of 30 experimental and 30 control). The experimental group received the Unicef life skills training package (Unicef Training Package) in 15 sessions in a 3 month period in the training groups. The tools of this study were Bar-on Emotional Intelligence Questionnaire and researcher-made demographic Questionnaire. Descriptive statistics and inferential statistics were used to analyze the research findings. The results of the study have shown that the training of problem solving skills had an effect on the emotional intelligence of women.

How does emotion regulation affect self-regulated learning? Anne-Kathrin Scheibe TU Darmstadt, Germany; Bernhard Schmitz

Studies based on the Strength Model of Self-Regulation suggest that emotion regulation (ER) and self-regulation compete for the same limited resources, but that positive emotions can counteract the depletion of resources. The objective of the present study (N=61 university students, Mage=24.3 years, SD=4.6) was to examine the impact of ER-strategies that differ in their partial efficacies (= ability to modulate negative and/or positive emotions) on important components of self-regulated learning (SRL) within an experiment. In all groups a negative emotion was induced by means of a film clip about animal testing (affect $\eta^2=.81$; heart rate $\eta^2=.32$). Subsequently, participants worked on a learning task that required SRL. We compared two experimental groups that used ER-strategies with differential partial efficacies (cognitive reappraisal, expressive suppression) during the film, and a control group (no regulation). Although instruction compliance was lower in the reappraisal group ($\eta^2=.31$), participants in this condition experienced more positive emotions after the film ($\eta^2=.09$) and had more self-regulatory resources available ($\eta^2=.10$) than did the participants in the suppression condition. In the subsequent learning phase participants with high post-film resource availability were better with respect to SRL-components than low-resource participants ($\eta^2=.08$). ER strategy-types that involved the enhancement of positive emotions (e.g., reappraisal) have proved to be favourable for self-regulatory resources and SRL-processes. More favourable strategies need to be identified in future studies.

Correlations of academic performance and affective factors in first year students Birgit Schreiber University of the Western Cape, South Africa

Several studies have emphasised the importance of addressing social and emotional factors in facilitating adjustment to Higher Education Institutions. The educational theories of Astin (1993), Tinto (1997) and Pascarella (1985), are key theories on person-environment fit and environmental impact, and underscore the importance of integration into, and engagement with, the Higher Education context as one of the key predictors of student success. The integration of support programs into the students’ academic experience is key in contributing to student success. The Living and Learning Program in this study is located in these Student Development and Support Theories. The Living and Learning Program is infused into the first year academic experience and aims to facilitate personal, social and academic adjustment and integration into the university; thus increasing student success. The objective of the study is to explore the impact of the Living and Learning Program on first year students and to explore any correlation between academic performance and affective factors. The research is quantitative using psychological scales and assesses (1) study motivation, (2) reduction of stress and increase in coping, and (3) network orientation. The results of the statistical analysis of the correlations are discussed. Implications for the program’s theoretical location are discussed.

Higher education policy in South Africa: Implications for student development and support Birgit Schreiber University of the Western Cape, South Africa

A document analysis of the Higher Education Policies in South Africa, with regard to their reference to Student Development and Support is presented. The results suggest that Student Development and Support’s role and function is only nebulously described. It is primarily within the discourse of disability and special education where mention of Student Development and Support is made, locating Student Development and Support in the area of remedial support. Furthermore, there is no coherent or co-ordinated organising principle which guides Student Development and Support in its role and function within Higher Education in South Africa. Qualitative research, interviewing 15 senior and executive members of three Higher Education Institutions, using content analysis, was undertaken to explore their perceptions of the Higher Education Policies with regard to Student Development and Support. The emerging themes suggest that there is a cursory knowledge of key Higher Education Policies. Furthermore, it emerges that there is a keen awareness of the desired outcomes as stated in the key Higher Education Policies in terms of student success. However, how the Student Development and Support domain is expected to contribute to student success seems unclear and challenging. Tensions around institutional diversity and institutional autonomy, juxtaposed with the emerging need for a national organising principle for Student Development and Support are discussed. The author hopes to contribute towards the complex debate on positioning Student Development and Support...
Support in Higher Education so that it may contribute significantly to the South African Higher Education challenges.

The benefits of team teaching: A quasi-experimental study with teacher students Katja Schwartz Christian-Albrechts-University, Germany; Uta Klusmann; Toni Ihme; Jens Moeller In educational contexts, many researchers stress the importance of co-operation in teaching. Recently, co-operation has been identified as a key competence in teachers’ professional development. For instance, co-operation is supposed to increase the efficiency and effectiveness of teaching, by promoting teachers’ reflections and improving teachers’ instructions. Especially in team teaching, as the most extensive form of co-operation is said to affect teachers’ motivation as well as teachers’ capability to teach. Little research exists concerning the question of whether the capability to co-operate increases during teacher students’ education. Innovative in the field of team teaching research, we conducted a quasi-experimental study to investigate the effects of co-operation on students’ motivation and performance. Thereby, we also integrate the level of education, differentiating between novice and advanced teacher students. Altogether 164 teacher students and 113 high school students took part in our study. All teacher students had to prepare and give a lesson to a high school student. The experimental group gave lessons in co-operative dyads whereas the control group worked on their own. Additionally, we differentiate as a quasi-experimental factor, novices and advanced teacher students. Our findings show that the effects of team teaching are associated with the level of professional experience. Team teaching led to higher students’ motivation when carried out by advanced teacher students. Novices showed better results working alone. There was no significant effect concerning students’ learning.

Inside the mind of adolescents diagnosed with Attention Deficit Hyperactivity Disorder: A pilot study Joseph Seabi University of the Witwatersrand, South Africa; Prashant Arvind-Pala; Florian Lar rue; Helene Sauzeon; Bernard N’Koaou

To date, over 30 years of research have been invested in the understanding of ADHD, with reference to diagnosis, management and treatment. However, not much is known about the experiences of adolescents with ADHD, and the impact it has on their psychological, emotional, and social well-being, particularly within the South African context. Once access and permission to use the Chris Hani Baragwanath’s Child and Adolescent Psychiatric Unit as a site was granted, the researchers together with the head psychiatrist set out criteria for the selection of participants. This included identification of potential participants by psychiatrists during their follow-up consultations with outpatients between the ages of 13 and 16 years, adolescents who have been diagnosed with ADHD for over six months. Although 14 potential participants were invited only five accepted the invitation. The sample comprised five adolescents (one female and four male, age range of 13 to 16 years). Racially, there were three blacks, one white and one Indian. The questions that were asked included: How is your behaviour in the classroom? What do you think a concentration problem is? How do you get on with your peers and educators? How is your scholastic performance? The results revealed adolescents’ vulnerability, emotional distress, the need to be acknowledged and recognized. The description of their behaviour, the account of their pain, and the struggles with scholastic performance all point to the fact that ADHD is not outgrown.

Development of children in South Africa: Determinants and effects of cultural diversity intelligence Hannah Seriki CIELARAKO, South Africa; Vuyiseka January The “Unthombo Wesizwe Children’s Programme” was started in order to equip young South Africans with tools to overcome the challenges of a multicultural society. The objectives of this study were (1) to gain insight into factors determining that children start developing “cultural diversity intelligence”, (2) to learn about the developmental process that took place for participants between July 2009 and September 2011, and (3) to understand the effects this process has on the children and their environment. A structured questionnaire was used to capture basic data and to ease monitoring of individual participants. Since the research focus is to explore the factors mentioned above, various qualitative methods were chosen to recognise and interpret experiences of the children and practitioners involved in the educational programme. These include focus group discussions, facilitators’ observations, children’s journals and video material, as well as open conversations with Unthombo Wesizwe’s management, parents and volunteers. We stored, managed and analysed data systematically, aiming to maximise the internal validity of the study. Our outcomes indicate that an enabling environment (e.g. parents, teachers) is an important prerequisite for children to develop cultural diversity intelligence, that it takes time, practice and support for cognitive concepts to be merged with behaviour, and that over time the children’s conscious involvement in their own internal development increases, as does the effect that this development has on the way of life in the children’s communities.

The comparison study of mental health in low and high academic achievement adolescents Maryam Sharayati Azad University of Birjand, Islamic Republic of Iran The aim of this study was the investigation of the mental health status of students with a weak academic status and students with a good academic status. 936 adolescents (470 girls and 466 boys) from high school were selected to two groups, as students with weak academic status and students with good academic status, and responded to the general health questionnaire GHQ-28 (Goldberg and Hillary, 1981). Results showed that students with a weak academic status have higher depression and somatic symptoms. Academic achievement of adolescents thus had a crucial role in mental health.

Investigation of indicators of learning outcomes from university evaluation reports Susumu Shibui NIAD-JE, Japan; Takayuki Hayashi; Masaaki Ida; Sounghee Kim There is an increasing demand for measuring student learning outcomes to improve the quality of higher education. In this paper, we analyzed the process of evaluators’ judgment of the university from the peer-reviewed university evaluation reports. The aim of this study is to clarify the indicators of student learning outcomes from a standpoint of evaluators’ decision making process. As a method, the difference in the description expressed by self-assessments reports submitted by universities and evaluation reports reflecting the evaluators’ judgment by using the text analysis. We extracted the evaluation reports of the National University Corporation Evaluation (2009, Japan), which concerns the description of the learning outcomes as a data. The data consists of the results of evaluation judged by 4 points scale and the text data including the reason they used for the judgments for 357 departments. The relationship between the categorical judgment toward the departments and the variety of description on the text were categorized to the indicators by the morphological analysis. The appearance of the indicators was counted. Results showed two types of 17 indicators. One is the quantitative indicators expressed by numerical data. The other is qualitative indicators expressed by universities’ practices. For the quantitative indicators, average scores in the highly rated and normally rated in 4 points scale were compared by t-tests. Some indicators showed the significant difference. These indicators are useful to construct the university evaluation system measuring student learning outcomes.

A study of teacher-trainees programmes and practices in mathematics Duduzile Sibaya University of Zululand, South Africa The aim of this study was to examine the level of proficiency of teacher-trainees (N = 165) at point of completion of their Bachelor of Education (B.Ed) degree. To this end, a standardised mathematics proficiency test was administered to the final year mathematics pre-service teachers. Classroom teaching practice observations and evaluations were also conducted. The results reveal that less than 50% of these teachers possess the content knowledge of mathematics as they exit the teacher training programme in their fourth year of study. Furthermore no correlation was found between marks obtained in the mathematics content proficiency test and teaching practice evaluation. The marks obtained in the latter were consistently higher than marks obtained in the former. The study concludes by discussing the findings and their implications for teacher preparation programmes.

The significance of school ethos on the academic performance of minority Xhosa learners Suzanne Singh Stellenbosch University, South Africa; Lorna Dreyer The breakdown of Apartheid in South Africa has opened the doors of all schools to all, regardless of race or language. The prospect of a better education lured many black parents to enrol their children in...
The future of disability research in Psychology and the ramifications for both theory and praxis rests heavily on the way in which disability is theorised, conceptualised and presented, in order to silence the stereotypes which have sought to exclude, marginalise and ascribe universal, fixed identity statuses as a vehicle to perpetuate stigma. Drawing on the research findings from a narrative inquiry which sought to explore the professional identity formation of individuals with disabilities employed in the mainstream labour sector, this paper asserts that new theories and research methodologies can do much to transition prior conceptualisations of medical hegemony, stereotypical non-disabled constructs and static perspectives of disability, in favour of an approach where the personal narratives of individuals with disabilities are heard. This aligns with the author’s views that there are multiple identities which are expressed variously through the complexity of individual experience. By considering the personal experiences of disability using thick descriptions, this paper supports the notion that narrative is an effective mode to transcend the effects of oppression (Thomas, 1999) by way of providing individuals with as much control as possible (Beazley, Moore, & Benzie, 1997) over the research process. The authors contend that research should seek to emancipate rather than oppress, and provide the platform for individuals to craft their personal self-identities as experts over their own lives. This includes the consideration that it is the epistemological and ontological lens through which research studies are conceptualised that have the power to either subjugate or emancipate individual experience.

A multilevel analysis on child and class predictors of teachers’ expectations in kindergarten

Sara Speybroeck KU Leuven, Belgium; Jan Van Damme; Sofie Kuppers

Because teachers’ expectations are known to influence children’s outcomes, it is important to study how these expectations are formed. Until now, most teacher expectation research focused on individual student characteristics. However, students and teachers interact within the broader context of the classroom. Therefore, teachers’ expectations may also be class-centered rather than only student-centered. This study examined the role of both child (gender, socio-economic status and ethnicity) and classroom characteristics (classroom composition based on children’s gender, socio-economic status and ethnicity) associated with teachers’ expectations in kindergarten. Data from 3785 children were analyzed by means of multilevel regression models. Results revealed that teachers had higher expectations for girls, children with a higher SES and minority children, after controlling for prior language and math achievement. Findings further indicated that expectations were higher in classes with a larger proportion of children with a lower SES. Finally, cross-level interactions showed that teachers’ expectations for minority children were higher in classes with a larger proportion of minority children. The findings suggest that teachers base their expectations on prejudiced information about individuals, at least concerning children’s SES. Minority children do not seem to be disadvantaged by their teachers. The results underscore the importance of investigating not only child predictors but also class predictors of teachers’ expectations. Furthermore, our data show that expectations are already formed for very young children who are at the beginning of their education.

A causal model development influencing teaching commitment in upper North-Eastern Thailand by multi-group analysis

Kunnida Srihomviang Mahasarakham University, Thailand; Sombat Tayrakham Mahasarakham University, Thailand

Dedication of teachers is an important factor determining teaching performance. The purposes of this study were: 1) To study causal factors influencing teaching commitment of teachers; 2) To develop a causal model; 3) To examine the invariance of the causal model. A set of samples consisting of 404 teachers with fewer than 8 years of teaching experience and 596 teachers with more than 8 years of teaching experience was drawn by a multi-stage sampling technique. The study instruments included scales of teaching commitment, self-efficacy, motivation, attitude towards teaching profession, and quality of working life. The data were treated by multi-group structural equation modeling analysis with a latent variable. The findings revealed that the model was consistent with the empirical data, i.e., the chi-squared test provided the results of consistency of χ²/df = 1.604, p = .473, CFI = 1.000, GFI = .978, AGFI = .979, RMSEA = .002, and RMR = .012. The model could explain 67.70 percent of the variance of teaching commitment. The direct effect was self-efficacy. The variables directly and indirectly affecting teaching commitment were: Quality of working life, and attitude towards the teaching profession. The indirect effect was motivation. The model was found invariant in terms of the model form and the parameters.

A comparison of the performance by dyslexic students on sequential and chunked presentations of both verbal and visual tasks in the WISC-IV

Ann Staunton Psychological Bureau Dublin, Ireland

This study builds on earlier research by the author which compared good and poor readers on a wide range of memory tasks. Results showed that good readers performed better than dyslexic students on sequential presentation of visual stimuli. Most significantly, it was also shown that the performance of dyslexic students was comparable to good readers on two dimensional or chunked presentations of visual stimuli. Dyslexic students are frequently found to have a deficit in verbal and visual sequential memory skills and it is commonly believed that this deficit is at the root of dyslexia. This study examines the WISC-IV profiles of dyslexic students in relation to scores achieved for sequential and chunked presentations of two dimensional tasks. In the verbal section of the WISC, scores achieved by dyslexic subjects for digit span are compared with scores achieved by the same subjects for letter number sequencing i.e. chunked presentation of verbal stimuli. In the performance section of the WISC, scores obtained for coding are compared with scores for the chunked visual presentation in symbol search. Findings confirm that dyslexic subjects have stronger aptitude for the

In their own voices: Methodological considerations in narrative disability research

Natalie Smith-Chandler Stellenbosch University, South Africa; Estelle Swart

Relationships among teacher’s emotional support and adolescent student efficacy and engagement

Alexandra Skoog University of Michigan, United States of America; Robert Jaggers

Social aspects of the classroom can have important implications for students’ academic and socio-emotional competence (Eccles, 2006). For example, a supportive classroom climate has been associated with greater academic motivation and engagement (Patrick et al., 2007; Wentzel, 1994). This presentation focuses on the relationship between classroom climate, middle school students’ academic and social efficacy, and engagement in the classroom. In this study, classroom climate reflects, participants included 277 6th students (M=11.5 years old, 58% White and 39% female) and 18 teachers (77% female) from a middle school in the Midwest United States. Students completed self-reports of their perceptions of teacher and peer academic and emotional support towards them (Patrick et al., 2007). They also completed measures of academic and social efficacy with teachers and classmates, and behavioural, cognitive and emotional engagement in school (Fredricks et al., 2004). Results suggest that teachers’ emotional and academic support was significantly related to students’ behavioural and cognitive engagement in the classroom. Additionally, there was a significant positive relationship between students’ report of peer emotional and academic support and their engagement along with the both their academic and social efficacy. Findings suggest the importance of social and emotional factors for a student’s classroom success. Teacher ratings of students’ social skills will help further illuminate the role of student characteristics in these relationships.
Enhancing social skills in troubled youth: The effects of UNESCO school projects

Christoph Steinebach ZHAW Applied Psychology, Switzerland; Christine Seiger

UNESCO Associated Schools Project Network (ASPnet) is a network of educational institutions that incorporate the goals and values of UNESCO into their educational, social, and organizational foundation. Prospective members go through an initiation process in which the students and faculty members of the institution are required to work together and complete projects that support the goals and values of UNESCO. This longitudinal study aims to examine the effects of the UNESCO ASPnet initiation group projects on adolescents and staff members of residential facilities for troubled youths. The study followed a residential facility for troubled male youths through the UNESCO ASPnet initiation process. Both quantitative and qualitative data were collected. Approximately 50 male youths and 15 facility members filled out standardized questionnaires every six months. 12 subjects (6 youth, 6 facility members) were interviewed every 12 months. Preliminary results from the first one and a half years found a significant increase in troubled youths’ social competencies, self-efficacy, resilience, and knowledge relating to culture, human rights and sustainability. Results also showed a correlation between youths’ level of engagement and youths’ level of self-efficacy and resilience. Staff members were very committed to the institution and satisfied with their work place already before the initiation process started. Nevertheless, the team cohesion increased significantly despite being more challenged by the process than the adolescents.

Enhancing supportive peer interaction: Comparing the effects of three different interventions

Christoph Steinebach ZHAW Applied Psychology, Switzerland; Ursula Steinebach

This is a longitudinal study that evaluates the effects of Positive Peer Culture (PPC) intervention on adolescents with behavioural problems. The intervention focuses on promoting mutual generosity, positive peer interaction, and positive peer influence. The aim of this study is to evaluate the effects of PPC compared to other forms of interventions. Two hundred male adolescents (age 14-17) assessed with behavioural problems were recruited from various institutions in Germany. The subjects were split into three groups, each group went through a different form of intervention. Interventions included: PPC, Guided Group Intervention (GGI), and classroom assemblies focusing on mutual support. Quantitative and qualitative assessments were both applied to measure changes in youth developmental outcomes. These outcomes include behavioral problems, self-efficacy, self-worth, readiness to help others, and violence and fighting over time. Quantitative measures were assessed using standardized questionnaires or specially developed questionnaires for this experiment. Qualitative information was collected through interviews with the adolescent subjects and the staff members that work with them in the institutions. All data was analyzed through t-tests and ANOVA. Preliminary results show statistically significant difference in youth developmental outcomes. Compared to other intervention groups, the PPC group showed a larger increase in self-efficacy, self-worth, and readiness to help others; as well as a larger decrease in behavioral problems, violence, and fighting over time. Adolescent subjects and staff members reported a increase in communication skills as well as an increase in acceptance of the PPC intervention.

Does happiness equal satisfaction? A closer look at optimism and job satisfaction in special needs educators

Louise Strydom The University of the Free State, South Africa

The aim of this article is to establish whether special needs educators (educators assisting learners with physical and learning difficulties) experience job satisfaction because of optimism or whether the personal growth satisfaction they attach to their occupation has an influence on their general job satisfaction. Job satisfaction in mainstream schools is low. The hypothesis was put forward that this could also be the case with special needs educators as there is no specific data regarding this group. Educators’ job satisfaction can be defined as the motivation to do the jobs, with a focus on personal, psychological, and professional variables. As a construct in the field of positive psychology, optimism refers to people with a positive outlook on life, and who believe good things will come their way. Because optimism plays a role in job satisfaction, the hypothesis can be made that high levels of optimism lead to higher levels of satisfaction. The research group consisted of 101 educators working at six different special needs schools in the Bloemfontein area, English- and Afrikaans-speaking, of both sexes, and from different race groups. Data was obtained by using a short-biographical questionnaire, the Minnesota Satisfaction Questionnaire and the Life Orientation Test-Revised. The results show that there is a difference between optimism and job satisfaction between educators in mainstream schools and those in special needs schools.

Two modalities of language used in an educational setting and the behaviour of deaf learners

Brandon Swanepoel WITS University, South Africa

Research conducted on the prevalence of behavioural adjustment in Deaf children and adolescents, in erstwhile countries, points towards an appreciably elevated percentage of emotional and behavioural problems amongst this population group when compared to hearing normative groups. Studies specify that the prevalence of behaviour and emotional problems in Deaf children and adolescents varies from 4.8% to 50.3%. This pioneering study is the first of its kind to research dissimilar modalities of language used as the language of learning and teaching (LoLT) in schools for Deaf learners and how this could possibly correlate to learner behaviour in the classroom. This study uses the Teacher Report Form (TRF) to investigate the types of behavioural problems displayed by Deaf learners in the classroom. It further investigates whether Deaf learners display certain types of behavioural problems when dissimilar modalities of language are used as the language of learning and teaching. The overall findings of this study suggest that teachers who use manually coded spoken language report an elevated prevalence of behavioural problems on the TRF compared to teachers who use South African Sign Language (SASL). Results further suggest that the group of teachers who use SASL report somatic complaints and attention problems as the most frequently encountered behavioural problems in their classrooms. In comparison the group of teachers who use manually coded spoken English (MCE) report social problems and attention problems as the most frequently encountered behavioural problems in their classrooms. Limitations of this study and suggestions for future research are discussed.

Against all odds—the role of intention in early childhood education teachers’ pursuit of higher education

Phuong To Mount Holyoke College, United States of America; Francine M. Deutsch

Early Childhood Education teachers in the United States, who are undereducated and underpaid, are currently being encouraged or required to obtain a college education. This two-year longitudinal study explored three questions: 1) Do teachers intend to go to school? 2) What factors inform teachers’ intentions? and 3) How does intention affect later enrollment? The study design was driven by Ajzen Theory of Planned Behavior. The theory posits that intention is predicted by attitude towards a behaviour, social norms, and perceived behavioural control; subsequently, intention and perceived behavioural control lead to the behaviour. In 2007, we recorded teachers’ intentions to pursue college, enrollment status, age, and proxies for Ajzen’s factors. In 2009, we assessed teachers’ actual enrollment status and collected qualitative data on what had helped and hindered them in enrolling. We found that 69.8% of the teachers intended to enroll. Age had the largest influence on teachers’ intentions – older teachers were less likely to plan for college. This relationship overwhelmed the effects of Ajzen’s constructs. Teachers’ intentions and enrollment in 2007 were both crucial predictors of their college enrollment in 2009. Yet, even when teachers had the intention, many of them could not successfully enroll due to practical and logistical issues, academic uncertainties, and disappointment with the ECE field. Our study adds the teachers’ voice to the ongoing debate on teachers’ qualification and compensation. More institutional support and financial incentives must be provided before college can be a realistic option for ECE teachers.

How student-teacher attachment influences learning motivation and learning behavior on fifth, seventh, and eighth graders

Jack Teng National Chung Cheng University, Taiwan, R.O.C.

The purpose of this research aims to explore how fifth, seventh, and eighth graders interact with their teacher and how the relationship affects their learning
motivation and learning behaviours. Student-teacher attachment can be divided into three elements, which are communication, trust, and anxiety. Teachers not only can provide students with a sense of security and proper challenges, but also can assist students to create successful learning experiences. According to Riley (2009), successful learning experience can help students explore the world. It is self-evident that students have good performance in some classes but not in all classes. Therefore, this research will consider elements of student-teacher attachment that affects learning behaviour and motivation from the teacher. This research involved surveys, comprised of three sets of questionnaires concerning student-teacher attachment, learning motivation and learning behaviours. A group test was conducted and the subjects are fifth, seventh, and eighth graders in Taiwan. Project result should be that students who have a better student-teacher attachment will have a better learning motivation and learning behaviour, also the effect of student-teacher attachment will have inverse effect to age. The conclusion of this research will provide insightful information for teachers of the importance of how student-teacher attachment will severely affect students’ learning motivation and learning behaviour.

ADHD knowledge and intervention among educators internationally
Mark Terjesen St. John's University, United States of America
ADHD is one of the most common psychiatric disorders of childhood. Accurate diagnosis of ADHD is often complicated because many of the problems associated with ADHD are also characteristic of other childhood behaviour disorders and symptoms of ADHD may vary across settings, caregivers and task complexity. Teachers are a very important part of this multidisciplinary team. Teachers are often the first source of referring children with ADHD (Snider, Busch, & Arrowood, 2003; Snider, Frankenberger, & Aspensen, 2000) and are often called upon to implement educational interventions. There is a growing body of research on American teachers’ understanding of this disorder and how this knowledge impacts their decisions. However, there is limited research examining ADHD knowledge and attitudes among teachers in other countries (Jerome, Gordon, & Huesler, 1994; Brook, Watemberg, & Geta, 2000; Ghanizadeh, Jafar Bahredar, & Reza Moctin, 2006). Those studies that do exist, suggest that knowledge and attitudes about ADHD may be culturally-bound and linked to training. This presentation will offer results from a multi-national study that investigated how teachers’ prior exposure and training pertaining to ADHD are related to their knowledge (and misconceptions) of the disorder. Specifically, the relationship between teacher knowledge of ADHD and prior referral decisions; the relationship between teacher knowledge of ADHD and prior education and training (ADHD specific and general); and cultural similarities and differences in the relationships described will be addressed.

Effects of academic procrastination on self esteem and test anxiety
Shefali Thaman University of Delhi, India
Procrastination in the academic realm holds many negative consequences. The objective of the present paper was to study the effect of academic procrastination on self esteem and test anxiety. It also aimed at studying the relation between self-esteem and test anxiety. The sample size taken was 60. The sample was divided into 3 groups of undergraduate students between the age group of 18-22 years from arts, science and commerce courses, with equal number of participants, 20 each. These groups were further subdivided into groups of males and females with an equal number of participants, 10 each. The data was collected from different colleges in New Delhi, India. The measures used are 16-Tuckman procrastination scale, Rosenberg self-esteem scale and Spielberger Test anxiety Inventory. Results showed that negative correlation between test anxiety and self esteem and positive correlation between academic procrastination and test anxiety was found to be significant at a level of 0.05. However, no significant relationship was found between academic procrastination and self esteem. By understanding the linkages between the 3 variables namely procrastination, test anxiety and self esteem, effective interventions in the form of solutions can be invented, enhanced and researched and spread to stem the tide of procrastination among students. Also, this study has set the stage for further investigation that controlling one variable namely procrastination can lead to changes in others, that is, self-esteem and test anxiety, and vice versa.

How emotion understanding affects peer acceptance and social behaviour in children with learning disabilities
Yuehua Tong University of Jinan, China
Emotion understanding refers to the ability to discern and understand others’ emotions, using situational and expressive cues that have some degree of cultural consensus as to their emotional meaning. It includes one’s knowledge about emotional states, interpreting the cause of emotion and the possibility of regulating emotions. The present study was to explore how emotion understanding affects peer acceptance and social behavior in children with learning disabilities (LDs). 90 children with LDs in China participated in this study. The results indicated that: (1) Recognition of basic emotion situation and self-conscious emotion situation in children with LDs had an impact on peer acceptance. (2) Recognition of facial expressions and self-conscious emotion, understanding internal causes of emotion, hidden emotion, and emotion change in children with LDs had an impact on social behaviors. (3) Different components in emotion understanding had different predictive powers for peer acceptance and social behavior. The implications for intervention are discussed.

Differences in studying and acquiring writing school genres among students of different educational levels: critical questions and discussions
Carmen Torres Universidad de la Republica, Uruguay
The aim of this paper is to present some results of an empirical study based on primary and secondary students of the public education system in Uruguay. The study is intended to describe differences in students’ achievement in different tasks, connected to text writing, selecting information and comprehension. It also includes a questionnaire about learning practices, preferences and conceptions, to which we only partially refer. We follow some Vygotskian ideas which separated the use of mediational means and social conditions for learning. The study shows that there is great heterogeneity among the achievements and learning conditions at the same level. Differences among levels tends to vary and the expected progression expected was not at all homogeneous. The approach allowed discussion of the significance of the study, and the role of written mediation of texts and different processes of learning and clarifying concepts in the education and development process, considering their importance.

Do number games improve six-year-old children’s number skills and arithmetical skills? Ulf Trofj Linkoping University, Sweden; Rickard Ostergren; Jessica Carlsson
This study examines the effects of playing number games on the development of basic number skills and arithmetical skills in children. The study is based on the theoretical view that numbers are represented as analogue mental number line and the greater the transparency of the mapping between physical material and the mental representation, the better the development of the mental representation. It is predicted that children playing the linear-number game will develop better basic arithmetical skills and a more accurate number representation compared to the other intervention groups, and the children playing the circular-board game will develop better basic arithmetical skills and a more accurate number representation than the non-board number activities group. Ninety children were randomly divided to three number game interventions, and thereafter engaged in six 20 minutes intervention sessions during three weeks. Prior to and directly after and 3, and 6 months after the intervention, number processing abilities and arithmetic abilities were assessed (e.g., counting; subitizing; enumeration; digit comparison; number-line estimation; addition; non-symbolic approximate addition). The study used a 3 (interventions) x 2 (pre vs. post test) experimental between group design. Two-factor ANOVA was used to evaluate and compare the effects of the interventions. The study has potential to generate knowledge regarding how different didactic tools facilitate children’s learning of early arithmetic, as well as insights concerning the mapping of the symbolic number system onto the innate number systems; if the innate non-symbolic number systems is sharpened through the acquisition of the exact symbolic number system.

How cognitive science provides the theoretical basis for reading methods in alphabetic orthographies
William Tunmer Massey University, New Zealand
A major aim of this presentation is to describe how cognitive science has provided the theoretical basis for resolving the “great debate” over reading methods in alphabetic orthographies. This debate, also referred to as the “reading wars”, has raged for more than a century with the pendulum swinging back and forth between approaches that emphasise the development of alphabetic coding skills, or phonics, and those that do not, such as whole word approaches or, more
Efficacy of educational psychology techniques in the development of oral expression

Silvia Ubillos University of Burgos, Spain; Jaime Ibanez; Ana Maria Aguilar

We will evaluate the efficacy of educational psychology techniques in developing the oral expression of native students (Spanish) and non-native students. The sample consists of 61 women with a mean age of 21.22 years (sd=2.85). The study consists of repeated measures (pre- and post-test) quasi-experimental design with matched samples. It has two independent variables (program and native language), and 6 dependent variables (phonological, grammar, lexical-semantic, socio-linguistic, pragmatic and strategic subcompetences or abilities). All participants were recorded on audiotape, and in order to evaluate the oral language, a scale was created. This scale consisted of 33 items which measured each of the sub-competences. Reliability indices were high. Results show that: a) psycho-educational techniques were efficient in developing oral expression in 4 of the 6 sub-competences (phonological, grammar, lexical-semantic and pragmatic); b) these techniques have a positive effect on students with different developmental processes and knowledge of Spanish (native-born and foreigner); c) the observed success was different depending on the baseline knowledge of the students: those who had a higher original competence in Spanish were those whose development was slower; d) there is a convergence in level of acquisition of some sub-competences which equals those participants who are immersed in different acquisition processes; e) the development in acquiring communicational competences is quite similar in groups with heterogeneous characteristics.

Mathematical-disability and working memory among special children

Devaraj Ushalaya India; Shruthi Mohan

Interpersonal skills are the skills people need to get along with others. Personal and interpersonal skills can be developed by working cooperatively and collaboratively with others, building and maintaining self-esteem, setting realistic goals and coping with anxiety. Interpersonal skills are best taught in small groups, whereby the teacher is a facilitator and activities are student-oriented, which provides increased opportunities for interaction and the exchange of ideas between students. We sought to determine whether there is any influence of collaborative learning on interpersonal skills, and also on science interest and attitude. Reliability indices were high. Results showed that the experimental group surpassed the control group significantly from pre- to post-test in interpersonal skills, and also on science interest and attitude. The main categories that emerged were these: The various roles that parents can play in health promotion in schools, knowledge about health promotion, barriers to health promotion and collaboration. Parents are the key stakeholders through which the health of their children can be promoted in schools. Parents perceive their role basically to be assisting their children. Various barriers exist in the creation of health promoting schools, which include: Poverty and unemployment, illiteracy, lack of knowledge and no confidence. Schools should initiate parental involvement and collaboration in health promotion.

Early signs of dyslexia

Jasmina Vukanovic The State University of Novi Po, Serbia and Montenegro

Developmental Dyslexia is a disorder in children who, despite average intellectual abilities, fail to attain the language skills of reading, writing, and spelling commensurate with their intellectual abilities. The aim is increasingly recognized that personal epistemology plays an important role in how students interpret their educational experiences, and that it significantly influences their thinking and reasoning processes, skills of argumentation, and classroom learning. Given our less than perfect schooling system our assumption is that students probably enter tertiary education with a limited and limiting view of knowledge which might adversely affect various aspects of their education. As such, this is a very significant area of inquiry that sheds light on how students view knowledge. Students' beliefs about knowledge, specifically in relation to their beliefs about the structure of knowledge, the stability of knowledge, sources of knowledge, speed of learning, and ability to learn, are highly relevant to their academic performance and learning experience. Performance of students in tertiary education is of grave concern as the throughput levels are unacceptably low. This prompted an exploratory qualitative study in which data was gathered through 10 in-depth interviews and 2 focus groups discussions with first year students. Interview transcripts were analysed in accordance with the principles of interpretative phenomenological analysis. The analysed data provided an indication of different levels of sophistication in students' epistemology. Mostly views evidenced an acceptance that truth is 'out there' and knowable, and that authorities are the source of knowledge. The implications of different views of knowledge for tertiary didactics are discussed.
of this study was to determine whether phonological awareness and short-term verbal memory could be early indicators of developmental dyslexia. The sample consisted of 194 first- and second-graders from two primary schools in Belgrade. The following tests were used: a shortened version of the WISC-R to determine intelligence scores, the assessment battery for dyslexia for Serbian children, the initial consonant deletion task to determine phonological awareness and the digit span task for measuring short-term verbal memory working-memory's storage capacity. According to multiple regression analysis the most significant indicator of the subsequent (un)successful reading of both younger and older schoolchildren was phonological awareness. The short-term verbal memory is, to a lesser extent, an indicator of the subsequent reading acquisition defined by the time needed for reading the text and by the text comprehension. The major conclusion from the experiment is that the phonological awareness assessment should be implemented into the regular procedure of assessing children's reading skills for school. In this way children in need of preventive stimulation within the inclusive program in primary schools could be identified.

A re-exploration of psychometric investigation of face-audience communication apprehension scales of Chinese college students 
Hongli Wang Guizhou Normal University, China; Weixing Zou Guizhou Normal University, China; Yi Yuan; Liming Xie; Zhaoqiong Yu; Wenjie Lan; Rong Wan

The aim of this study is to develop a better scale with which the magnitude of Chinese college students’ Face-audience Communication Apprehension (FCA) can be measured and an investigation into the status quo of Chinese college students’ Face-audience Communication Apprehension. The project is presided over by professor Wang hong-li from Guizhou normal university of China and sponsored by the National Social Science Foundation of China. Following the rules of psychometrics, first a pre-survey scale with 79 items was made and with which 1,200 students (50 from each university) from 24 universities was chosen randomly from 17 provinces or municipalities of China, including Beijing, Shanghai, Sichuan, Guangdong, etc. were surveyed. Among 1,057 valid samples obtained in pre-survey, 529 of the ones distributed in the odd number group were put into the exploratory factor analysis (EFA) and the rest into the confirmatory factor analysis (CFA). The latest (revised in October, 2011) Chinese College Students’ Face-audience Communication Apprehension Scale, with four dimensions (platform apprehension, interview apprehension, affairs-handling apprehension, group-within and outside-campus communication apprehension) and 32 items involved, has high reliability and validity in accordance with the demands of psychometrics. This scale can be formally used as a survey instrument to measure the magnitude of Chinese college students’ Face-audience Communication Apprehension.

Visual-spatial abilities in dyslexic individuals in different orthographies and age groups
Evelin Wittruk University of Leipzig, Germany

The theoretical background is based on the controversial findings regarding visual-spatial abilities in dyslexic individuals and the clear link to the gender dependency of these abilities. Our selected studies ask about visual-spatial abilities in dyslexic individuals depending on the orthographic system, age and gender. The methodology involves three experiments with age and IQ matched samples of dyslexic and non-dyslexic individuals, the use of non-linguistic materials, and accuracy, reaction time measurement. In the first experiment, working memory performances were investigated in children with a mean age of 10.26 years from different orthographic background (Cantonese ideophonic, Arabic segmental and German alphabetic script). The second experiment, based on the computerised possible-impossible figures paradigm (decision and matching demands), involved adolescents with a mean age of 17.16. In the third experiment abilities of mental rotation, mental model construction and vividness of visual imagery were measured in adults with a mean age of 23.04. The findings of the first experiment show no significant discrimination between dyslexic and non-dyslexic children regarding visual-spatial working memory functions compared with highly significant discrimination regarding auditory working memory functions. Path models demonstrate the function of visual-spatial abilities on reading and writing achievements in the frame of different orthographic systems. In the second and third experiment, we could confirm our assumption of visual-spatial advantages in dyslexic adolescents and adults, particularly in male dyslexics. Conclusions regarding the development of compensation strategies are possible.

The cultural basis of epistemological beliefs of Chinese students: Relationship between values and reliance on authority
Angel Ky Wong HK Institute of Education, Hong Kong; Eric Lo

Exploring the cultural basis of epistemology is important to further our understanding of this construct (Hofer, 2008). The present study aims to add to this understanding by exploring the cultural correlates of Chinese students’ epistemological beliefs systematically. Previous researchers have revealed that Authority in Knowledge, one of the epistemological beliefs, can be consistently extracted in Chinese respondents (e.g. Chan & Elliott, 2002), but not in western samples. This has been attributed to the emphasis on respecting authority in Chinese culture. This conjecture is empirically examined in this study by relating epistemological beliefs to 2 indicators of culture, namely specific socialisation values and general cultural values which were examined by a newly developed Multi-dimensional Filial Piety Scale and the Schwartz Value Survey respectively. The cornerstone of Chinese socialisation is filial piety which is characterised by hierarchical parent-child relationships in which unquestioned respect of those higher in the hierarchy is expected from those lower in the hierarchy. If this familial role relation is transferred to teacher-student relationships, students would be unwilling to challenge knowledge passed on by teachers. 340 university students have completed the 2 surveys. It was found that hierarchy-based filial piety that signifies the subordination of individual interest to parental demands correlated significantly with Authority in Knowledge, but no relationship was found for affection-based filial piety. For general values, a stimulating life was negatively correlated with Authority in Knowledge. The implication of these findings to the conceptualisation of epistemological beliefs would be discussed.

Adolescents’ academic emotions and self-efficacy in learning Chinese and mathematics
Junmei Xiong Central China Normal University, China; Huashan Liu

The study aimed at describing adolescents’ affective experiences across two subject settings, namely Chinese and mathematics. Tenth graders (n = 641) from three senior high schools in China were administered the Academic Emotions Questionnaire – Mathematics (Pekrun et al., 2005) and the AEQ – Chinese (modified based on AEQ – M, Pekrun et al., 2005). Results emerged as follows: (1) Positive emotions, negative emotions and self-efficacy across two subject settings were significantly correlated but with low correlational levels, which indicates that adolescents’ affective experiences in learning Chinese and mathematics are not identical. (2) Within the Chinese or mathematics setting, self-efficacy positively correlated with positive emotions (enjoyment and pride), and negatively correlated with negative emotions (anger, anxiety, shame, hopelessness, and boredom). MONCOVA statistics found that boys reported significantly more negative emotions than girls in Chinese; male adolescents’ mathematics self-efficacy was significantly higher than that of female adolescents; boys reported significantly more positive emotions, and fewer negative emotions than girls in learning mathematics. (3) Between the Chinese and mathematics settings, MONOVA statistics found that male adolescents’ self-efficacy was not significantly different; however, female adolescents’ Chinese self-efficacy was significantly higher than their mathematics self-efficacy; boys reported more pride and less boredom in mathematics than in Chinese; girls reported more negative emotions in mathematics than in Chinese. The above findings suggested that control belief (self-efficacy) is associated with academic emotions across Chinese and mathematics settings.

Senior high school students’ self-efficacy and academic emotions in learning Chinese and mathematics
Junmei Xiong Central China Normal University, China; Huashan Liu

To investigate the relationship between self-efficacy and academic emotions in Chinese and mathematics learning, 800 tenth graders from three senior high schools in China were sampled randomly and administered the Academic Emotions Questionnaire-Mathematics (Pekrun, Goetz, & Frenzel, 2005) and the AEQ-Chinese. Data analysis based on a valid sample of 641 participants (boys 301, girls 340) with a mean age of 16.20 found: (1) The relationship between self-efficacy and academic emotions across the two subject settings were similar, namely self-efficacy positively correlated with positive emotions and negatively correlated with negative emotions. (2) Academic emotions have domain-specificity. Paired samples correlations found that academic emotions across two subject settings were positively correlated with each other but with low level of correlations. Paired samples T-testing found
that students had more pride, anger, anxiety, shame, hopelessness, but less boredom in learning mathe-
matics than in Chinese. (3) When academic achievement was controlled as a covariate, MON-
COVA statistics found that academic emotions and self-efficacy did not have gender differences in
learning Chinese. However, boys reported signifi-
cantly higher self-efficacy and more positive emo-
tions, and less negative emotions than girls in learn-
ing mathematics. The above findings suggested that
self-efficacy is relevant to academic emotions across Chinese and mathematics settings, and low
self-efficacy is strongly associated with more neg-
ative affect.

The influence of self-esteem, attributional style, and organisational climate on tea-
chers’ psychological empowerment with a sample of Chinese teachers
Dajun Zhang Center for Mental Health, China; Jin-
liang Wang
The present study examined the influence of self-
estee, locus of control, and organizational climate
on Chinese teachers’ psychological empowerment. Self-esteem is thought to be related to psychologi-
cal empowerment. When an employee feels that he
or she is valuable as a human being, this positive self-evaluation extends to the workplace, resulting in
a more positive, desirable work behavior (Ban-
dura, 1977). Individuals with an internal locus of
control are more likely to believe that they have the
ability to influence their work context and are
therefore more likely to feel empowered than indi-
viduals with an external locus of control (Luo &
Tang, 2003). Researchers have proposed that psy-
chological empowerment is influenced directly by
the work context, implying that organizational cli-
mate may have a direct influence on psychological empowerment (Conger & Kanungo, 1988; Spreit-
zer, 1995). In this study, participants were 1272
Chinese teachers, who were asked to fill in the
measurement of psychological empowerment, self-
estee, locus of control, and organizational climate
assessments. Results indicated that self-esteem was
a positive predictor of psychological empowerment.
Sevreral dimensions of organizational climate,
namely professional communication, decision-mak-
ing, appraisal and recognition, supportive leader-
ship, and professional growth, can predict psycho-
logical empowerment. Locus of control was not a
predictor of psychological empowerment. We con-
cluded that self-esteem and organizational climate
have significant effects on psychological empower-
ment. This research has enriched our understanding
on factors influencing psychological empowerment
in Eastern culture.

Relationship between group learning during inquiry learning: Analysis based on method
of complex networks
Fengjuan Zhang Central China Normal University,
China; Chuang Gao
Little is known about the group learning relation-
ships during the process of inquiry learning. When
students search for information, ask questions from
teachers and communicate with peers, according to
the perspectives of information theory, learning can
be seen as an action of transmitting information. The
present study recorded and reconstructed the rela-
tionship of group learning in inquiry learning from
the views of information theory, and extracted the
characteristics of interactive network. The paper
originally used the analytical method of complex
network to study inquiry learning. Participants were
161 students from the 11th grade in Fuzhou city,
China, who had taken part in a course of inquiry
learning. Complex network models of inquiry learn-
ing were constructed based on several inquiry learn-
ing indexes (correlation coefficient, participation de-
gree, activity degree), which were collected by a self-
made-up survey of inquiry learning. Results showed
that the relationship between students could be repre-
sented as visually intuitive. The teacher could fix
the students who had a high influence quickly and knew
the concentration trend of the group promptly. More-
over, models comparison showed that multi-way
learning could be more useful to improve the quan-
ty of information and effectiveness of learning than
that of single way of learning.

The impact of mindfulness meditation on academic well-being and affective teaching practices
Tahereh Ziaian University of South Australia, Australia
University education is changing rapidly in response
to globalisation, technological development, cultural
and social change. Academics are teaching in an
environment of unprecedented access to information
and rapid electronic communication. Universities
have invested considerable resources in the develop-
ment of courses and intellectual outcomes, but have
given little attention to the emotional or affective
aspects of learning. These factors combine to produce
a learning environment where both staff and students
may minimise the depth of human interaction despite
the commonly accepted view that emotion is essen-
tial to successful teaching and is a vital influence in
the learning process. Using action research, this study
investigated (1) the impact of mindfulness meditation
by academic staff on the affective domain of teaching
and learning and (2) the mindfulness meditation
impact on psychological well-being among academic
staff. Throughe convenience sampling technique, aca-
demic staff from diverse disciplines at the University
of South Australia’s Centre of Regional Engagement,
were recruited to the study. Staff completed a mind-
fulness meditation program including meditation practice of five minutes, twice a day, for a 9 months
period. A series of workshops and individual tele-
phone interviews were conducted during this period.
Early findings of the research indicate that mindful-
ness meditation increases staff awareness of the af-
fective domain and promotes their mental well-being.
In this paper results of the study are reported with
particular emphasis directed to strategies to promote
affective learning. This study provides important data
related to the application of mindfulness meditation
to teaching and learning in a tertiary environment.

Educational strategies of Kazakhstan in the
era of globalisation
Nazgul Anarbek Al-Farabi Kazakh National Univer-
sity, Kazakhstan; Dina Dzhusubalieva; Aigerim
Mynbaeva; Elmira Kalymbetova
The purpose of the study is to review and develop
educational strategies as the foundation of the educa-
tional policy of Kazakhstan in the context of the
globalisation of society. Higher education and sci-
ence in the era of globalisation have become stra-
egic resources of the country. In the last 20 years
the higher education system was updated because of
independent Kazakhstan exercise principles of the
Bologna Declaration after signing it in March 2010.
The main principles of Bologna Declaration are
realised in Kazakhstan at the state level: In 1998
the creation of the national system of education
quality rating, in 2003 the implementation of the
test unit system, the signing of the Magna Charta by
leading universities of Kazakhstan, in 2004 the
development of test standards new generation, the
adoption of the three-stage educational system, in
2005 the adoption of the academic degree quality
assurance standard model, in 2007 the adoption of
the Law of the Republic of Kazakhstan “On Edu-
cation, in 2009 the new occupation classifier was
adopted etc. At the present time 55 state civilian, 13
non-civilian, and 81 non-state universities are in-
volved in the educational activity. The number of
higher educational institutions decreased from 176
in 2005 to 149 in 2011, for the reason that they did
not meet the requirements of the Bologna Declara-
tion. The index, number of students for every teach-
er, has also declined from 16.25 in 2003 to 15.1
in 2011. Thus, educational strategy, developed over
the 20 years of the independence of Kazakhstan,
is a strategy of renovation of the content of educa-
tion and building a national system of education.

Adolescent conversations about gender-
based violence
Caryn Bachrach South Africa
This poster reports on a conversations analysis study of
groups of adolescents in an interaction around
the topic of gender-based violence. The purpose
was to understand WHAT adolescents talk about,
and HOW they interact in order to clarify both
therapeutic and educational implications. Two
groups of adolescent boys and girls participated in
discussions about the topic “What is the role of
gender in violence in the SA society?” Findings
indicate clear differences between boys and girls
in their understanding of what violence is about,
and the ways in which they participate in the con-

Gifted children in Sudan: A biographical study
Khaliq Ali Sudan Academy of Sciences, Sudan
This study aims to identify gifted children in the
State of Khartoum, Sudan. To achieve this aim
the researcher has applied the Standard Progressive
Matrices Standard (SPM) to a representative group
of 832 gifted children selected randomly from pri-
mary schools, both males (430) and females (402)
with age ranges between 8-16 years. Additionally,
the SPM was administered to fathers (458), mothers
(358) and teachers (116) of these gifted children.
The study showed that the average IQ of gifted
children was 129.35 points, and it was 102.35 for
fathers, 102.05 for mothers and 106.03 points for
teachers. Generally, it showed that gifted children
were more intelligent compared to their parents
and teachers and the differences in IQ were significant
on point 0.01 level. Finally, several implications for
future studies were reached.

Teenagers in Sudan: A biographical study
Khalil Ali Sudan Academy of Sciences, Sudan
To achieve this aim the researcher has applied the
Standard Progressive Matrices Standard (SPM) to a
representative group of 832 gifted children selected
randomly from primary schools, both males (430)
and females (402) with age ranges between 8-16 years. Additionally, the SPM was administered to fathers
(458), mothers (358) and teachers (116) of these gifted children. The study showed that the average IQ
of gifted children was 129.35 points, and it was 102.35 for fathers, 102.05 for mothers and 106.03 points
for teachers. Generally, it showed that gifted children were more intelligent compared to their parents
and teachers and the differences in IQ were significant
on point 0.01 level. Finally, several implications for
future studies were reached.

What students think they feel is different from what they really feel

Madeleine Bieg University of Konstanz, Germany; Thomas Goetz; Anastasiya Lipnevich

Studies have consistently demonstrated that individuals’ scores on global self-reports of emotions (traits) are generally higher than their self-reported emotions assessed in real-life situations. One plausible explanation for such discrepancy is that global trait ratings may be influenced by various beliefs that individuals hold, whereas state-based assessments are more direct and less susceptible to memory biases (Robinson & Clore, 2002). This intensity bias appears to hold true for the domain of academic emotions, with factors contributing to this discrepancy being largely unclear. The current study examined whether student academic self-concept explains the difference between trait and state assessments. We hypothesized that academic self-concept positively predicts the discrepancy between trait and mean state emotional self-reports in positive emotions (H1) and negatively predicts it in negative emotions (H2). Questionnaire data from N=119 German students, from grade 8 and 11, were collected, that captured their general academic emotions (enjoyment, pride, anxiety, anger, and shame) and self-concept in four subject domains. Additionally, data on emotional states were collected through the use of the experience sampling method over the span of two weeks (N=1525). Consistent with our hypotheses, analyses revealed that students’ academic self-concept predicts the trait – mean state difference for positive and negative achievement emotions in the expected direction. Thus, for example, students with lower self-concepts tend to exaggerate their negative trait emotions as compared to actual state assessments. Methodological and practical implications are discussed.

Perfectionism in South African university music students: Correlations with academic motivation and performance anxiety

Madaleen Botha North-West University, South Africa

Perfectionism is often associated with the positive characteristics of motivation, effort, and achievement (Bieling et al., 2003; Mills & Blankstein, 2000; Stoeber & Rambow, 2007). In contrast, undergraduate university students, often driven by socially prescribed perfectionism, have been found to be more anxious, avoid asking for help when needed, and tend to regard others as a source of motivation. As a result, these students delivered inferior academic performance (Mills & Blankstein, 2000). The aim the current mixed methods study is to examine the relation of perfectionism with academic motivation and performance anxiety in first-, second-, and third-year music students. Furthermore, the music students and their year of study will be compared in terms of perfectionistic traits and the correlation between academic motivation and performance anxiety. A total of 93 music students from four South African universities, namely Stellenbosch University, University of the Free State, North-West University, and University of Pretoria, were involved in the study. Data was collected through a questionnaire and semi-structured interviews. The questionnaire included the Multidimensional Perfectionism Scale (Frost et al., 1990), the Work Preference Inventory (Amabile et al., 1994), and the Performance Anxiety Inventory (Rae & McCambridge, 2004). Ten students were randomly selected to participate in an individual face-to-face interview consisting of open-ended questions. Preliminary findings of the research will be reported and discussed.

The influence of boredom on creativity

Julia Cada University of Munich, Germany; Reinhard Pfekrun; Kou Murayama

Boredom has been discussed as a dysfunctional achievement emotion, which has a detrimental influence on attention-based activities. However, it has recently been proposed that boredom can promote creativity. The current study aimed to unravel this potential positive aspect of boredom - the facilitative effects of boredom on creativity. Undergraduate participants (N = 76) were asked to wait in a room by themselves before they had to work on a creativity task. In a boredom condition, participants saw a slower clock than two control conditions while they were waiting, although the actual waiting time was the same across the three conditions. The feeling of time not passing fast enough was supposed to induce boredom. Creativity was measured with a divergent thinking task, in which participants were asked to generate as many words as possible within eight minutes for four different categories. The results indicate that participants in the boredom condition felt more boredom during the creativity task than those in the control conditions (real time and faster time), indicating that clock manipulation during the waiting period successfully induced lingering boredom. In addition, participants in the boredom condition generated more original words than those in the fast control condition, suggesting that boredom may indeed promote creativity. Potential benefits of boredom in creative settings were discussed.

Investigating eye movements during reading of Chinese college students with different English comprehension abilities

Haoyang Cheng Soochow University, China; Dianzhi Liu

As eye movement data have proved to be valuable object indicators in reading, the study investigates eye movements of Chinese college students during English reading comprehension, to disclose different reading strategies, and provide suggestions for improvement of poor readers. 40 students participated, as good or poor readers, whose English comprehension abilities were distinguished by College English Test Brand 4 achievements. The number for each group was 20. Participants first completed text reading containing about 150 words within 2 minutes and then answered questions which appeared with the text, as soon as possible. College English teachers ruled out critical areas and assessed the validity of the questions. EyeLink 2000 (pupil and cornea recognising mode) tracked eye movements to provide data for Independent-Sample T-Test after matching accuracy. The findings are: 1) while reading text, good readers had shorter mean fixation duration, larger saccade length and larger fixation ratio of total fixations on critical areas than poor readers; 2) good readers made fewer fixations on questions during problem solving, but the fixation number on questions was a higher proportion of total times than those of poor readers. The results suggest that good Chinese college students acquire faster English reading speed through large reading chunks; they do not assign energy equally, but pay more attention to critical areas and questions, which indicates the advantages in key information searching and discrimination-making. Future research should set a stricter answering time to reflect the diversity of different readers more accurately.

Assessing teachers’ responses to peer victimisation: The use of illustrated vignettes

Josafa Da Cunha Federal University of Parana, Brazil; Sheri Bauman

The role of teachers to prevent and reduce peer victimisation has been highlighted in the literature, but most research on this topic has been conducted in North American or European samples. This paper builds on the knowledge within the field to provide a nuanced perspective on the attitudes and responses of teachers towards peer victimisation. Participants were 70 teachers from Brazilian schools, who completed a questionnaire where seven illustrated vignettes depicting overt and relational aggression incidents were presented. Each vignette was followed by open ended questions about their response to each of the involved students and to the situation in general, and four close ended items assessing their perception about the need for intervention, gravity, efficacy to address similar situations, and frequency of similar episodes in their own schools. The responses of teachers to each scenario were coded, adapting the categories of responses proposed by Bauman and Del Rio (2006), and the following strategies were identified: inquiry, involve adult resources, general support, develop social skills, involve classmates, discipline and no intervention. In comparison to the relational aggression scenarios, overt aggression incidents received higher ratings in regard to its severity (t=3.6; p<0.05) and need for the intervention from teachers (t=3.3; p<0.05), while the association between these perceptions and the responses reported by teachers are also explored. Discussion acknowledges the strengths and limitations of the use of illustrated vignettes in the assessment of responses to peer victimisation.

Afri twin: Reflections of teachers’ experiences

Werner De Klerk North-West University, South Africa; Michael Temane; Alida Nienaber

The Afri Twin is a collaboration between a British school, a South African township city school, and a school from a township or rural community in South Africa. The intention is to build friendships, for schools to visit one another, exchanging teaching ideas, and to gain first-hand experience of the different conditions in which the individual schools are operating. The aim of this poster/report is to explore teachers’ experience of the Afri Twin; how...
they think the Afri Twin can help promote resilience in schools, and to determine the teachers’ experience of the school as an organisation. A mixed method approach was used to collect data. The researcher developed a questionnaire with open-ended and close-ended questions that was handed out at the 2nd International Afri Twin Conference in Cape Town. A sample of 20 male and 34 female participants, of whom 17 were from the UK and 37 from SA, from 46 different schools were used. Data analyses yielded the following themes: Reasons for teaching at their school, experiences and effectiveness of Afri Twin, benefits for the school, and how the Afri Twin can help improve/ promote resilience in schools. The conclusion underlined the satisfaction of the participants with their working environment, the effectiveness of the Afri Twin (believing that the Afri Twin can contribute to resilience in schools), thus possibly contributing to the well-being of the school.

Abilities of deaf and hard-of-hearing children to name objects
Nadezda Dmic University of Belgrade, Serbia, Serbia and Montenegro; Tamara Kovaeev; Ljubica Isakovic
Sign language is a natural means of communication for deaf children, comparable with the expressive potential of spoken language, and it gives them communication and cognitive experiences. It also influences the development of thinking to a great extent. The aim of our study was to assess the level of knowledge of object names within the scope of written, signed, and spoken language. The study encompassed 83 pupils enrolled in grades three to eight attending schools for deaf and hard-of-hearing children in Serbia. The instrument used was The Linguistic Assessment of certain components of Dysphasic Syntax (D. Blagojevic) - the segment Naming of objects. The children were given pictures, one by one, of common objects, including: knife, scissors, spoon, watch, book, matches, brush, pencil, eraser and drinking glass, and were asked to name the objects in written, spoken, and sign language. A qualitative and quantitative analysis of the obtained data was completed. The results show that deaf and hard of hearing pupils are best at naming objects while using sign language, followed by written, while they showed the lowest level of competence in naming objects using verbal expression (all of the obtained results are statistically significant at a level of 0.01). With the use of sign language the pupils were most efficient in naming the objects book, and scissors and knife when using verbal expression. The assessed group of deaf and hard of hearing pupils had the lowest scores when attempting to name the object matches.

Reading ability and motivation of German primary school girls and boys: The teachers’ perception
Martina Endepohls-Ulpe Institut für Psychologie, Germany
While the results of the PISA surveys show considerable gender differences in reading competencies for older students, results in studies with younger children are not that clear. PIRLS 2006 detected only very small differences in several countries. In Germany the difference was significant but also very small. Nevertheless, in the last years numerous measures were initiated at German primary schools to improve the reading competencies of boys. Studies in the field of mathematics have shown that teachers have stereotyped attitudes towards girls’ mathematical abilities. This has detrimental effects on girls’ self-concepts and their achievement in this subject. Little is known so far about corresponding processes for reading competencies. The presented study analyses the assessment of gender differences in children’s reading abilities and reading motivation by German primary school teachers. 172 teachers filled in a questionnaire with several questions on reading competencies, reading behaviours and reading interests of girls and boys. Differences between the appraisal of girls and boys and differences between the answers of male and female teachers were analysed by analysis of variance. Results show that teachers assume significant gender differences in reading competencies, reading motivation, and reading behaviour in favor of girls. Interestingly, male teachers assess these differences to be even greater than female teachers do. As a consequence it seems necessary to analyse and discuss the influence of these stereotyped perceptions on boys’ reading self-concepts and reading motivation. Results are also discussed with respect to the ‘feminization of teaching’ discourse.

The relationship between music involvement and school engagement in adolescence: A case for the arts
Osai Esohe University of Michigan, United States of America
Research in psychology has found that engagement in school is positively related to higher academic outcomes and positive school behaviors for adolescents. Various aspects of personal identity may influence student engagement and this paper explored the aspects of students in relation to their peers on engagement and achievement. Prior research has attempted to make a case for the arts by using arguments of transfer, suggesting an instrumental value of arts on specific academic skills (Deasy, 2002). Though a few studies of arts to academics transfer have discovered significant results, a more meaningful argument may be for the inherent value of arts - specifically the dispositional outcomes cultivated by involvement in the arts (Eisner, 1998). One such disposition may be engagement, conceptualised as level of commitment, participation, and attraction to a school environment (Fredericks, 2004). The sample consisted of 342 adolescents surveyed as part of longitudinal study called Childhood and Beyond (CAB) and measured outcomes in affective engagement and GPA, related to their level of involvement in music. Multiple regression analyses showed that students who played an instrument demonstrated significantly higher levels of affective engagement within school and had higher GPAs than students who did not participate in music. Students identified as having a "high music identity" earned higher GPAs than other music-involved peers. Both sets of findings, related to engagement and academic achievement, indicate that students who participate in music in school have positive school outcomes and suggest a case for arts in terms of enhancing students’ motivational relationship with school.

Relationship between autonomous university-life motivation and daily life skills in Japan
Norisaki Fukuzumi Tokyo Denki University, Japan; Shoji Yamaguchi
In this study, the Autonomous School-life Motivation Scale was developed in the framework of the organismic integration theory (Ryan & Deci, 2000). The relationship between Autonomous School-life Motivation for university students and Daily Life Skills was examined. Participants were 267 university students from the first to the fourth grades. They completed the Scale of Autonomous University-life Motivation in which we expected five subscales: amotivational reasons, external reasons, internalised reasons, identified reasons, and intrinsic reasons following previous studies and the scale of Daily Life Skills (Shimamoto & Ishii, 2006). Statistical Package for Social Science (SPSS version 14.0) has been used for the statistical analyses. Positive correlation coefficient was observed between intrinsic reasons and the total score of Daily Life Skills. Positive correlation coefficient was observed between identified reasons and the total score of Daily Life Skills. Negative correlation coefficient was observed between amotivational reasons and the total score of Daily Life Skills. These results suggest that there is a relationship between Autonomous University-life Motivation and Daily Life Skills in university students.

Learning environment of gifted primary school children in Lithuania
Sigitas Girdziunaskiene Vilnius University, Lithuania; Aida Simeliene; Grazina Gintliene
The purpose of this study was to explore environmental factors affecting achievement of gifted children using multi-informant approach and to examine home and school factors associated with the educational performance of gifted students. The concept of environmental catalysts as motivational aspect in talent development stems from Gagne’s theory of giftedness (2005) and is one of the structural elements in the Munich model of giftedness and talent (Heller, 2005). The sample consisted of 40 gifted primary school children aged 7–9 years identified using Raven’s Coloured Progressive Matrices (CPM) scores at 95 percentile and higher. The learning environment of gifted children was examined using reports from their teachers and parents and data were analysed in comparison with data about the home and school environment of classmates of gifted children. Teachers and parents reports revealed some positive and negative aspects influencing the learning situation of gifted children at school and their motivation to learn. The study also showed differences in parents and teachers reports concerning learning problems of children.

Initial ELT teacher training: Reflective teaching/learning: The case of the unknown language teaching
Ciro Gutierrez Asciano Universidad de Las Palmas de GC, Spain; Daniela Cecic
Teacher trainees should master their reflective and critical skills during their initial teaching practices, to support professional learning and development. Reflective teaching is an educational approach essential to raise the awareness of their roles as
teachers. It is not only about thinking about teaching, but also about the exploration of more critical underlying assumptions. An experiment was done at the University of Las Palmas with 25 students studying their last year of the degree in English Language and Literature just before starting their pre-service training. The main objective was to draw their attention to suitable strategies and approaches when teaching any foreign language, alongside reflecting about themselves as future teachers and as current language learners. The research consisted of teaching an unknown language for 90 minutes during 4 sessions, each of them taught using a different methodological framework. At the end of each session students had to answer an open-question questionnaire and reflect about their experiences in a journal. The data were analysed qualitatively and by identifying patterns and organising the answers into similar categories. In this paper, we will focus on the analysis of those questions related to the communicative teaching approach, paying special attention to the way the students perceived and evaluated the methodology and strategies presented to them. The results reveal that reflecting on your own learning process and observing others teach enhance considerably prospect teachers’ receptive competence.

Relationship between self-efficacy, self regulation and locus of control with educational achievement
Mohammad Hakami Islamic Azad University, Islamic Republic of Iran

The purpose of the present research was to investigate the relationship between self-efficacy, self regulation and locus of control with the educational achievement of 120 female junior high school students majoring in mathematics. The method of sampling was accidental clustering sampling. The students were from regions 2 and 10 of Tehran. The instrument for assessing student’s self-efficacy was the questionnaire of Jerryy-Jinarks and Morgan (MISES) with a reliability of 0.77; and for self-regulation it was the Martinez-pons questionnaire with a reliability of 0.71. The mean score of the 2nd year of school was used as educational achievement. To analyze the data, the descriptive statistics and inferential statistics methods (Pearson correlation, multiple regression, stepwise) were used. The results revealed that there was a positive significant relationship between self-efficacy, self-regulation, internal locus of control and educational achievement. However, there was no significant relationship between external locus of control and educational achievement.

Effects of Argumentation method and Argument stance on knowledge enquiry skills
Ruey-Yun Horng National Chiao Tung University, Taiwan, R.O.C.; Jiang Jyun-Hwong

Previous western research showed that personal responsibility for decision making can influence the degree of regret. However, in social-orientation Chinese society, children usually have to obey their parents for important decisions, such as choosing college majors. Therefore, children’s attribution to parent’s responsibility can alter children’s degrees of regret. The purpose of this research including three studies is to examine the effects and mechanisms of obedience or disobedience on regret. All the results of the pilot study (n=34; age=45) and 2 following studies (n=143,268; age=18,18) showed that to obey parents made participants more regretful than to disobey. Study 1 provided that sacrifice mediated the effects of obedience or disobedience on regret, and household economic status moderated the effects of sacrifice on regret. Study 2 revealed that responsibility attribution to parents mediated the effects of obedience or disobedience on regret, but responsibility attribution to self did not. Overall, these findings echoed the author’s expectations and showed that regrets in Chinese society are mostly associated with their significant others and “great self”.

Using S-HTP method to evaluate the effectiveness of environmental education: a longitudinal study
Miyoshi Isobe Minami Kyushu University, Japan

While concern about environmental problems increase, educators and practitioners around the globe are discovering a new appreciation of the importance of environmental education starting at the preschool level. Concomitantly, it is becoming even more important to assess the effectiveness of environmental education programmes designed for young children. The purpose of this research was to explore the validity of children’s drawings using the Synthetic-House-Tree-Person (S-HTP) method as one of the techniques for the evaluation of the impact of environmental education on preschool children’s psychology. The subjects of this study were twenty-one 5-year-old pre-school children who were asked to draw a picture of a house, a tree, and a person on an A4 sheet of paper by using a black pencil for 4 times over the academic year, once every two months. After a systematic examination of the drawings, it became clear that, despite the unskilful drawing expressions, 5-year-old-chil- dren recurrently express, in their drawings, recent experiences that were meaningful and that had an impact on them such as sleeping in a tent while camping, baking potatoes on bonfires, seeing a bird’s nest, etc. Moreover, it was also observed that these drawing expressions gradually become more refined over time. The next step in this research project is to compare drawings of children in different educational environments to further evaluate the validity of S-HTP method in assessing the impact of environmental education for children.

The impact of individual and external factors on academic achievement in early adolescence
Danilo Jagenow Free University Berlin, Germany; Frances Gottwald; Diana Raufelder

The most important factors for academic success are intellect, learning styles, achievement motivation and personality. Besides internal factors, external factors such as the quality of social relationships are essential for academic achievement. The current study examined different learner types concerning the interdependence between peer- and teacher-relationships, personality and achievement motivation in the context of academic success. The sample included 1089 students (53.9% girls, 46.1% boys) from the 8th grade (Mage=13.25 years) attending secondary schools in Berlin who answered questions about personality (FFPI) motivational achievement, social relationships and grades. Latent Class Analysis revealed different motivational types: (1) peer learner (36.3%), (2) teacher learner (10%), (3) peer and teacher learner (26.9%) and (4) independent learner (26.8%). Using multinomial logistic regression, it was found that the peer and teacher learner type scored higher on sociability than all other learner types. Additionally, this group also scored higher with regard to autonomy, in comparison with the peer and independent learner types. Moreover, the independent learner type showed higher emotional stability than the peer and teacher learner type, as well as the peer learner type. With respect to academic achievement the peer and teacher learner type had better grades than the independent learner type. The results suggest differences in academic achievement and personality between the four identified learner types, but no significant differences in academic success (grades). The awareness of differences in the interdependence of social relations, personality and academic achievement could help to improve students’ academic success.

Reconstructing the education system in Haiti: Building on new foundations
Chantale Jeanie Université Laval, Canada; Maître Mullier; Wilfrid Azare

In the aftermath of the 2010 earthquake that violently shook the country, Haiti is now working towards its reconstruction. The educational system, for one, is in
need of a new start. Many Haitians and international organizations such as Unicef, Oxfam, etc. agree that the educational system should undergo a major makeover. Bases for such major changes, however, cannot be imposed upon them regardless of Haiti’s culture and social system. This study explores the perceptions and opinions of Haiti’s professors and student teachers about the present situation, and the direction towards a better school system. Many studies have provided ideas about the dimensions that make up for teaching effectiveness or quality (e.g. Marsh, 1991; Seidel & Shavelson, 2007). Models usually vary from 2 to 9 dimensions, but it is difficult to predict which model will be appropriate in a specific context. Working from Chenski, Radid, Bekkali and Talbi (2010) and other works, the authors produced a list of teaching effectiveness related dimensions and submitted it to university professors and student teachers of a few Haitian universities. Based upon these dimensions, participants were asked to describe a “good teacher” and how competent they believe the Haitian educators to be on those dimensions. Results describe the structure of the questionnaire, the consensus and disagreement about quality of teaching and teachers’ competencies, as well as conceptions of what kind of improvements would be most beneficial to them. Consequences for teachers’ initial and continued training will be discussed.

Validation of an Haitian teacher efficacy scale

Chantale Jeanrie Université Laval, Canada; Maître Muller; Wilfrid Azare

The construct of teacher efficacy (TE), defined as teachers’ belief in their ability to organise, and execute, courses of action necessary to bring about desired results (Tschannen-Moran et al., 1998) has been shown to be related to many positive learning, and work, outcomes in students, such as performance and job satisfaction. Most research on TE, however, has been conducted in the Western World (Klaske et al., 2010). Results obtained in the US or in Eastern Europe may not generalise perfectly to educators from African or Caribbean countries, where teaching and learning conditions might be considerably different. The purpose of this research is to develop a teacher efficacy scale that is relevant to the Haitian reality, where one teacher’s initial training can vary from high school level to a university degree, and where basic pedagogical material is often lacking. It seems, therefore, essential to build a scale that will target the specific reality that Haitian teachers meet in their classrooms, since many teacher efficacy scales do not, indeed, meet the specific standards set by Bandura (Skalavik & Skalavik, 2010; Tschannen-Moran & Hoy, 2001). Interviews with local high school and university professors will be used to create items in line with self-efficacy theory, and with Bandura’s guidelines for developing a self-efficacy scale (Bandura, 2006). Factor structure will be analysed and both scales will be compared with those of other widely used TE questionnaires.

Primary school educators’ perceptions of emotional problems during middle childhood

Tamlynn Jefferis North-West University, South Africa

The aim of this study was to explore the perceptions of primary school educators regarding emotional problems in children, as well as their perceived role therein. In order to reach these aims, a qualitative exploratory research design was used, and focus group interviews were conducted with primary school educators from three urban schools in Gauteng, South Africa. The focus group interviews were transcribed verbatim, and the transcripts were analysed through thematic content analysis. Themes regarding educators’ perceptions include externalised and internalised behaviours, changes in children’s usual behaviour, the impact on school work, and physical or behavioural signs. In addition, the following themes emerged regarding the perceived role of educators in relation to emotional problems in children: educators identify emotional problems in children and love and support those children, they play an active role in the lives of children, and educators utilise resources to assist them with interventions. Participants in this study show insight into emotional problems in children, and are in need of extra support and resources from helping professionals such as counsellors, psychologists and social workers in order to intervene more effectively with children suffering from emotional difficulties.

Bruner’s concept Attainment Model of scholastic achievement as compared to conventional methods of teaching biology

Devaraj Kalaimathi Ladywillodingon Institute of Advanced Study in Education, India; Eun Yeon Objectives: (i) To study the effect of Bruner’s concept Attainment Model of scholastic achievement as compared to conventional methods of teaching biology in relation to intelligence, cognitive style and academic performance; (ii) To study the effect of Ausbel’s Advance Organiser Model of scholastic achievement regarding the same; and (iii) to study the relative effectiveness of Bruner’s Concept Attainment Model and Ausbel’s Advance Organiser Model. The sample consisted of 210 students of Class XI, enrolled in a government higher secondary school and government high school, divided into three groups (n=70 each), two experimental groups and one control group. Pre-test, post-test control group quasi-experimental design was employed. The statistical technique of three-way analysis of variance (3x2x2) was used on gain scores for finding out the main effect and interaction effect of teaching techniques. The experiment was conducted in three stages. It was found that there was a significant difference in effect among various teaching techniques, in the students’ learning concepts of biology.

Children’s understanding of internet traceability: A case study from Japan

Tetsushi Kamakura The University of Tokyo, Japan

One especially difficult area in Information ethics education for young children is education about the technical side of the Internet. According to previous research in concept learning, it is essential for effective education to clarify whether there are any unknown misconceptions supported by children’s daily experience. Hence, from the viewpoint of educational psychology, this study attempts to reveal children’s actual conditions of knowledge about traceability in cyberspace through semi-structured interviews. Sixteen Japanese sixth grade students with diverse characteristics were selected as interviewees according to their responses to a preliminary questionnaire. The interviews included five questions: about (1) daily Internet experience, (2) ten technical terms, (3) Internet traceability as common belief (No Context), (4) Internet traceability on a specific occasion (With Context), and (5) the sources of current thinking. After word for word transcription, card making was conducted consulting the K3-method (Kawakita, 1967; 1970) and qualitative analyses were repeated three times using these cards. As a result, firstly on the descriptive level, this study found eight components by which children’s actual understandings were adequately described and also found that the interrelation between these components can be visually represented by the triangle block model. Secondly, on the interpretative level, this study focuses on one characteristic concept commonly observed among the interviewees. This concept can be named the profile-only concept. Children who have this concept consider that deliberately disclosed online profiles are the only resource whereby users may be traced on the Internet.

Relationship between parenting style and exam anxiety among students in middle schools

Abolghasem Khoshkonesh University of Shahid Beheshti, Islamic Republic of Iran; Maryam Fakhri; Afzane Sadi

The purpose of the research was to determine the relationship between the parenting style and dimensions and exam anxiety in the in the middle school male and female students. A correlation method was used and the population consisted of all middle school students, male and female, of the city of Tehran. The samples were 60 students in middle school in Tehran (30 females and 30 male) that were selected using multi-step cluster sampling. Participants in this study responded to parenting style and dimensions questionnaire (PSDQ, 2001), and Philips exam anxiety scale (EAS, 1999). Results showed that there is a significant relationship between the authoritative dimension of parenting style and dimensions and the amount of the exam anxiety. The authoritative dimension of parenting style can give rise to the prediction of the amount of the exam anxiety more than other dimensions and parenting styles. Other dimensions make for less exam anxiety in students, because such students have the abilities of being independent and extraverted in this regard.

 Burning out during the practicum: The case of trainee teachers

Constantinos Kokkinos Democritus University of Thrace, Greece; George Stavropoulos; Aggeliki Davazoglou

The present study tests the whether student teachers experience burnout during the practicum and investigates the role of person and environment characteristics in the prediction of burnout dimensions. Data were obtained from a survey administered to 174 Greek student teachers at the beginning and at the end of a 4-week practicum. The questionnaire included measures of general and teacher self-efficacy, trait anxiety, epistemologies about knowledge acquisition, conceptions about teaching and learning, academic achievement, perceptions of the orga-
The moderating effects of the mathematics test emotion model
Yi-Mei Lee National Taipei University of Education, Taiwan, R.O.C.; Chiu-Ya Fang; Shiang-Liang Chen; Ten-C Shen; Shiu-Hsun Huang; H.C. Huang

How to help ESL students with low achievement to be interested, and to gain confidence, in learning English has bothered many teachers since English became part of the formal curriculum in Taiwan elementary schools in 2001. Therefore, the purpose of this study was to explore whether a shared-reading remedial programme could influence the students’ English learning, and which aspects would be influenced. Six seventh-graders were invited to join the programme because their English ability fell far behind that of other classmates. Levelled picture books were used in the programme, and the teacher combined phonics and reading strategies in the teaching process. The programme lasted for ten weeks, two hours each week. Qualitative data, such as interviews with the teacher and students, the students’ logs and worksheets, the teacher’s teaching journals, and the classroom observation records, were gathered and analysed to examine the students’ changes and the influences of the shared-reading programme. Before and after the remedial programme, three standard assessments were taken by the six students for triangulation. There were three main findings. Firstly, the students were very interested in reading English picture books, and had more confidence in learning English. Secondly, they enjoyed the programme and, over time, actively joined the discussions. Thirdly, they had better results in standard assessments and the school monthly tests in the end of the programme. Finally, reasons for the remarkable changes were explored.

Helping students learn English through a shared-reading programme
Yee-Mei Leou Tainan Institute of Nursing, Taiwan, R.O.C.; Chiu-Ya Fang; Shiang-Liang Chen; Ten-C Shen; Shiu-Hsun Huang; H.C. Huang

How to help ESL students with low achievement to be interested, and to gain confidence, in learning English has bothered many teachers since English became part of the formal curriculum in Taiwan elementary schools in 2001. Therefore, the purpose of this study was to explore whether a shared-reading remedial programme could influence the students’ English learning, and which aspects would be influenced. Six seventh-graders were invited to join the programme because their English ability fell far behind that of other classmates. Levelled picture books were used in the programme, and the teacher combined phonics and reading strategies in the teaching process. The programme lasted for ten weeks, two hours each week. Qualitative data, such as interviews with the teacher and students, the students’ logs and worksheets, the teacher’s teaching journals, and the classroom observation records, were gathered and analysed to examine the students’ changes and the influences of the shared-reading programme. Before and after the remedial programme, three standard assessments were taken by the six students for triangulation. There were three main findings. Firstly, the students were very interested in reading English picture books, and had more confidence in learning English. Secondly, they enjoyed the programme and, over time, actively joined the discussions. Thirdly, they had better results in standard assessments and the school monthly tests in the end of the programme. Finally, reasons for the remarkable changes were explored.

A research on the subjective well-being of college students based on the comparison of traditional method and the method of ecological momentary assessment
Dongmei Liang South China Normal University, China; Zhang Min-Quing; Xiao-Peng Li

The objective of the study is to tell the difference between the traditional Subjective Well-being scale and the EMA method in the SWB of college students. 36 Chinese college students were asked to participate in the measurement of SWB with the traditional Subjective Well-being scale and the EMA method. The results show that the SWB level is higher in the college students group and there is no difference between the genders. There is no difference in the average score of the students SWB in the first week but it makes a difference in the two weeks score. The EMA method illustrates that the results would be highly affected by mood swing, the most negative things and the end affect when students were asked to recall their SWB through some time. The results of SWB will be more accurate when the traditional Subject Well-being scale and the EMA method are integrated.

The integration of the drafting and instruction of teaching cases with teacher education curriculum
Pei-Yun Liu National Dong Hwa University, Taiwan, R.O.C.; Heng-Chang Liu

The combination of the case teaching method and teacher education curriculum will not only help a preservice teacher to think like a teacher, but also bridge the gap between teaching theory and practice. The authors try to integrate educational psychology with mathematics instruction. It demonstrates both the knowledge of educational psychology and pedagogical content knowledge of mathematics required to analyse a teaching unit. By applying theory to teaching objectives, teaching development, and teaching practice, our research finds that a teacher can actually improve his/her pedagogical content knowledge and professional knowledge. This research adopts the action research approach. The authors collected and analysed the reports and reflections written by 31 preservice teachers along with video and its verbal transcript of discussions of the teaching cases. Two evaluators independently categorised and interpreted the data utilising the constant comparative method and reached .87 rater consistency reliability. The authors
also triangulated data collected from different timing, sources, and methods to ensure the research reliability. This research concludes that preservice teachers participated in the discussion have gained better understanding on clarifying teaching objectives, arranging systematic teaching activities, and reflecting on application of educational psychology theory in subject curriculum design and instructional practice through expert teacher tacit knowledge scaffolding. However, the preservice teachers who lack teaching experience need more practical experience in addition to the discussion and reflection of teaching cases. Preservice teachers need to learn the expert teacher’s thinking and decision making knowledge in teaching to acquire personal teaching intelligence in the “teaching-reflection-teaching” dialectical process.

Promoting student centered-learning: How do third year psychology students experience an active learning curriculum? Errolyn Long UNISA, South Africa; Errolyn Long; Anthea Lesch; Jason van Niekerk; Jamil Khan

This paper presents the findings of a qualitative study on how third year psychology students experienced an active learning curriculum at Stellenbosch University. The aim of the study was to investigate how third year psychology students experienced an active learning curriculum. An additional aim of the study was to access students’ perceptions of the educative benefits and barriers of participating in such a curriculum. The curriculum included the following activities: pair-share-thinking, discussions, debates, a system of online tutorials, and a group problem-solving exercise. At the end of the module, all students were invited to participate in a focus group to speak about their experience of the curriculum. An independent facilitator, who was not from the same university, conducted two focus groups. Themes and sub-themes emerged from the data which seems to have provided an opportunity for further research. The findings revealed that students expressed frustration and difficulty when they used group work. The primary issues of concern with regard to class interaction were student indifference and reluctance to participate in activities. However, students reported benefiting greatly from the outcomes of the curriculum. Participants reported the lecturer to be supportive, whilst others felt there were high expectations requested from them. The findings of this study will therefore assist in the development and implementation of successful outcomes of this active learning curriculum. The limitations of this study includes sample size, and the demographics of Stellenbosch University are not the same as those of other countries.

Views of teachers regarding low achievement in the subject of English in Indian schools Vijay Malik Aastha College of Education, India; Rajender Yadav

English is a school subject in lower primary schools in many Indian states. But it poses challenges for teachers and learners resulting in low achievement of students. August, D. 2006; Calderon, M., 2011; U.S. Department of Education, 2009; and Rama Mangnathan, 2009, have conducted studies which are relevant. This study’s purpose is to know teachers’ views about low achievement of students in English at High School Level, with a random sample of 50 teachers from 15 High Schools of the Kurukshetra district of the Haryana State (India), through a descriptive survey method, using a questionnaire. The study revealed that 55% of teachers considered high pupil to teacher ratio as a factor of low achievement in English; and the lack of competent teachers of English was considered a reason by 68% teachers. 55% of teachers indicated a lack of audio-visual aids, while 22% of them viewed proper supervision and guidance as the issue. 45% Indicated proper checking/correction of homework; 35% lack of proper understanding of teaching methods; 48% a defective examination system; 45% illiteracy of parents; 58% ineffective in-service teacher training programmes; 47% irregular school attendance of the students; and 25% indicated miscellaneous other reasons as an explanation of low achievement in English. The study has implications for Educational Administrators, Teacher Trainers, Heads of School for organizing meaningful in-service teacher training/professional development programmes. Teachers of English can take note of the issues revealed by this research, and future researchers can find insight about research methodology, issues involved on the basis of results of the study.

Developing a reading strategy for grade II adolescents with varying abilities Di Terlizzi Marisa St Stithians Girls’ College, South Africa; Marisa Di Terlizzi; Helen Dunbar-Krige

Much research exists on teaching reading comprehension skills. Yet although teachers are aware that strategies need to be taught, there is little information available on how to teach these strategies to adolescent learners (Anderson & Roit, 1993 in Cantrell & Carter, 2009, p.196). Reading comprehension skills are usually taught in the foundation phase, leading to what Snow and Moje (2010, p.66) refer to as an ‘inoculation fallacy’ - a myth in education that by focusing on literacy instruction up until grade 3 the learner is "protected permanently against reading failure." These authors emphasise that reading instruction needs to continue into secondary school, and not be limited to the foundation phase (2010, p.66). Yet Biancoarosa and Snow (2004, p. 4 in Cantrell et al., 2009) suggest that little is known about the processes that adolescents use to comprehend text (Biancoarosa et al., 2009) during an important phase of schooling when "learning to read" becomes "reading to learn", (Stanovich in Vogt & Shearer, 2003, p.161). The authors decided to consider the question: "What is an appropriate reading intervention strategy for grade II adolescents to address reading comprehension difficulties and enhance overall reading proficiency?" This research question will be approached using an action research methodology to gather both quantitative and qualitative data from learners and teachers to inform future reading intervention programmes for adolescents.

Interpretation and effects of bullying among school going children in a rural school Sikhumbuzo Mfusi Walter Sisulu University, South Africa; Thami Ndllovu

Bullying is intentional, repeated hurtful acts, words, or other behaviour committed by a child or children against another child or other children. Such hurtful acts are a result of one or more individuals getting what they want through intimidation and domination toward someone who is perceived as being weaker. As a form of aggression among children bullying has detrimental consequences that can last for a long time. It also poses serious challenges to educators and everyone involved in the schooling system, given that the school environment is supposed to present children with an opportunity to negotiate and renegotiate relationships, self-image and independence. Because of its prevalence in South African schools and the difficulties associated with its conceptualisation, there appears to be a need to expand knowledge regarding its nature and effects on the victim. This paper does this by presenting the results of a study that was conducted in three rural Eastern Cape schools. Using a sample of thirty children from three different primary schools, the authors explored the children’s knowledge and experiences of bullying. Incidents of bullying reported by educators, and the perceived effects thereof were also coded. The analysis and results of the collected data are interpreted and discussed within the context of bullying and its effects on the victims.

REUSSITE: A multidimensional tool conceived to detect teenagers’ school difficulties Marie Noelle Monpie UPJL, France; Jean Wallet; Emilie Brard

This presentation refers to REUSSITE, a tool built by our research team to grasp the problems faced by 11-17 year old secondary students: using cognitive, psychosocial, and psycho-emotional aspects of teenagers’ school difficulties. Our tool measures learning process troubles caused by the gaps in basic school ability. Gesell, Vogtksy, Piaget, Zazzo et have shown that intellectual function development needs harmony and fundamental time and space guiding marks. We have found that, besides the teenagers’ desire to think and learn, there is a tendency for teenagers to gather information without establishing any link between the collected thoughts, which seem randomly interrupted in time and space. REUSSITE considers that teenagers are going through adolescence process, whereby they have to reorganise the relationship they have with their environment. The new relationships are based on the separation process (separation-individuation process of child development – Mahler & Blos) from the parental figures which in turn are synchronised by the establishment of other types of relationships with themselves and their pairs. As such, psychosocial and psycho-emotional adaptation mechanisms are called upon. 2500 teenagers from rural and urban areas of Picardie, France, participated in this pen and paper test lasting 50 minutes. Their potential difficulties have been identified through their responses to a scale measuring: verbal, numerical and abstract reasoning, different aspect of socialisation, quest of new distances (self and others), depression, ability to deal with conflicts, life project, body image.

A meta-analysis of research on the efficacy of life skills training programs on interpersonal relationships in Iran Azam Moradi Payame Noor University, Islamic Republic of Iran; Maryam Molavi; Razieh Fatahime

The purpose of this research was a meta-analysis of research on the efficacy of life skills training
programs on interpersonal relationships, and to investigate the effect of these programs on interpersonal relationships in Iran. Of the research that has been completed throughout Iran regarding the efficacy of life skills training programs on interpersonal relationships, 10 studies were selected according to their methodology and had inclusive criteria for meta-analysis. The results showed a 0.234 effect size for the efficacy of life skills training programs on interpersonal relationships. In conclusion, the results of this meta-analysis showed that in Iran, life skills training programs have a moderate effect on interpersonal relationships, which is similar in other countries.

The use of peer reflecting team practices to co-create meaning about student experiences of the MBChB II Course at Stellenbosch University

An-Maree Nel Stellenbosch University, South Africa

The second year of the MBChB course at Stellenbosch University is known to be challenging, as significant numbers of students fail in this year. The dominant discourse is that it is impossible to pass this year, while maintaining a balanced lifestyle, contributing to students’ despair, often leaving them feeling overwhelmed, anxious and demotivated. Weingarten (2010) conceptualises “reasonable hope” as the actions people take, with others, to make sense of what exists currently, in the belief that this prepares them for what lies ahead. She characterises “reasonable hope” as a relational practice that seeks goals, and routes to those goals, accommodates doubt and despair, and is grounded in the premise that the future is influenceable. Drawing from the work of Anderson (1987) and White (1999), peer-reflecting teams were facilitated in an attempt to co-create multiple descriptions of students’ experiences, challenge dominant discourses, create an empathic conversational space that makes room for the acknowledgement of fear and despair, and allow for new possibilities and meanings around student efficacy to emerge. Three reflecting teams, consisting of second and third year students, were facilitated in a classroom setting, utilising a tiered approach. Feedback from students indicated that this was useful to them, and they requested that we continue with this practice. This poster is a representation of how peer reflecting team practices can co-create conversation al spaces, that not only inspire a feeling of hope, but also constitute the “doing” of reasonable hope. This work is positioned within a social constructionist epistemology.

Effects of academic life events on motivation in the academic domain

Takuma Nishimura University of Tsukuba, Japan; Shigeo Sakurai

Self-determination theory proposed two types of motivation, autonomous, and controlled motivation. Autonomous motivation consists of intrinsic motivation and the type of extrinsic motivation with which people have identified an activity’s value. Controlled motivation comprises the type of extrinsic motivation in which people wish to obtain a reward and avoid shame. Many studies have shown that autonomous motivation leads to positive outcomes, while controlled motivation leads to negative outcomes. However, we have not completely understood how each type of motivation develops and changes. Therefore, we focused on the role of life events related to academic activities and investigated the relationship between these events and motivation. Japanese junior high school students (N = 486; 241 boys and 245 girls) participated in a survey, which contained the Japanese version of Autonomous Motivation Scale (AMS; Nishimura, Kawamura, & Sakurai, 2011) that measured the two types of motivation, Life Events Scale for Academic Domain (Nishimura, & Sakurai, 2011) that consists five factors: acquisition of future perspective, perception of academic support, achievement experience, failure experience, and acquisition of intrinsic value. A multiple regression analysis was conducted to investigate the effect of life events on motivations. The results indicated that autonomous motivation was enhanced by achievement experience, and acquisition of intrinsic value. Conversely, controlled motivation was enhanced by achievement and failure experience. We found that how to change motivation, and achievement experience, has a positive and negative effect that increases both types of motivation.

Negative expectation and the effects of affective forecasting

Masayo Noda Kinjo Gakuen University, Japan

This study empirically investigated affective forecasting on learning motivation for students expecting to achieve negative results, according to their motivational type. In the experiment, participants were assessed on their motivation for learning and asked to predict subsequent examination scores. Participants then imagined how they would feel if they were to receive more positive feedback on the examination than what they had predicted; finally, they were asked to respond to the motivation measure once more at the end of the experiment. Those participants expecting to achieve negative scores were selected based on their predicted examination scores. Analyses were performed on motivational type (2) x affective forecasting (2). A significant two-way interaction was revealed, and differences between the two motivational types were discovered. For highly motivated students, less self-determined motivation, such as extrinsic motivation, was highly influenced by affective forecasting and yielded lower motivational scores, while more self-determined motivation, such as identity-seeking motivation, was highly influenced by affective forecasting and yielded higher motivational scores. On the other hand, there were no clear effects of affective forecasting on motivation for less motivated students. The results demonstrated that the impact of affective forecasting on motivation is mediated by students’ motivational types, for those expecting to achieve negative results. In other words, the emotional response forecasts would increase learning motivation for students more motivated for learning, even if they expect a negative outcome for future achievement.

The effects of openness to diversity and ethnocultural empathy on institutional integration

Martin Nolasco Purdue University, United States of America; Ayse Ciftci

As college campuses across the United States experience growth in both diversity and the number of students enrolling each year, retention rates have not reflected this nor have they greatly improved over the last twenty five years (Barton, 2002). What is preventing more college students from persisting in academic institutions through to graduation? Institutional integration has been found to be a key component in student persistence through to graduation (Pittman & Richmond, 2007). Therefore, in this study, we propose to examine institutional integration in a group of economically disadvantaged college students at a university in the Midwestern United States of America. Based on the literature on suggesting the importance of openness to diversity and ethnocultural empathy on institutional integration (Fuertes, Sedlacek, Roger, & Mohr, 2000; Chang & Le, 2010; Le & Johansen, 2011), we will collect data using Miville-Guzman University-Diversity Scale - Short Form (M-GUDS-S; Fuertes et al., 2002), The Scale of Ethnocultural Empathy (SEE; Wang et al., 2003), and the Institutional Integration Scale (IIS; Pascarella & Terenzini, 1980). In light of the existing research, we ask what is the relationship between institutional integration, openness to diversity, and ethnocultural empathy? Using regression analyses, we expect that openness to diversity will influence institutional integration such that high levels of openness to diversity will predict higher institutional integration. Likewise, it is predicted that ethnocultural empathy will influence institutional integration such that high levels of ethnocultural empathy will predict higher institutional integration. Possible implications will also be discussed.

Parents’ and children’s perceptions and reactions towards cyberbullying

Dorit Olenik Shemesh The Open University of Israel, Israel; Tal Heiman

Cyberbullying (CB) refers to bullying harassment of others by means of new electronic technologies such as the Internet, cell phones etc. (Smith et al., 2008). Recent studies have found that more and more children are confronted with this ‘new face’ of bullying and that CB affects emotional, behavioural and social aspects in children lives (Dehue et al., 2008), while parents have a critical role in tackling CB. The current study examined adolescents’ and parents’ perceptions as well as reactions towards CB. The study comprised 2 samples: 1) 93 parents (mean: parent age = 44.6, S.D. = 5.7), 2) 28 pairs of parent/child (56 participants) (mean: parent age = 31.7, S.D. = 4.2) (mean: child age = 10.42, S. D. = 1.19). All participants completed questionnaires regarding Cyber-victimisation, Cyber-perpetration, emotional and behavioural reactions. Findings of the parents group (sample 1) revealed that 9.5% of the parents reported knowing that their child was a cyber-victim, 12.5% reported that their child was a witness to CB, and none of them reported their child’s perpetration. Parents viewed CB as causing intensification of other problems, while parents have a critical role in addressing CB. The current study examined adolescents’ and parents’ perceptions as well as reactions towards CB.
Evaluation, planning and exhibits design in museums: the Spanish experience. 
Eloisa Perez-Santos Complutense University Madrid, Spain 
Permanent Laboratory of Museums for the Public is an ongoing research, training, communication and dissemination project about state museums in Spain carried out for the Spanish Ministry of Culture. The investigations carried out by the Laboratory include evaluation of exhibits. The evaluation of Farnesiana by Orient Exhibition (Dec 2009-Oct 2010) is the first example of a complete evaluation carried out in Spain. The model of Evaluation and Development of Exhibitions Process implies three forms of evaluation (front-end, formative and summative) integrated from the early stages of development exhibition, design and production. The front-end evaluation was made in the planning phase, in order to explore the interests, knowledge levels and misconceptions of the potential public on the topic raised. Formative evaluation was conducted during the design phase, to get information about some elements and methods to present especially problematic museographic topics. Summative evaluation investigated visitor changes (learning, attitudes, subjective image, and previous errors) as a result of the exhibition. The data collected in the front-end evaluation showed the iconic and semantic mental map of the visitors that was used for structuring the exhibition discourse on mental images, expectations, and knowledge. Formative evaluation revealed information about the attraction power of the texts and the communication and comprehension level of the titles. Finally, summative evaluation allowed knowing the exhibition effectiveness: increased knowledge, and elimination of erroneous preconceptions. Results revealed the degree of understanding and satisfaction with the global visit experience which was much higher than in other occasions.

Students serving humanity: Working adult undergraduates’ interest in service learning 
Lindsay Phillips Albright College, United States of America 
This presentation focuses on incorporating service learning activities in the teaching of working adult undergraduate students. Service learning is defined as ‘a teaching and learning strategy that integrates meaningful community service with instruction and reflection to enrich the learning experience, teach civic responsibility, and strengthen communities’ (servicelearning.org). 35 adult students (ranging in age from 27 to 61) participated in a mixed methods (quantitative and qualitative) survey. The survey assessed volunteer experience, interest in specific types of service learning, and sought qualitative information on how instructors could incorporate activities while also being sensitive to the schedules of adult students. Participants also completed the Volunteer Motivation Inventory (Emson & Dunlop, 2004). The majority of participants (71%) reported that they were interested in service learning activities in general, and that rate increased to 86% if a service learning activity replaced a course requirement, such as a paper or examination. Per qualitative responses, about half of the respondents prefer to volunteer on their own, while the other half believed that service learning opportunities should be increased. Participants interested in service learning discussed the importance of local opportunities, and in particular, opportunities that do not conflict with work schedules. I will address limitations of this survey, including the limitation that students who completed a voluntary survey might be more receptive to service learning than the average student. I will present a review of responses and implications to assist psychologists who teach adult undergraduate students.

Guidelines to address barriers to learning in senior secondary schools 
Christo Pienaar NMMU, South Africa; Marius Botha 
The aim of this research was to establish guidelines for teachers and parents to address all the Barriers to learning that learners face in Senior Secondary schools. The interpretative qualitative research method was employed. Data was collected through semi-structured interviews with 20 teachers in Port Elizabeth. Transcribed text were analysed by Tech’s ‘8 steps for the determining of common themes and Sub-themes’. The theoretical framework was based on Bronfenbrenner’s systemic theory of child development. This study shows how interrelated systems influence learning and why a holistic systemic approach to learner support is necessary. The findings of the study indicate that teachers need support in order to enable them to support all their learners, but that all systems has a part to play. Recommendations regarding learner support were made for the micro-, meso- and macro systems. The study makes a contribution towards a systemic approach to learner support, which becomes more and more important as the implementation of Inclusive Education rolls out.

Congruency of identity style, emotional intelligence and self-efficacy as predictors of marital adjustment 
Fariba Pourjali Payamnoor University, Islamic Republic of Iran 
The study seeks to explain the interactive and relative effects of congruency of identity style, emotional intelligence and self-efficacy on marital adjustment. It made use of simple random sampling in selecting 55 married couples (110 men and women). The study sample responded to four valid and reliable instruments. The Identity Style Inventory (ISI), Emotional Intelligence Scale (EIS), General perceived self-efficacy scale (GSE) and the Marital Satisfaction Scale (EMS). Data analysis involved the use of Pearson correlation and multiple regression procedure to investigate the predictive capacity of the independent variables on the dependent variable. The results indicated that the four independent variables, when taken together, were effective in predicting marital adjustment. Each of the variables contributed significantly to the prediction of marital adjustment. On the basis of this finding, it is suggested that congruency of identity style, emotional intelligence programming and self-efficacy intervention techniques will benefit teachers immensely in marital adjustment.

Fighting a homogeneous logic: Reflections on teacher training able to support diversified work with learners 
Vivian Carla Bohm Rachman PUC-SP; Brazil; Claudia Davis 
This study aims to develop cooperative research in a Brazilian school, in order to construct a modality for teacher training that promotes the use of diversified teaching strategies for students with different knowledge and experiences. Guided by the assumptions of Socio-Historical Psychology and Historical-Critical Pedagogy, it starts by identifying the main needs of the school and the key aspects of its culture. Then, the teacher who had the greatest difficulties in teaching 9-year-old students was selected and monitored for one semester, during which she was helped to plan, carry out and evaluate the activities she employed to teach her students. At the end of each of these cycles, there were discussions about her advances and difficulties, which were shared with other schoolteachers. The research procedures involved understanding how the teacher planned lessons and taught them, helping her to improve planning and teaching, and then analysing how she performed those aspects of teaching without help, identifying how she had advanced in relation to her starting point. All the activities undertaken by the teacher were followed by a discussion. This allowed her to think about what she did and what she could have done, conceiving new ways of planning and executing diversified teaching activities. Preliminary results indicate changes in the way the teacher assesses and conducts her pedagogical practices, as well as benefits for the remaining teachers, allowing them to enrich the teaching-learning process.

Psychological features of ethnic consciousness in the conditions of family education 
Zhanat Sarybekova Eurasian National University, Kazakhstan 
The objective was to research the psychological features of ethnic consciousness in family education among Kazakh teenagers. The method “Who am I?” (M.Kun, T.Maripartlend); method of personal self-appraisal research (S.A.Budassi) and questionnaire “Features of ethnic consciousness in the conditions of family education.” Development of ethnic consciousness in teenagers is caused by features of the intra-family relationship. The features of ethnic consciousness of teenagers depending on style of education, and a national identity was revealed as a result of this research. Intra-family relationships in Kazakh families are filled by ethnic traditions and customs to a greater degree, than in Russian families. In the Kazakh family more attention is given to acquiring a national identity, both national traditions and customs (the Kazakh family - 75, %, Russian-48 %). Kazakh and Russian families differ on such parameters, as quantitative structure of a family, domination, psychological atmosphere of a family and perception of a family’s members, types of hierarchy of ‘power-submission,’ style of education and acquaintance of the child to its national identity.

The impact of social support on task choice and performance in task conflict situations 
Jongho Shin Seoul National University, Korea, Republic of; Jaehee Choi; Myungsop Kim; Eunha Kim; Kyung Eun Kim; Eunkyoung Chung; You-kyoung Lee; Sangin Shin; Eun Byul Cho; Sungjo Jin; Eun Yeon 
The purpose of this study was to examine the effects of social support on task choice and performance in a
goal conflict situation where "have to" and "want to" goals were both presented at the same time. Based on the goal conflict researches that students are more likely to choose what they want to do over what they have to do and the need for a proper intervention to lead students to choose what they have to do first, we hypothesised that social support will help students choose what they have to do first as well as increase their performances. For this study, students from kindergarten and elementary school were divided into four groups: The informative support and support from adults group, the informative support and support from peers group, the informative support only group, and the no support group. All students were presented with a contrived conflict, for example, students in elementary school were asked to choose between playing a computer game ("want to") or engaging in a less interesting creative story writing assignment based on given pictures ("have to").

The overall experimental results showed group differences: Students from the no support group showed a significant lower frequency in selecting first the "have to" task over the "want to" compared to the students who received social supports. However, the performances of the students did not show any group differences. These findings suggest that social support in conflict situations of "have to" versus "want to" increases motivation in learning.

Problems of adolescent students of Indian senior secondary schools
Rajender Singh Kurukshetra University, India
Adolescence is most crucial and full of stress and strain with many problems. A descriptive survey method was used, and the sample of this study consisted of 100 adolescent students from four senior secondary schools (25 students each of those schools) of Raedi-nagri, Haryana, India. A questionnaire was used. After seeking permission from concerned School Authorities, data was collected through administering the questionnaire. In context of research questions, the study indicated that 57% of adolescents considered their parents careless about their needs; 51% viewed parents’ vigil on their family activities as problematic; 55% opined that their parents were restricting for their friends circle; 60% that they were not giving them freedom to do work; 70% were scared of their teachers without any cause; 58% had hesitation in sharing difficulties with teachers; 56% were worried about the future; 50% did not feel free while attending social functions; 59% hesitated to meet people; 58% felt shy due to poor economic conditions of their family; 53% were scared of getting married; and 50% opined that their classmates were making fun of them. The study therefore has implications for teachers who can provide sex education through indirect methods, while still transferring curriculum content. The study also has implications for further research in adolescent education.

Exploring challenges and needs of students with visual and physical disabilities in higher education
Nolwazi Somtezewu UNISA, South Africa; Lazarus Mgqana; Rossano Wells; Amidevi Reddy
People living with disabilities in South Africa are amongst the designated groups that require empowerment to effectively participate and contribute positively to both the regional and national economy. Tertiary education seems to be the most significant socio-economic empowerment tool that could be used to empower members of this designated group. As an ODL institution that commits to advancing social justice and aims at creating an enabling environment, UNISA promotes student access and success for persons with disabilities. The aim was to explore the challenges and needs of students with visual and physical disabilities at UNISA Kwa-Zulu Natal. Focus group interviews were used to collect qualitative data and emerging themes were extracted using thematic analysis. The study revealed that cost, flexibility, admission criteria, and specialised support services for students with disabilities, were the main reason for students selecting UNISA as higher education institution of choice. However, there were definite challenges for both groups relating to access and use of resources as well as attitudinal barriers. Implications for interventions, especially with regard to advocacy, awareness training and inclusive consultation processes are discussed.

The indicators for evaluating teachers’ quality in mainland China and Taiwan
Hechuan Sun Shenyang Normal University, China
The enhancement of teachers’ quality requires effective teacher evaluation. Effective teacher evaluation requires scientific, measurable, achievable, realistic and applicable evaluation indicators. In order to find out such indicators, this study has conducted both qualitative and quantitative research on the current existing indicators used by the governments for evaluating teachers’ quality in mainland China and in Taiwan. In the qualitative research part, indicators at three different levels for evaluating teachers’ quality in Taiwan and Mainland China were carefully compared. In the empirical research part, based on the findings of the first three parts, questionnaires were developed. 1157 copies of questionnaires were distributed to teachers, school administrators and headteachers in primary and secondary schools in 11 areas of Liaoning Province of China. The number of valid feedback copies of the questionnaires was 806.

Then, SPSS11.5, EXCEL and factor analysis were used to analyse the valid feedback data. Based on the data analysis, three conclusions were drawn. First, almost all of the indicators for evaluating teachers in Taiwan were accepted by mainland respondents. Second, the feedback viewpoints on “what formulated appropriate teaching plans” and “mastery of professional knowledge on teaching subjects” showed significant differences between teachers from urban schools and from rural schools. The rural school teachers paid much more attention to “teaching plans and the subject knowledge of teaching”. Third, the viewpoints on “communication and cooperation with parents” have shown significant difference due to respondents from different types of schools.

Children’s coping strategies in response to different types of school bullying
Suresh Sundaram Annamalai University, India
School bullying is a complex challenge for the entire community. It has serious consequences, not only for victims and perpetrators, but for the entire school. Addressing bullying is crucial in schools and in the classroom. There are only a few studies which have examined the relationship between bullying behaviour and coping strategies in the Indian context. Hence, an attempt was made to investigate the relationship between the same. The sample was made up of 400 students aged 11–15 years. All of the students were seventh to ninth graders. The Olweus Bully/Victim Questionnaire and Children’s Coping Strategies Checklist were used to collect the data. The findings of this study reveal that children’s coping strategies differ, not only according to the level of bullying, but also according to their age and gender. This study concludes that specific coping strategies of children can be raised to overcome victimisation.

Relationship between values of a test and the method of conducting a test
Masayuki Suzuki The University of Tokyo, Japan
A test may negatively affect the learning motivation and strategies of students (Gipps, 1994), and thus it is important to analyse the procedure of conducting a test effectively. In recent years, researchers have
examined students’ perspectives on testing and showed that students’ views of the test’s value are related to their learning motivation and strategies (Hong & Peng, 2008). For example, Suzuki (2011) defined values of a test as the students’ perception of the test’s purpose and role, and suggested that while conducting a test, teachers should emphasise the purpose as improvement or pacemaker. However, previous research has not substantiated how values of a test are formed. The present study investigates the relationship between values of a test and the method of conducting a test. We focus on teachers’ approach to informed assessment and the contents of a test as the method of conducting a test. Teachers’ approach to informed assessment is to inform students about the test’s purpose and grading standards (Murayama, 2006). Data were collected from 1357 students from six junior-high schools and four high schools using a self-reported questionnaire. We conducted multilevel analysis, and the results showed that informed assessment and contents of a test had an important role in forming its value. Hence, it is essential for teachers to inform students about the test’s purpose and grading standards and introduce practical tasks in tests.

Active procrastination, passive procrastination and task-related beliefs in academic settings
Eri Takizawa Gakushuin University, Japan

Recently, a positive aspect of procrastination was researched by several studies. According to Chuk-Choi (2005), passive procrastination is a traditional, negative style of procrastination and active procrastination is an effective style and not considered to be related to negative outcomes. The aim of this research was to examine effects of two trait procrastination and task-related beliefs (self-efficacy, intrinsic value, and perceived cost) on actual procrastination and academic settings. The participants were 85 undergraduates in Tokyo. They were asked to fill out questionnaires on trait procrastination and task-related beliefs and assigned an essay task as homework. The dates on which they started and submitted the task were recorded. From the results of hierarchical multiple-regression analysis, several interactions between trait procrastination and task-related beliefs were significant. The interactions indicated that (1) if students in high passive procrastination have high intrinsic value on the task, the number of days passed before they started the task was about the same as that of students in low passive procrastination and (2) if students in high active procrastination perceive high cost of the task, the number of days passed before they started the task was smaller than that of students who perceive low cost, but concerning students in low active procrastination, the relationship between perceived cost and the number of days was opposite. As a whole, the results suggest that the relationship between each trait procrastination and actual procrastination behaviour is differently mediated by task-related beliefs.

The interactive effect of mastery and performance goals on temporal comparison
Masaru Tokuoka Hiroshima University, Japan; Kenichi Maeda

Achievement goal theory postulates that competence of mastery goals is defined as intrapersonal standard, whereas competence of performance goals is defined as interpersonal standard (Elliot & McGregor, 2001). Contrary to this notion, Daron, Dompnier, Gilliéron, and Butera (2010) demonstrated that not only performance goals but also mastery goals related to social comparison orientation. The results indicated that mastery goals associated not only intrapersonal standards but also interpersonal standards. In line with the results, it is hypothesised that performance goals also are associated with both standards. The purpose of present study was to examine relation between temporal comparison and achievement goals. Temporal comparison is the comparison about the same individual comparing him/herself at two different points in time (Albert, 1977). Japanese university students completed a self-report survey assessing their personal achievement goals (i.e., mastery-approach goals, mastery-avoidance goals, performance-approach goals, and performance-avoidance goals) in English courses and their temporal comparison orientation (TCO). Multiple regression analysis showed that interaction between mastery-approach goals and performance-approach goals were significantly associated with students’ TCO. The interaction indicated that the lower mastery-approach goals endorse, the stronger the link between performance-approach goals and TCO. Results were discussed in terms of definition of competences of mastery goals and performance goals.

Bullies and victims at public secondary schools: The educators’ perspective
Reyagalaletsa Tom University of Venda, South Africa; Pilot Mudhozovi

Bullying is widespread and perhaps the most under-reported safety problem in public schools. It occurs more often at school than on the way to and from there. As schools continue to address the problem of bullying and its consequences, an understanding of the perpetrators of bullying and their victims is important for creating successful prevention and intervention strategies. The study sought to understand bullies and victims from the perspective of educators at public schools. An exploratory design was employed. Eight participants were purposefully sampled for the study. Semi-structured interviews were conducted with the participants. Phenomenological explanation was used to analyse data. It emerged from the study that bullying is prevalent in public schools. There are diverse factors associated with both bullies and victims. There is need for early identification of learners who are likely to engage in bullying as well as those likely to be victimised by their peers.

Utilising socio-drama to develop sensory integration in adolescents who present with mild cognitive impairments
Talita Veldsman University of Johannesburg, South Africa

Why do some people learn more effectively than others? Why do certain children present with behavioural difficulties, even though they come from stable, and loving, home environments? The process of sensory integration allows us to handle tasks of everyday living, but also to read messages within our environment, and to respond appropriately. If we struggle to integrate these messages through our senses, we often find it difficult to learn, behave and socialise with ease. The PhD study is aimed at developing sensory integration skills with a group of adolescents in a school for children with mild learning impairments, through the use of socio-drama. The study is embedded within the mixed methods design, and takes place within a positive psychology and constructivist framework. It derives from various theories such as a culture of creativity, developmental theories, and theory of sensory capital.

Demands coming from family diversity: Perspective of elementary school teachers
Adriana Wagner UFGRS, Brazil; Patricia Scheeren; Lisiane Saroiva

The school has been a stage of an increasing number of demands coming from the family diversity. In search of understanding these demands, this study presents the view that primary teachers have about what the family requires from the school, when it comes to educating their children, and the actions they undertake to deal with these requirements. It was conducted in a focus group with 10 teachers from public and private schools in Porto Alegre, Brazil, with ages between 26 and 53 years. All of them were college graduated and their professional experience ranged from 4 to 24 years. Data analysis resulted in two axes themes - Demands and Actions to face demands - which were organised in different categories in the Demands axis, which deals specifically with the needs that families show for the teachers, the following categories were found: limits, organisation outside school daily life, perpetuation of dependency as opposed to autonomy, counselling and inclusion. Regarding the axis Actions to face demands, that deals with the ways school adapts to respond to family needs, the categories were: intra-school actions, which means that these actions are consistently taken from all the staff and sectors of the school, and individual actions, undertaken only by teachers. Data revealed that teachers receive very complex demands of their students’ families and these, sometimes, go beyond the boundaries of the school. Thus, the effectiveness of their actions is questioned by the families, because teachers are not always available or prepared to deal with such demands.

Relation of faculty characteristics to their role expectation
Hung-Che Wang National Dong Hwa University, Taiwan, R.O.C; Te-Sheng Chang

Expectations can influence employees’ motivation and performance (Hardré & Cox, 2009). The major purpose of this study was to identify role expectation by examining a nationwide sample of 27,283 professors from 163 universities in Taiwan. This study employed the method of an questionnaire survey that consisted of 6 dimensions. This study investigated the relationship between faculty role expectation and their characteristics (gender, discipline, rank, and public/private institutions) by descriptive statistics, independent t test, and one-way ANOVA. The results showed that the order of mean scores in faculty’s role expectation is as follows: Supporting students, teaching courses, advancing social development, doing research, promoting social justice,
and building their own institute’s reputation. The private faculty gave a higher score on promoting social justice than their public counterparts. Male teachers had higher expectation scores than the female faculty on doing research and building their own institute’s reputation. Faculty in humanities indicated the highest expectation level on supporting students, teaching courses, bringing about social development, and promoting social justice. Full professors expressed a higher expectation on enhancing social development, doing research, and promoting their own institute’s reputation than others. Previous research (Devries & David, 1972) found that university faculty were more concerned with their research performance than other responsibilities. The paper found results different from the findings of previous research. Implications for university faculty, university management, and the field of role expectation are discussed.

A 6-year tracing experiment on Chinese non-English major postgraduates’ recognition of 100 commonly used English sentences
Hongli Wang Guizhou Normal University, China; Hong Liu; Jinghua Li; Jing Luo
The Natural Numeral Marvelous Imagery Memory (NNMIM) was invented in 1985 by Wang Hong-li, professor of Guizhou normal university of China. Two experiments using NNMIM were conducted in 2005. A six-year tracing experiment based on previous experiments was undertaken in which five postgraduate students (volunteers) in psychology major were subjects. During the experiment, subjects’ memory effects were tested 16 times by recalling, and only the items (sentences) failed to recall would be memorised again. The result of experiment indicates that: (1) The postgraduates who applied the ‘Method by Memorising the Concrete Objects Associated with the Shapes of Arabic Numeral’ to Produce Marvelous Imagination (MMCOASAPM) of the NNMIM to memorise and recall the 100 commonly used English sentences, could recite them well in sequence backward, forward, and randomly. The average reaction time of reciting sentences randomly is less than 2 seconds. (2) It can transform the materials of the short-term memory into long-term memory quickly, and effectively prevent them from the interference of proactive and retroactive inhibition, so it’s useful for keeping memorised information in six years. The retention rate ranged from 72% to 100%, and its retention curve is widely different from Ebbinghaus’s forgetting curve. (3) With the materials in strong sequence, large quantities and the hardness to memorise, it’s an effective method for memorising them. So, it’s a special and efficient method which is worthy of being recommended widely in learning English. (4) The keys to improve the memory efficiency are the well-storing skills of memory, storing methods, and memory cues.

Exploration of trans-disciplinary service model in the South African context
Welma Wehmeyer South Africa
The aim of this study is to investigate trans-disciplinary assessment and intervention as an effective service model for the treatment of learning barriers within the South African inclusive education system. The need for this study was born from my experience as an Educational Psychologist in private practice, working in the field of learning barriers. I often encounter parents, teachers and healthcare professionals who are frustrated and disillusioned with the intervention process due to lack of professional cohesion and integration of treatment goals. Children who experience barriers to learning require assessment and intervention from multiple professionals with different areas of expertise. Independent assessment by various professionals results in fragmented views of the problem and consequently incoherent therapeutic intervention. A need exists for effective collaboration in which a single coherent assessment can emerge and be translated into a single, comprehensive set of intervention recommendations. Trans-disciplinary assessments and intervention are conducted as part of a qualitative descriptive research design. Results will be used to evaluate the effectiveness of this service model for the South African education context.

Curriculum practice: The fusion of modern and post-modern perspective
Zhimin Wu Jiangxi Normal University, China
This paper reviews modern and post-modern perspective on the curriculum, comparing between the two. In the light of the difficult problem of implementation about the post-modern curriculum, post-modern psychotherapy techniques are applied to post-modern perspective on curriculum practice. The innovation is the introduction of an intermediate variable FNPM (Solution focused brief therapy, Narrative therapy, Performing therapy and music) as a binder, to successfully promote the organic integration between two perspectives on the curriculum. In the course of the teaching of evolutionary psychology as an example, the fusion provides workable technical steps or procedures. The results show that the course is more open, rich and diverse; there are more interactive and dialogic between students and teachers; teaching language and situation is more supportive and critical; students study easily.

Session Type: Invited Addresses
The power of the gender-math stereotype: Far beyond expectations
Pascal Huguet Aix-Marseille Université, France
Performance situations where a negative stereotype about ones group applies can prove self-threating. This predicament, called stereotype threat (ST), is especially likely in individuals who excel in and are highly identified with the stereotyped domain. Where bad stereotypes apply (e.g., women and math), members of these groups can fear being reduced to those stereotypes, which may ironically lead to underperformance and stereotype confirmation. Here, we offer evidence that even middle-school girls show a performance deficit in ordinary classroom circumstances when they simply come to believe that the task at hand measures math skills. ST also operates in girls who explicitly deny the gender-math stereotype, suggesting that those who succeed in math do so in spite of a real obstacle. Likewise, our recent results with graduate women at the top of math-science-engineering education indicate that those outstanding models may themselves suffer from ST. Taken together, these findings show how problematic the gender-math stereotype can be for females throughout their academic life, and thus contradict the view that this stereotype is no longer operating in our modern world.

Literacy and multilingualistic skills: A challenge for education in Latin America
Maria-Regina Maluf PUCSP, Brazil; Bruno Viviscorsi; Pascale Planché; Evelyn Clement; Bruno Villette
Research in educational psychology in Latin American countries is currently carried out within a huge framework of diversity. Despite these differences among countries, literacy can be seen as a path to social equality and progress in Latin America. The cognitive psychology of reading made important advances in the last 40 years, and currently encompasses its own features as a theoretical, research and teaching approach. This presentation embraces this theoretical/methodological approach which investigates the mental mechanisms implied in reading and writing learning. We will present the results of experimental training research. This research provided evidence that every child can learn how to read and write at school and can also overcome learning handicaps provided that teaching methods include metalinguistic skills training. This approach may be particularly useful among socially vulnerable children who have no stimulating reading or writing experiences in their everyday life.

Rethinking the theory and practice of bilinguial education: Challenges from linguistically diverse societies
Ajit Mohanty Jawaharlal Nehru University, India
The key concepts underlying bilingual education (BE) are interrogated in view of the inadequate extension of its theory and principles to diverse contexts. As BE gets increasingly deciphered in linguistically complex societies going beyond the dominant monolingual myopia, neutrality of the concepts underlying BE (such as ‘language immersion’) have to be questioned (Skutnabb-Kangas & McCarty, 2008) and purportedly powerful explanatory tools in the field like ‘balanced bilinguialism’, Cognitive Academic Language Proficieney (CALP) based cross-linguistic transfer and categorical distinctions between monolingual, bilingual and multilingual proficiency found to be grossly inadequate with emerging insights from multilingual societies as in Asia and Africa. Recent programs of mother tongue based multilingual education for indigenous/tribal children in India (Mohanty & Panda, 2010; Panda & Mohanty, 2009), Nepal (Hough, Magar, & Yonjan-Tamang, 2009) and many other countries (Mohanty, Panda, Phillipson, & Skutnabb-Kangas, 2009) underscore the need for alternate views of the pedagogic principles for effective MLE. Intervention strategies in our MLE Plus program for tribal MT children in Orissa, India will be discussed to demonstrate that innovative pedagogic practices founded on children’s cultural knowledge and community engagement in oracy and literacy activities bring a new perspective to understanding the principles underlying MLE for children in diverse societies. It is argued that effective classroom learning and development of multilingual proficiency in programs of MLE must go beyond the limitations of the theory and practice of BE and also cease to be promoted as
From misperception to mobilisation: Re-thinking the paradigm of prejudice
Stephen Reicher
South Africa
Since Gordon Allport’s seminal study of ‘The Nature of Prejudice,’ antipathy to members of other groups has been understood as a matter of misperception rooted either in individual dispositions, universal cognitive biases, or else specific intergroup contexts. In this talk I shall argue that such an approach ignores the way that our understandings are shaped by the many voices urging us to respond to other groups in different ways. Our views derive less from processes of passive contemplation than of active mobilisation. I then sketch out the very different questions and answers that derive from a ‘mobilisation’ approach to intergroup antipathy. First, why do elites seek to mobilise prejudice? Second, how do elites mobilise prejudice? Third, when is prejudice successfully mobilised. Such an approach brings together studies of elites and of masses, of leadership and of collective understanding. I shall illustrate the approach with evidence drawn from multiple studies in many different countries. Since Gordon Allport’s seminal study of ‘The Nature of Prejudice,’ antipathy to members of other groups has been understood as a matter of misperception rooted either in individual dispositions, universal cognitive biases, or else specific intergroup contexts. Session Type: Invited Symposium

Symposium title: PANEL: Competence as a common language for professional identity and international recognition: Can the current models of competence be integrated and accepted as a means of addressing current global challenges?
Convenor: Dave Bartram

Competence as a common language for professional identity and international recognition: Can the current models of competence be integrated and accepted as a means of addressing current global challenges?
Dave Bartram
SHL Group Ltd, United Kingdom
The discussion will provide an opportunity for the panel to comment on the papers presented in the preceding two symposia and to address the issues arising from them in terms of the potential for international agreement on psychologists competences. The panel will be asked to comment on the following questions: What are the global challenges we are typing to address? Is it possible to agree on a globally acceptable model of the competencies required of practitioner psychologists? Would such a model be a meta-model onto which others can be mapped or one intended to replace existing national models? Has enough work been done nationally and internationally to be able to specify such a model or meta-model? Is it practical to consider some form of certification or registration at an international level? The Chair will invite questions and comments from the audience.

Symposium title: PANEL: Contextualising Psychology in South Africa: A vision of serving humanity through a meaningful regulatory framework
Convenor: Tholene Sodi

Contextualising psychology in South Africa: A vision of serving humanity through a meaningful regulatory framework
Tholene Sodi
South Africa
The purpose of the panel discussion is to engage with the audience on the Professional Board for Psychology’s role, functions and strategy. In the process the Boards role in the profession will be demarcated and re-emphasised. The philosophy of the Board that informs the proposed new Scope of the Profession and Scope of Practice regulations will be conveyed. This will inform further discussions on the suggested guidelines for implementation, the alignment of education and training, and registration categories and registers. Time will also be devoted to a discussion on current challenges faced by the profession of psychology in South Africa. The first of these relate to the role of psychology in meeting the needs of the greater South African population through, among others, the expansion of the deployment of registered counsellors and job allocation for these practitioners. Other challenges to be addressed are: the Boards administration, Board examinations, the role of the psychometrist in psychology in South Africa, revision of the code of ethics, a national test classification and accreditation framework, and the timing of the commencement of internships.

Symposium title: PANEL: Indigenous research for enriching education and training of psychologists
Convenor: Janak Pandey

Indigenous research for enriching education and training of psychologists
Janak Pandey
Central University of Bihar, India
The last quarter of the 20th Century witnessed questioning of universal nature of psychological science leading to acceptance of limitations of dominated US-European psychology. The notion of unity of science and universal generalizations was considered as myth. Scientific generalizations can only be context specific. The cultural traditions socio-economic-political realities across societies are more varied than alike and therefore and knowledge of psychological phenomena must necessarily be social constructed leading to plurality in science. Effective professional practice is dependent on the quality of knowledge constructed in the socio-cultural and eco-system where it is applied. The panel discussion is designed to discuss inclusion of indigenous research approach to enrich education, training and competently and relevant application of psychological knowledge for greater humans welfare.

Symposium title: Peer victimization in urban U.S. secondary schools
Convenor: Sandra Graham

Early adolescents’ responses upon witnessing peer victimisation in school
Amy Bellmore
United States of America
Given the passivity of many adolescents upon witnessing peer victimisation, the goal of this study was to evaluate the features of school-based peer victimisation events that promote helping. A sample of 470 early adolescents (52% girls; 71% white, 9% black, 6% Latino, 2% Asian, 1% American Indian, 8% multiethnic, and 3% other) reported likelihood of helping and specific helping behaviours with an experimental vignette method and through descriptions of recently witnessed real-life victimisation events. With both methods, the identity of the victim predicted likelihood of helping and specific helping behaviours above and beyond the contribution of other key personal characteristics including gender, empathy, communal goal orientation, and previous victimisation experiences. Examination of adolescents’ real-life experiences yielded systematic patterns between their responses and their reasoning about the responses undertaken. The results illustrate the relevance of taking into account peer victimisation event characteristics for promoting witness intervention in adolescence.

Peer victimisation in urban secondary schools
Sandra Graham
UCLA, United States of America
Peer victimisation (harassment or bullying) is a serious problem in schools worldwide. Victims often feel more lonely, anxious, and depressed than their non-victimised peers and that they sometimes do more poorly in school. In this symposium, four papers are presented that highlight new thinking about victimisation in urban secondary schools, with a particular focus on the larger social and cultural context in which the experience unfolds. The first two papers address how victims cope with their experiences. First, Adrienne Nishina compares middle school students’ reports of hypothetical coping (e.g., what do you usually do) to actual coping (i.e., what did you do when that happened to you) using a daily diary method. In the second paper, April Taylor examines the ethnic context of victimisation in urban middle schools by examining whether victim feelings worsen (report more distress, self-blame) when the perpetrator is someone of their own ethnicity. Given the passivity of many adolescents upon witnessing bullying incidents, the third paper by Amy Bellmore examines the conditions under which middle school students might be willing to come to the aid of victims. The last paper by Sandra Graham examines longitudinal relations between victimisation and academic achievement.
across middle school and high school to examine the chronicity of bullying experiences and their effects on achievement over time.

Longitudinal relations between victimisation and academic achievement in urban middle schools and high schools

Sandra Graham UCLA, United States of America

Being a victim of peer harassment places an individual at risk for both psychological and academic adjustment problems. In this presentation, I examine the longitudinal relations between the chronicity of bullying over middle school and high school and how chronic bullying is related to academic achievement and adjustment at the end of high school and one year later. Participants were 2000 students recruited in 6th grade and followed to one year past high school. The multi-ethnic sample was recruited from 11 different middle schools and then followed as they transitioned to over 50 high schools. With an average retention rate of about 75 percent. Using data on self-reports of victimisation over 7 waves of data (spring of 6th to 12th grade), latent classes were created in middle school and high school, documenting patterns of chronic and fluctuating perceived victimisation. Additional analyses will examine the predictors of victim class membership; whether class membership is stable from middle school to high school using latent transition analysis, and the long-term academic consequences of victim class membership at the end of high school and one year beyond. This will be one of the first studies to document the distal consequences of chronic victimisation across the critical middle school and high school years.

Coping with daily peer victimisation in school: What matters for maladjustment?

Adrienne Nishina University of California, Davis, United States of America

There has been a recent focus on coping strategies that may protect youth against peer victimisation experiences. However, little is known about what students actually do in response to specific peer victimisation events. In the present study, daily report methodology (assessing victimisation, coping, and adjustment on 5 days across 2 weeks) was used to examine reports of general, versus daily coping. The sample included 150 urban ninth grade students (50% boys, 50% girls) who attended an ethnically diverse public high school in California. Students reported on their general coping strategies – that is, the degree to which students felt they typically used social support, problem solving, distancing, internalising, or externalising behaviours when they encountered stressful experiences. They also reported on the coping they used in response to actual peer victimisation events (using daily reports). Interestingly, correlations between frequency of estimated strategy use on the general coping measure was only moderately associated with frequency of actual strategy use as reported in the daily reports (rs ranged from .29 to .38).

The two measures were unrelated (r = .06) for the use of social support. Specifically, while students reported that they generally use social support in response to stressful experiences, they were not often reporting its use in response to actual daily peer victimisation. Variations in coping as a function of aspects of the peer victimisation event will be examined. Additionally, associations between coping response to peer victimisation (measured both generally and daily) and psychosocial adjustment will also be presented.

Attributions and adjustment for victimisation by same vs different-ethnicity peers

April Taylor California State University, United States of America; Erin Cue; Dana Tote California State University, United States of America

An ethnically diverse sample of American 6th grade students completed peer nominations that were used to identify students with reputations as victims. Self-report data on psychosocial adjustment (anxiety, self-worth, depression) and recent victimisation experiences were gathered, in addition to attributions for peer harassment. Participants’ parents reported the degree of ethnic socialisation, and the overall ethnic make-up of each student’s middle school was recorded. Three attributions for victimisation were identified (self-blame, external factors, and behavioural/situational factors) that were systematically related to both frequency of victimisation and psychosocial adjustment. Students who blamed themselves for victimisation reported greater maladjustment compared to those who attributed victimisation to external or situational factors. How these relationships are moderated by qualities of the perpetrator (i.e., similar or different ethnicity), diversity of school, and parental socialisation will be examined. Research suggests that experiencing victimisation by a demographically-similar versus different peer will yield greater maladjustment, particularly when the victim’s ethnic group is well-represented in the school. Likewise, parental socialisation about victimisation might have buffering effects on outcomes to the degree that adolescents learn to attribute victimisation to external or situational factors rather than themselves. The findings highlight the need for more research on adolescents’ attributions for victimisation and how schools and parents influence students’ meaning-making about their experiences. Implications for intervention and the particular vulnerabilities of subgroups of victimised adolescents will be discussed.

Psychology in Argentina

Lucia Rossi UBA, Argentina

Medical and Philosophical trends push until applied psychology merges and conquers place in institutional field: counselors at laboral psychology; social workers in prevention and environment diagnosis in the 20’s; psychometrics and psychodiagnostic in clinical and educational psychology in the 50’s. The univiersity career is born in several public universities round 1950. Since 1985, according a national regulation, psychotherapy is a practice allowed to psychologists. General degrees in Psychology are given as a result of a 5 year university training. basic and professional skills in Psychology.psychotherapy is guarantied by university. Today several theoretical perspectives, paradigmes and professional practices in all applicative fields are included in the curricular plans of undergraduate psychologists while specializes studies concern to posgradual level. Argentina has one of the highest levels of psychologist per inhabitant.

Symposium title: The status of psychology in Uganda

Convenor: Peter Baguma

The institutions that teach psychology in Uganda and the curricula

Peter Baguma Makerere University, Uganda; Ve Kamanjire

Psychology is taught at Universities and tertiary institutions. A number of curricula have been implemented in Uganda. Successes include: having a specialised undergraduate programmes namely Bachelor of Industrial/Organisational Psychology and the Bachelor of Community Psychology; Content selected to meet local needs and context; Use of multidisciplinary approaches (curricular augmented with courses outside of psychology); Curricula designed by Ugandans; and Curricula provide for more than what is widely provided for undergraduate programmes. Challenges include: the use of about 95% materials generated from the West; Little or no materials developed from the local context for teaching and learning; Lack of infrastructure to support teaching and learning; Lack of a critical mass of Psychologists in the country (less than 10 PhDs and less 100 Masters in all specialisations); Lack of funding from government and industry to spur research and publication; Lack of a professional body to regulate training and practice. As a way forward it is necessary to Generate a critical mass of local psychologists to spearhead development of indigenous materials for teaching; Establishment of a professional board of psychology to regulate training and practice; Source for funding from gov- ernment and industry to support research and publication; and Establish infrastructure to support teaching and learning including laboratories, teaching aids.

Symposium title: Psychology in Argentina

Convenor: Maria Richaud

Clinical Psychology in Argentina

Eduardo Keegan Argentina

One of the singularities of the history of psychology in Argentina is the prevalence of clinical interests over any other aspect or application of psychological knowledge. Psychoanalysis and psychodynamic psychotherapies have traditionally dominated the Argentine professional psychology scene. In the late 70s, a number of psychologists trained in the United States developed systems theory and therapy in Argentina, but they were mostly concerned with family therapy and never seriously challenged the pax psychoanalytica. Cognitive-behaviour therapy (CBT) entered the scene in the 90s, but it is impact became significant only in the second half of the past decade. As in many other countries, CBT became popular due to its empirically-supported efficacy for treating common mental disorders in a short number of sessions. Also, CBT was the perfect antagonist to Lacanian psychoanalysis, the dominant form of psychoanalysis in Argentina since the 70s. Research in the field has grown dramatically over the last two decades due to changes in public policies. However, the prevailing view is that psychotherapy is more an art than a science, although interest in evidence-supported treatments has clearly increased.
African forms of psychology in Uganda

Julius Enom Uganda

In Uganda, and Africa at large, psychologists exist in various forms: they were called traditional healers. Traditional healing had many specialists: those who worked with the spirit, those who specialized in fortune and misfortune telling, and prediction, and those who specialize in herbs and herbs that work on the nervous system. Like in any other specialty, quacks existed in these types of healing: these have been called magicians, sorcerers and night dancers. These types of quacks were used by foreigners to discredit the profession of traditional healing, to discourage traditional psychologists. Curricula existed for training of these specialists. In Uganda there are organisations that specialise in training these specialists, or psychologists. A good example is Prometra, which offers courses on traditional healing: these have been called magicians, sorcerers and night dancers. These types of quacks were used by foreigners to discredit the profession of traditional healing, to discourage traditional psychologists. Curricula existed for training of these specialists. In Uganda there are organisations that specialise in training these specialists, or psychologists.

Employability of psychology graduates in Uganda

Paul Nyende Uganda

This topic tries to answer the question “What makes psychology graduates employable in Uganda?” If the question is answered then we have ways through which we can fight unemployment among psychology graduates in Uganda. It helps in planning too. Psychology students gain skills which can be applied in a wide range of careers. Psychology graduates gain an impressive range of skills that make them highly employable: A key factor is that psychology graduates acquire diverse knowledge and an impressive range of skills that make them highly employable across an enviable range of professions that offer real prospects. Psychology programmes deliver skills employers want, such as people skills, numerical skills, the ability to understand and work with statistics, effective communication and the ability to work productively in teams - and this gives students a real edge when competing with graduates from other disciplines. In Uganda we teach students skills in consumer psychology, advertising, career counselling, education, the health professions, human resources, management and social services. Obviously, psychologists are good researchers and this makes them get absorbed quickly. This implies that Studying psychology helps prepare graduates for many different types of work in the public, private sectors and the NGO world. Psychology students go for further training in Europe and the USA.

Supporting early literacy acquisition by Zambian children

Heikki Lytinen United States of America; Robert Serpell

Acquisition rates of basic literacy in the current mainstream of Zambia’s Government Primary Schools are conspicuously low even relative to other countries in sub-Saharan Africa (SACMEQ). This indicates that early literacy learning across a broad sample of schools in Lusaka city, and to test several alternative hypotheses about the causes of failure to learn to read. Selected groups of children and teachers were exposed to graphophone, a computer-mediated letter-sound correspondence learning environment, designed by Lytinen, adapted for the Zambian language franca Nyanja, and instantiated on cell phone handhelds with headphones. Children were introduced to the game on site at school, under the guidance of a trained facilitator, in a small group of learners, over a series of short play sessions affording each child about two hours of playing time over three days. 600 boys and girls, aged 6-8 years were sampled from 42 schools catering to various socioeconomic catchment areas. Individual assessments were conducted at school before and after intervention, of children’s preliteracy skills, mastery of spelling, oral language comprehension and arithmetic skills. Complementary sub-studies have documented teacher
skills and attitudes, teacher training, and children’s home background. Results are presented on the impact of familiarity with the medium of initial literacy instruction in Grade 1, quality of initial literacy instruction in Grade 1, quality of initial literacy instruction in Grade 1, and quality of initial literacy learning support at home.

**Symposium overview**

**N.K. Chadha University of Delhi, India**

The symposium will raise and discuss issues revolving around overall career development and management for all segments of diverse Indian society. It is intended that the rich discussion and paper presentations will bring to the fore the present gaps in career counselling in India. Some key issues like the need for continuous guidance and training initiatives for career counsellors, approval of career centres, ensuring employment of the deserving workforce, and professionalisation of career counselling in India will be explored further. The future potentials of career counselling like equitable employment, economic growth and human resource development will be looked into. The parallels will be drawn between International efforts in the area of career advancement to Indian efforts with the intention of bridging the gap so that career development in India is able to match the International standards of professionalism and functioning. In general this symposium will create awareness about need for career counselling and its professionalisation for sustainable human development in general and for Indian society in particular.

**Continuing education and credentials**

**Rekha Dayal India**

The paper highlights the role of India Career Development Association (ICDA) as an organization monitoring and providing continued education to career counsellors to upgrade their knowledge and skills as well as an approving body for the functioning of career centres providing career counselling. Once training, education, and credentialing are implemented, the establishment of the profession of career development in India will be well underway. However, the economy and job markets are constantly changing. To keep abreast of these and other changes, career counsellors and related professionals need to engage in continuing education. The India Career Development Association (ICDA) and its credentialing division would be tasked with creating the areas of training needed for continuous learning and with approving providers of such training. As the profession of career development begins to take hold in India, public and private sector organisations should be encouraged to establish career centres. Such centres likely exist in colleges and universities where students obtain information about available jobs. Individuals who work in these current centres as well as those who will work in newly established centres should be required to obtain the proper training and credentials to provide quality services to their clients. The ICDA should be tasked with developing guidelines for career centres and should provide centres with a “seal of approval” indicating that each centre has met or exceeded these guidelines.

**Career development in facilitator/advisor training**

**David Reile** R/S Foundation, United States of America; **Barbara Swarth**

The presenters will talk about the development of Career Development Facilitator training and its potential scope and benefits. In 2000, The Career Development Leadership Alliance (CDLA; now the R/S Foundation) created the first complete Career Development Facilitator (CDF) training programme for the NCDA. Since then, this programme has been revised and updated and has become the basis for training in Bulgaria, Canada, China, Germany, Japan, Korea, New Zealand, Romania, and Turkey. CDLA has created a version of this training (Offender Workforce Development Specialist) for the US National Institute of Corrections, for those working with transitioning prisoners (those returning to work after prison). CDLA has also created a distance version of the training curriculum that allows students to complete nearly all of their training via internet and CD-ROM. This has become popular in the United States and has been recently piloted in Kenya. Career Development Facilitators work in a variety of career development settings. A CDF may serve as a career group facilitator, job search trainer, career resource centre coordinator, career coach, career development case manager, intake interviewer, occupational and labour market information resource person, human resource development coordinator, employment/placement specialist, or workforce development staff person.

**Psychotherapy at the crossroads: The desires and challenges of an African-sensitive approach in South Africa**

**Convenor: Estelle Swart**

For many years psychotherapy and counselling within the South African context has been and still remains to be a service available to a privileged minority. Many Black South African have gone through their schooling, career and social development stages without ever having had an opportunity to undergo such services, even when it was a dire necessity. Even when offered, psychologists use approaches that are Western and not suitable for the general South African population. This lack of suitable intervention led to the need for culturally sensitive psychotherapeutic approach that takes into context the lives and stories of individuals as an important part of their self identity. This paper argues the need for transformation of the field of Psychology in South Africa and the African continent to culturally relevant and diverse intervention methods in psychotherapy practices. This will give promise to wholeness, balance and well being of all individuals, communities and society in general. An African sensitive approach to psychotherapy and healing that provides a way to understand the transformation on the psychology, experience, interpersonal interaction and social positioning of clients is therefore explored. This will acknowledge complementary approaches and traditional forms of healing that are attractive to many individuals both because of the limitations of psychotherapy centres and the cultural and societal “pressures” on treatment and intervention is essential. Often, the outcome of the intervention is compromised by the mismatch between intervention and culture. This presentation will examine the change perspective or Chang Ge and provide examples of strategies by examining an intervention programme initiated by a graduate school of education in the South Florida community.

**Symposium title: Conceptualising effective multidisciplinary intervention programmes in higher education**

**John Lewis Nova Southeastern University, United States of America**

The conceptualisation of multidisciplinary approaches to the implementation of effective strategies in a multicultural community will be examined. Participants from three graduate level programmes in a large independent not-for-profit university in South Florida, USA, will provide an overview of the demographic changes in South Florida showing more than fifty percent of the population speaking English as a second language and more than twenty percent being born outside of the United States. The three programmes represented are Education, Law, and Clinical Psychology all covering doctoral level education. Conceptual models will be presented as well as information on existing intervention programmes that serve the multicultural community.

**Symposium title: Conceptualizing and implementing intervention programs and strategies in a multicultural community: A multidisciplinary perspective**

**Convenor: John Lewis**

**Mentoring clinical psychology students for effective cross cultural interventions**

**Shauna Fieldstone Nova Southeastern University, United States of America; John Lewis; William Dorfman**

This presentation will examine various approaches to mentoring clinical psychology doctoral students. It will provide three separate perspectives from a large doctoral training programme: (1) The academic parameters including admissions procedures will be evaluated, (2) clinical pre-practicum, practicum and pre-internship issues will be outlined and discussed; and (3) the perspective of a current doctoral student preparing to enter the profession will be presented.

**The Chan Ge perspective**

**Michael Gaffney Nova Southeastern University, United States of America**

Change is neither linear nor sequential. Making sense of societal and cultural “pressures” on treatment and intervention is essential. Often, the out-
The role of school psychologists in school development in South Africa: The challenge of intersectoral collaboration

Nadeen Moolla
University of the Western Cape, South Africa

School psychologists in South Africa are employed by the state to provide psychological services to schools. The role of school psychologists has been debated and contested nationally and internationally for many decades, with the need for a paradigm shift in school psychology practice and redefining the role of school psychologists being highlighted. In this paper, the roles and practices of school psychologists are explored, with a focus on the nature of collaborative work engaged in when facilitating school development. In particular, challenges that emerge when school psychologists work with other sectors to facilitate school development are investigated. Six categories of challenges facing school psychologists when they collaborate with other sectors to facilitate school development emerged during this study. These were the roles and boundaries, personal and interpersonal factors, organisational challenges, training and development, discourse and worldviews, and the wider education system. The recommendations are presented as practical, well-grounded responses to the challenges that emerged in the study and are expounded as suggestions for consideration at various levels in the system, from micro (individual level) to macro (level of the state). This research contributes to the development of school psychology as an educational field and a profession in South Africa. The findings illuminate the challenges of grappling with personal and professional expectations of roles and practices, and also provide guidelines regarding how school psychologists can work with schools as systems and how the collaborative nature of school psychology practice in relation to school development can be improved.

Critical considerations in contemporary educational psychology in South Africa

Estelle Swart
Stellenbosch University, South Africa

Educational psychologists have always played an important role in the assessment and support of children with learning difficulties and more specifically children with disabilities. The international and national shifts in perspectives about barriers to learning and development. In all, this seminar hopes to stimulate on-going discussion about the changing nature of the practice, theory and training of Educational Psychology in South Africa and, hopefully, broader than this one country.

An argument for a stronger foothold in the training and practice of educational psychology in South Africa

Estelle Swart
Stellenbosch University, South Africa

In current-day South Africa, where society-changing policies are crafted and implemented, it is given that the training and practice of Educational Psychology cannot be unaffected. As shown by the newly amended scope of practice for Educational Psychologists, there is a need to rethink the training paradigms of Educational Psychology practitioners such as psychologists and learning support teachers. Even in the run-up to this amended scope of practice, it became clear that practitioners and academics involved in the promulgation process had to draw on knowledge and skills many were not formally trained in. Critical community psychology is presented as a knowledge base in which skills can be developed for Educational Psychology practitioners and academics so that they can better negotiate their changing environment. Critical community psychology is a strain of community psychology with added awareness about the role that power and the distribution of power plays in the creation and maintenance of personal, relational and collective wellbeing. The argument in this paper is that this greater psychopolitical awareness may assist the Educational Psychologist to practice in fuller knowledge of the complexity of structures and society. Applications of this psychopolitical awareness in the paper are: A reflection on the debilitating tendencies created by a past South African educational philosophy and an analysis of the role power plays in the promulgation process of the said scope of practice.

Critical frameworks and legislation for childhood disability: Implications for educational psychology

Estelle Swart
Stellenbosch University, South Africa

Educational psychologists have always played an important role in the assessment and support of children with learning difficulties and more specifically children with disabilities. The international and national shifts in perspectives about barriers to learning and development. In all, this seminar hopes to stimulate on-going discussion about the changing nature of the practice, theory and training of Educational Psychology in South Africa and, hopefully, broader than this one country.

The role of behavioural problems and peer relations in the intention to attend higher education

Pamela Maras
University of Greenwich, United Kingdom; Amy Potterton; Thomas McAdam

In the UK, the current economic climate has led to increases in tuition fees. Previous research has shown that such increases can lead to reductions in the number of students enrolling for HE and these reductions may disproportionately impact groups of lower socioeconomic status (SES) (Neil, 2009). It is therefore important that attempts are made to identify possible targets for interventions to increase the likelihood of low SES students attending higher education. As well as presenting students with academic and financial challenges, attendance at university also requires that students form new relationships with their fellow students. As such, peer relationship difficulties may impact upon adolescents’ intentions to attend HE. Addressing these problems may therefore increase adolescent intentions to attend HE. The present study set out to explore the role of behavioural/emotional problems and peer relations with the intention to attend HE. We used a sample of 1106 adolescents aged 13-16 years old from deprived areas of South-East England. Measures of self-reported emotional, behavioural and peer problems, and identification with peers were used to predict adolescents’ intentions to attend HE, while controlling for academic ability. Results showed that emotional and peer problems were negatively related to the intention to attend HE. However, identification with peers was found to interact with peer problems. When peer problems were elevated, peer identification did not affect intentions to attend HE. However, when peer problems were low, high peer identification led to reduced intentions to attend HE, and low peer identification led to increased intentions.

Symposium title: Educational psychology as psychosocial justice: Under what conditions?

Convenor: Tim Corcoran

Educational psychology as psychosocial justice: Under what conditions?

Tim Corcoran
Victoria University, Australia

This symposium gathers a group of international scholars to discuss the possible conditions under which educational psychology theory and practice might sustain psychosocial justice. Psychologists’
work in schools and learning communities is largely oriented to individualized and internalized understanding. Be that via compliance with dominant learning theories and their influence on curriculum and pedagogy or by the promotion of public normativities through categorization and assessment practice, the relationship between psychology and education has been maintained by a mutual interest in the individual as the primary unit of analysis. The papers in this session share a commitment to imagining psychological practices explicitly founded upon principles of equity and justice. In doing so, the discussion moves to critically question conditions under which theory and practice might jointly engage levels of personal, interpersonal, organizational and communal experience. One way this can be achieved is by inviting the notion of psychosocial justice, a concept capable of moving beyond the traditional distributive and procedural binary, acknowledging how inextricably linked the process is to the outcome in educational practice.

Psychosocial justice, education and the human condition

Tim Corcoran Victoria University, Australia

As we move within and across contemporary socio-political contexts and practices, occupying different positions along the way, we are changed by what we do, the ways we engage each other, and our world. For example, an explicit ontological commitment by psychologists and educators to certain professional practices is a sign of active participation in preferred forms of life or a commitment to what can be termed psychosocial justice. An orientation of this kind is central to the production of our own and others narratives, specifically in creating a sense of belonging to, and an emergence of, community. In responding in this way to kinds of universal and localised understandings, acknowledgement of difference or diversity is vital. In this paper I outline how process oriented knowledging practices are concerned with becoming, not simply being, seeking to understand the complex and unfinished nature of personhood and community made available through education. Being open to relationally-bound, process orientations invite practitioners to critically reconsider a wide range of activities in formal and informal educational settings including: Professional training, pedagogy, curriculum and assessment, and teacher/ learner and adult/child positioning.

Changing the subject: The past, present and the future of educational psychology

Tim Corcoran Victoria University, Australia

Potentially, educational psychology could cover the most exciting of epistemological terrains - how people live and develop from infancy, through childhood and thus through the rest of their lives! Instead of realising such creative opportunities, however, educational psychology is in danger of becoming obsolete, ignoring as it often does, complex models of the individual, the social or the relational which can be found in more intellectually substantive realms such as psychoanalysis, philosophy and neuroscience, for example. Too often, educational psychology has sought to focus on models of learning, narrowly conceived; on analyses of behaviour disconneceted from experience; and on essentially asocial individuals, somehow fractured from a human world of others. This has led in some countries to a preoccupation with assessment practices in which individual young people can be scrutinised according to crude conceptualizations of difference and in which the quantification or categorization of disability are utilized as a means of justifying social exclusion on an industrial scale. It is argued that while educational psychology in the 20th century became synonymous with the needs of government, it might yet be possible to trace our roots to a more genuinely scientific 19th century fascination with what it is to be human. The future of educational psychology might still lie in the past.

Justice, not adjustment: Activism as (self-)education

Athanasios Marvakis Aristotle University, Greece

The complicity between theorising learning in formal educational practices and the dominant societal order derives from educative theory’s blind compli- ance to deliver tech-knowledge only on the ‘how’ of learning. Such a tech-knowledge does not question the dominant arrangements of the educative practices. Thus, the whole dialectic between practice and theory is reduced to the simple sequence: First practice, then theory. This “principle of simp- lification” relies on - and promotes - a technocratic self-(mis)understanding of the social sciences as being servants of the dominant status quo. If we want to do away with this complicity, we have to rethink both educative practices and learning theo- ries, so as to restore the dialectical unit of practice/ theory. A starting point is to reclaim the autonomy of learning – as a particular practice of the learning subject – before and beyond its being the mere effect of the practice of the educator. Reclaiming the autonomy of learning for the developing subject means reclaiming not only the process (the "how") but also the content (the "what" and the "why") of learning. This reclaiming and restoring will be dis- cussed with reference to my own participation in social practices, in real-experimental initiatives (German: Real-Experiment; W.F. Haug). These ac- tivist initiatives consist of two moves: Transforma- tive interventions and (self-)education. Learning solidarity presupposes and enhances the doing (ap- plication, organisation) of solidarity and vice versa.

How educational psychologists promote human rights and psychosocial justice in schools

Jace Pillay University of Johannesburg, South Africa

Despite the legislation on human rights, democracy and psychosocial justice the violation of human rights still exists 17 years down the line of South African democracy. This is clearly evident in the escalation of psychosocial issues such as HIV/AIDS, crime, vio- lence, poverty, child abuse, and child-headed homes, to name just a few. This should come as no real surprise since the majority of people in the country were psychologically negatively affected by apartheid. As such, there is an indisputable need for psychological interventions to have a broader focus on community and society as a whole, especially when psychosocial justice highlights inequality in society. This includes the way in which burdens and responsibilities are unequally distributed along structural lines that foster exclusion for many and inclu- sion for some. In this paper I argue that psychologists could play a critical role in promoting human rights, democracy and psychosocial justice through their involvement in schools, using education and psycho- logical interventions as a vehicle to change. They can facilitate psychosocial action in learners and teachers to change the country to make it more democratic and just, thus improving the human condition. Hence, this paper critically examines how psychologists themselves envisage their role in developing and promoting human rights, democracy and psychoso- cial justice within the context of schools.

Symposium title: Focal Symposium - Toward Africentric theories of developmental education

Convenor: Bame Nsamenang

Kenyan siblings and peers as educational stakeholders

Maureen Mweru Kenyatta University, Kenya

Past research has revealed the multiple influences siblings and peers have on young children’s lives. Most of these published research reports are based on studies that have been carried out in developed countries as there is little empirical research from developing countries, and Africa in particular, fo- cusing on this issue. The objective of this paper is therefore to highlight the role of siblings and peers as educational stakeholders in a developing country and Kenya in particular. The paper is based on a review of literature and on research carried out by several researchers including the author. The paper reveals the presence of sibling teaching and peer mentoring among children and it also demonstrates that when instructing children, older siblings and peers use culturally appropriate teaching methods and materials. Locally available materials such as sticks, stones and mud for example are used in the teaching episodes. The teaching episodes are also characterised by the inclusion of traditional games, singing, dancing, use of riddles and storytelling. This paper also discusses the implications of these finding for teacher’s professional skills and school education. The paper for example argues that just as children use objects found in their environment, and culturally appropriate teaching methods such as songs, stories and games, so too should teachers adopt similar teaching strategies and avoid the use of culturally inappropriate materials and processes.

Symposium title: Improving psychology by internationalizing the curriculum: Global learning at Northern Arizona University case study

Convenor: Sherri Mccarthy

Global learning at a US university: NAU case study

Harvey Charles Northern Arizona University, United States of America

Colleges and universities are gradually coming to accept the necessity of acting more intentionally in facilitating global learning experiences for all stu- dents. The American Council of Education’s Interna- tionalisation Collaborative and the American Associa- tion of College and University’s Shared Futures Initiative are important projects in the US to help institutions embrace global learning as part of their curriculum strategy. While these approaches are large- ly directed at the general education programme, this
paper will explore a global learning strategy that uses the academic disciplines as the principal site for global learning, one that aims to afford students substantial, multiple and intentional encounters with global perspectives. It will discuss the imperative for global learning as well as the institutional context that must be built in order to facilitate these changes in the disciplines. It will then discuss the themes of global learning (sustainability, diversity and global engagement) that effectively define and shape the changes made in the curriculum to help students achieve global competence. Finally, it will discuss the three principal tasks that departments must accomplish in pursuit of this objective. These tasks include, in the first instance, developing global learning outcomes articulated in the language of psychology as a discipline. The second task involves developing strategies in the curriculum and the co-curriculum that psychology can adopt to help students realise the global learning outcomes. Finally, it will address assessment strategies that can be employed to demonstrate the extent to which students are realising the global learning outcomes committed to earlier in the process.

Global learning in a psychology department
Keelah Laura Dickson Northern Arizona University, United States of America

This presentation highlights how the NAU Psychology Department thoroughly and thoughtfully embedded the three Global Learning Outcomes of Diversity Education, Global Engagement, and Environmental Sustainability into the programme’s curriculum and co-curricular learning opportunities. We developed learning outcomes, a comprehensive set of learning strategies, and assessment strategies that align with the thematic global learning goals. It is our contention that well-developed liberal education skills can contribute to student achievement within the psychology major. Collaborative faculty-student research opportunities facilitate students’ development of these skills. Consistent with Goal 8: Sociocultural and International Awareness of the APA Guidelines for the Undergraduate Psychology Major, students will recognise, understand, and respect the complexity of sociocultural and international diversity. Complementing cross-cultural psychology coursework, many faculty members integrate cultural and global diversity within their courses. Our department facilitates undergraduate and graduate student study abroad opportunities. Faculty members lecture and teach abroad, consult for international organisations, conduct cultural/global research with international collaborators, and present at international conferences. Building on APA’s goal related to the applicability of psychology, students will understand and apply psychological principles to environmental sustainability. Several psychology faculty members conduct environmental sustainability research, are active in NAU’s environmental programmes, and teach sustainability-oriented coursework. The learning outcomes of this university-level initiative afford an opportunity for psychology to serve humanity.

Improving psychology by internationalising the curriculum
Sherri McCarthy Northern Arizona University-Yuma, United States of America

Internationalisation of psychology knowledge has increased substantially in psychology education, teaching and training over the past two decades (Karandashev, 2009). Although the discipline has been international in focus from its beginnings and scholarly exchange has continued in regions throughout the world, teaching of psychology has not been particularly international in orientation in many countries, including the United States, until recently. Several events around the beginning of the 21st century led to increased interchange among teachers of psychology around the world, and resulted in more international content and curriculum in psychology programmes. Globalisation of psychology education has emerged as a new form of internationalisation which includes not only collaboration among institutions from different countries but also a rapidly-developing international curriculum. This presentation will summarise the key events since the beginning of ICOPE that have led to Division 42’s establishment within IU/PsyS, introduce resources and ideas for further internationalising the psychology curriculum for instructors around the world, and then provide a brief overview of how the internationalisation process is unfolding at one university; a case study of the process at Northern Arizona University, a state university with approximately 25000 students in the USA.

Ethical research in schools in challenging contexts
Marietjie Oswald Stellenbosch University, South Africa; Estelle Swart

Psychologists perform many roles, amongst others that of researcher. Ethics codes provide a common set of principles and standard upon which psychologists build their professional and scientific work. A set of standards however only crystallize in a process of relationship-building. Our research in schools in challenging contexts sensitized us to the personalized, socialized and politicized nature of research. We consequently employed participatory research methods to co-construct understandings with the teachers in the various projects. Within the context of low teacher morale and distrust, relationship-building characterised by an ethic of care formed the foundation of our work. This paper aims to deconstruct the construct ethic of care in participatory research. The feminist ethic of care framed our understanding by placing the role of relationships at the heart of social, political and philosophical theory. The caring act is therefore embedded in a developing and ongoing relationship amongst researchers and participating teachers. In an effort to explore and describe how this relationship develops, we identified four important building-blocks for participatory research in schools and illustrate these with examples from our data. For us an ethic of care in research implies collaboration, gaining access as a continuous process, building of relationships and mutual enablement. In partnership with teachers we learn together what it means to embody the above mentioned principles.
Nothing is as simple as we might wish for: education in adverse circumstances

Marietjie Oswald Stellenbosch University, South Africa

Education in South Africa is currently overburdened by complex and interrelated conundrums that desperately need to be solved. These challenges are particularly evident in communities facing adverse circumstances and negatively impact the working lives of teachers and the provision of quality education for all learners. As researchers working within the ambit of educational psychology, we maintain that our research efforts should have a pragmatist twist. This symposium therefore represents our particular research initiatives to explore some of the pervasive challenges impacting education in an effort to find ways of actually bringing about meaningful change. The presenters will discuss the intricacies of doing research when inspired by an ethic of care as seen from a feminist perspective; explore the identity trajectory of a teacher working in a challenging context from a cultural-historical activity perspective; and show, from a social constructionist viewpoint, how teachers make meaning of their experiences in an elementary school situated in a community where low income levels are prevalent. The last study exemplifies a special effort to apply a bi-ecological framework understanding the classroom behaviour of children who live in conditions of continuous adversity. The papers foreground that ‘nothing is as simple as we wish for’, but also signify our concerted efforts to employ different theoretical lenses to better understand and address the realities that trouble education system.

Classroom behaviour of children living in contexts of adversity

Celeste Paterson University of Stellenbosch, South Africa; Marienchen Perold

Many communities in South Africa are exposed to continuous adversity in the form of poverty, malnutrition, violence, crime, overcrowding, neglect and oppression. Continuous exposure to adverse living conditions can have a negative impact on a child’s development. This study was undertaken in an attempt to understand the classroom behaviour of children who live in conditions of continuous adversity. The effects that adversity could have on children’s classroom behaviour and thus also on their academic performances, their emotional states and their interactions with peers were explored. A bi-ecological theoretical framework was employed to inform meaning-making of the findings. This study was undertaken within an interpretive paradigm, using a qualitative methodology in gathering data. The data was analysed using a constant comparative method in order to reach an understanding of it. Research findings indicated that most of the participants displayed inappropriate classroom behaviour which included poor academic performance, withdrawal types of behaviour as well as externalising disruptive behaviours such as aggressive interaction with the teacher and their peers. The participants also presented with some physical and emotional complaints which could be interpreted as traumatisms, symptoms and they reported negative emotional experiences which include anger, sadness and anxiety. Contextual factors which contributed to the findings were reported on. Enabling teachers through in-service training aimed at developing deeper understandings of troublesome classroom behaviour is recommended.

A teacher’s identity trajectory within a context of change: a cultural-historical activity perspective

Marienchen Perold University of Stellenbosch, South Africa; Marietjie Oswald

This paper originated from a study into the care and support practices of teachers in a primary school in a historically disadvantaged community in the Western Cape Province. Currently the community is still experiencing trauma as an assortment of prevailing socialills. An ethnographic study was designed and qualitative methodologies were employed. Data was collected by means of semi-structured individual and focus group interviews, as well as group discussions. Apart from rich data on the care and support practices of teachers, research findings also revealed, as an interesting offshoot of the research, identity trajectories of long time teachers in the school. In this paper we apply a cultural-historical activity theoretical (CHAT) lens to explore the identity trajectory of a prominent teacher in the school in the context of change in education. CHAT is among number of approaches that move away from the individualist and mentalist notions of human development toward viewing it as embedded within socio-cultural contexts and intrinsically intertwined with them. CHAT also views human subjectivity (identity) as stemming from and existing within activity-processes. One’s identities are social products drawn from the social history, actively internalised and re-authored as one’s expressions of these identities enter into new circumstances and new activities as evident during the transformation on macro-political and –educational, as well as institutional level in South Africa since 1994. Becoming more aware of the profoundly constitutive effects of language and enactment, might provide possibilities for positive re-authoring of teachers’ troubled identities.

Symposium title: Psycho-educational experiences of children from child-headed households in South Africa

Convenor: Jace Pillay

Psycho-educational experiences of children from child-headed households

Jace Pillay University of Johannesburg, South Africa

The HIV/AIDS pandemic is adding more strain to the already overburdened safety nets of families and communities in South Africa. The emergence of the child-headed household and the rising number of orphaned and vulnerable young people. More youths are at risk and become victims of abuse without the protection of adults - many are traumatized when left to fend for themselves. Hope, as a protective phenomenon, builds resiliency, empowering young people to rise above their harsh circumstances. A social constructionist inquiry with a grounded theory research design was conducted with four youths from a secondary school in Soweto in partnership with a non-governmental organisation. Data analysis was based on conversations over a nine-month narrative therapeutic journey with the youths and included individual and group interviews, expressive art exercises, and photovoice to capture their hopeful experiences. By identifying what helps youths to nurture hope in their lives, support structures that provide opportunities for growth rather than merely helping them to cope, invite us to challenge more conventional understandings of support for vulnerable young people. The story of our journey provides a broader understanding of the processes of nurturing hope in the context of vulnerable young people. The findings offer an alternative view of hope from the generally accepted Western understandings which are essentially individualistic. A 4D perspective of hope is presented which recognises the importance of hope as a practice and the role of possibilities in empowering youth to transcend adversities in seeking a better future.
individual interviews, focus group discussions, narratives in the form of life histories and incomplete questionnaires. Atlas.ti software was used to conduct both a content and comparative analysis of the data. The findings provide a vivid picture of the actual difficulties experienced by the children from child-headed households, such as a variety of negative emotions and behaviours, poverty, crime, HIV/AIDS, changing roles and the lack of safety and security. However, it also displays the psychological resilience of many of them to survive despite all odds being against them. To this effect, five papers focusing on different aspects of child-headed households, such as gendered experiences, life skills, social support, weaving a circle of care and specific psychological and educational interventions will be presented in an interactive session soliciting the critical engagement of the audience. Special focus will be given to the role that community as well as critical and positive psychologies play in understanding and supporting the psychological well-being of children from child-headed households in South Africa.

Symposium title: Social categories and asymmetries in interactional contexts
Convenor: Kevin Whitehead

Food troubles: A window into inequality among university students
Yasmine Dominguez-Whitehead University of the Witwatersrand, South Africa

In the context of what is quite likely the most unequal society in the world, how is inequality manifested among university students in South Africa? What are the reported experiences of students? How do students make sense of their reported experiences? And how are inequalities reflected and reproduced in the reported experiences of different groups of students. I address these questions by focusing on students’ reports of food troubles and issues, and by paying particular attention to the use of linguistic and interactional practices produced in students’ reports. In examining the experiences of students who report food acquisition struggles and those of students who display they have ample access to food, shared food troubles vs. food as an individual matter emerge as a prominent food related dichotomy. I conclude by examining the potential consequences of these findings for the question of whether and how students with vastly divergent reported experiences and sense-making with respect to matters such as food can engage in social relationships on an equal footing.

Symposium title: The status of psychology in Uganda
Convenor: Peter Baguma

The status of psychology in Uganda
Peter Baguma Makerere University, Uganda

The symposium presents institutions that teach psychology in Uganda and the curricula and employability of psychology graduates in Uganda. The challenges of practising psychology in Uganda are highlighted. The symposium details the history of Western psychology in Uganda, highlights the African forms of psychology in Uganda, and the role of psychology in socio-economic development of the country.
Noise psychological effect in Isfahan hospital environments

Moalood Amiri Isfahan University, Islamic Republic of Iran; Hamid Oreyzi

Observations have shown that noise is at the head of the list of complaints by both personnel and patients in hospitals. The aim of the current study was to find the source of disturbance due to hospital noise, and discriminate between ‘object’ and ‘people’ sources of noise production. Ex-post factor was the design of the research. In order to investigate the relationship among variables, distress due to hospital noise was investigated among a sample of 161 post-operative patients in 23 hospitals located in Isfahan. Participants were selected according to systematic random sampling method. Participants completed patient disturbance due to hospital noise (Topf, 1985), Weinstein’s (1978) sensitivity to noise and social desirability scale. Objective noise was measured via self report developed especially for the current study. Findings indicate increment of sensitivity to noise causes increment of distress due to hospital noise (DDHN), while disturbance due to hospital noise (DDHN) increase when noisy utilities and social desirability scale. Objective noise were increased in contrast to common sense. DDHN decrease when roommates were increased, in contrast to common sense of roommate noise. Based on the research finding, the degree and rate of reaction to noise can be determined, but in two different directions for things (noisy utilities) and persons (number of roommates), the first to increase and the second to decrease DDHN. Implications in hospital environment for decreasing perceived annoyance of noise were discussed.

Why do people switch to new technologies?
Developing a conceptual model to explain technology transition

Anamitra Basu IIT Bhubaneswar, India; Nils Urback; Rahul Thakurta

Owing to the current era’s rapid surge in information technology, new technologies constantly replace those that are being used. Users often start using new technologies, often in parallel to existing solutions, if the new technology seems to be an improvement on the old one. Users must then decide whether they want to switch to new technologies or retain the already established ones. The term ‘technology transition’ refers to the act of moving from one technology to another. In this paper we report on the development of our research model for explaining technology transition and we provide an answer to our research question of why people switch to new technologies. We base the model on the theory of reasoned action and the theory of planned behavior, amongst others, and derive our hypotheses accordingly. By focusing on the individual perspective, we intend to enlarge our understanding of the psychological and social processes that influence technology transition. The theoretical explanation and empirical evidence that we put forward are expected to extend the previous contributions in this field of research and to provide new insights for practitioners.

Relationship between emotional intelligence and decision making in a complex and stressful environment

Leonore Bourgeois IRBFA, France; Mourad Bensalah; Bruno Deben; Jean-Claude Ardoul; Anthony Vacher

This study assessed the relationship between Emotional Intelligence (EI), emotional states and medical performance during emergency care by military physicians. Our hypothesis was that emotion and cognition interact and influence decision performance in a complex and stressful environment. Military resident physicians (n=21) were placed in simulated emergency-care conditions with a patient simulator. The participants were divided into two groups based on the median of their scores at the “Trait Emotional Intelligence Questionnaire”: EI high level and EI low level. For half of the participants, war sounds were played in the background during the simulation, for the other half no such sounds were present. Before and after the exercise, emotional states were assessed using the “Positive And Negative Affect Schedule”. Performance was evaluated based on diagnosis accuracy and solution relevance using a five-point scale. Performance was higher, and negative-affect scores were lower, for participants in the high-level EI group, than for the other half of the participants. Moreover, negative-affect scores were negatively correlated with performance (r=−.57; p<.05). War sounds during the exercise had no significant influence on performance nor on emotional states. The results suggest that emotional intelligence is an important skill that improves decision making and lowers negative emotional states in stressful situations. These findings underscore the potential importance of emotional training in professional decision makers who have to operate in complex and stressful environments.

The effect of visual instruction on quantity and quality of seeing action

Shadi Derakhshan Isfahan University, Islamic Republic of Iran; Hamid Reza Oreyzi

Recognising the behaviour of others in a real environment is a multiple phenomenon that can be observed as a process of events. Humans as perceivers, subjectively unitise information from ongoing behaviour. But what is the pattern and characteristic of this unitisation? An answer to this question is the aim of the current research. Participants were 70 undergraduates of psychology who participated in management psychology and were familiar with concepts related to in basket and role playing. Material was a 10 minute film about management roles. Hypotheses were about unitisation rate (quantity) and unitisation pattern (quality) in judgments of three groups of participants, namely, base rate without instruction, learning instruction and concept formation. Findings indicated that underlying participant observational process was unitisation of ongoing behaviour. Unitisation rate (quantity) and unitisation pattern (quality) were fine grained and different in the learning group relative to other groups. Implications of these findings were discussed to solve philosophical debates according to phenomenology of visual perception. Significant implication in directing the interview session was another aspect of the current paper.

Vigilance decrements in closed circuit television surveillance

Fiona Donald University of the Witwatersrand, South Africa; Weiqiao Fan; Shu Fai Cheung

This study examines the presence and nature of vigilance decrements across different sub-samples in a closed circuit television (CCTV) surveillance task. CCTV has largely been assumed to be effective because it is such a good technology. However, few studies have focused on operator performance or examined whether detection rates in real-time CCTV surveillance are subject to the vigilance decrement over time. The vigilance decrement has been well-documented in simple laboratory vigilance tasks but mixed results have been obtained for real-world tasks. Therefore it is important to examine the existence and nature of potential decrements in CCTV surveillance. In view of individual differences in vigilance performance, vigilance decrements were also examined in participants with different surveillance backgrounds. The current research examined vigilance decrements in three sub-samples: operators from two types of CCTV surveillance operations and novices (students) with no previous exposure to CCTV surveillance. 13 generalist operators, 29 specialist operators, and 31 novices observed CCTV footage for 90 minutes and were required to detect specific behaviours associated with theft. A vigilance decrement was found for generalists and novices. However, specialists maintained their performance for an hour and then detection rates significantly increased in the last thirty minutes. Reasons for different susceptibilities to the vigilance decrement and implications for the nature of tasks and choice of samples used in vigilance research are discussed.

Detecting significant events during closed circuit television surveillance is not easy: How do operators approach this?

Fiona Donald University of the Witwatersrand, South Africa

This research aims to understand how closed circuit television surveillance operators approach the challenging task of detecting significant events that are inconspicuous and occur fleetingly. Low detection rates for CCTV surveillance suggest that detecting significant events is not easy, especially when detection needs to occur proactively and in real time. There is little previous research on how operators approach the viewing and detection processes, and what approaches are associated with higher detection rates. Forty-two CCTV surveillance operators and 31 novices (N=73) observed ninety-minutes of CCTV footage and were required to detect specific target behaviors. At the end of the task they interviewed regarding their approaches. This exploratory research identified two broad approaches to the detection process: an active process involving the formation and testing of hypotheses regarding what was occurring, and a passive process of watching and waiting for visually conspicuous events to occur. These approaches were associated with statistically
significant differences in detection rates. The relate to the multiple resources theories of attention and the mindlessness theories of vigilance. More importantly, however, the research contributes to theory regarding visual search and detection with complex and dynamic visual stimuli. It has practical implications for the selection and training of CCTV surveillance operators.

Psychological implications of automated detection in visual search
Craig Donald Edith Cowan University - Perth, South Africa; Antony Bridges

Security technologies used in detection are increasingly being accompanied by automated detection capabilities or “visual analytics” through the use of software algorithms. These are seen to assist operators in the scope and quality of coverage of detection. Effectiveness varies across the types of technology used, the clarity of indicators, and complexity of the visual images being processed. Despite its increased use, automated detection is unlikely to replace operators in the next ten years, but will have major effects on how their work is structured, tasks, and the interaction with the technology. While the use of automated detection is often proposed to support the operator, it can also create additional burdens. Because the automated algorithms performance varies according to scene complexity, in order to achieve a reasonable level of detection a false alarm rate also needs to be tolerated. The human has a limited ability to tolerate false alarms within any automated system. This can lead to a breakdown in trust by the operators if it happens too often and the technology is seen as unreliable, a disregard for correctly identified threats which get ignored, or a situation where the real target passes unnoticed elsewhere on the image. It is also clear that automated detection can supplement the operator functions, but issues remain on the relationship between human and algorithm detection.

Qualitative human error analysis in medicine
Ricardo Gades-Buettrich Leuphana University, Luebeck, Germany; Nicki Marquardt; Rainer Hoeger

In most industries between 70% and 90% of all factors that can potentially cause an accident refer to human error. Human error research in industrial high-risk socio-technical systems has a long tradition, but is relatively new to medical settings where it started to become more important just two decades ago. Despite lacking official statistics, 70% - 80% of all incidents and accidents in the medical sector have been attributed to human error in the medical field. In light of these alarming figures, the present research aims to identify sources and causes for human error in the medical sector. The conceptual framework of the present study is based on Gordon Dupont’s Dirty Dozen Model which includes twelve error categories for human error in aviation, covering organisational and social aspects but also considers individual factors which can provoke human errors. For the current study, 18 qualitative interviews based on the Critical Incident Technique were conducted with medical doctors, medical-technical assistants and nursing staff. The interviewees had to retrospectively describe specific events which led to critical incidents or situations. Based on the Dirty Dozen Model the interviews were analysed with regard to the mentioned causes that provoked errors. After the sources of error have been identified and extracted from the interviews, the second step was the classification of possible combinations of different error sources, since human error often results from the interplay chaining of multiple error sources.

Do alarms trigger more reactions than comparatively neutral cues?
Torsten Guenzler Berlin Institute of Technology, Germany

It has recently been shown that the cry wolf effect (neglect of unreliable alarms) can be avoided by giving operators the chance to check the raw data behind an alarm. Ironically, this opportunity to check may in turn cause antipodal irrational behaviour. People tend to “overcheck” highly unreliable alarms and consequently corrupt their overall performance. The underlying mechanisms are not well understood. Thus, the aim of the present study was to examine whether it is the “alarm” labeling of the cues that triggers a tendency to react and, given the opportunity to check, potentially overreact. Therefore 65 participants performed two computer based tasks simultaneously, both embedded in the Multi-Task Operator Performance Simulation (M-TOPS). One of which, a monitoring task (quality control in a brewery), was supported by an automated detection aid, which was framed differently between participants. In one condition it was introduced as an alarm system (emitting alarms), in the other as an assistance system (emitting cues). In both conditions the findings of Gérard and Manzey were replicated. Alerts with a false alarm rate of 90% were ignored by few participants only, while most tried to check many or all alerts. Results are similar for both framing conditions, so there is no evidence for any specific impact of the alarm-framing. These findings suggest that even if overchecking is some kind of domain-specific behaviour, this is not due only to the alarm-framing itself.

Care reminder and knowledge delivery for reproductive families
Biqing Huang Tsinghua University, China; Peng Zhu

Reproductive family healthcare in China becomes of great importance in social and economic aspects because of China’s one-child-one-couple policy and rapidly increasing economic status. Healthcare should be accessed by all members in the reproductive family, including the child-bearing woman, her husband and her incoming children. Care services should be delivered to family members through reproductive healthcare stations/centres supported by government. We developed a system of care reminders and knowledge delivery for reproductive families and applied it in Jiangsu Province, China. First, we outlined a care flow process for bearing women and raising children, organised various knowledge for all stages in the caring lifecycle and mapped particular knowledge to each step of the care process. In each step, families can get or access required knowledge via the internet or mobile devices. Some important treatments which must be taken are sent by carrier via cell phone or automatic voice phone.

Comparison of expert and novice eye movement behaviours during landing flight
Wei Liu Beijing University of Posts and Telecommunications, China

The aim was to study expert and novice eye movement patterns during a simulated landing flight for providing references to evaluate flight performance and training of pilots. The subjects were divided into two groups of expert and novice according to their flight simulation experience. Eye movement data were recorded when they were performing landing task. Comparison of expert and novice flight performance data and eye movement data was made. It was found that the differences between expert and novice lay not only in flight performance but also in eye movement pattern. Performance of expert subjects was better than novice. Expert subjects had shorter fixation time, more fixation points, faster scan velocity, greater scan frequency and wider scan area than novice subjects. It was also found that eye movement patterns of expert subjects bring lower mental workload than novice subjects. Thus, flight performance is related to eye movement pattern. Effective eye movement pattern is related to good flight performance. The analysis of eye movement indices can evaluate pilots’ flight performance and provide a reference for flight training.

The evaluation method of mental workload on visual interface in cockpit
Wei Liu Beijing University of Posts and Telecommunications, China

To establish a system to evaluate the mental workload on the visual display interface in an airplane cockpit after synthesising three kinds of mental workload assessment techniques, i.e., main task measure method, physiology measure method and subjective evaluate method. The evaluation indices of every kind of assessment techniques were defined, and the amount of each index through experiment and subjective inquiry was gained. Weighted average was calculated and a quantification of the evaluation value of each kind of evaluation method was got. At last, with the weighted calculation of the above three evaluation values, the evaluation value of mental workload on the visual display interface in an airplane cockpit was obtained. Results in M kinds of different designs of visual display interface in airplane cockpit, the synthetic evaluation value of one design was the smallest and the mental workload of this design was the smallest. The design of the smallest mental workload was chosen prior to the final scheme of visual display interface in the airplane cockpit. The evaluation system is combined with present main evaluation methods of mental workload and utilises their advantages. The evaluating results can be quantified more directly and clearly. With this evaluation system, the mental workload can be evaluated during the design of visual display interface of an airplane cockpit and the best scheme can be confirmed.

Team situation awareness in sports: Case study with a coach and three high level athletes
Anne-Claire Macquet French Institute of Sports (INSEP), France

It is recognised that Situation Awareness (SA) is shared among team-members. The coach and elite
Temporal dynamics of user experience: Judgements of visual attractiveness, usability, and emotions over time

Michael Minge
Berlin University of Technology, Germany

User Experience emerged as an extension of the traditional concept of usability providing a holistic perspective on the user’s interaction with technology. The concept includes perceptions of different product qualities (pragmatics, hedonics) and user emotions. There is empirical evidence that perceptions of product features are not independent, but influenced by each other. More aesthetic systems are perceived as more valuable and therefore more usable. Tractinsky et al. (2000) characterised this as a halo effect: “Beautiful is good”. The experience of interaction is a temporal phenomenon that develops over time. Consequently, we assume that also judgements and emotions dynamically change when a user interacts with a system. Under laboratory conditions temporal influences of product features on users’ perceptions and emotions were investigated. Ninety-six participants worked on simulated interactive products, which varied in their visual aesthetics (high/low). During specific periods, usability flaws were experienced (in the beginning, in the middle, or at the end). A control group worked on flawless simulations. Judgements of visual attractiveness, usability, and emotional feelings were collected before, during, and after the interaction. Results show that systems are perceived as (a) more usable in case of high aesthetics (hedonic halo effect), (b) more visually attractive in case of no usability flaws (pragmatic halo effect), (c) less usable if flaws are experienced at the end (recency effect), and (d) more attractive at the end (mere exposure). Moreover, the product’s aesthetics positively influenced self-reported emotions and the overall acceptance.

Much more than meets the eye: Emotion perception in human-robot interaction
Michael Oehl
Leuphana University of Lüneburg, Germany; Rainer Hoeger; Hans-Ruediger Pfister; Felix Siebert; Nils-Torge Telle

The socio-emotional interaction with robots will become an important part of our daily lives in the future. To ensure that socially and viable human-robot interaction, crucial design and appearance features of robots need to be considered. However, on the one hand it is still far from clear which design criteria robots should meet to be capable of adequately expressing affective states and on the other hand if humans are capable of interpreting these affective expressions of robots correctly. Most studies on this topic use highly artificial or restricted settings. In order to examine the importance of salient robot design aspects with regard to emotional human-robot interaction, our current experimental study investigates how different types of robots are perceived in authentic and complex settings including multimodal emotional expressions. To ensure this authenticity and complexity we used scenes from robot movies. The different scenes showed robots that systematically differed in their anthropomorphic appearance and behaviour. Participants rated these scenes regarding the robots’ appearance and ability to express and convey basic emotions (fear, sadness, anger, joy, vs. neutral) in affect-provoking situations. Results showed that participants were able to classify different types of robots portrayed in movies according to their anthropomorphic appearance and behaviour, and capability of expressing emotions. Moreover, the so-called uncanny valley effect in robotics was found. Results are discussed in terms of their impact on future robot design and emotional human-robot interaction. Implications for further research as well as for applied issues are outlined.

Neurophysiological error analysis in the context of accident research
Janna Protzak
Berlin Institute of Technology, Germany

According to official statistics, road accidents are still the major cause of death in many industrial countries (e.g. German Federal Statistics Office, 2011). The majority of fatal crashes are caused by human error. It is therefore important to highlight human factors as a key aspect in the area of accident research. Even with highly automated driver support systems, it is still human behaviour that determines the outcome of critical situations. A promising approach to analyse human action, is the usage of neurophysiological methods, e.g. electroencephalography (EEG). By transferring this method out of a laboratory context into lifelike scenarios, it is possible to obtain a realistic research approach. Patterns extracted from EEG-data can serve as an indicator of intended behaviour through the underlying neural activity. One of them is Error preceding positivity (Epp). This action potential was found before erroneous task performance (e.g. Allain et al, 2004; Hajecak et al., 2005). Therefore it can be used for early error detection. EEG-data from 20 participants was taken while they were responding to a modified flanker task with foot pedals. A first data inspection suggests the possibility of obtaining incorrect reactions before the pedal was actually depressed. Further follow up studies will show whether this potential can be found in real driving situations by using accelerator and brake pedals. Such results may help to develop and improve driver support systems.

Agency model and safe/unsafe behaviour in Chilean miners
Ariel Quezada
Universidad Adolfo Ibánez, Chile

Cultural Psychology has produced increasing interest and developments in the last decades. Traditionally, the literature describes different cultures as promoting different values. An important difference in values refers to cultures that promote individualism versus those that promote collectivism (Markus and Kitayama, 1991). Recent findings stress differences between members of the same culture. For example, findings reveal differences in agency models among middle class and working class individuals (Stephens, Markus and Townsend, 2007; Savani, Markus, Naidu, Kumar and Berlia, 2010; Stephens, Markus and Fryberg, 2011). The Agency Model of cognitive processing could have consequences in causal attribution of several behaviours, e.g. safe/unsafe actions. This study tries to uncover these differences in Chilean mining industry workers, describing differences in Agency Model between managers and operators. Our procedure (adapted from Savani et al., 2010) consists of requesting participant’s own judgements about whether an actor’s actions (shown in a 6 min. standard video) are voluntary decisions or not. Expected results are to find differences in judgments among managers and operators. These differences could imply consequences for safety rules in the industry (generally designed by managers) and for safe/unsafe work related actions (generally involving operators exposed to high energy sources).

Development of a questionnaire assessing discomfort: The disco-scale
Felix Siebert
University of Lüneburg, Germany; Christoph Ruth; Wiebke Mahfeld; Michael Oehl; Hans-Ruediger Pfister; Rainer Hoeger

Due to the increasing amount of automation in vehicles, the role of the driver changes from having an active part in the driving of the vehicle, to a reactive monitoring task. This change might be relevant to the comfort experienced by the driver. But how can this comfort be assessed? Generally, comfort can be defined as a mood, being pleasant but not especially aroused. Literature proposes measuring discomfort instead of comfort since it is a deviation from the normal state and therefore easier to notice. Since currently there is no subjective questionnaire to measure discomfort in Human-Machine Interaction (HMI), we developed a 14-item scale to measure discomfort of the driver - as an indicator for the absence of comfort - considering the following aspects: Discomfort, demands, risk, and loss of control. The questionnaire was applied in an explorative driving simulator study analysing crucial aspects of future automation. In this experimental study, the distance between the automated vehicle and another vehicle driving ahead was varied in different driving situations.
The internal consistency of the questionnaire was high ($r = .91$). A first validation of the questionnaire was conducted on the basis of driving behaviour and the reliance on the automation. Results suggest that this questionnaire is a useful tool for assessing discomfort in the automated HMI. This first version is focused on, but not limited to, automation and advanced driver assistance in vehicles. A generalisation of the scale for further research, as well as for applied issues, will be discussed.

The roles of audio-subliminal stimulus in power-to-take game

Xianghong Sun Institute of Psychology, CAS, China; Li Ning

Previous studies have shown that subliminal visual stimulus (SVS) could influence people’s perception and judgement through visual priming. How about subliminal auditory stimulus (SAS)? Does it work as well? In this study, a power-to-take game (PTG) was used as an experimental task to investigate the effect of ASS. During the game, the light music named ‘Spring’ was played continuously as background music, with/without subliminal speech (SS) ‘cheer up’ being played. If present, the SS was played repeatedly, once a second. The PTG scores, self-ratings of emotion, and skin conductance were recorded as dependent variables. In Experiment 1, 42 subjects (19 male, 23 female) aged 20–26 were randomly divided into two groups: a control group (play PTG with a light music background) vs. an experimental group (played PTG with a SAS-combined light music background). The results showed that SAS did not make people feel angrier but a little happier, and allowed them to earn more points in the game. In Experiment 2, 64 subjects (32 male, 32 female) aged 18–25 were randomly divided into four groups: 2 SVS (PTG with vs. without SVS) by 2 SAS (PTG without vs. with SAS). The data showed that SAS+SVS made people feel happier, and allowed them to earn more points in the PTG game than the other three groups. In conclusion, both SVS and SAS had a significant effect on emotion and decision making, and the combined condition (SVS + SAS) increased the effect.

One fatality too many: Mining accidents sense-making and safety training

Christian Van Tonder Curtin University, Australia; Johann Groenewald

Precious metals mining (gold and platinum in particular) remains the industry with the highest recorded number of fatal occupational injuries (cf. McGwin et al., 2002; Oldfield & Mostert, 2007) - unquestionably a dangerous occupation (Perrow, 1999). Significant investments by mining houses in safe mining practices have reduced the year-on-year incidence of accidents, but the frequency of accidents and injuries remain unacceptably high (DME, 2008, p. 19). This also occurs against the backdrop of extensive, continuing behavioural sciences research into the interrelatedness of organisational safety practices and individual safety, mostly in sectors other than mining (see Beus, Payne, Bergman & Arthur Jr., 2010; Clarke, 2006; Dollard & Bakker, 2010; Nahrgang, Morgeson & Hofmann, 2011; Naveh, Katz-Navon & Stern, 2011; Neal & Griffin, 2006; Zohar & Luria, 2005). By contrast, studies that considered the cog-
nitive-behavioural models and dynamics with regard to accidents are less common. Drawing on sense-making and mindfulness constructs (cf. Weick, 2001; Weick & Putnam, 2006) the current study aimed to deepen understanding of these dynamics by focusing on a specific accident. Semi-structured interviews and a focus group were conducted with an injured employee, his team members (9) and eight mining officials. Themes extracted through content analysis revealed meaningful variation in respondents’ attribution of causes to the accident. These were influenced by situational (positional) bias, and deficient perception and cognition, which resulted in impaired sense-making. The significance of the findings (and implications) for ongoing research, mining practice in general and safety training in particular, are briefly considered.

The effect of mere-exposure on user experience of interactive systems

Marlene Vogel Berlin Institute of Technology, Germany; Manfred Thuring

The importance of user experience (UX) for designing interactive systems has increased remarkably over the past decades. UX consists of different components (Mahlke & Thüring, 2007), can be subdivided in different phases (Pohlmeier, Hecht, & Blessing, 2009; Karapanos, Zimmermann, Forlizzi, & Martens, 2009) and is increasingly considered as a dynamic phenomenon, highly influenced by several factors, e.g. time, prior experience and increasing familiarity with an interactive system. Due to these characteristics, questions arise like what are the drivers of UX? How do they change over time and what is the resulting user experience and user judgment for specific systems? It is assumed that the mere exposure effect (Zajone, 1969) could possibly be an influencing factor for UX in pre-use phases. The effect of mere exposure and its influence on likability were studied many times over for miscellaneous stimuli (Bornstein, 1989). In the present laboratory experiment the influence of mere exposure on aesthetic and usability evaluation of an interactive system has been examined in a pre-use situation. The results show that exposure, and the amount of exposure, play a significant role when the aesthetic and usability aspects of a smart-phone are evaluated. It can be concluded that increasing exposure leads to increasing aesthetic ratings for well designed and decreasing ratings for bad designed systems. The pre-use condition had also an influence on usability evaluation of positive and negative designed systems, which differed significantly from evaluation of these systems used in an interactive situation.

The relevance of likelihood alarm thresholds for operators’ behaviour and performance

Rebecca Wicerek Berlin Institute of Technology, Germany; Dietrich Manzey

The design of alarm systems is an important issue in the field of human-machine interaction. Alternatives to the binary alarm concept are needed to deal with existing problems. Recent research has shown that the use of likelihood alarm systems (LAS) leads to a reduction of the cry-wolf effect – that is, ignorance of alarms due to a high number of false alarms. The benefit is an increase in operator performance. These positive effects have been found especially under high workload conditions of high. However, relatively little is known about the effect of different threshold settings within the context of LAS. A multi-task pc-based simulation environment was used to investigate the behaviour of 45 participants in interaction with three LAS that differed with regard to their second threshold. Participants of the three different groups worked under two conditions of workload respectively. Response frequencies and performance data were collected and analysed. Results indicate that the most liberal threshold led to significantly less ignorance of alerts than did the more conservative ones. This behaviour resulted in significantly less misses, significantly more hits and a significantly higher overall-sensitivity. The increase of workload led to a significant decrease in performance when thresholds were more conservative, whereas performance in interaction with the more liberal system remained unchanged. These findings indicate that threshold setting of LAS is an important issue for designers of alarm systems because it affects the behaviour and performance of operators using such systems.

Virtuality in applied psychological studies

Alexander Voiskounsky Psychology Department, Moscow State University, Russian Federation

Virtuality can be treated as a three-fold unity. The phenomenological view says virtuality refers to each human’s uniqueness in mechanisms of categorization of outer world’s events; virtuality is personalized. The accepted measure of the point of each view was the number of users referring to its terms, freely produced by respondents. Two surveys, administered in Moscow with University students as respondents (N=90, total number of the produced terms is 282, many terms are repetitive), show that the media view is the most common, the phenomenological view is marginal, the cognitive science view is in between. The 2nd survey showed a shift towards producing more terms referring to the cognitive science view. Although the perspectives of the cognitive science view are the most promising due to success of technologies and useful applications, the other two perspectives suggest possible biases to be discussed. The suggestion is that the likeability of biases (described in both the media and the phenomenological studies) has to be taken into account while pursuing the cognitive science paradigm in the use of virtual realities in applied studies.

Detection of driver distraction by driving performance indices

Lu Yu National Committee on Children, China; Xianghong Sun

The increasing use of mobile phones and IVIS (In-Vehicle Information Systems) has been a major cause of traffic accidents, as a result of driver distraction. A promising way of solving this
problem is to detect driver distraction via in-vehicle warning devices. In this research, we focused on the detection of driver distraction by drivers’ behaviour data. Data were collected in a middle-fidelity driving simulator. 18 participants took part in the experiment and accomplished the single driving task, and driving with a secondary task, respectively. The secondary task was doing arithmetic problems which caused the distraction situation. Participants’ performance data such as steering angle, accelerator degree, car following distance, vehicle velocity, vehicle position in the road, etc. were recorded. Based on the data, the discriminating features of drivers’ distraction state were first extracted. Then, Hidden Markov Model combined with Boosting algorithm was used to detect driver distraction by the features. The results indicated that it was feasible to detect driver distraction by simple drivers’ performance indices. The accuracy of the correct detection was more than 80%. The potential applications of this research include the design of the in-vehicle distraction warning device and the evaluation of driver distraction.

Aging and distal effect anticipation when using tools

Michael Oehl Leuphana University of Luneburg, Germany; Ines Heber; Christine Sutter; Luisa Dahlmanns

The impact of age on controlling tools with sensorimotor transformations is surveyed with regard to action control. Recent evidence lets us assume that the distal action effect (e.g., moving cursor on a display) rather than the proximal action effect (e.g., moving hand that manipulates the tool) determines the efficiency of tool use. In Experiment 1 different gains were explored with a motion- and a force-controlled tool. In correspondence with our assumptions the results revealed evidence that Fitts’ law holds for distal action-effect movements, but less for proximal action-effect movements. Most importantly, this was not only true for the motion-controlled tool, but also for the force-controlled one. Especially for the elder group we found a more efficient use of the motion-controlled tool in comparison to the force-controlled tool, while the gain did not show any impact at all. In Experiment 2 the dominance of the action effect on motor control was confirmed in an experiment with a digitizer tablet. The tablet amplitude was held constant, but again, movement times followed the perceived index of difficulty on the display. This was even more pronounced in the elder participants. It is concluded that Fitts’ law did not rely on the movements of the motor system, but on the distal action effects on the display (changes in visual space). With aging distal action-effect control plays an increasing role on perceiving and controlling tools with sensorimotor transformations.

Session Type: Posters

Investigating the relationship between job enrichment and job performance among employees of the Isfahan railway general office

Hamid Arab University of Isfahan, Islamic Republic of Iran; Masood Ashrafabady; Mohamad Kajbaf; Mojtaba Gashool

The aim of the study was to investigate the relationship between job enrichment and job performance. The test subjects were 150 employees of the administration department of the Isfahan Railway organisation, who were selected according to random sampling. In order to assess the job enrichment, Rif and Tanil’s questionnaire (1973) was employed, and to measure the organisational performance, the organisational performance questionnaire Yar Mohammadian (1370) was applied. The achieved results were analysed through the Pearson correlation statistical method. The results of the study indicated that there is not a significant relationship between job enrichment and the aspects of job performance (employees’ ability, and organisational context). Contrary to the above findings, there is a significant difference between job enrichment and other aspects of job performance (explicitness of the goals, employees’ motivation, education and assessment, validity and organisational support).

Information overload: To face increasing challenges in today’s world of employment

Michael Sprenger University of Innsbruck, Austria; Christine Unterrainer University of Innsbruck, Austria; Pierre Sachse

Cognitive psychology approaches demonstrate the limits of human information processing. During the work process, people are regarded as information processors with restricted capacity (Miller, 1956; Halford, Baker, McCredden & Bain, 2005). While findings with regards to information overload are increasingly based on experimental studies (Eppler & Mengis, 2004), in-depth, contextual insights into the working world are scarce. Using a combination of methods, N=41 (qualitative) and N=122 (quantitative) employees of different service backgrounds of "information-intense-organisations", were included in this study to gain more clearance into the presence of information overload and its structure, major components and determinants. Following the theoretical principles of the concept of information overload (Edmunds & Morris, 2000; Bawden & Robinson, 2009), specially developed methods for the assessment of information load, information overload and determinants as well as respective research tools and scales taken from the field of work psychology were applied. The results confirm the presence of information overload and its relevance to organisations. Major factors that contribute to information overload have been discovered. On a quantitative level of analysis, significant condition-based stressors and resources as well as personal behavioural and health characteristics while experiencing information overload were identified, whereby the results in some cases varied significantly between the different services. Further the analysis on a qualitative level proofs an increasing demand on today’s information society (due to technological progress) that needs to be overcome through individual strategies within the work process. Significant practice-related influential factors will be clearly illustrated.

Generic cognitive strategies in design problem solving: is there any additional benefit to the evaluation and decision-making?

Constance Winkelmann Business School Potsdam, Germany; Winfried Hacker

We are interested in how generic cognitive strategies may assist the decisive early phases of engineering design problem-solving. We analysed, in detail, strategies aimed at the scarcely-considered phases ”assessment of conceptual solutions” and ”selection of a solution.” First, engineering students in the experimental group, had to develop a complete list of the requirements of the device to be designed. Next, they had to select and justify the most suitable one of three presented solutions. The experimental group were given short texts on generic cognitive procedures. The control group worked without these assisting texts. The experimental group applied their lists of requirements more systematically, testing each requirement for each of the solutions more thoroughly, distinguishing more often between indispensable versus only desirable requirements, and considering further improvements of the favoured solution, compared with the control group. The integration of generic cognitive procedures into engineering design education is recommended.
Research Area: Environment/Sustainability

Session Type: Papers

Children’s perceptions of the natural environment: Creating child and environmentally friendly cities
Sabirah Adams University of the Western Cape, South Africa; Shalzy Savahl

A child friendly city (CFC) is the embodiment of the rights of the child manifested in the policies, programmes, and laws of a city, wherein the natural environment (NE) is deemed critical. Premised upon a child participatory perspective, this study aimed to explore the manner in which adolescents perceive the NE and the creation of a CFC, as there is limited research concerning this. This study employed the epistemological position of social constructionism, and the theoretical framework of the Person-environment (P-E) fit theory. Methodologically, a qualitative research design was adopted employing four focus group interviews with children aged 13 and 14 years in grade 9. The study was conducted in Parkwood, a low-income area in the Western Cape Province of South Africa. Thematic Analysis was utilised to analyse and interpret the findings. The findings indicated that the participants perceive the NE through the lens of safety as natural areas in their community are characterised by crime, violence, and pollution. The participants thus fall outside the prevailing categories of the social and cultural construction of childhood as they undergo an immense burden of adversity and suffering, breaching what childhood is supposed to signify. Ultimately, the participants revealed that their community is not child friendly, and suggested the requirement for a child and environmentally friendly city, considering the natural world as crucial in the creation of a CFC. The participants therefore proposed that environmental education be incorporated into the school curriculum to instil a greater awareness of environmental issues among their peers.

Feeling good about compliance: Affective consequences of environmental appeals
Jan Willem Bolderdijk University of Groningen, Netherlands; Linda Steg; Ebru Dogan

Environmental campaigns typically frame the benefits of specific energy-saving actions in monetary (e.g. X dollar savings), rather than environmental terms (e.g. X less grams of CO2). The underlying assumption is that appealing to environmental concern alone is insufficient to motivate pro-environmental behavior. We however argue that environmental frames may exert an emotional impact: they turn an otherwise neutral decision (e.g. do I turn off the lights in my office?) into a moral dilemma, giving the decision whether or not to save energy an emotional charge. We explored this hypothesis in three experiments. Study 1 revealed that drivers feel worse about consuming energy when they are confronted with environmental consequences (‘Turning on the aircon emits X grams of CO2’) as compared to monetary consequences (‘Turning on the aircon costs X eurocents’). Study 2 suggests that this pattern is not limited to people who endorse environmental values. We found that, regardless of interpersonal differences in environmental values, people feel better about complying with an environmental appeal (‘Checking your tires protects the environment’) than a monetary appeal (‘Checking your tires saves money’). Study 3 tested the real-world implications of these findings. In a field experiment, we found that drivers we more likely to comply to environmental rather than monetary tire-check appeal. These results suggest that the way pro-environmental appeals are framed in campaigns may influence how people feel about compliance, thereby potentially affecting persuasion.

Reflecting on littering: A shiny surface activates the concept of cleanliness
Ron Broeders University of Technology, Netherlands; Cees Midden; Jaap Ham; Daniel Lakens

Environmental, social, and aesthetic problems initiated research on understanding and preventing littering. For instance, according to Cialdini and colleagues (1990) litter attracts litter and clean environments stay clean. Furthermore, recent reports suggested a less intentional and deliberate perspective on littering because people often are not aware of their littering behavior. Combining this with the notion that information media-campaigns do not warrant permanent behavioral changes, we present three studies with a social cognitive approach to littering. From infancy individuals learn through repeated experience that clean objects shine. People may thus associate visual shininess with cleanliness. Put differently, when people are confronted with shiny surfaces, possibly the concept of clean becomes cognitively accessible subsequently influencing behavior. In Study 1, after being exposed to a Stroop-like task presenting synonyms for clean and unclean with shiny or dull font styles, participants categorized clean synonyms with dull font styles or unclean synonyms having shiny font styles. Study 2 investigated judgments under uncertainty. These differed significantly depending on font style. Participants translated clean synonyms into shiny Chinese characters above guessing average, thereby conceptually replicating Study 1. In Study 3 participants cleaned more when exposed to shiny rather than dull table tops, confirming expectations that a shiny environment activates cleaning behavior. Our data indeed suggests a cognitive link between perceptual shininess and cleanliness. Regarding littering this may lead to interesting interventions and behavioral effects, for example environments with shiny elements (e.g. tiles) could result in less littering and more binning of waste.

Household electricity use in South Africa: A systemic study of an individual intervention
Mathilda Du Preez University of Pretoria, South Africa; Claire Wagner

There is a lack of published research on the impact of human behavior on the environment in the South African context. Environmental problems due to behavioural choices of humans necessitate changes in behaviour patterns. The aim of this study was to determine the effectiveness of an intervention, with an individual in a household, on the households’ electricity usage. A description of the conservation strategies employed by households as perceived by the individual (participant) and how participants in the different research sites strategised about saving electricity is provided. Volunteers from three research sites in Pretoria, with distinctly different socioeconomic contexts, were selected for the study and randomly assigned to two experimental groups. After a baseline measurement of kWh for one week, different interventions in the two groups took place. In total the kWh use of 41 households was measured, 20 interviews were conducted and six focus groups were held. The results provide a better understanding of the effect of an individual intervention in a household, describing strategies employed for saving electricity and differences in addressing efficiency in the home linked to socioeconomic context. It seems that the intervention did not have a significant effect on the energy savings achieved in a household and that the largest contributor to significant residential savings would be dispelling ‘myths’ about electricity consumption. Suggestions for expansion of the research, including a questionnaire survey amongst a representative sample of South Africans to test the findings from this study, are made.

Perception of climate change and pro-environmental behaviour in Taiwan
Ruey-Ling Chu Institute of Ethnicology, AS, Taiwan, R. O.C.; Shu-Wen Yang

The main purpose of this study is to examine the current public perception of climate change and coping behaviours towards global warming and climate change in Taiwan. Although there are clear changes in the abatement behaviour, for example environments with shiny elements (e.g. tiles) could result in less littering and more binning of waste.

Psychological distance impacts environmental attitudes
Margaret Dust Chicago State University, United States of America; Elizabeth Arnott-Hill

Environmental concerns have reemerged the public spotlight in recent years. A growing awareness of these issues has led to education initiatives that seek to inform the public about actions that individuals can take to positively impact the environment. The present study sought to extend current research by investigating the impact that psychological distance had on subsequent environmental attitudes. Students in a sample from an urban, non-traditional university were exposed to one of four
counterbalanced versions of a questionnaire. Participants were first asked various demographic questions and three open-ended questions about specific environmental attitudes. In the second part of the questionnaire, each version presented a number of environmental scenarios that ranged from close and personal (a child is affected by pollution) to distant and impersonal (a penguin in the Antarctic is affected by pollution). Participants were then asked to indicate their level of agreement with a related pro-environmental message. As predicted, the psychological distance – or perceived distance – of the participant from the problem was related to that individual’s level of agreement with a pro-environmental message. This relationship held for both the temporal and spatial versions of the psychological distance questions. The type of environment in which the participant was raised also predicted responses to the open-ended questions. These results suggest that tailoring environmental arguments to the audience – so as to make the message personal and the impact immediate – may aid in their overall effectiveness.

Causal direction and amount of spontaneous change in environmental attitude and attitude toward nature

Florian Kaiser Otto-von-Guericke University, Germany; Terry Hartig; Adrian Bruegger

Promoting a positive environmental attitude and, thus, ecological engagement in individuals by means of advancing their attitude toward nature seems possible but represents only one of three options: causality can go in either of two directions or can be bidirectional. To date, we do not have any evidence in favor of one of the three options. Based on longitudinal data of 251 persons, we additionally explored the malleability and, thus, the likelihood of spontaneous change in the two attitudes. In our research, we found that the great majority did not change in the extent of their appreciation of nature and in the extent of environmental-protection engagement across more than two years. If spontaneous change occurred at all, it happened as an increase in both attitudes simultaneously. By means of a cross-lagged structural equation model, we corroborated once again the substantive connection between the two attitudes, but could not find reliable knowledge regarding the direction of their causal relation.

Forecasting the mobility culture of an ageing society: Constraints and perspectives

Uwe M. Kleinemas University of Bonn, Germany; Georg Rudinger; Uwe Kleinemas; Nicolas Haverkamp

The current study focused on three objectives: (1) Conceptualization of scenarios of German Mobility for the year 2030 and evaluation of their significance for mobility behaviour, (2) collection of data about the desires and needs of the “baby-boomer” generation, and (3) identification of necessary and desirable changes to optimize their fit with the anticipated traffic environment. Methodologically, a transdisciplinary working group of experts developed self-consistent scenarios, referring to a model of influence environments. Furthermore, a representative population survey of 1000 “baby-boomers” has been carried out, covering their current mobility habits, future requirements and needs, lifestyle preferences, and mobility related attitudes. The results show: (1) Two controversial scenarios, suggesting either innovations with younger people as trend setters or a negative development with a mismatch of needs and mobility reality. (2) Strong demand for improvements in public transport and expectancy of more frequent slow-mode mobility in the future. (3) Desirable Changes: Communication of ‘Intermodality’ as a guiding principle of traffic participation, promotion of innovative developments in slow mode traffic, and ‘good design for all’; creating an environment free from hostile properties towards any group of traffic participants. These results support rational policy decisions. First of all, they indicate relevance and urgency of intervention to maintain future mobility. Secondly, they can trigger an open discourse of the implications of demographic change. Thirdly, they offer operational clues within the intervention levels of the individual, the technology, and the spatial environment.

Putting your money where your mouth is: The effects of intrinsic versus extrinsic life values on willingness to pay and protect the environment

Lisbeth Ku University of Macau, Macao

Based on Self Determination Theory (Ryan & Deci, 2000), the present research hypothesised that individuals who endorse intrinsic life values such as affiliation and community over extrinsic values such as money and image would be more willing to protect the environment. Findings from 169 university students (study 1; M=21.11 years, SD=1.10), and from 347 adults (study 2; M=31.65 years, SD=14.48), showed that higher endorsement of intrinsic over extrinsic values was indeed related to more pro-environmental attitudes, more engagement in pro-environmental behaviours, and a higher willingness to pay to protect the environment. Study 3 experimentally primed intrinsic versus extrinsic values by momentarily brightening either intrinsic values (n=54) or extrinsic values (n=53). Compared to the control group (n=50) who did not receive any value manipulation, participants in the intrinsic values prime condition donated significantly more money, while participants in the extrinsic values prime condition donated significantly less money to pro-environmental causes.

An exploratory study into the cultural underpinnings necessary for sustainable development in organisations

Michael Leary University of South Africa, South Africa

It’s become increasingly important for organisations to adopt a sustainable development approach in their functioning if they are to survive and prosper. Organisations are discovering that substantial value can be generated through sustainability, while improving the quality of customer’s lives and the community in which they function. Previously, sustainability was viewed as organisational efforts to protect the environment and reduce carbon footprints. Nowadays, sustainability/sustainable development emphasises the economic, environmental, social and institutional factors leading towards more sustainable business. There’s a paradigm shift in the way organisations respond to the need to adopt sustainability approaches in their business dealings. To achieve sustainable development, organisations have to focus understanding and application of sustainable development in their everyday functioning, to inculcate this thinking and approach into their organisational culture. An important attribute of culture pertinent to the sustainable development perspective is that culture creates meaning and common understanding in organisations and as such is the necessary focus by which organisations approach sustainable development. This study aims to determine an organisational culture that drives and underpins sustainable development. To achieve this, a tribal group that has been successful for hundreds of years in ensuring sustainable development within their tribal community is investigated. The findings as they relate to culture and sustainable development are extrapolated to organisational culture and sustainable development in organisations. Emphasis is placed on the manner in which the underpins and supports sustainable development, in the tribal group and in business organisations. Further, a model is proposed for sustainable development in organisations.

Human sustainability and well-being in a changing world

Anna Leonova Moscow State University, Russian Federation; Thomas McAdams; Amy Potterton Contemporary approaches in studies of individuals’ adaptation to a dynamic social life/technological environment will be considered with the accent on the analysis of regulatory mechanisms of ongoing human activity in demanding conditions. The methodology of multi-level assessment of human sustainability in terms of maintaining mental health and well-being will be discussed in the framework of activity theory and the relevant concepts of psychological stress (Leontiev, 1975; Broadbent, 1985; Lazarus, 1991; Leonova, 2008). The emphasis will be on the integration of two hitherto independent lines of research - the situational dynamics of human functional states (HFS) and the individual’s abilities to cope with stressful life events. A new model of individual stress-resistance, elaborated on the basis of the ‘state-trait’ paradigm (Eysenck & Eysenck, 1985; Spielberger, 1970, 2006; Leonova, 2008, 2010), will be described. The results of recent experimental modeling studies (task switching under the influence of negative emotional feedback) and series of empirical research (carried out on personnel working under extreme job demands) exemplify the diagnostic properties of this integrative model. As a continuation, the ways of development of relevant psychological technologies for the correction of currently-evoked negative HFS and the compiling of a long-term health promotion/stress resilience program will be outlined. In addition, there will be presented new data of representative twin studies on the genetic involvement in some but not the other components of individual sustainability to stress (Leonova et al., 2011).

A psychological interpretation of Chinese wisdom of sustainability

Ming Li Beijing Forestry University, China

The most urgent problem the world is facing is environmental sustainability. The Chinese axial cannon, I-Ching or The Book of Change, presented
a cosmological guideline to solve this problem. An interpretation from psychological perspective will be very useful in retrieving the ancient wisdom of sustainability of the fast growing developing country. It will be valuable for both China and the world to utilise its rich psychological cultural heritage. Based on the discourse of The Book of Change, the present paper tries to elucidate 4 subjects for further discussion. (1) The psychological methodology of The Book of Change; (2) The behaviour model of appropriateness of The Book of Change; (3) A new ethic of sustainability implicated in The Book of Change; (4) The existential awareness of the earth and the heaven of The Book of Change.

UTAUT factors that lead to the acceptance of a Solar Recharge Booth
Musa Maluleke University of the Witwatersrand, South Africa
Environmental degradation and environmental deple- tion are concerning issues that have received a great deal of attention for a number of years. There is growing concern that the environment has to be maintained and protected for the sake of future generations. The aim of this research was to inves- tigate the important factors of the Unified Theory of Acceptance and Use of Technology (UTAUT) which would explain the Intention to use the Solar Recharge Booth. The research proposed that Envi- ronmental Concern and Age would moderate the relationship between the UTAUT factors and Inten- tions to use the Solar Recharge Booth. The sample consisted of 108 students from the University of the Witwatersrand, who were invited to participate in the research through purposive and snowballing sampling. The statistical analysis utilised was mul- tiple linear regression analysis in order to find out which factors would predict Intentions to use the Solar Recharge Booth. The results showed that Performance Expectancy, Social Influence and Fa- cilitating Conditions were able to explain the Inten- tions to use the Solar Recharge Booth, whilst En- vironmental Concern and Age were not signifi- cant predictors of Intentions to use the Solar Recharge Booth. This research is important because as con- cerns over environmental degradation increases there is a need to investigate what factors will encourage people to adopt more environmentally friendly technology.

Toward sustainable psychology
Girishwar Misra University of Delhi, India
Under the influence of modernist ideology, psychol- ogy nurtures a model of the human being with self as autonomous entity, equipped with the capacity to choose, and control. This paper critically reviews the evidence about the viability and potential of this model, and empirically examines the conceptualisa- tion of the "optimal way of being." A study of the narratives from young adults in India about the con- ceptualisation of the optimal way of being (n=250) was conducted. The data revealed existence of a disconnect between external materialistic strivings, and the robustness of well-being. Being deficit driv- en, externally directed, and object dependent, the prevailing model has contributed to violence, mind- less consumption of environmental resources, and preference for materialistic values like seeking wealth, possessions and status. It is positively related to suffering, and unpleasant emotions, and substance use; healthy and compassionate human interactions are undermined, and instead, the tendency for ego- tism and greed are encouraged. This results in per- sonal suffering and low compassion. Regulating needs emerged as the core theme in conceptualisa- tion of an optimal life. A balanced approach to the pursuit of material and sensual pleasure that allows the flourishing of harmony in life, emerged as the key pathway for well-being. This requires inculcating a sense of equanimity, contentment, and inner peace through mind training. A sustainable psychology would contribute as much as possible to the well- being of others and to protect the environment. The policy and research implications of the emerging grounded theory of optimal way of being are indi- cated.

The detrimental effects of litter: A study examining the impacts litter has on well- being
Sabine Pahl United Kingdom; Richard Thompson
The negative effects on the environment from leav- ing litter, have been well documented. Marine litter alone has been responsible for about 100,000 ma- rine mammal and 700,000 seabird deaths each year. Even though previous work has indicated that litter is not only detrimental to the environment but also to visitors, there is little research known that has examined the impacts on visitors directly. A short laboratory study examined this. Participants (n = 79) rated a series of images according to five mea- sures: (1) aesthetic preference; (2) behavioural preference; (3) happiness; (4) arousal; and (5) restor- ative potential. To manipulate litter, the stimuli were systematically designed. All stimuli were taken on the coast during low tide with similar element weather conditions and from a sitting looking-out-to-sea perspective. The scenes were then either (1) clean; or had (2) seaweed; (3) visitor-litter or (4) fishing-litter scattered in the lower quarter. Litter was found on the shore and represented the major categories of litter typically found. To link this research with the previous environmental literature, (clean) categories of other environments were also used. Findings statistically show that the two lit- ter environments were the least beneficial condi- tions compared to both the clean and seaweed identical environmental conditions and also com- pared to the other environment categories. Thus, these findings show that litter is not only detrimental to the environment but also to our wellbeing. Future work, that will be discussed, plans to exam- ine this further by exploring possible implications and solutions.

Evaluation of the introduction of a charge on single-use carrier bags in wales: Attitude change and behavioral spillover
Wouter Poortinga Cardiff University, United Kingdom
Wales is the first country in the U.K. to introduce a charge on single-use carrier bags in order to curb their use. From October 2011 onwards, shoppers will have to pay 5 pence for each single-use carrier bag at point of sale. This presentation will report preliminary results of a field experiment evaluating the attitudinal and behavioral impacts of the bag charge. Around 500 telephone interviews were con- ducted in Wales before the introduction (September 2011). The same respondents were re-contacted six months after the introduction of the bag charge (April 2012). A similar survey was conducted in England as a control group. It is expected that the charge will substantially reduce the use of such bags in Wales, and that – due to cognitive disso- nance/self-perception processes as well as experi- ences with the benefits of the policy – the policy will become more acceptable after its implementa- tion. It is further explored whether the policy may lead to behavioral spillover in other waste-related behaviors as a result of the development of more positive waste-related attitudes and norms.

A segmentation of Welsh sustainability atti- tudes and behaviours
Wouter Poortinga Cardiff University, United Kingdom
The presentation reports on a sustainability segmen- tation project commissioned by the Welsh Govern- ment. The aim of the project was to identify different publics with regard to their views on sustainability. A detailed questionnaire was designed that included the theoretically relevant constructs of personal values, beliefs on environmental and economic sus- tainability, perceptions of climate change and energy security, attitudes to ‘living and Wales’, and social capital and place attachment (n=1,538). The internally consistent scales formed the basis for the hier- archical cluster analysis identifying three suitable cluster solutions. A K-means cluster analysis with 5 random starts identified six clusters as the most stable solution. The segments were found to have distinct socio-demographic profiles as well as differ- ent behavioural patterns regarding household energy use, transport, waste production and recycling, and water use. Fifteen ‘golden questions’ were selected from the original scales to replicate the six segments with 70% accuracy in future research. The presenta- tion will further report on the naming process designed to ensure that the segment labels are evi- dence-led, easy to communicate, and owned by pol- icy makers across different departments of the Welsh Government.

Climate change tacit knowledge, coastal dis- tress and subjective well-being in vulnerable coastal cities of India
Parul Rishi NITTR, Bhopal, India; Ruchi Mudaliar
A behavioural study of climate change tacit knowl- edge, coastal distress and subjective well-being (SWB) was conducted in vulnerable coastal cities of India to assess the climate change awareness of respondents together with understanding the climate stress, SWB and coping/adaptation. Primary data were collected from 550 respondents using the Cli- mate Change Perception Inventory (CCPI) using a multistage sampling technique. The results indicated a good level of awareness in terms of tacit knowledge and climate change impacts among coastal people. However respondents were found to be dissatisfied with the way developed nations were exploiting the common resources for their luxurious lifestyles, causing resource and environmental stress. They expressed their ability to cope at individual/group/ institutional level but adaptation effort was found to be limited, in spite of the moderate to high SWB. A moderate level of coastal distress was experienced, and they expected more efforts on the part of gov- ernment and environmental institutions for dealing
with climate change in coastal cities and suggested various adaptive strategies in this regard. The study has strong implications for coastal institutions and media for a proactive and responsive approach for generating awareness and in managing the climate change related issues in the coastal areas. Future interventions must incorporate the socio-psychological dimensions of climate change to enhance the awareness and adaptation efforts of coastal communities.

The ethical environment: An interpretation of environmental psychology by the optics of the existential phenomenology

Vitor Sampaio PUC-SP, Brazil; Marlise Bassani PUC-SP, Brazil

Environmental Psychology studies the relationships between people and the physical; natural; built environment (Basani, 2003), focusing on spatial, temporal, cultural realms (Moser, 2002). This work aims to contextualise environments that allow social living and the formation of social networks, which will be studied under the existential-phenomenological thinking. This analysis focuses on a global environment and the factors contributing for social bonds, takes into consideration the fundamental disposition of being-in-the-world as a starting point to understand how people socialise with their own environments. The concept of being-in-the-world postulates that men are launched to a future that is presented at their horizon of significance. This openness to the future is only possible in the world where the human dwell and dwell is "being-with". Thus, under phenomenological thinking, an environment facilitates the formation of social bonds. To reflect about the environment as a space built and transformed by who lives and interacts with it, loaded with affection and history, drives the conception of this environment as a ethical environment. Ethics, from the greek ‘Ethos’, or men’s dwelling-place, is the "living-with", the coexistence of being-in-the-world. According to Heidegger, ethics is always situational, given by the "being-with" while dwelling in the world. This analysis refers to the Ethical Environments, which grants the formation of social networking, co-existence and the ethics of dwelling, as well as the possibility of development of such Ethical Environments.

Personal relations with nature as the feature of ecological consciousness

Nazym Satybaldina Kazakh National University, Kazakhstan; Kamilla Manakova

The purpose of the research was the identification of types of environmental consciousness among people in three age groups: 18-25 years old, 40-50 years old and 65-75 years old. Environmental consciousness is determined by the psychological features of personal attitude towards nature. The basis of the personal attitude towards nature is reflection of the individual’s necessity in natural objects and processes. The main features of the personal attitude towards nature are: the breadth, intensity and awareness of needs. The study tested 150 people (50 people of each age group), both male and female. A survey research method was used to assess the type of personal attitude towards nature is. The study used the following methods: "Naturofil," "Alternative," "Dominant," "Aesop".

According to the survey in 18-25 the aesthetic type of interaction with natural objects prevails, in 40-50 years - the pragmatic type, and in 65-75 years - a practical type. People are willing to explore the nature between 18 and 25 years old. In 65-70 years old the desire to investigate is almost absent.

Causes for attention to nuclear power plant in Japan

Kazuhiro Takemura Department of Psychology, Waseda University, Japan; Takashi Ideno; Tsuyoshi Hatori

The Fukushima Daiichi nuclear disaster, the largest nuclear disaster since the Chernobyl disaster of 1986, occurred as a series of equipment failures and the release of radioactive material at the Fukushima Daiichi Nuclear Power Plant, following the Great East Japan Earthquake and the subsequent tsunami on 11 March 2011. We analysed relations between the intensity of radioactive contamination in Fukushima and Tokyo, the number of articles about nuclear power plants in the Asahi Shimbun, and internet search queries of nuclear power plants (via Google) during 11 March 2011 – September 2011. Correlation analysis revealed that query-based internet searches of nuclear power plants in Fukushima and Tokyo were strongly related to the intensity of radioactive contamination in Fukushima. Numbers of articles related to nuclear power plants for Asahi Shimbun were significantly, but weakly, correlated to the numbers of query-based internet searches. Results of correlation and partial correlation analyses suggest that social attention to nuclear power plants was more strongly influenced by the intensity of radioactive contamination in Fukushima than by newspaper articles about nuclear power plants. We also analysed impacts of the intensity of radioactive contamination, the rate of change of radioactive contamination (first derivative), and acceleration of change of radioactive contamination (second derivative) on the retrieval of information about nuclear power plants in Fukushima and Tokyo. Multiple regression analysis results showed that the increasing rate of change of radioactive contamination in Fukushima had the strongest impact on internet searches in Fukushima and Tokyo.

A bright view on sustainability

Leonore Venhooven University of Groningen, Netherlands; Linda Steg; Jan Willem Bolderdijk; Kees Keizer

The prevailing idea regarding sustainable behaviour is that people see it as an altruistic act. This point of view suggests that although sustainable behaviour is beneficial and positive on a collective level, it is perceived as costly and negative for the individual. But does sustainable behaviour indeed trigger such negative emotions? Recent correlational research (e.g. Brown & Kasser, 2005) reveals that sustainable people are happier than those who do not engage in sustainable behaviour. Therefore we suggest that sustainability is associated with positive instead of negative emotions. In the present research, we test this assumption and investigate whether the effect is general, or limited to people with strong biospheric values. To control for socially desirable answers, we used an Implicit Association Task (IAT). As our results show, the combination of positive and sustainability words was processed more quickly than the combination of negative and sustainability words, also when participants had weak biospheric values. So counter to the prevailing idea, people perceive sustainability as something positive – even when they don’t see “protecting the environment” as one of their core values. Our findings could have important implications for the viewpoints taken in sustainability campaigns. At the moment, most campaigns are focused on reducing the assumed negative emotions associated with sustainable behaviour, while the current study shows that people don’t perceive sustainability as something negative. So instead of reducing negative emotions, campaigns should focus on strengthening the already present positive emotions to get the best results.

The multi-selection forward judgment mechanism for new energy entrepreneurial change decisions in Chinese organisations

Zhongming Wang Zhejiang University, China; Wei Xiong Lai

With the down-turn of world economy and over-confident booming of a new energy industry in China, green-energy entrepreneurship firms are increasingly faced with incremental decision challenges. Previous research on strategic decision making could not fully explain the mechanism of the incremental decision process. The objective of this study was to find out the characteristics and incremental mechanism of entrepreneurial change decisions under highly-uncertain industrial transformation and up-grading process for solar energy entrepreneurship in Chinese organisations. An in-depth multi-case study methodology was adopted in this study. Altogether, three cases of solar energy entrepreneurship firms in Zhejiang Province, China, were systematically investigated. Executive managers and entrepreneurs were interviewed and the case focus discussion sessions were carried out. The results of this study showed that the green entrepreneurial change decision process was highly dynamic and progressive with multiple correlates of global, technological, innovative, risky, collective, social, governmental, and organisational factors. The multi-case analysis demonstrated a parallel distributed processing along with the adaptation-selection-development model of organisational change and strategic entrepreneurial decision making. A multi-S (selection) forward judgment mechanism was formulated and tested in order to interpret the dynamic change decisions and capture the incremental decision process for progressive green entrepreneurship and new energy entrepreneurial change in Chinese organisations.

Social influences on individual adaptation to climate change

Diana Woelki University Magdeburg, Germany; P. Schultz; Florian Kaiser

In addition to protecting the environment here and now, policy making recently involves persuading people to adapt to the expected climate changes. In a first survey in 2010, we assessed the status quo of people’s general ecological behavior (i.e. GEB; see Kaiser, F.G., 1998) and climate adaptation in a selection of German municipalities particularly vulnerable to climate change, to find out through Rasch-modelling about the one-dimensional structure of the two correlated phenomena (r=67). Thus, based on the intrinsic pro-environmental motivational level
and our knowledge of its geographical distribution, two community-based interventions were developed for low and average motivated groups. Embedded in a public campaign the interventions deploy social norms and social competition combined with specific behaviours regarding energy and water use, mobility, transportation, consumerism, the protection of health and property as well as political and social engagement. In addition, people received feedback on their district’s average motivation compared to the whole municipality. In a post-intervention survey the efficacy of the two interventions with regard to the adoption of climate-relevant behaviours was assessed through 2X2 ANOVA, with respect to the control and pre-intervention sample. The applicability of these interventions to promote adaptation to climate change will be discussed.

The research about the birth behaviours’ effect on the ecosystem carrying capacity

Jianping Wu Beijing Forestry University, China; Lihong Ye

This paper discusses the effect of birth behaviour on the ecosystem’s carrying capacity. It analysed the effect of fertility desire on the size of population from the angle of economic, society and culture. And then a point is raised that patriarchy, sex prejudice and poverty fostered the individual’s birth desire and then stimulated the population growth. In China, the sex ratio at birth population already broke through the cordon. Gender imbalance is becoming a serious social problem. The view that population growth will lead to the increase of pollution has been further discarded in this article. The rapid increasing of pollution will be following the exponential growth of population. So the pollution caused by human activity will bring huge environmental pressure on terrestrial ecosystem. The formula of the effect on ecosystem by population amount and human activity is P^A*T. The formula is read as: The impact of a group to the ecosystem is the product of three factors. The first one is the size of the population; the second one is the per-capita affluence which is measured by consumption; the third one is the technologies which cause the increasing consumption and ecological damage. In the formula of ecosystem’s carrying capacity, population’s effect is huge.

Research on the air quality of Beijing: The difference between the subjective evaluation by the public and the api reports by the environmental protection agency

Liu Hong Ye Beijing Forestry University, China; Jianping Wu

The objective of the study was to explore whether the subjective evaluation of the air quality by Beijing residents is different from the API reported by the Environmental Protection Agency (EAP) and whether different groups have the same air quality criteria. 90 people were randomly selected to evaluate the air quality of Beijing via 76 photos which were taken in 38 days (two photos per day) from December 2010 to March 2011. The comparison between the subjective assessment of the public and the API reported by EAP was then made. The test shows the evaluation of the air quality of Beijing by the public is more severe than the API by EAP, p=0.01. The one-way ANOVA shows that group category (students, working people, and retirees) has a marginally significant influence on the evaluation of air quality, p=0.075. The level of education and the air quality of the subject’s hometown has a significant impact on their assessment of the air quality of Beijing, the former p<0.05, the latter p=0.01. It was concluded that gender does not have a significant effect on the evaluation of the air quality of Beijing, while the level of education, group category and the air quality of the subject’s hometown do. Specifically, people with an education level above master’s degree, working people and the subjects with best and worst air quality in their hometown have stricter criteria on air quality.

The analysis of the accommodation and the place identity of minority students in Beijing

Jiajun Yin Beijing Forestry University, China; Jianping Wu

The objective of the study is to reveal the relationship between accommodation and the place identity of minority college students in Beijing thus helping students adapt to their cultures better and faster. 300 students were randomly selected. They complete the adolescent social adjustment questionnaire and urban identity questionnaire. The t-test shows that the difference in accommodation between is significant, p=0.01, but not significant in place identity, p=0.274. The correlation is significant r=0.184*. But R²=0.216, so the regression analysis is not suitable. It was concluded that nation has a significant effect on accommodation while not on place identity. Gender does not have a significant effect on both accommodation and place identity. The better place identity, the better accommodation; but the place identity can not make predictions of social adaptation.

Session Type: Posters

Predictors of environmental risk and mental health: The role of quality of life

Saretta Beets North-West University (Potch), South Africa; Vera Roos; Dewald van Niekerk; Michael Temane

Quality of life is of importance to individuals as it may influence mental health positively. Unfortunately, quality of life may be affected negatively if the environment makes demands on the lives of especially the poor in rural areas, when they are affected by environmental risks, for example, fires, floods, drought and epidemics. The aim of this study was to determine the role of quality of life in the prediction of the relationship between environmental risk and mental health. For purposes of this study quality of life was conceptualised as including: (1) access to or ownership of agricultural land, (2) ownership of livestock, (3) access to medical facilities, (4) access to water, and (5) access to electricity. Data were collected by means of a questionnaire and participants were selected from a district prone to environmental risks. The results show that the relationship between environmental risk and mental health was not influenced by quality of life and that those who were better off (higher quality of life) had a lower score on mental health despite being more protected against environmental risk than the other group. It was concluded that future studies on environmental risk could use a more qualitative approach to elicit information about the types of strengths and resilience of individuals in areas prone to environmental risk.

Climate change as a determinant of lifestyle changes and strange living conditions in Cameroon: Which coping strategies?

Effange Emilia UB, Cameroon; Effange Ngowo

About 80% of the poor in Cameroon live in rural areas and work primarily in agriculture, and nearly 35% of GDP comes from agriculture and related activities. Close to 70% of the national labour force is employed in agriculture. These statistics show that Cameroon largely depends on agriculture for the well-being of its citizens. However, the effect of global climate change resulting from global warming is not only hitting the agricultural sector in Cameroon but also human development. One immediate impact seriously affecting the human population in Cameroon is poverty and its adverse effects on human development. Using a triangulated approach, qualitative measures were adopted to access and collect data on climate change and farming products in Cameroon. There were also observations and recording of data in weather stations across Cameroon. Interviews were also conducted on participants’ experience of reduction in streams, the drop in farm products and the perceived implication on their developmental agendas. Findings showed significant decreases in standards of living, manifest in low income as a result of a significant decline in farm products. Other emerging effects are poor health, lack of education, child mortality, low life and work expectancy and, in many cases, general misery malaise and hopelessness is on the rise. The disappearance of certain food crops is also affecting nutritional habits and life styles are generally changing. Typical coping strategies emerging are migration into city centres, family planning to reduce child-care burden, continuing and life-long education, white-collar career orientation and mechanized farming.

Sitting well-being and psychosocial support: A place-based perspective on 18 to 25 year olds’ processes of (re)establishing well-being following the Victorian bush fires

Samantha Mordech Victoria University, Australia; Liz Short

Psychosocial paradigms are the preferred frameworks for supporting individuals and communities
through disaster relief, recovery and redevelopment processes. Within these paradigms, children and adolescents are considered particularly ‘at risk’ of heightened distress. However, the experiences and needs of ‘older’ young people (18–25 year olds) are not understood or addressed. The field is yet to specifically attend to this group’s recovery processes, limiting the development of strategies of integrated community-wide (and other forms of) support. Additionally, burgeoning fields of inquiry consider place an important component of psychosocial well-being and recovery. In the context of disaster, however, place is continually approached in deficit-based terms undergoing understanding of the potentially restorative aspects of environments and places and their role in meaning-making, resiliency and support. This study provides a place-based analysis of 18 to 25 year olds’ processes of (re)establishing well-being following the 2009 Victorian Bush fires. Semi-structured interviews with young adults, workers and experts in the field inform a situational analysis of the resources and processes that promote and/or hinder young adult’s psychosocial well-being and general mental health, with a focus on developing greater understanding of the role of place in their recovery processes. Aspects of people, relationships, activities, resources, processes, neighbours and places are involved. Findings are considered in the context of research, community psychology and disaster recovery policy, and inform recommendations for researchers and service providers engaged in supporting young people and mitigating the impact of future disasters on well-being and communities.

Session Type: Invited Symposiums

Symposium title: Community-based approaches to addressing environmental problems

Convenor: Paul Schultz

Energy teams: A cooperative community-based approach to residential energy efficiency

Paul Schultz California State University, United States of America; Samuel Gordon; Jennifer Tabana; Marsha Walton

Residential energy efficiency offers an important target for reducing energy consumption, conserving natural resources, and reducing greenhouse gas emissions. One promising strategy involves cooperative activities in which groups of residents come together on a regular basis to discuss energy issues in their homes and communities, set goals, engage in activities, and report back to the group. This presentation summarises a cooperative pilot program implemented in Syracuse New York. The program involves groups of 5–10 households working collectively on a series of structured activities designed to promote more efficient uses of energy in their homes. The activities were integrated into a workbook, and included monitoring, lighting, electronics, heating and cooling, and weatherisation. The activities were designed for both in-person energy teams and on-line energy teams. The presentation summarises the approach, discusses the exercises and materials, and presents preliminary data from program implementation.

Using persuasive technology to promote sustainable behaviour

Cees Midden Eindhoven University of Technology, Netherlands

Sustainable living is to a large extent the outcome of how consumers use the technology surrounding them. Seen from this perspective the rather strict separation of technological and behavioral solutions is not only artificial but also detrimental to finding real sustainable solutions. Based on a series of experimental studies, I will show how persuasive technology can intervene in these user-system interactions by using intelligent agents to change human attitudes and behaviour. Artificial agents like robots and avatars go beyond the function of a simple tool by adopting social behaviours that allow for exerting social influence on human behaviour. This raises the question, which factors cause the transformation of an object into a social actor? I will discuss how the level of perceived social agency influences the attitudinal and behavioural effects of a persuasive intervention, and which psychological processes are underlying these effects. Ambient Persuasive Technology can be employed to provide feedback that needs less cognitive resources, can persuade the user without receiving the user’s conscious attention, and in general, can be more influential than more focal forms of persuasive technology. Various types of automatic processing in persuasive communication will be discussed. Sustainability is basically a social phenomenon. In that context, I will show that persuasive technology is not only able to influence the behaviour of individuals, but also of groups, among others, by providing various types of feedback on the group level.

The Goettingen approach of sustainability science: Integrating the defining characteristics of sustainable development, and sustainability science

Peter Schmuck University Goettingen, Germany

The Goettingen approach of sustainability science consists of seven elements comprising specific tasks of scientists to fulfill the research cycle. The approach presupposes a group of scientists willing to co-operate, and sharing an intrinsic sustainability motivation. The first task is defined as the traditional scientists’ role (traditional research producing scientific knowledge). The other six tasks are different practical problem-solving activities taking place consecutively: select a critical global problem, formulate an alternative solution starting at a regional level, search for political and financial support, search for practice partners, perform a pilot project on local level, transfer toward the regional, national and global level. The case of renewable energy villages in Germany is presented to illustrate how we work. A pilot project was initiated between 2000 and 2005, with a bioenergy village utilising heat and electricity from local renewable energy sources. Since 2005, more than 50 German villages emulated the model village. A psychological longitudinal study (with questionnaires and interviews) was performed in the model village, testing the hypothesis that well-being is improved as a consequence of the transition. The results, show, from interview data, that the sub-sample of the villagers who engaged in the project support the hypothesis, while, from questionnaire data, that a greater sample of less active villagers, that the hypothesis is not supported.

The significance of hedonic values for sustainable behaviours to mitigate climate change

Linda Steg University of Groningen, Netherlands; Ellen Van der Werff; Goda Perlaviciute

Research has shown that values play an important role in environmental actions. Environmental attitudes, preferences, and actions appear to be particularly related to self-enhancement (egoistic) versus self-transcendence (altruistic and biospheric) values. We aimed to demonstrate that hedonic values also play an important role in the environmental domain. In a series of four questionnaire studies, we found consistent support for our hypothesis that hedonic, egoistic, altruistic, and biospheric values can be distinguished empirically, suggesting that the distinction between the four types of values is not only theoretically meaningful, but also recognised by consumers. Importantly, in line with our expectations, hedonic values appeared to be significantly and negatively related to a range of environmental attitudes, preferences, and behaviours, even when the other values were controlled for, indicating that hedonic values inhibit pro-environmental choices. Our results suggest that it is important to include hedonic values in environmental studies, and that interventions aimed to encourage pro-environmental actions to combat climate change should consider the hedonic consequences of the relevant actions, as these may be important barriers for behaviour change.

Using social marketing to further biodiversity conservation at local government level in South Africa

Angelika Wilhelm-Rechmann Nelson Mandela Metropolitan University, Germany; Richard Cowling

South Africa is a mega-diverse country and has a long tradition of conservation. To preserve its biodiversity, it will be necessary to include biodiversity priorities in the land use planning systems of rapidly developing local municipalities. We used social marketing to investigate how local land use planners as well as their hierarchies could be convinced to change their behaviour towards the meaningful inclusion of existing biodiversity-maps in their decision-making processes. Social marketing is the strategic application of highly successful marketing technologies to further societal good instead of commercial gain. We conducted formative research in six coastal municipalities in the Eastern Cape and used interviews, a ranking exercise and discourse analysis. We found that land use planning administrators were generally favourable towards biodiversity maps, but face considerable resistance from their hierarchies as their main barrier to behavioural change. In an upstream approach we therefore investigated locally elected councillors too. We found, that they do value their environment personally and appreciate nature’s value for tourism. However, environmental issues have a low priority, the term “biodiversity” is hardly understood. The frame
analysis revealed a fundamental opposition between “development” and “environment”. Furthermore, conservation is frequently interpreted as being a socially unjust endeavour, disrespectful towards people and lacking realism. Based on these insights we have developed the outline of a behaviour change project to improve the implementation of legal provisions and the use of biodiversity maps.

Social normative interventions to promote environmental attitudes
Diana Woelk; University Magdeburg, Germany; Paul Schultz; University Magdeburg, Germany; Florian Kaiser; University Magdeburg, Germany

In addition to protecting the environment here and now, policy making also involves persuading people to adapt to the expected climate changes. In a first survey in 2010, we assessed the status quo of general ecological behavior and climate adaptation in a selection of German municipalities particularly vulnerable to climate change. Using Rasch modeling, results showed one dimensional structure, with the two phenomena correlated at r = 0.67. Based on the intrinsic pro-environmental motivational level and our knowledge of its geographical distribution, two community based interventions were developed for low and average motivated groups. Embedded in a public campaign, the interventions used social norms and social competition combined with specific behaviors regarding energy and water use, transportation, consumerism, the protection of health and property, as well as political and social engagement. In addition, individuals received feedback on their district’s average motivation compared to the whole municipality. In a post-intervention survey the efficacy of the two interventions with regard to the adoption of climate relevant behaviors was assessed. The applicability of these interventions to promote adaptation to climate change will be discussed.

Symposium title: Psychological contributions to mitigating climate change
Convenor: Linda Steg

Attitude towards environmental policy measures related to value orientation
Tommy Garling; Sweden; Andre Hansla; Anders Biel

It has been found in previous research that environmentally-friendly behaviour correlates with people’s value orientation, which ranges from self-enhancement to self-transcendence. We claim that independently of value orientation, people are concerned about the consequences of climate change and other current environmental problems, but that those high in self-enhancement are less willing to pay the costs of mitigation and adaptation. Supporting our claim Study 1 (n = 91) shows that for environmental policy measures implemented to abate different environmental problems incurring non-transparent personal costs (e.g. governmental subsidies), the influence of value orientation on attitude towards the policy measures is fully mediated by environmental concern. This implies that costs for the environmental policy measures also mediate the influence of value orientation, when the personal costs are transparent (e.g. congestion charges for driving), the influence of value orientation is partially mediated by environmental concern. This interpretation is corroborated in Study 2 (n = 71) showing that while the influence of value orientation on attitude towards eco-labeled household electricity is not mediated by environmental concern, it is fully mediated by reluctance to pay surcharges for eco-labeled electricity. Value orientation also moderates the influence of reluctance to pay in that reluctance had an effect on attitude only for those with a self-enhancement value orientation.

Atitudes toward nuclear power as a solution to climate change
Wouter Poortinga; Cardiff University, United Kingdom

Climate change is arguably the greatest environmental threat the world is facing currently. The UK has set itself the legally binding target of 80% greenhouse gas emissions by 2050 against a 1990 baseline. Meeting this target requires major shifts towards low-carbon energy production. Various industry and policy actors have argued that nuclear power (NP) is a low-carbon energy technology that may contribute to climate change mitigation. In this study we draw upon the results of a nationally representative British survey (n = 1822) to explore how the general public has responded to this repositioning of NP, with the specific aim to examine whether (1) public attitudes to NP have changed as a result of the repositioning, (2) the explicit framing of NP as a method of addressing climate change leads to increased support, and (3) concerns about climate change are positively related to support for NP. The current study found that only a minority express unconditional support for NP; although an explicit framing of NP as a solution to climate change was found to lift support. Overall, support for NP was negatively correlated to climate change concern. Only when NP was given an explicit ‘reluctant acceptance’ framing - allowing people to express their dislike for NP alongside their conditional support - it became positively correlated to climate change concern. These findings suggest that concern about climate change will only increase acceptance of NP under limited circumstances.

Symposium title: Value-behaviour gap: How to fill it in?
Convenor: Goda Perlaviciute

Are social value orientations expressed automatically?
Gert Cornelissen; Universitat Pompeu Fabra, Spain

Drawing on the social intuitionist model, we studied the hypothesis that social value orientations are expressed automatically in behaviour. We compared spontaneous and more deliberated decisions in the dictator game and found that social values determine behaviour when responses are based on the automatic system. By means of both mediation and experimental analyses we further demonstrate that the automatic expression of social value orientations is mediated by perceptions of interpersonal closeness. A reasoning process can subsequently override these automatic responses and disconnect decisions from perceptions of interpersonal closeness. This results in lower levels of other-regarding behaviour, at least for prosocials.

Why the value-action gap can look larger than life: Value conflict and spillover effects in environmental behaviour
Gregory Maio; Cardiff University, United Kingdom

Inspired by the principles used to market physical products, campaigns to promote pro-environmental behaviour have increasingly emphasised self-interested (e.g., economic) reasons for engaging with a self-transcendent cause (i.e., protecting the environment). This presentation will review psychological evidence about values and behaviour suggesting that the activation of self-interested values (e.g., wealth, power) decreases the likelihood of self-transcending action. Thus, when self-interested reasons are given for performing a self-transcending action, this may actually lower the probability of enacting subsequent self-transcending behaviours. The presentation will demonstrate this implication by describing two experiments that made salient different information about car-sharing, an environmentally beneficial activity. Experiment 1 made salient either the self-interested (financial) impacts of car-sharing, the self-transcending (environmental) impacts of car-sharing, or neutral travel information (control). We then observed the extent to which participants recycled paper. Experiment 2 replicated this design, adding a condition that simultaneously made salient both types of reasons for car-sharing (financial and environmental). Results from both studies revealed increased recycling rates only when self-transcending reasons alone were salient; whenever self-interested reasons were included, recycling was not significantly greater than control. Congruent with value theory, an emphasis on the self-interested reasons for performing one environmental behaviour may reduce the likelihood of performing other, unrelated pro-environmental behaviours.

Situational and dispositional influences on desirability of pro-environmental products
Goda Perlaviciute; University of Groningen, Netherlands; Siegwart Lindenberg; Linda Steg

Different goals may guide product choice. Choosing pro-environmental products is more likely when a goal to protect the environment is salient. What influences this salience? On the one hand, contextual cues might prime pro-environmental goals in a particular situation (cf. Bargh, 2006). On the other hand, this salience might derive from strong pro-environmental values (Lindenberg, 2009). Our research integrates both factors and suggests that pro-environmental goals are most salient and most likely to increase the desirability for pro-environmental products when they are situationally primed and supported by strong, dispositional values. Revisiting previous findings (Verplanken & Holland, 2002), Study 1 demonstrates that pro-environmental primes (i.e., words like ecological, nature) increased the preference for pro-environmental products over cheaper products, but only when environmental values were strong. The effects, however, could be ascribed to semantic associations between prime and dependent measure, rather than to salient pro-environmental goals. Study 2 rules out this explanation by showing that priming negative environment-related words (e.g., trash, smog) resulted in rating a pro-environmental product as tastier, especially when environmental values were strong. The
results cannot be explained in terms of semantic associations (why would negative words lead to positive taste evaluations?) and seem to be goal-driven (people rate products that align to their goals as tastier, Allen et al., 2008). These studies confirm our hypothesis that the salience of pro-environmental goals is a co-product of situational primes and strong environmental values.

Overview of the symposium ‘Value-behaviour gap: How to fill it?’

Goda Perlaviciute University of Groningen, Netherlands

Concern about the others and the environment does not always translate into corresponding actions. In the current symposium, we analyse this so-called value-behaviour gap (e.g. Blake, 1999; Kollnuss & Agyeman, 2002) in the environmental domain and discuss under which conditions values do translate into pro-environmental behaviour. Speaker 1 establishes a link between human values and environmental behaviour. Acting pro-environmentally aligns to self-transcendental values and is most likely when these values are activated. In line with the value theory, pro-environmental action becomes less likely when self-interested values are activated. The following two talks take chronic value strength into account. Speaker 2 focuses on pro-social values and proposes that those are likely to guide corresponding actions, provided the absence of de-liberate processing. Speaker 3 argues that pro-environmental behaviour is most likely when it is supported by strong environmental values and situationally primed. The final two talks focus on psychological universals that should be considered when explaining value-behaviour relationships in the environmental domain. Speaker 4 introduces environmental self-identity as a mediator of the value-behaviour relationship. Although being rooted in environmental values, environmental self-identity is also influenced by past behaviour and thus more susceptible to change. Speaker 5 discusses spatial bias and shows that people’s concerns about the environment may diminish because of downplaying the severity of environmental problems in their closest environments.

Cross-cultural evidence for spatial bias in beliefs about environmental problems

Paul Schultz California State University, United States of America

Prior research has shown a tendency for environmental problems to be rated as more severe at the global level than at the local level. The present paper reports re-analyses of a large cross-cultural dataset (Study 1, k = 22, N = 3,277) and a new cross-cultural data (Study 2, k = 5, N = 634) examining the prevalence of this spatial bias in the rated severity of environmental problems along with analyses of individual and country-level predictors of this bias. Results from multilevel modelling analyses showed that spatial bias was greater for individuals from less populated communities and with stronger place identity. We interpret these results as evidence for a “place-serving bias” in which the bias tempers the severity of environmental problems in one’s local area. Considering the large cross-cultural evidence, we argue that spatial bias is a plausible candidate of a psychological universal identified by research in environmental psychology.

Factors influencing the environmental self-identity

Ellen Van Der Werff University of Groningen, Netherlands; Kees Keizer; Linda Steg

Based on recent findings (Gatersleben, Murtagh & Abrahamse, 2011; Van der Werff, Steg & Keizer, 2011) we suggest that the more strongly people endorse biospheric values, the more they perceive themselves as an environmentally friendly person (i.e., the stronger their environmental self-identity), which in turn influences their pro-environmental behaviour. Being rooted in values, this suggests that the environmental self-identity is (to a certain extent) stable over time and situations. However, in the current study we propose that next to this stable part of the environmental self-identity, there is also a part which can be influenced, for example by stressing people’s past environmental behaviour. In a series of studies we tested our hypotheses and indeed found that focussing people on their past environmentally (un)friendly behaviour influences their environmental self-identity and even affects environmental actions. Secondly, we found that values have an influence on identity next to past behaviour. Our studies suggest that environmental self-identity is indeed stable to a certain extent (i.e., influenced by values) but also partly susceptible to change (i.e., influenced by past behaviour). With the current studies we aim to provide more insight into the concept of environmental self-identity and opportunities to stimulate pro-environmental actions.

Social influence approaches to encourage resource conservation: A meta-analysis

Wojciech Abrahamse University of Victoria, Canada; Linda Steg

Would somebody be more willing to start recycling if they knew that their friends were all recycling? Would a household start saving energy when they are told their energy use is above the neighbourhood average? Social influence refers to the ways in which our behaviour is affected by what other people do, or by what other people think. Various insights from theories of social influence have been applied as part of interventions to promote behaviour change, such as the use of social norms, the use of social learning, and the use of social comparison processes. The question arises: Is social influence as effective as is sometimes assumed? This review integrates research on social influence approaches to encourage pro-environmental behaviours via meta-analysis and it outlines what remains to be learned about the potential mechanisms linking social influence to behaviour change. A random-effects meta-analysis with a sample of 21 studies revealed that social influence approaches were more effective, when compared to a control group, but that they were not necessarily more effective when compared to other intervention strategies. The effectiveness tended to be different for different social influence approaches, and for different target groups. These findings raise a number of important questions, and we propose a research agenda for better understanding the underlying process through which social influence results in pro-environmental behaviour change.

Symposium title: Community-based approaches to addressing environmental problems

Convenor: Paul Schultz

Eco-message: Creating opinion leaders to reduce energy consumption in residence halls

Janet Swim The Pennsylvania State University, United States of America; Brittany Bloodhart; Matthew Zawadzki

Energy competitions are a popular method of attempting energy reduction. Certain assumptions, however, often correspond with these competitions including whether participants will (1) know effective ways to change their behaviours; and (2) care enough to alter their behaviours. Innovation diffusion literature suggests these two assumptions can be addressed with effective opinion leaders. Effective opinion leaders are experts on the innovation in question and persuasive sales people. Often research illustrating the importance of these characteristics comes from examining whether effective opinion leaders have these attributes. In contrast, in our research we created effective opinion leaders by, first, teaching 29 students living in residence halls about personal energy reduction behaviours and, second, assisting them to be sales people for energy reduction. In order to create experts we applied a pro-active coping model that taught leaders effective behaviours to change and allowed them to experientially determine barriers and facilitators of behavioural change pertinent to a student population. To assist them in being sales people they practised communications with each other that prepared them for barriers and facilitators to their social influence attempts. Our programme successfully altered opinion leaders’ personal behaviours and improved the success of an energy competition. For instance, in contrast to residence halls without trained opinion leaders, residence halls with these leaders significantly reduced their average kilowatt hours of energy used during an energy competition and continued to use less energy after the competition had ended.

Session Type: Symposia

Symposium title: Doing global good: Psychologists at the United Nations impact on international issues and invitation to all for involvement

Convenor: Judy Kuriansky

Committees and commissions at the UN: Accomplishments and how you can give input

Florence Denmark United States of America

Psychologists are involved in various committees and working groups that address global problems. This presenter has been integrally involved in many such committees, including the Committee on NGOs (CoNGO), Committee on the Family, and the Committee on Ageing. The latter conjuncts with her role as chair of IAAP Division 7, Applied Geropsychology. She will describe the activities and accomplishments of these committees, including, for example, special occasions like the International Day of Older Persons. The presentation will describe how ICP
conference attendees can give input through their research and how they can contribute their statements and other advocacy, as well as describe representative’s responsibilities and how students become interns.

Psychologists at the United Nations: Impact on international issues and invitation for involvement

**Judy Kuriansky** Columbia University Teachers College, United States of America

This presentation describes the increasingly active role psychologists are playing at the United Nations and how conference participants and other psychology professionals can be involved. Psychologists are representatives of many national and international organisations accredited at the UN with the Department of Public Information and the Economic and Social Council. In these roles, they do many activities to influence the inclusion of mental health issues in the policies and procedures of the UN and related agencies. These include: advocating at commissions, like the Commission on Social Development (CSD) and the Commission on the Status of Women (CSW); observing high level member state meetings, like the General Assembly; drafting and submitting statements to governments and commissions on the importance of mental health; participating in working groups on issues like human rights, aging, indigenous peoples, gender, migration and refugees; implementing field humanitarian projects; and working with UN agencies like WHO, ILO and UN Women. A major accomplishment is the growth of “Psychology Day at the United Nations,” on issues like diplomacy and STEM education (girls’ education in science and technology). Workshops and parallel events by psychologists have also increasingly been accepted, CSD, CSW and DPI/NGO conferences. In a recent groundbreaking move, the United Nations released a report “Mental Health and Development.” Another exceptionally major development is the formation of a new Psychology Coalition, to unify impact on international issues. Field projects by psychologists addressing the Millennium Development Goals (e.g. eradicating poverty, empowering women and combating HIV/AIDS) will be described and videos will be shown.

Psychology day at the United Nations: Applying psychology science to human rights

**Neal Rubin** United States of America

This presentation describes in detail Psychology Day at the United Nations, which has become a yearly tradition, including the organisation, participation, subjects and outcomes of this important event. Topics have included, for example, “Reach Them, Teach Them: The Role of Psychology in Achieving Universal Access to Education”, diplomacy (“Psychology and Diplomacy: Negotiating for Peace and Human Rights”, and the April, 2012 5th Psychology Day on “Contributions from Psychology to the UN”) and “Human Rights for Vulnerable People: Psychological Contributions and the United Nations Perspective Information” will be given about how ICP conference participants can get involved. This event celebrates the contributions of psychological science to addressing global human rights as well as educate those gathered regarding the advocacy efforts of psychologists to promote the mission of the United Nations. For example, the day typically begins with a morning briefing at UN Headquarters on a central theme facing the world community. Expert panelists representing the Department of Public Information, representatives of Member Nations and psychologists, frame the issue from the perspective of the Secretariat, governments, agencies of the UN and civil society. The afternoon sessions combine keynote speakers and workshops highlighting the work of psychologists around the world. The focus is on demonstrating a variety of innovations implemented by psychologists in the effort to address the day’s theme. The goals of the workshops are first, to illustrate how psychologists design responses to the behavioural dimensions of human rights problems and second, to encourage the future engagement of those gathered with the challenge of integrating our knowledge base with potential approaches to relieving human suffering. Therefore, the purpose of the proposed presentation will be to inform attendees regarding Psychology Day at the United Nations and to promote the commitment of international psychologists with the global human rights agenda.

Population-level restoration phenomena and development of research on restorative environments

**Terry Hartig** Uppsala University, Sweden

In his presentation of psychological ecology, Kurt Lewin famously called on psychologists to consider non-psychological data with regard to their meaning for the boundary conditions of individual and group behaviour. Yet Lewin’s call seems to have been largely forgotten. In recent decades, psychology as a discipline has turned further inward, with more and more researchers studying brain-behaviour relations, to the neglect of the social ecology in which behaviour plays out. Although this inward turn has yielded apparently valuable findings, it has also entailed opportunity costs. Warnings raised in social epidemiology about related concerns are instructive in this regard. Classical social epidemiologists acknowledge the value of individual-level research on the mechanisms of diseases, but they also note the limitations of such research. For one, variation in health across populations, or within a population across time, is not necessarily explainable through reference to individual-level factors. For another, when everyone in a population is exposed to some environmental condition, it cannot readily be identified as an individual-level determinant when research uses samples from that single population. In this presentation, I will summarise studies of variation in mental health that acknowledge these limitations. In these studies, analyses of aggregate time series data for dispensation of psychoactive drugs to the Swedish population were guided by psychological theory concerned with environmental supports for psychological restoration or environmental constraints on restoration. These studies raise questions that can help to advance restorative environments research involving individuals and small groups.

Restorative effects of water environments

**Sabine Pahl** United Kingdom; **Kayleigh Wyles**

Recent research in our lab has addressed water as a key feature of restorative environments. Water may be present outdoors (e.g., coastal environments) or indoors (e.g., aquaria), and it can be experienced directly or through various media. This presentation will summarize three strands of research on the restorative effects of water environments, or Blue Space. (1) We demonstrate the stress-reducing effects of indoor subaquatic scenes. Exposing participants to
large tanks in an aquarium after a stressful task, with virtual water environments can benefit from being more active (e.g., swimming) ones. To sum up, this research examines novel approaches to understanding restorative natural environments. The results are promising for the use of water environments in stressful or painful contexts, and for understanding active uses of Blue Space for restoration.

Sleep-promoting effects of contact with nature
Agnes Van Den Berg University of Groningen, Netherlands; Sander Koole

A wealth of research has shown that contact with nature relieves body and mind from stress and worries. Given that stress can disrupt sleep, we advance the novel hypothesis that contact with nature may improve sleep quality. We conducted a first test of this idea in a survey among 220 participants (181 males; mean age 23 years) to explore possible links between contact with nature and sleep quality (measured with the Pittsburgh Sleep Quality Index). Results showed that participants who could view nature in the indoor setting in which they spent most of their time in the last month reported better subjective sleep quality and less day-time disturbances compared with participants with a view of a built setting, the sky, or a mixed setting. On the basis of this initial survey, we will select individuals with sleep problems for a follow-up experiment. In this experiment, half of the participants will imagine themselves in a natural environment before going to sleep. The remaining participants will imagine themselves in a built setting. The dependent variable will be sleep quality. This experiment, whose results will be presented at the conference, will shed light on the causal impact of contact with nature on sleep quality. With these studies taken together, our program of research may inform potential benefits of contact with nature.

Symposium title: Understanding everyday sustainable practices in organizations (co-conveners R. García Mira and D. Uzzell)
Convenor: Giuseppe Carrus

Drivers and barriers to low-carbon practices: Individual and organisational factors
Marino Bonaiuto Sapienza Università di Roma, Italy; Giuseppe Carrus Sapienza Università di Roma, Italy; Eugenio De Gregorio; Fridanna Marchiolo; Stefano Dominici; Mirilla Bonnes

In this paper we will present the results of a qualitative study, carried out with the aim of assessing the existing everyday practices and behaviours in the workplace, which have an impact on the level of greenhouse gas emissions, in a large Italian company in the energy production sector. The environmentally-relevant everyday practices in the organisations referred to three main categories of organisational practices: (1) Consumption of materials and energy; (2) Waste generation and management; (3) Organisation-related mobility. There are three different sources of data and information were used: (a) Interviews with key-informers situated at different levels of decision-making; (b) Focus Groups; (c) Analysis of organisational documents. All the material gathered was subject to thematic content analysis procedures, using Computer Assisted Qualitative Data Analysis Software (CAQDAS), specifically the ATLAS.ti software. Results from the three data sets converge in showing the presence of main barriers (e.g.: ‘Time is a barrier for sustainable mobility’; ‘There is no automatic switch off of lights at work’) and drivers (e.g.: ‘People save energy at home to save money’; ‘The organisation encourages policies of consumption reduction’) at both the individual and organisational levels. These identified factors are incorporated into a theoretical model, predicting sustainable individual and collective practices in the workplace. This model will be subsequently tested in a quantitative study, conducted through standardised psychometric tools. The implications of the findings for more sustainable working environment and practices will be discussed.

Positive and negative spill-over effects in environmental behaviour
Angela Ruepert University of Groningen, Netherlands; Jan Bolderdijk; Linda Steg; Kees Keizer

Many campaigns have been developed that try to induce specific pro-environmental behaviours. However, the effectiveness of these initiatives, in addressing the present environmental problems, is not only determined by the extent to which they spark the targeted behaviour, but also by their effect on pro-environmental behaviours in other domains. Does the induced targeted behaviour strengthen other pro-environmental behaviour (positive spill-over effects) or inhibit it (negative spill-over effects)? The findings of research on spill-over effects (in other fields) are inconsistent; both positive and negative effects (Geiser, 2001 and negative spill-over effects (Mazar & Zhong, 2010) have been found. How can we explain these contrasting findings and how do they apply to environmental behaviour? We propose that the circumstances under which the initial behaviour is evoked is the key factor in determining whether this behaviour will result in positive or negative spill-over effects. Specifically, we reason that positive spill-over effects (in environmental behaviour) are more likely when the original behaviour is believed to result from one’s own volition (i.e. self-determined). Negative spill-over effects on the other hand are more likely when the original behaviour is believed to be brought about by external factors. The presented experiments give insight in the mechanisms behind spill-over effects, and their application for promoting pro-environmental behaviour.

How to encourage organisations to adopt environmentally-friendly policies
Linda Steg University of Groningen, Netherlands

Under what conditions are firms in market societies likely to adopt environmentally-friendly policies? On the basis of goal-framing theory, we argue that government pressure is a key source of environmentally-friendly policies of firms. Furthermore, we propose that value-based voting by citizens is a highly important source of pressure on governments to do so. This implies that we should understand how to strengthen and prioritise biospheric values in the citizenry. Following the so-called embedded-value process, we argue that in modern societies, biospheric values and value-congruent actions heavily depend on scientific information on contradictions in our way of life with regard to sustainability. Such information identifies threats to important aspects of our way of life, and it is such threats that help strengthen and prioritise values and promote value-congruent actions (as things to be preserved). The influence of science in this respect is aided by public debate, NGOs and by processes of sheer contagion in which people with more intense values influence people with less intense values. Finally, we identify consumer organisations and NGOs that are influenced by the values citizens hold as vital for controlling whether or not firms actually conform to government policies.
Research Area: Ethics

Session Type: Papers

Are you fit to practice? The role of the statutory regulator and the BPS
Carole Allan British Psychological Society, United Kingdom

In July 2009, a legislative change gave the Health Professions Council the mandate to regulate all applied Psychologists within the United Kingdom. This role was previously undertaken on a voluntary basis by the professional body, the British Psychological Society. As the statutory regulator the HPC maintains a public register of those "fit to practice" and in the interests of public protection takes action against individual practitioners who breach mandatory standards of ethics and competence. A detailed analysis of complaints made against Practitioner Psychologists was undertaken from the public records of "Fitness to Practice" hearings. Findings show that there were relatively high levels of complaints against Psychologists compared to other groups regulated by the HPC. The majority of complaints were related to breaches of ethics and professional conduct rather than for impaired competence. A range of sanctions were applied and in some instances Practitioners were removed from the register, effectively removing the ability to undertake practice anywhere within the UK. Findings will be used to illustrate the complementary role of the professional body in supporting practitioners to attain and maintain their fitness to practice. This is achieved by, ensuring that trainees are aware of professional values and that these are reflected within the curricula and assessments and by developing practitioner roles through promoting the understanding of professional and ethical issues and their application in complex contexts.

Ethics, impunity and the struggle for human rights in South Africa: The case of Wouter Basson, aka Dr Death
Umesh Bawa University of the Western Cape, South Africa

Health professionals have had a long history of sanctions for their involvement in human rights abuses. The medical experiments of Josef Mengele in the Second World War, and the consequent censuring of his gross human rights abuses at the Nuremberg trials, clearly underlined the ethical obligations of health professionals to use their expertise and knowledge to promote human rights. The argument forwarded by Josef Mengele: that in times of war the military code supersedes that of the health professional’s ethical responsibility, was found wanting. A similar argument was made by Wouter Basson, a South African medical doctor who worked within the Apartheid military apparatus, using his knowledge to develop chemical and biological weapons for use against opponents of that government. This presentation will discuss issues pertinent to the ethical responsibility of health professionals in situations of war and conflict, and challenges the legal frameworks used in obfuscating culpability, thereby offering immunity to human rights violators in the health sector. Case material on Wouter Basson, drawn from the public domain, will be used to highlight this tension between the requirements of the law, and that of the health professionals’ code of conduct. It will offer some direction that statutory health professional organisations could utilise to ensure that a human rights culture is embraced by all health professionals.

Second order ethical practice in counselling psychology: Theory, practice and process
Elizbeth Du Preez Auckland University of Technology, New Zealand

This paper explores second order ethical decision making by offering a theoretical, practical and process model that can be used within counseling psychology. This is contrasted with first order linear models, and comparisons are drawn in terms of its usefulness in therapeutic practice. It is suggested that second order ethical decisions are more responsive to context, culture and relationships, and offer a responsible alternative to existing models.

Comparative study on moral socialisation of Mencius and Xun Zi
Yuanyuan Gan Nanjing Normal University, China

Moral socialisation is an important research category of social psychology, but most moral socialisation theory comes from western psychology. Although the concept of “moral socialisation” has never been proposed in Chinese psychology, the thought of moral socialisation was contained in Chinese Confucian culture. The paper presents the moral socialisation thought of Mencius and Xun Zi to enrich the theoretical system of moral socialisation. Through analysing and comparing their thought, it is found that the difference of moral socialisation between Mencius and Xun Zi established the basis of Mencius’ good nature of humans and Xun Zi’s evil nature of humans, and the difference of their moral socialisation mainly shows in three respects: the aim, the core content and the realisation way of moral socialisation. Mencius holds that the process of moral socialisation is that a social individual becomes the one featured with benevolence, righteousness, courtesy and wisdom through self-education, such as “Yang Qi”, “Gua Yu”. Xun Zi holds that the process of moral socialisation is that a social individual comes from abiding by rules and etiquette through external-education, such as building a unified moral education system, setting examples, and constructing a favourable social environment. Although their ideas of moral socialisation are different, they provide positive reference meaning for Socialist Spiritual Civilisation Construction.

Have you read the policy on plagiarism? An investigation of students’ perceptions of a university’s policy
Judith Gullifer Charles Sturt University, Australia; Graham Tyson

Research has established that the term plagiarism is open to a wide range of interpretations, resulting in confusion among students and staff alike. Psychological theory and research suggests that a thorough understanding of an individual’s perception of an issue or problem is an essential requirement for successful change of that person’s attitudes and behaviour. A previous focus group study of perceptions of plagiarism revealed six themes: confusion, fear, perceived sanctions, perceived seriousness, academic consequences, and resentment (Gullifer & Tyson, 2010). Based on the results of the qualitative study, an online questionnaire was developed to further examine those themes and to test a model that postulates the relationship between them. An invitation to complete the survey was sent to all 3092 domestic students at an Australian University and 4477 students completed it. The research reported in this paper looks only at the students’ understanding of the institutions policy on academic integrity. The data obtained were examined in terms of year of study, Faculty, e.g. Arts, Science etc, and whether the students were studying on-campus or by distance education. The data confirmed the findings from the previous focus group study indicating that confusion regarding what behaviours constitute plagiarism was evident. The implications of these findings are discussed.

Psychology as a scarce resource
Hanle Kirkcaldy University of Pretoria, South Africa

Decisions regarding the allocation and rationing of scarce medical treatments are made every day and in many different settings. Psychological services can be seen as a scarce health resource. There are many demands on psychological service delivery, and a scarcity of suitably qualified personnel. When there are clinical indications to see particular patients, and just too few psychologists to do the work, it becomes an ethical dilemma to choose between patients. In developing countries, the allocation of services has become a contentious issue, particularly in the public sectors of service delivery. Also, practitioners in private practice, work within managed health care insurance systems and are therefore not immune to the challenging decision-making processes relating to treatment. Psychologists and managers therefore have to decide on which grounds services are rendered, and on which grounds they are refused, as well as which type of services should be rendered, and under which circumstances. These processes should be fair and just to the patient, but also to the health care practitioner. Mental health care legislation in different countries strives to provide equitable, efficient and the best possible services to the most people, while meeting the challenges of limited budgets and staff. In this paper these concepts are considered within the context of psychology. The applications of the theories of justice and ethics that underlie access and allocation issues are taken into account. There is a constant challenge to the profession of psychology to approach these dilemmas regarding service allocation, in an ethical defensible manner.

The role and the responsibility of psychologists in ethical violations in the media
Yasin Koc Bogazici University, Turkey

Since the emergence and the rapid development of media channels, psychologists’ relationships with the media has been exposed to perpetual change. On the one hand, psychologists who dealt with the influences of the media on individuals and groups have attempted to identify the benefits and problems of
the media to promote the development of positive media. On the other hand, psychologists have also used the media as a medium for information sharing and self-advertisement. To facilitate the interaction of the psychologist with the media, in terms of ethical violations in the media, psychologists’ role also varies: they can be either the actors of the ethical violations or they can identify particular ethical violations and draw public’s attention to them. In the light of the discussion, a few media examples are discussed from Turkey and the U.K. by comparing the ethical codes concerning the media interactions from EFPA, APA, BPS, CPA, and TPD (Turkish Psychological Association).

Automaticity, consciousness and moral behaviour

nicki marquardt rhine-waal university, germany

There has been a rising interest in automatic or intuitive judgmental processes within the psychological research during the last decades. Psychologists now largely concentrate their research on automatic judgments and their interplay with conscious and controlled evaluations and overt behaviour. The present study examines the relationship between automatic mental processes and moral decisions in business. Based on the dual-process view in implicit cognition, it is argued that moral judgments can rely on two different modes of information processing (automatic vs. controlled mental processes). In order to test this assumption, a large study involving genuine managers and business students was conducted. The participants were supposed to work on a complex ethical decision-making task. Automatic processes were assessed with reaction-time measures [e.g. Implicit Association Test (IAT) and Restricted Focus Viewer (RFV)]. Different questionnaires were used to diagnose controlled or conscious judgmental processes. The results indicate that latency-based measures of automatic mental processes have a better predictive validity for moral decision-making behaviour than questionnaire-based measures of controlled processes.

Addressing the ethical imperative in cross-cultural projective assessment

elizabetha matthews south africa; lizette matthews; cecilia bouwer

The ethical principles of psychological assessment emphasise accommodation of the uniqueness of the client. In this regard, language and cultural differences pose a particular challenge in projective assessment. The value of the Thematic Apperception Test (TAT) in psychological assessment is widely recognised, specifically when working with children and adolescents. We examined the possible TAT-culture link in mono- and cross-cultural assessment situations with adolescents, with a two-fold aim: to investigate the influence of a dynamic assessment technique of questioning (DATQ) with projection plates in mono- and cross-cultural situations, and the influence of culture on the process and product of the assessments. A qualitative, multiple case-study of ten participants was undertaken. A test-training-continuation-of-test situation was created, using seven projection stimuli, two discussion protocols and the Scoring Sheet for the Psychocultural Scoring System (SSPSS). Data analysis and interpretation entailed projection analysis, structural analysis of the stories, analysis of the participants’ experience of the Murray-method versus the DATQ and a conversation about culture, and comparison of the SSPSS results with the context of the projections and the conversation about culture. Main findings of our study suggest cultural influences on responses and process, and a DATQ influence of enriching projection responses, positive emotional experiences of the assessment, and lessening of cultural barriers. In the light of these findings, we consider the various challenges of ethical assessment in cross-cultural assessment situations.

A research-based approach to creating ethical healthcare institutions

shireen noor mahomed university of kwazulu natal, south africa

In recent years, globally there has been a significant increase in media and professional reports regarding unethical and fraudulent practices in both the public and private health care sectors. Questions have been raised as to whether these sectors focus predominantly on profit generation and rationalisation of resources. Such work environments have the potential to give rise to increased ethical dilemmas. The perceptions and behaviours of professional health care workers impact their decision making generally, including their ethical decision making processes. Thus an investigation of ethics in this context is of value. The aim of the study was to investigate whether private and public health sector employees in South Africa differ in their ethics perceptions and related perceived professional behaviours. This study consists of 366 participants drawn from both the public and private health care sectors in KwaZulu-Natal. A questionnaire was used to gather the data, using stratified random sampling. Significant differences were found between the perceptions of the public and private health care sector employees. In addition, there was a significant association between frequency of felt moral obligation to report unethical behaviours and the behavioural tendency to address or report such behaviours. The study provides useful information for understanding perceived ethical behaviours among health care employees and the development of high integrity ethical work environments.

Development of moral behaviour in a group of South African university students

cisco nortje university of the free state, south africa

New requirements of the HPCSA require that all Health Care Science students need to complete an ethics course during their training. Many courses are presented as theoretical modules focusing on principles rather than on being internalised. In order for students to benefit from an ethics course the information should be internalised and systemically applied in order for students to understand why it is important for them to behave ethically. Research was conducted during the presentation of a course to fourth year university dietetic students. The difference of the course is in the presentation methods and applying method making use of cognitive modification methods where students are placed in ethical dilemmas and challenged to argue from a moral point as well as from an ethical point and to discern what the differences are and which kind of behaviour would be more beneficial to their patients’ clients. This is a new approach to ethics and the research done is the first of its kind in South Africa to ascertain whether students’ moral behaviour will be influenced by a course in ethics. Students had to complete a biographical questionnaire as well as a Moral Behaviour Scale at the start of the course as well as the end of the course. In order to determine whether a difference in moral judgement is evident between the measurements, a t-test for dependent groups will be performed. The results will be shared at the conference.

Using a two-tier test to assess Taiwan graduate students’ misunderstanding of research ethics

ju-an pan institute of education, nctu, taiwan, republic of china; chien chou

The purpose of this study aims to explore the (mis) understanding of research ethics of Taiwan graduate students. In this study, we developed a two-tier test with 12 two-level multiple-choice questions categorized into 6 types of research misconducts. The first tier comprised real-case scenario statements with a true-false response, asking the test participants whether the research conduct was acceptable or not. The second tier was in a multiple-choice format with four different reasons to support the response for the first tier. In other words, the students need not only to judge whether the scenarios are acceptable first, but need to clarify the appropriate reasons for their identification. In the pilot test of this study, graduate students in Taiwan were selected to answer the two-tier test. A total of 253 valid data were collected. The results demonstrated that only 1.5% of students correctly answered all the first-tier questions while no student chose all the second-tier reasons correctly. The pilot study also concluded that the students showed lower accuracy in the categories of (1) duplicate publication, (2) infringement of copyright, (3) plagiarism, and (4) improper definition of authorship specially. A revision of the two-tier test has been conducted according to the data analysis of the pilot study. Up to the present, the second wave of data collection with more participation is in progress. After the data collection, we will compare and verify the results with the prior findings. Conclusions, implications and recommendations for future research will also be provided.

Confidentiality as a weapon: Traps in professional interventions

henry price mindpath consulting, australia

Confidentiality is rightly a core value for psychologists, and many other professional helping service practitioners. Traditionally this focuses on the importance of the practitioner respecting individual privacy, and autonomy, in order to promote a safe problem-solving context for a client. Confidentiality traps are normally identified in terms of conflicting priorities for the practitioner, for example where upholding strict confidentiality for a client may potentially represent a danger to a third person. However, other confidentiality traps exist.
This paper focuses on situations where a participant, in an organisational helping process, strategically uses confidentiality to further their own agenda at the expense of other participants, individuals, the professional helper, or the effectiveness of the process. Three case study examples drawn from organisational interventions, such as employee assistance counselling and mediation, are presented. The paper notes the role of dual clientele in such work and its potential to complicate the practitioner-client relationship. The case studies are used to firstly, recognise and outline the difficulties, together with their impact if not actively managed; secondly, suggest strategies for appropriately responding to the trap; and thirdly, briefly explore the implications of these situations for professional practice and ethics. The conclusion is that confidentiality remains essential, but a naive understanding that ignores its potential to be used as a ‘weapon’ by a participant in a helping process is itself a potentially dangerous trap for the practitioner.

Multiculturalism and ethics
Ilse Ruane  
University of Pretoria, South Africa; Vicky Timm

One of the main ethical purposes of professional therapeutic training and registration with the HPCSA is to ensure that psychologists graduating from the system are capable of effectively counselling different clients. Within the South African population, as is the case further afield, client needs are diverse and often non-Western. This means that it is critically important that psychologists are equipped to meet these varied needs and are knowledgeable regarding the ethical implications of providing a multicultural appropriate service to this diverse client population. In South Africa, multicultural counseling it is not really an area of specialisation, although it has received attention and there have been calls to work in culturally sensitive ways to meet the ethical requirements of the profession. It appears that the foundation of a democratic South Africa and the growing recognition of different forms of discrimination, such as racism, classism and sexism (and other gender-related discrimination), has resulted in focused interest on ethnic and minority status within the field of counseling. The onus thus falls to the individual psychologist to equip themselves with the necessary knowledge and skills to provide a multicultural appropriate service. Multicultural approaches to therapy are essential for the ethical practice of psychology, specifically for those working in South Africa’s diverse population. This paper explores the various ethical issues related to multicultural counselling in a practical and facilitated manner, as well as perhaps uncovering a few more.

Psychology and ethics serving humanity: The role of informed consent
Lizette Schoeman  
University of Pretoria, South Africa

The informed consent process is perhaps the one area in the medical setting where patients with diverse cultural backgrounds, disparate socio-economic circumstances, and various background stressors, should be treated with respect. If valid informed consent is attained, an added psychological benefit will be obtained. This study focused on the role informed consent plays in helping patients to cope with their illness, while enhancing and equalizing their knowledge and perceptions of cancer. Two hundred patients with cancer of the oesophagus were entered in this study. The patients completed a perception and knowledge of cancer questionnaire, whereafter they went through the informed consent process. The perception and knowledge questionnaires were repeated and a coping questionnaire completed. Most patients indicated that the informed consent process helped them to cope better with their cancer. The change in perception scores were statistically significant (p<.0001), with the uneducated gaining most from the informed consent process. The Informed consent process not only provides patients with the necessary information regarding their illness and medication, but the added attention, and information also help patients to cope better with their illness. Information may play a valuable role in serving humanity by reducing health disparities caused by education and social diversity while having added psychological benefit.

The influence of personal and nonpersonal contexts on moral judgment and the moderating effect of consequence
Fang Sun  
Central China Normal University, China; Ying Fan; Liang Yang

For a long time moral judgment has been the focus of psychologists. Green put forward the double processing model, distinguishing personal moral dilemma (emotional processing) and nonpersonal moral dilemma (cognitive processing). Personal situations includes: (1) Causing serious bodily injury, (2) damage is committed by a specific individual or group, and (3) damage is from direct threat. This study aimed to probe the difference of the acceptance of moral problems between personal and nonpersonal moral situations, and then study the consequences moderating role in it. The study used within subjects test design, classic overpass and trolley dilemma story, on behalf of the personal and the nonpersonal situations respectively. The influence of reading ability and writing attitude on the experimental results were controlled. Results supported Green’s assumption; moral acceptance of personal situation was less than that of nonpersonal situation, overpass dilemma was 3.800 on average, trolley dilemma was 5.060 on average, and t-test showed the difference was of significance. The experimental materials were revised to study the effect of damage consequence, in the personal situation one was dead instead of injured, and in the nonpersonal context one can save five people instead of five saving one. The result showed that in nonpersonal moral situations moral acceptance was lower than in personal situations, overpass dilemma was 6.420 on average, trolley dilemma was 2.480, t test showed that the difference was significant (t = 15.501, p < 0.001). Explaining consequences in this process has a moderating effect.

Corporate social responsibility in China: Indigenous conceptual dimensions and questionnaire development
Shangkun Xu  
Renmin University of China, China

After over two decades of hefty economic growth, China has to face the negative effects of economic development. The concept and theory of CSR have become a really hot topic grabbing the utmost attention of academia and enterprises in China. The purpose of this study is to identify China’s indigenous conceptual dimensions of corporate social responsibility (CSR), to develop a measuring questionnaire of CSR, and to promote the theory development and model structure in Chinese CSR study. In the first study, we employed an inductive analysis of CSR in China, based on an open-ended survey of 630 CEOs and business owners in 12 provinces in China. In the survey, we collected 2811 CSR sample responses. After examining the quantitative data we identified nine dimensions of CSR, six of which are similar to their western counterparts, and the other three never mentioned in western literature. Moreover, two of the widely seen CSR dimensions in the west have no embodiments in China. In the second study, we applied two group discussions and collected CSR descriptions. We used content analysis to test the above results. Finally, we designed a questionnaire of CSR and conducted an exploratory factor analysis and a confirmatory factor analysis to confirm the reliability and validity of the CSR questionnaire. Suggestions are offered for future research building on the CSR dimensions and questionnaire development introduced in these studies.

Perceptions of an authentic supervisor’s personal integrity and character (ASPIRE) as a moderator
Thomas Li-Ping Tang  
Middle Tennessee State University, United States of America; Hsi Liu

We investigated the extent to which people’s meaning of money (love of money, LOM) moderates the relationship between perception of the authenticity of supervisor’s personal integrity and character (ASPIRE) and propensity to engage in unethical behaviour (PUB) among 266 part-time employees who were also business students in a five-wave panel study. We found that unethical behaviour intention (PUB) was significantly correlated with their high Machiavellianism, low self-esteem, and low intrinsic religiosity. Our counterintuitive results revealed that the main effect of love of money on PUB was not significant, but the main effect of ASPIRE was significant. Further, we focused on the significant interaction effect between LOM and ASPIRE on unethical behaviour intention that provided profound, interesting findings: Low (or high) levels of ASPIRE were associated with high (or low) levels of unethical behaviour intention for those with high LOM, but not for those with low love of money. We discuss results in the light of supervisors’ ASPIRE, individual differences, ethical environment, and perceived demand characteristics on behavioral ethics.
how CSR affects employee behaviour and organisational performance in emerging markets using Chinese data. This study collected data on CSR, employee behaviours and organisational performance of Chinese businesses based on 1268 firms in 12 provinces. Firstly, we conducted an inductive analysis to identify the conceptual paradigm of CSR in China, and constructed a measuring questionnaire for nine-dimensions of CSR and five-dimensions of employee behaviour. Secondly, we employed two econometric models in the framework of OLS (Ordinary Least Squares) Regression Model and Ordered Probit Model respectively to verify the theoretical hypothesis. The empirical results indicated that CSR leads to positive employee behaviour and positive employee behaviours lead to positive organisational performance. However, the relationship between CSR and organisational performance is non-significant. Finally, we discuss the significance and non-significance of this replication. The internal influence mechanism of CSR on organisational performance is also included in the discussion.

**Session Type: Posters**

**Saudi contribution to an international study on college students’ attitudes toward cheating**  
*Hamid Reza Oreyzi, Imam University, Saudi Arabia; Ali Ratner*

An international study, across 5 countries, assessed students’ attitudes toward cheating. The countries were Mexico, Saudi Arabia, United States, United Kingdom, and the Netherlands. Compared to other countries, very few Saudi students expressed a willingness to engage in cheating. 80% of students in other countries expressed a willingness to cheat. The results from all countries, including Saudi Arabia, will be presented. Cultural reasons for the low level of Saudi cheating will be presented. The methodology employed a questionnaire concerning willingness to accept a college degree for money, without attending class. Students’ reasons for willingness or unwillingness to cheat were recorded and analyzed.

**The role of organisational virtuousness and organisational citizenship behaviour in professional moral courage**  
*Majdieh Sadat Khoshouei, University of Isfahan, Islamic Republic of Iran*

The aim of this study is to examine the role of organizational virtuousness and organizational citizenship behaviour in employees’ professional moral courage. The statistical population consisted of all employees in Isfahan Tele Communication in 2011. From this population, 141 employees were selected using random sampling. Data were collected through administration of scales of organizational virtuousness (Cameron, Bright, Caza, 2004), organizational citizenship behaviour (Podsakoff, MacKenzie, Moorman, Fetter, 1990) and professional moral courage with five dimensions including moral agency, multiple values, endures threat, goes beyond compliance, moral goal (Sekerka, Bagozzi, Charmigo, 2009). Data were analyzed with the use of Pearson’s correlation coefficient and hierarchical regression analysis. Results showed that there were significant positive correlations between organizational virtuousness with multiple values, and organizational citizenship behaviour with moral agency, multiple values, and the ability to endure threat and go beyond compliance. Also, hierarchical regression analysis shows that, organizational virtuousness predicts going beyond compliance and organizational citizenship behaviour has predicts moral agency, multiple values, and the ability to endure threat and go beyond compliance.

**Ethical dilemmas faced by health care professionals in Accra, Ghana**  
*Angela Ofori-Atta, University of Ghana Medical School, Ghana; Anna Edwin*

100 health care professionals were asked what their most difficult dilemmas at work were, and how they had resolved these. Results showed that resolution was associated with how long they had practiced, and length of ethics training received. A surprising finding was that the commonest dilemma for caregivers in a psychiatric facility was related to fear of violence from patients.

**Misconduct and whistle-blowing in nursing profession: Important but neglected issue**  
*Hamid Reza Oreyzi, University of Isfahan, Islamic Republic of Iran; Abolghasem Nouri; Narjes Manjoughi*

Misconduct in the nursing profession is prevalent, but incidence of it can be prevented, and the risk in some cases, can be reduced, with reporting of errors and misconduct. This study investigates different types of errors and misconduct in nursing areas, comparing misconduct in public and private hospitals, and, finally, investigation of patients’ reactions to misconduct. These reactions are categorised in two groups: whistle-blowing and non-whistle-blowing activities. The statistical society of this study included all nurses in public and private hospitals of Isfahan in 2011, and the sample included 300 nurses who were selected using random cluster sampling. In this study, Errors and Misconduct Check List, and Whistle-blowing Scale were used. For misconduct rating, Friedman and chi-square were used. Results show that, in general, lack of enough human resources of nurses, due to standards, as the most prevalent misconduct in hospitals. In comparing the two types of hospitals, favouritism and nepotism, and allowing incompetent people to work with patients, were significantly seen more in the private hospitals, and theft of patient property and impaired working conditions (because of alcohol or drug use) were seen significantly more in public hospitals. Furthermore, 62% of the participants were whistle-blowers and 32% were non-whistle-blowers. It seems that information enhancement of type and rate of error occurring in hospitals, could improve attention increment and sensitivity to these errors, and also cause appropriate action to be taken to prevent their incidence.

**Review of data on ethical issues from the establishment of psychology bodies in Cyprus to the present**  
*Kyriakos Platrites, Pancyprian Psychological Association, Cyprus; Georgios Metaxas*

This presentation aims at researching the various aspects relating to the professional ethics of psychologists in Cyprus. The data presented here dates from the establishment of the first body of psychologists in Cyprus in 1980 to the present, looking at the milestones that came about during the consolidation of the Codes of Ethics. All the cases of professional ethics violation that occurred, and all complaints that were filed against psychologists, have been researched. The data for each case of violation have been classified in the following categories: (i) Method of filing of complaint (i.e. inquiries conducted by the pertinent bodies, written complaints suggested to pertinent bodies anonymous/anonymous complaints). (ii) Type of violation (i.e. sexual harassment, overcharging, money extortion, issues of confidentiality). (iii) Management of complaints (i.e. rejected, pending, under examination, under hearing and referral to another suitable body). (iv) Case outcome (i.e. retraction, disciplinary infraction, exoneration). Findings revealed a poor tracking of data concerned with the violation of professional ethics and malpractice issues, before the establishment of the Pancyprian Psychological Association in 2007. Institutional restrictions that are still valid today, as well as matters relating to the function and the coordination of the professional bodies, obstruct the control procedures and administration of ethical violations. This presentation offers some suggestions for the improvement of the implementation of ethics by psychologists in Cyprus.

**Ethics and psychology taking hands in serving humanity: Pregnant mothers attitude towards HIV testing**  
*Lizette Schoeman, University of Pretoria, South Africa; Anne-Marie Bergh, University of Pretoria, South Africa; Theresa Rossouw, University of Pretoria, South Africa*

Paediatric HIV is a preventable disease. Routine testing for HIV/AIDS in the context of an overwhelming public health emergency is ethically defensible on the condition that individual rights are protected and the negative consequences of being tested (and found HIV-positive) are minimized by appropriate social and institutional support services. This study aimed to explore the reasons why pregnant women refuse or accept being tested. Interviews were conducted with mothers who gave birth in antenatal clinics and who consented to participate in this study. The interviews were analysed qualitatively. Participants were hesitant to be tested because of the stress it would cause in their lives. Many indicated that the stakes would be too high if they found out that they were HIV positive. Some first explored alternative medicine in a hope to be cured, while others continued using alternative medicine and faith healing whilst on ARVs. Cultural factors play a role in the decision-making process and in turn also throw light on the more complex issues of HIV testing. These will be explored further as well as how it may have an impact on the ethics discourse in South Africa.

**Session Type: Invited Addresses**

**Bioethics and biopolitics: Using movies to explore complex ethical dilemmas regarding psychology and human rights**  
*Juan Michel Farina, Universidad de Buenos Aires, Argentina*
Provoking participative provocateurs: Shades of gray in ethical landmines
Greg Gormanous Entertainment Psychologist, United States of America; Carol Webb
This is an interactive panel session designed to ensure diverse cultural, national, and ideological perspectives. Attendees are provocateurs who judge each scenario as ethically acceptable or not. Ethical complexities are presented whereby participants’ judge contextually varied ethical scenarios—reflecting shades of gray—in order to separate key facts from context. Scenarios include issues of flirting/romance, ethnic/cultural/women’s, confidentiality, etc. Attendees react to a series of contextually varied clinical and work psychology ethical scenarios. The main thesis is context matters. Contextual variations apply different cultural and national perspectives in order to provoke discussion. Context is why ethical panels/regulators reach different decisions with essentially the same information about alleged violations. Discussions will deal with how ethical issues are perceived differently when embedded within different contexts. Example Scenario—clinical: A military psychologist treating troops in Iraq was ordered to offer services to local residents. The psychologist had Christian religious items in her office. The local clients were non-Christian. A non-Christian local client complained. The psychologist continued to provide services without removing the religious items. Variation: A military psychologist treating troops in Afghanistan was ordered to offer services to local residents. The psychologist was an agnostic but was an avid collector of art items. He displayed a jade Buddha and Christian crosses. Most of the local clients were Muslim. Many of these clients expressed discomfort.

Example scenario - work psychology
Carol Webb United States of America
A work psychologist uses his company’s website to promote a side business in which he has a substantial financial interest. Although he does this with the company’s permission, he does not disclose his financial interest in the other business to his employer. Contextual Variation: A work psychologist is employed by a major manufacturing corporation. He encourages the managers of the corporation to use a certain company as a supplier of raw goods. The psychologist owns a significant financial interest in the supplier but does not disclose this information to his employer.

Ethical principles for a global psychology: Building bridges across cultures
Carole Sinclair Canada
The globalisation of the world and of psychology presents many ethical challenges and dilemmas for psychologists. As psychologists around the world, work more closely together, and as regions and nations become more multicultural, we are challenged to understand (and be respectful of) perspectives and values that are different from our own. The purpose of this workshop is to demonstrate that ethical principles and values that are common across cultures can be used to bridge differences and help us to deal with such ethical challenges and dilemmas. The ethical principles of the Universal Declaration of Ethical Principles for Psychologists, developed by an international
working group under the auspices of the International Union of Psychological Science and the International Association for Applied Psychology, will be used as a framework for the workshop (i.e., Respect for the Dignity of Persons and Peoples; Competent Caring for the Well-Being of Persons and Peoples; Integrity; Professional and Scientific Responsibilities to Society). The historical roots of these ethical principles across cultures and centuries will be outlined, with an opportunity to discuss their current interpretations, imbedded values, and applications. The workshop will then move to a discussion of different models of ethical decision making, the cultural variability of such models, and the Universal Declaration’s place in the model spectrum. Small group discussions will be used to explore the application of the Declaration’s ethical principles and values to dilemmas in research, teaching, and practice, and to practice skills in ethical decision making.

Indigenous psychologies and ethical decision-making: Implications for practice
Nhlonhla Mkhize University of KwaZulu-Natal, South Africa

Ethical discourse is dominated by Western approaches. Premised on self-contained individualism, the view that individuals exist independently of culture, history and time, mainstream Western ethics tend to ignore cultural influences in favour of “universal” explanations. To understand ethical decision-making in indigenous societies, it is important to come to terms with the “social reality” of the people in question. Social reality constitutes the manner in which human interactions are understood, roles defined, and transactions enacted. Due to differences in social realities, clinicians and researchers are likely to encounter multiple and overlapping health-care systems among indigenous peoples. The ethical implications of practising psychology in such contexts are discussed. Self-contained individualism is problematic in traditional African settings where selfhood is not only communally defined but is also distributed in space and time. With reference to concepts such as professional boundaries, time perspective and informed consent, the ethical implications of the tensions between communal and individualistic conceptions of selves are discussed. Dialogical ethics, in line with the African tradition of lekgotla or ibandla, is explored as a possible alternative to the individualism-communality antinomy in ethics. The implications for clinical supervision are highlighted.

Session Type: Symposia

Symposium title: A global ethical lens for psychologists and supervisors fostering winds of change
Convener: Carol Falender

Global ethics in competency-based practice and supervision
Carol Falender University of California, United States of America

Complexity of ethics in global psychology is enhanced in clinical supervision. Individual ethics codes, many anchored in Western thinking and the American Psychological Association Code, have been a structure for international conceptualisation of psychology professional ethics. As increasing diversity and global psychology are realities, psychologists are constrained by rule-governed ethics, desirous of integrating human, contextual, and personal factors into ethical decision-making. In this respect, the Canadian Code and the Universal Declaration of Ethical Principles for Psychologists provide guidance for supervisors. For supervisors, the situation is complicated by the power differential rendering supervisees powerless in asserting beliefs and knowledge for fear of negative evaluation or professional consequences. As a result, harm is inflicted on clients through cultural misunderstanding, unexamined beliefs, assumptions, or strict adherance to rule-governed ethical codes without attention to diverse worldviews. The purpose of the proposed symposium is to provide approaches to ethics critical to practice and clinical supervision. Perspectives will include commentary on competency-based clinical supervision and the power of the major form of transmission of the profession of psychology to future generations—and approaches to ethical problem solving that are vignetted driven; transforming supervisory approaches to common cultural/ethical misunderstandings in the areas of informed consent, confidentiality, competency, and professional boundaries through a moral/ethical framework that supports humanistic values through collaboration, humility and self-awareness, ethical implications of “social realities” through dialogical ethics to understand ethical decision-making in indigenous societies.

The winds of change support supervisors working across cultures
Jean L. Pettifor University of Calgary, Canada

Within psychology there is an increasing interest in addressing supervision as a special area of practice with its own specialised knowledge, skills and commitments. Recently the rapid globalisation of the world provides a strong impetus for change that supports supervisors in bridging the gaps across cultures and worldviews. We review the many ways in which supervisors are gaining support in meeting the challenge to give priority to serving the needs of the client as opposed to complying with the supervisor’s home grown codes of conduct that may do harm to the culturally different client. Typical areas for cultural differences include informed consent, confidentiality, competency, and professional boundaries – thus placing the psychologist and supervisor in a dilemma. We discuss an expanded concept of multi-cultural competencies, an expanded concept of supervisor-supervisee dyads, a moral/ethical framework that supports humanistic values, an ethical decision-making model that is client- and value-based, and an emphasis on collaboration, humility and self-awareness. Practical suggestions are made for cross-cultural supervisors in negotiating the best interests of persons and peoples. The search continues for universal human values that provide foundations for ethical practice. Supervisors encounter problems on the front line. Supervisors are powerful agents for changing practices to meet the challenges of globalisation.

Approaches to teaching ethics in psychology
Stephen Behnke American Psychological Association, United States of America; Yesim Korkut; Nina Dalen; Knut Dalen; Heather Gridley

The purpose of this symposium will be to explore ways of teaching ethics at all levels of professional development. Four panelists with extensive experience in teaching ethics will explain their preferred teaching methods. These panelists, from different parts of the world, will speak from multiple perspectives. Panelists will explore how teaching psychology ethics is similar across different nations, cultures, and developmental stages, and then will go on to examine how teaching ethics differs along each of these dimensions as well. Thus, a focus of the symposium will be for panelists to interact with one another and the audience to explore how various issues, including subject matter and contextual aspects, affect teaching strategies. Panelists will speak from their personal experiences in teaching ethics to address what has succeeded, and what has failed for them, and will offer recommendations about optimal approaches for teaching ethics to psychologists. Panelists will provide samples of teaching materials they have found helpful.

Teaching ethics: The ethics telephone counseling service (ETCS)
Knut Dalen University of Bergen, Norway

For psychologists, learning ethics is a continuing process during the entire professional career. Some ten years ago, we established the Ethics Telephone Counseling Service (ETCS) for members of the Association. When encountering ethical dilemmas, members of the association can call the ETCS and discuss their dilemmas with members of the Ethics board. The ETCS is frequently used. The experiences from the ETCS were published in European Psychologist in 2006 http://www.ipsypcontent.com/content/v1t5r363265251462/fulltext.pdf In the symposium, data from recent years will also be added. Psychologists calling the ETCS seek counseling for a range of ethical dilemmas. Ethical dilemmas concerning confidentiality are those most commonly presented. Dilemmas concerning integrity are also fairly common, whereas dilemmas concerning competence are rarely presented. There is virtually no difference in frequency and nature of consultation based on how long a psychologist has been licensed. Only minor gender differences are observed in the use of the ETCS. In the symposium, possible implications for teaching ethics and ethics education as a continuous process utilizing the ETCS will be discussed.

Teaching ethics to psychologists: The ethics blog
Nina Dalen Aleris Ungplan and BOI, Norway; Knut Dalen; Yesim Korkut; Stephen Behnke

Teaching ethics is relevant at all levels of professional development. More than two years ago, The Ethics blog was introduced at the official web site of the Norwegian Psychological Association http://www psykologforeningen.no/Fag og profesjon/Fagblogger/Nina-Dalen-etskblogg. The blog comments on current issues affecting psychologists’ ethics. These are often matters which may be relevant in national as well as international media.
Examples are the psychologists, who after the 22 July tragedy in Norway, were asked to comment on the offender’s mental health. Another example is a newspaper article about a complaint about psychologists breaching confidentiality in social media (e.g. Twitter or Face book). Selected blog articles with reference to ethical principles will be presented, including blog comments from colleagues. Comments from colleagues summarize important aspect of teaching ethics: identify ethical dilemmas; different approaches to meet the dilemmas, with no right or wrong answers; and see how the dilemma combines common attitudes and professional knowledge. In this perspective, teaching and learning ethics is a continuing process during the entire professional career.

Teaching ethical psychology in diverse practice contexts
Heather Gridley Victoria University, Australia

My approach to teaching ethics in psychology at both honours (fourth year) and postgraduate (professional training) levels has two related aims: To develop students’ understanding of the standards of ethical and professional conduct expected of psychologists, and to enhance their awareness of the diverse nature of the discipline and profession. Combining these two aims enables students to learn how psychologists apply ethical principles in a range of real-world contexts. Working in small groups, pre-practice students visit and interview a psychologist working within a particular field (for example, community psychology, organisational psychology, clinical psychology...). Their resulting group presentations add depth and groundedness to the whole class’ experience, rather than just relying on the literature (or the lecturer). At postgraduate level, we focus on the practice environment rather than the individual psychologist. Students select an ethically problematic aspect of professional practice, and base part of the report of their agency visit and interview on consideration of: Previous and current approaches to the problem - how these reflect prevailing community attitudes, and the implications for practitioners the political, social, family, legal, organisational, professional and personal contexts in which the problem arises and the operation of factors such as power, ethnicity, class and gender in relation to the problematic issue of the Australian Psychological Society’s Code of Ethics and accompanying Ethical Guidelines. In this way, students come to realise that ethical practice is more than a risk management exercise, and is embedded in a wider context than practitioner-client dyads.

Ethics in industrial-organisational psychology in South Africa: Perspectives on the SIOPSA Future Fit 2009–2103 Professional Ethics Project
Leon Van Vuuren University of Johannesburg, South Africa

The psychology community is preparing itself for unprecedented growth as professional discipline. With this growth comes new challenges, and in particular, ethics challenges. During 2008 the Society for Industrial-Organisational Psychology in South Africa (SIOPSA) commissioned a project to: (1) Assess the state of ethics in the profession of I-O Psychology in South Africa; (2) Make recommendations to enable structured management of ethics in the profession. This symposium is aimed at presenting an integrated perspective on the sub-projects of the broader research initiative that was undertaken to meet the Future Fit Professional Ethics Project goals.

The need for continuous introspection on ethical imperatives in the profession of I-O Psychology
Theo Veldsman University of Johannesburg, South Africa; Aimee Ferreira

The changing face of work and organisational structures that provide contexts for work increasing present challenges pertaining to the practice of I-O Psychologists in being experts on human behaviour in the workplace. New challenges in professional ethics continuously emerge in the science and practice of the profession and how its members deal with workplace related organisational and human behaviour challenges responsibly. This paper represents a renewed perspective on the role of professional ethics from three philosophical vantage points, namely normative ethics, meta-ethics and descriptive ethics. The need for ethics as a component of existential justification of the place of the profession in society and professional status is also revisited.

The growing phenomena of cross-border reproduction
Lindsay Childress-Beatty American Psychological Association, United States of America

This paper will begin the symposium by summarising the psychological literature concerning the growing phenomena of cross-border reproductive care as well as serve as a backdrop to the discussions of psychological practice and ethics. Focus will be given on explaining the breadth of the phenomena including an overview of the countries throughout the globe most often involved, the various services in reproductive medicine offered, and the legal and psychological relationship created between the parties. Cross-border reproduction will be compared and contrasted with typical services in reproductive medicine offered domestically in many countries. Focus will be given on the literature concerning why “intended parents” are travel ing in order to build their families including factors such as the costs and availability of similar services.

Syposium title: Emerging issues impacting test development in four different areas of practice
Convenor: Thomas Oakland

Emerging issues in ethics in Latin America
Andrea Ferrero Universidad Nacional de San Luis, Argentina; Ruben Ardila; Andres Consoli

By the 1970 most countries in the region had their own psychological associations and ethics in psychology began to evolve. Most of these countries also passed laws regulating the practice of psychology, and developed training guidelines which specifically include ethics content. Main national ethics codes have been developed considering cultural differences and also socio-historical development, avoiding foreign biases but considering global guidelines.

Professional ethics in I-O Psychology in South Africa: Inspiration, guidance and regulation
Linda Fourie University of Johannesburg, South Africa; Aimee Ferreira

There seems to be a lack of clarity as to exactly how ethics in the profession has historically been managed. Three institutions may have potentially been involved in the regulation and management of ethics in the profession: The Professional Board for Psychology of the HPCSA, the Psychological Society of South Africa (PsySSA) and the Society for Industrial and Organisational Psychology of South Africa (SIOPSA). However, scrutiny of their documents provided ambiguity as to exactly what the respective roles and responsibilities of the institutions are in managing ethics in the profession, and how these roles interact. A qualitative research intervention produced pertinent perceptions of the three stakeholders in this regard. A frame of reference that describes and demarcates the respective roles and responsibilities and how these could optimally intersect, is presented and discussed.

Syposium title: Last chance procreation in a connected world: Ethics and practice in cross-border reproduction
Convenor: Lindsay Childress-Beatty

The growing phenomena of cross-border reproduction
Lindsay Childress-Beatty American Psychological Association, United States of America

This paper will begin the symposium by summarising the psychological literature concerning the growing phenomena of cross-border reproductive care as well as serve as a backdrop to the discussions of psychological practice and ethics. Focus will be given on explaining the breadth of the phenomena including an overview of the countries throughout the globe most often involved, the various services in reproductive medicine offered, and the legal and psychological relationship created between the parties. Cross-border reproduction will be compared and contrasted with typical services in reproductive medicine offered domestically in many countries. Focus will be given on the literature concerning why “intended parents” are traveling in order to build their families including factors such as the costs and availability of similar services.
in their country of origin, religious issues and prohibitions on the use of certain procedures, and the impact of some countries’ regulations concerning issues such as disclosure to offspring, restrictions and limitations on the use of certain procedures, and restrictions on the parties able to use various procedures. Attention will also be given to the nature and motivation of participation by gestational carriers and egg and sperm donors. Research involving the impact generally of reproductive medical procedures on the offspring produced will be summarised, with a specific focus on possible additional impact due to the cross-border aspects of the treatment.

Ethical issues in cross-border reproductive care
Lindsay Childress-Beatty American Psychological Association, United States of America
This paper will discuss broad ethical principles such as justice, respect for autonomy, and the dignity and rights of the person, as well as the professional psychological ethics related to this development in infertility practice. Consideration of ethical principles results in a variety of questions for discussion. How does one think about patient autonomy in the context of possibly large financial, educational, and power differentials between the intended parents and gestational carrier? Is the use of the gestational carrier a positive valuation of a woman’s reproductive potential or, alternatively, exploitation? What parties are impacted but not considered in the arrangement? For example, how does one weigh the possible positive or negative psychological and financial consequences to the carrier’s family? How does one think about the use of cross-border reproductive care to circumvent national laws and the possible impact on the countries’ health systems? Are the ethical issues resolved if the treatment is IVF (in vitro fertilisation) without the use of a gestational carrier? The paper will then consider the professional ethics issues that arise when counselling intended parents in light of these broader ethical principles. The psychologist will be called to help the patients consider medical and legal issues, the impact on all parties, and unintended consequences, when providing education supporting informed consent. The psychologist will need to consider issues such as how to manage personal beliefs and assess their competence when patients are involved in cross-border reproductive care.

Last chance procreation in a connected world: Ethics and practice in cross-border reproduction
Lindsay Childress-Beatty American Psychological Association, United States of America
This symposium presents a series of papers concerning a burgeoning and challenging area of "medical tourism" Cross-border reproductive care. This is being increasingly addressed by governments, medical and mental health professional organisations, and patient advocacy groups. This industry involves participants from many nations around the globe. Participants travel to receive medical treatment for infertility that may not be permitted or available for them in their home countries due to, for example, their sexual orientation, the high cost of treatment, religious prohibitions, or requirements related to disclosure to offspring. The first two papers of the symposium will set the stage for the later discussion of the professional practice and ethical issues involved in cross-border reproductive care. The symposium will begin with a discussion concerning the extent of, and reasons behind, such infertility care. A second paper will illustrate the practical impact of failure to attend to the legal issues involved in this area focusing on possible harm to the parties involved (gestational carrier, intended parents, and resulting offspring). Practice issues in professional psychology will then be explored through a discussion of various international infertility counselling standards. Issues for exploration with intended parents in treatment, and cultural issues in transcultural and international infertility counselling will be discussed. The final paper will explore the broader ethical principles involved, as well as the professional ethics of psychologists confronted with cross-border care in infertility practice. A discussant will lead the audience in a discussion of the practice and ethical issues presented.

Bringing home baby: Legal issues in cross-border reproduction
Elizabeth Grill Weill Medical College, United States of America
This paper will explore the legal issues involved in cross-border reproductive care with an eye toward how failure to attend to those legal issues can cause harm to the parties involved (gestational carrier, intended parents, and resulting offspring). Representative legal cases involving citizenship and parentage will be explored. These cases involve situations such as parents unable to return to their home country with the child, children born without a nationality, and gestational carriers considered to be the legal parent of the child. Discussion will also centre on the impact of failure to agree on certain medical issues in advance such as the number of embryos transferred, selective reduction of multiple embryos, management of health issues of the gestational carrier or fetus throughout the pregnancy, and payments for any additional medical care of carrier after birth. This discussion will provide additional illustration of this complex area to facilitate the discussion of the ethical and professional practice issues involved.

The involvement of mental health professionals in cross-border reproduction
Linda Hammer Burns University of Minnesota Medical, United States of America
This paper will begin with an explanation of how mental health professionals in various countries often become involved in counselling infertility patients considering or obtaining cross-border reproductive care. Specific focus will be given to international infertility counselling standards and the varying international requirements for involvement of mental health professionals in reproductive medicine generally. Once confronted with intended parents who are involved in cross-border reproduction, what are common issues and topics that a mental health professional should consider exploring with intended parents who plan to travel for reproductive services? What are common issues and topics that a mental health professional should consider exploring in post-treatment counselling? How does the mental health professional provide counselling regarding the implications of various treatment options to the donor, gestational carrier and current and future offspring? Limited research concerning the perspectives regarding cross-border reproductive care of mental health professionals involved in infertility counselling will be discussed. This paper will also explore clinical issues in trans-cultural and international infertility counselling and the common issues that arise when donors, gestational carriers, intended parents, and the medical and mental health professionals involved, are from different countries and cultures.

Symposium title: Legal-ethical issues in working with families and couple: The perspective of psychologists from different cultures
Convenor: Alfred Allan
The responsibility for the “other”: The African conception of ethics
Lesiba Baloyi United States of America
Ethics serve as guidelines for the appropriateness or inappropriateness of the behaviour of the practising psychotherapists. Ethics are premised on universal and professionally defined code of conduct that regulates the relationship between psychotherapists and their clients. The difficulty with ethics is that there is a tendency to define them from the universalist or ‘centre’ perspective. This global perspective is mostly at the expense of the oppressed and marginalised epistemologies and cultural beliefs of the indigenous peoples of Africa. Ethics are inextricably linked to people’s epistemology and culture. Ethics are therefore culture and context specific and should be interpreted with this understanding in mind. For example, among the Bantu-speaking African people the responsibility for the ‘other’ takes precedence over narrow individual interests. On this basis, the balance between the psychotherapist’s ethical responsibility towards the individual client in relation to the cultural imperatives, interests and well-being of the ‘other’ is difficult to deal with. I argue that the African communal core ethic, that of the responsibility for the ‘other’ should form an integral part of the code of ethics of the psychotherapy practice in Africa. I illustrate and support this argument by means of a case study.

Challenges for culturally sensitive ethical practice in working with families in multicultural contexts
Sabine Hammond Australian Catholic University, Australia
Working with couples and families add complexity to professional practice as psychologists need to consider a range of ethical, professional and legal issues. Informed consent, confidentiality and boundary issues raise key challenges in working with families. Psychologists may find themselves caught between the individual needs of their clients, the needs of the couple or family, and the needs or requests by external agencies. Moreover, in multicultural societies the issues can be accentuated by differences in understanding and valuing of these considerations. This paper explores key profession-
Ethics

Walking a fine line: The Aboriginal psychologist working with families and the community
Victoria Hovane Australia
The intra-familial sexual abuse of Aboriginal children is a serious social problem in Australia. Consequently developing effective responses is of critical importance. A key element of an effective response is that it takes account of Aboriginal culture so that the response is culturally relevant. In the context of the dynamic interactions between the prevailing dominant non-Aboriginal culture and Aboriginal cultures in Australia today, a number of ethical issues arise. This paper will outline key ethical issues faced by Aboriginal psychologists when working within Aboriginal families and communities in response to the sexual abuse of Aboriginal children in Western Australia.

How well do codes of ethics provide guidance for psychologists working with couples and families?
Ann Stark University of Tasmania, Australia
This paper builds on a presentation given at the 29th Australian Family Therapy conference (2008) but focuses specifically on the dilemmas faced by psychologists working with couples from the many different backgrounds that comprise Australian society. While a recent (2007) revision of the Code of Ethics of the Australian Psychological Society, adopted in 2010 by the Psychology Board of Australia as the code of reference for Australian psychologists, accommodates in some part the concept of a client being more than one person and widens the definition of associated person, multiple practice dilemmas remain. The concept of the relationship as a client, common to couple therapists, is not easily accommodated within current codes of ethics and client, common to couple therapists, is not easily accommodated within current codes of ethics and...
Applying the Human Rights Construct to Psychology

Ann Watts, Entabeni Hospital, South Africa

The human rights construct has a long history in law and its philosophical basis and content have evolved over the centuries. In its modern incarnation, the human rights construct is strongly linked with various treaties and declarations of the United Nations; specific legislation in countries; and the judicial interpretation of these legal documents. The philosophical basis for these legal instruments appears to be a universal recognition of the dignity of humans. In contrast with law, the human rights construct has only recently emerged in the discourse around the professional ethics of psychologists. The recognition of the dignity of humans has, however, been an important focus of ethics, psychology. The question that will therefore be explored in this paper is whether the human rights construct is redundant in professional ethics of psychologists.

Ethical principles and human rights: The role of psychology

Adnan Farah, University of Bahrain, Jordan

Similar to any other professions, psychologists have very well-known ethical principles which are viewed as a vital aspect of their practice. Psychology is based on human rights and requires ethical behaviour on the behalf of psychologists. Ethical principles and human rights can therefore be seen as two sides of the same coin. Throughout psychology education, research and a better understanding of human behaviour, many psychologists and educators can work for social, economic and political change and integrity nationally and internationally in the universal struggle for human rights. Psychologists, therefore, can educate and train students for ethical practice by integrating teaching about ethical principles, as well as human rights in the psychology curriculum. Psychology educators have an accountability, not only to teach students about ethical practice and human rights, but also to prepare students to be advocates and take roles in working toward changing organisations and laws that oppose ethical and human rights. Some suggestions are presented to serve as guidelines and initiatives for psychologist and psychology educators to support ethical principles and human rights.

Dealing with ethical dilemmas arising from historical, political or religious changes

Yesim Korkut, Bahcesehir University, Turkey

The main idea of this symposium is to explore how virtue and politics both play important roles in the development of moral/ethical guidelines and of various declarations of human rights. An understanding of the historical and current context of such relationships can provide a foundation for using the positive aspects of politics to achieve the greater good of human kind. Several questions will be discussed. Historically how have politics influenced codes of ethics and the interpretations of human rights - both positively and negatively? Today how are professional ethics and human rights similar and how different? To what extent do both ethics codes and declarations of human rights require updating in order to reflect the current issues and social political context of the day? What is the role of enforcement in both professional ethics and human rights? How universal are ethical principles and statements of human rights? How can we combine virtue, ethics, and human rights with political strategies to build a better world? How do political strategies help or hinder? Presenters from different countries and different histories will present their perspectives. What do we need to do differently?
The relationship between emotional stress, self-efficacy, self-regulation and mental fatigue of college athletes

Yuan Jiang, Beijing Sport University, China

Stress is closely related with the status and performance of an athlete. It is also the research focus in sports psychology. The relationships between athletes’ emotional stress, self-efficacy, self-regulation and mental fatigue are gradually focused. This research attempts to study the complex relationships between college athletes’ emotional stress, self-efficacy and mental fatigue. The author hopes to provide a theoretical basis for training athletes and improving their performance. This study used the Athletes Training State Monitoring Scale, taking the subscale of emotional stress, self-regulating, self-efficacy and mental fatigue as the main variables in the study. A sample of 512 college athletes were randomly selected to complete the questionnaire. The results of the structural equations modelling show that emotional stress not only had a direct impact on mental fatigue, but also had indirect effects through self-efficacy and self-regulation. This showed the mediating role of self-efficacy and self-regulation between emotional stress and mental fatigue. Emotional stress could positively predict mental fatigue; however, self-efficacy and self-regulation negatively predicted it. Meanwhile, further data analysis also showed that the longer campaign experience and higher athletic rank the college athletes had, the higher self-efficacy and better self-regulating ability they would obtain. Self-efficacy and self-regulation have mediating effects between emotional stress and mental fatigue. Emotional stress can positively predict mental fatigue; self-efficacy and self-regulation would negatively predict it.

A study of emotional competence of sports personnel

Shyam Lata Juyal, Gurukul Kangri University, India; R. Rafuddin, Anu Dandona

In recent decades increasing interest has been attracted towards relationship between emotional intelligence and healthy behaviours and mental health. The concept of learning emotional competence through sports has received little attention by researchers. This study explores the emotional competence of athletes among the sample of 160 participants as an effect of boarding (80 boarding and 80 day scholars), sports (40 sports and 40 non-sports) and gender (20 girls and 20 boys) of adolescents sports personnel. Findings revealed that sports per-
sonnel are more competent emotionally than non-sports personnel, day scholars showed more competence than the boarders and in gender, sports boys of day scholars are found to be highly competent emotionally than the girls of non-sports as well as boarders. Study concludes that sports play a significant role for enhancing emotional competence of day scholars boys as compared to participants of its counterparts.

Diagnostics of time perception in high achievement sports

Sergey Leonov Lomonosov Moscow State University, Russian Federation

This article analyses and defines the concepts of synchronicity of the movements as well as silent counting in synchronised swimming. Synchronised swimmers (Russian junior team, N = 20) were selected as a sample according to their sport activity and time perception, time judgment, and time experience (Adam et al., 1974; Brown, 1995; Hancock et al., 1992; Zakay, 1998; Burle et al., 2000; Grondin, 2001; Wearden et al., 2007). Performance in synchronised swimming is accompanied by a musical composition, various parts of which are played using different tempo. Certain characteristics of physical movements that athletes must perform synchronously are associated with the music and units of counting which serve for sportswomen as tools for control of synchronisation. To study the characteristics of silent counting associated with rhythmic movements, the athletes were asked to listen to a sample tune and to press a key in those moments when they were silently counting the melody rhythm. The test melody included a music sample which was to accompany the athletes’ performance at the competition. This method allowed us to identify and to study various individual and group temporal characteristics of silent counting, in accordance with the results of measuring the movements of keystrokes. It was shown that there are individual temporal characteristics of silent counting which are specific to each athlete, and do not embrace similar features of other athletes, though all synchronised swimmers perform as a team. Results obtained demonstrated the necessity for objective measures of silent counting as an important index of synchronisation among athletes, in order for it to be successfully used by a coach.

Transformational leadership and exercise attendance: The mediating role of basic psychological needs

Lauren Mawn Bangor, United Kingdom; Calum Arthur; Sarah Roberts

Transformational leadership (TL) has been shown to positively influence sport participation (Rowland, 2006). Little is known about mechanisms by which TL impacts participation. Self-determination theory (SDT: Deci & Ryan, 1985), specifically basic psychological needs, offers a potential for examining these mechanisms. SDT posits that satisfaction of the basic needs of competence, autonomy and relatedness, promote the internalisation of behavioural regulation and enhance well being. Indeed, the satisfaction of basic needs have been shown to impact leisure time physical activity. The current study investigated the mediating role of basic needs in the TL and exercise participation relationship. 155 British Military Fitness (BMF) exercise attendees took part (Male=54, Female=101, Mage = 32.61±10.07). Participants completed online measures of attendance (times per week), transformational leadership (DTTL-I: Callow et al., 2009), and basic needs satisfaction scale (Gillitt et al., 2008). Correlations revealed that intellectual stimulation (I.S.), high performance expectations (H.P.E.) and appropriate role model (A.R.M.) significantly correlated with attendance, (r = .169, p ≤ .05; r = .225, p ≤ .01; r = .171, p ≤ .05) respectively. Relatedness and competence significantly correlated with attendance, (r = .319 , p ≤ .01, r = .285 p ≤ .01) respectively. Meditational regression analysis revealed relatedness fully mediated the relationship between H.P.E. and attendance, and, the relationship between A.R.M. and attendance. Interestingly, autonomy was not related to attendance. Therefore, partial support for basic needs as a mechanism for the TL and exercise participation relationship is offered.

The development and implementation of a mental toughness training programme for semi-professional cricketers

Michael Mcinerny Rhodes University, South Africa; Gary Steele

Increasing professionalism in sports has provoked both a reassessment of the way in which athletes train and perform, and an attempt to address all the elements that have an impact on levels of performance. Mental toughness has been recognized as one of the most important psychological attributes in achieving performance excellence across multiple sport settings. Yet, despite this, little research has been conducted into mental toughness development. This research seeks to answer the question: What insights can the development and implementation of a mental toughness program for a semi-professional South African cricket team provide regarding mental toughness development? Using the Organisation Development Process model within an action research framework, a program was developed in collaboration with the Border Cricket Team and Coaches. Incorporating elements that focused on education, environment, awareness and mental skills, the program was implemented in both individual and group settings during the off- and pre-seasons. An analysis of the participants’ experiences identified the positive short- and long-term impact, while acknowledging difficulties in managing and incorporating environmental factors. This study highlights the importance of the participants’ context in determining the selection of the most effective techniques and components on which to focus an intervention. Future research could facilitate program design through the improvement of existing models of mental toughness development in order to identify the salient factors and mechanisms involved in the development process.

An exploratory analysis of losing possession in professional soccer

Mosenh Shafizadeh UCL, United Kingdom; Shirley Gray; John Sproule; Terry McMorris

The aim of the present study was to develop a measure that determines the reasons for losing possession in professional soccer. 55 national soccer teams that took part in the 2006 and 2010 World Cup games were selected for this study. The Losing Possession Observational Checklist for Soccer was developed and applied to games in these tournaments. The results of inter-rater and intra-rater reliabilities showed that the new checklist had good stability (K = .75) and objectivity (K = .75). In addition, the results of exploratory factor analyses showed that losing possession in soccer included skill execution and parameterisation, skill under stress, and speed and timing problems that accounted for 77% of common variance. In conclusion, current findings demonstrated that losing possession in soccer is multidimensional in nature and consists of motor and cognitive factors on the basis of specialist and statistical confirmation.

A study of goal orientation, aggression and passion among medal winner boxers and non-medal winner boxers

Kuldeep Singh Punjab University Chandigarh, India

The present study was planned with the objective of assessing the difference between medal winner boxers and non-medal winner boxers on goal orientation, aggression and passion. It was expected that there will be a significant difference between medal winner boxers and non-medal winner boxers. A randomized sampling technique was used. The study was conducted on two groups, i.e. medal winner boxers and non-medal winner boxers. A total 60 male boxers were selected as respondents. They were further divided into two groups, i.e. 30 medal winner boxers and 30 non-medal winner boxers. The subjects were administered the following tests under standard conditions: (1) The Task and Ego Orientation in Sports Questionnaire (Duda, J. L. 1989), (2) the Aggression Questionnaire (Buss & Perry, 1992), (3) the Passion Questionnaire (Valerand, R.J. et al. 2003). As per theoretical models and research evidence, the results showed a significant difference in goal orientation, aggression and passion between medal winner boxers and non-medal winner boxers.

Assessing mental toughness in a South African context: Investigating psychometric properties of three mental toughness inventories in a South African sample

Gary Steele Rhodes University, South Africa

The current paper investigates the psychometric properties of three currently available mental toughness inventories in a sample of university-level cricketers in the Eastern Cape, South Africa. Paper-and-pencil versions of the Psychological Performance Inventory-A (Golby, Shepard, & van Wersch, 2007), the Mental Toughness Inventory (Middleton, Marsh, Martin, Richards, & Perry, 2004), and the Sports Mental Toughness Questionnaire (Sheard, Golby, & van Wersch, 2007) were administered to university- and club-level cricketers, drawn by means of purposive sampling that produced varying levels of socio-economic status and a diverse range of cultural groups. The Athlete Burnout Questionnaire (ABQ; Raedeke & Smith, 2001) was included in the assessment package as a means of investigating discriminant validity. Descriptive statistics, internal consistency and construct validity of the mental toughness inventories were investigated, with convergent validity being assessed by means of correlations between the three
mental toughness inventories and the discriminant validity of the mental toughness inventories being assessed by means of correlations with the ABQ. The psychometric properties of the three mental toughness inventories will be discussed in terms of the reliability and validity of these inventories. The effect of socio-economic status and cultural and environmental factors on mental toughness scores were examined by means of factorial ANOVAs. These results will be discussed in terms of the importance of taking these issues into consideration when developing mental toughness programs in a South African context.

The purpose of this study was to explore the sport psychological development of high school netball players in South Africa and explore differences in Mental Toughness (MT) among players of different age groups. To achieve this purpose, 976 netball players from 56 schools across South Africa ranging from 11–19 years, (mean age = 15.45 years; sd = 1.921) were included in the study. Participants were asked to complete the Mental Toughness Questionnaire and the Sports Competition Anxiety Test (SCAT). Data were collected during training camps. The collected data were analyzed using frequencies, descriptive statistics, analysis of variance (ANOVA), and Pearson’s product moment correlation. The results of the study showed that there are significant differences between overall mental toughness (OMT), age and even hours training, amongst the netball players. The results also suggested that there is an increase in psychological skills from age 13 to age 16, but not much from age 16 to age 19. Even with this development, the level of mental skills by age 19 is not high. It was concluded that Psychological Skills Training (PST) intervention is needed between the ages of 13–16 years of age in order to equip these players with the necessary psychological skills set to perform at the highest level in their sport.

Development of motor skills using symbolic tools
Aleksander Veraksa Moscow State University, Russian Federation
Although many studies have been conducted on the role of symbolic tools in acquisition of motor skills (Garza, 1998; Poolton et al., 2006), few have been devoted to the preschool age (Sawada et al., 2002). This study was designed to investigate the possibility of employing iconic and symbolic tools in movement acquisition by preschool children. The movement chosen was alternating inner and outer sides of feet in moving a ball across a field with a subsequent shot at a goal. The tools chosen were an iconic scheme that focused children on their body’s spatial position and its relation to the position of the ball, and a metaphor of a two-headed snake that chases a mouse into a hole. The participants were 24 male young soccer players, attending a sport school in Moscow, Russia (M=5.8). A short animated movie depicting the movement to be acquired using the iconic scheme and the metaphor was presented. All participants were divided into two groups balanced according to the physical conditions of the players (coordination, endurance, velocity), as rated by 4 independent football coaches on a subjective scale from 1 to 7. The experimental interventions continued for 4 months (12 individual meetings each 7–10 minutes long). A test of the movements was performed after every 4 sessions, filmed and evaluated by 4 coaches. Experimentally, overall effectiveness of symbolic tools in teaching motion skills to young football players was demonstrated. Those of them taught using symbolic tools (a metaphor) achieved higher quality of skill execution than their peers who were taught using iconic tools (scheme).

Theoretical construction of elite athletes’ mental model
Guo Li Zhang Beijing Sport University, China
The concept of mental model was first proposed by psychologist Craik. He suggested that mental model thought reality as constructing a “small model” and used it to predict, make attribution and explanations. Later the concept was also mentioned by American psychologist Peter. He looked at mental models as people’s opinions and actions towards their surroundings and they are planted deeply in people’s minds. The article aims to introduce the mental model into the field of sport psychology. Through literature analysis, the author drew the conclusion that mental model was an open, dynamical system which included support, dynamic and control of three subsystems. The support system was the most fundamental system which consisted of some stable elements such as intelligence and personality. The dynamic system was a main system which included dynamic elements, such as motivation and self-efficacy. The control system was the most critical one, which consisted of self-control and self-regulation. In summary, the support system was the basis which provided preconditions for athletes to participate in training and competitions. The dynamic system was the key, it stimulated athletes’ motivation and improved their self-efficacy in competitions. The control system was the guarantee which guided the dynamic system in the right direction. Only when three subsystems coordinated well could elite athletes perform their best in competitions. For psychological selection, the support system was the basic requirement. For psychological training, dynamic and control systems were both the focus and training target. Therefore, making theoretical construction for elite athletes’ mental model had important theoretical and practical significance.

Impact of amount of information and level of skill on basketball players’ intuitive judgement of attack fake
Lizhong Chi Beijing Sport University, China; Chenya Liu
With the development of basketball, ‘attack fakes’ are being used more often, especially in NBA, World Championships and other high-level competitions. It is difficult for defenders to identify the fake, which also puts forward higher requirements for defense. Based on previous studies on fake, considering the related affecting factors, this study selected the skill levels and the amount of information as independent variables, and tried to explore their effects on intuitive judgement. Forty basketball players (all men, mean age is 20.4 years old) participated in the study. Videos clips of ‘attack fake’ were selected from Olympic basketball competitions as intuitive decision-making materials. The results suggest that: (1) The amount of information has a significant effect on the accuracy of attack fake intuitive judgement. The more information, the faster intuitive judgement is. (2) The level of basketball players has no significant effect on the quality of attack fake intuitive judgement.

The sport psychology of chess: A psychological, electroencephalographical and physiological case study
David John Edwards University of Zululand, South Africa; James Beale
The sporting game of chess requires players to remain in relatively stationary positions. This provides an ideal environment for the controlled measurement of related cognitive psychological, neurological and physiological components. The chosen research methodology for the present investigation involved a single case study, correlational design with quantitative and qualitative components. Electroencephalographic (EEG) and physiologic measures were quantitatively recorded. Qualitative appreciative inquiry data were thematically content analysed. The single male participant was chosen on the basis of qualitative research criteria, which included his established relationship with the second author, experience of playing chess, insight into, and willingness to discuss his experiences. Consent was obtained and confidentiality maintained. Cognitive psychological, EEG and physiologic measures were recorded on two separate occasions. The first occasion involved measurements during a rest period followed by three chess games against a player of similar World Chess Federation (FIDE) and England Chess Federation (ECF) ratings. The second occasion involved measurements during a rest period, followed by computer based chess games against players of similar FIDE rating, followed by puzzle and book chess games respectively. The quantitative EEG (delta, theta, alpha, sensory motor rhythm, beta and gamma means), physiology (blood volume pulse, skin conductance, respiration rate) and cognitive psychological qualitative appreciative inquiry results are presented in relation to the player’s perceptions and experiences. Recommendations for future research are made.

Mental skills in South African and United Kingdom university students: Reliability analysis of Bull’s Mental Skills Questionnaire
David John Edwards University of Zululand, South Africa; Stephen Edwards; Philip Denyer; Richard Buscombe; Ben Steyn
Mental skills are holistic, naturally occurring abilities and/or techniques that can be trained for specific settings such as sport and exercise. Established inventories often lack sufficient exploratory analysis to support their use across international samples. This study was conducted to investigate the internal reliability of the Bull’s Mental Skills Questionnaire
Exercise across two distinct populations. Data were collected from 215 South African (SA) and 209 United Kingdom (UK) male and female, university students (M=19.49; SD=1.87 and M=22.17; SD=5.20, respectively). Following appropriate ethical procedures, volunteers completed the MSQ, which consists of seven mental skill subscales: imagery ability, mental preparation, self-confidence, anxiety and worry management, concentration ability, relaxation ability and motivation, which produce a total score. Cronbach alphas for the SA and UK samples for the seven subscales fell within the range: 0.61–0.82 and 0.44–0.83, respectively. Internal reliability for the total MSQ scores were 0.89 (SA) and 0.88 (UK). Pearson correlations indicated moderate to strong relationships between sub-scales and total score, 0.54–0.75 (SA) and 0.59–0.73 (UK), with items across both samples correlating with their respective sub-scale at the p<0.01 level. This work supports the internal reliability of the MSQ and indicates that practitioners may use the inventory with some confidence when working with similar international samples. Future work is planned to expand the study to include additional international samples.

Exercise frequency, learning work climate, sleeping problems, positive and negative affect
Daniu Garcia University of Gothenburg, Sweden
The present study tested the relationship between exercise frequency, work climate, sleeping problems, and affect. Workers (N = 204) self-reported exercise frequency and their experience of the climate (measured by the Learning Climate Questionnaire) and affect (measured by the Positive Affect Negative Affect Schedule). The participants also reported sleeping problems. A positive affective experience (i.e., frequent positive affect and infrequent negative affect) at work was positively related to all work climate and sleep variables and to confidence, team style, opportunities to develop, guidelines on how to do the job, and contentedness. Moreover, exercise frequency was related to contentedness and also moderated the relationship between affect and work and sleeping problems. Physical activity seems to reduce stress symptoms and improves mental states, and in the long term, enable arousal levels to be more appropriately adjusted for cognitive work and by increased stress resistance.

Rate of aggression in athlete and non-athlete students
Maryam Kelhani Mashad Azad Islamic University, Islamic Republic of Iran; Arash Miri Far
Study and research about aggression plays an important role in sport. Many social science scholars believe that sport in its different forms is a reflection of society. The word aggression refers to behaviour in which a person intends to harm himself and/or others or to ignore the well-being and welfare of himself and/or others. The present study begins by describing the rate of aggression in athlete and non-athlete students and tries to compare them. In this descriptive causative comparative study, 293 high school students were selected and divided in two groups, athlete and non-athlete, and responded to Buss and Perry’s (1992) aggression questionnaire. The results of the study showed no significant difference in athlete and non-athlete students regarding the rate of aggression but there was significant difference in male and female students regarding the aggression. Girls had more anger than boys. Probably sport and physical activities can affect aggression in two different ways. If it’s done with the aim of play and leisure it can lead to control and a reduction and release of aggressive energy. On the other hand if it is done in the form of competition some of the internal and external pressures such as worrying about the result, coaches’ and team mates’ expectations and spectator pressure may not have a positive effect on reduction of such behaviours. Gender also plays an important role in the type of aggression that one can display or express.

The effectiveness of group mental counseling and exercise interventions on depression and body-esteem of young men with simple obesity
Chen Li China
The aim of the study is to explore effectiveness of group mental counseling and exercise interventions on depression and body-esteem of young men with simple obesity. 64 depressed young men with simple obesity were divided into experimental group and control group, and the interventions comprise 4 treatment combinations (Psychological intervention: Problem solving therapy or supportive counseling, exercise intervention, behavioural intervention or psychoeducation) delivered by psychologists over 6 sessions on a weekly basis: A group mental counseling and an aerobic exercise intervention. Structured assessments occur at baseline, mid-point, end-point (8 weeks) and at a 4- and 6-month follow-up. The depression and body-esteem were measured by Beck Depression Inventory and Physical Self-Perception Profile. The result showed that the intervention of group mental counseling combined with aerobic exercise is much more effective than other interventions. The combined interventions have the potential to prevent the progression of early symptoms and distress to later and potentially more serious stages of depression and induce the likelihood of on going problems associated with the risk of persistence and recurrence.

Regional homogeneity changes in professional Chinese chess players revealed by resting-state functional magnetic resonance imaging
Dongmei Liang South China Normal University, China; Qiyong Gong; Minqiang Zhang; Chengyi Liu
The aim of this study is to investigate the effect of Chinese chess training on local functional connectivity of the brain. The analytical method regional homogeneity (ReHo), which calculates the Kendall’s coefficient of concordance (KCC) between time series of blood-oxygen-level dependent (BOLD) signal of a given voxel and those of its neighbors in a voxel wise manner, was applied in the analysis of resting-state functional Magnetic Resonance Imaging (rs-fMRI) data between 26 professional Chinese chess players (PRO, seven female, 11 male masters and eight male first level players) and 26 novices (10 female). There are differences between male masters and male first level players. Also, differences exist between PRO and male novices. Specifically, the ReHo of male masters increased in right insula and decreased in right cerebellum anterior lobe. The ReHo of male PRO increased in right superior temporal lobe and decreased in right cerebellum posterior lobe and right precentral gyrus. There are negative correlations between training years as well as rating points and the ReHo of right superior temporal gyrus. Also, there are negative correlations between rating points and the ReHo of some other regions. Rs-fMRI and ReHo analysis reveals training induced differentiated local connectivity of brain function in PRO, between them and novices. The changed ReHo of some regions show negative correlations to training years and rating points. Due to its ease of implementation, noninvasive nature and its ability to localise single abnormal sites, this method may be a useful tool for studying training induced plastic changes.

Research on the effects of dragon boat participation on psychological characteristics of adolescence influenced by China’s regional Lingnan culture
Bin Liang CBU, Chongqing, China; Hui Zhang
Both culture and sports can contribute to psychological characteristics. China’s regional Lingnan culture has an inevitable positive and negative influence on psychological characteristics of local adolescents and their overall psychological characteristics are as follows: More comprehensive acceptance to new things but less intensive absorption, more active ideas but less action, more preference for direct profit but less accumulated commitment and more skillful response to changes but less disciplined. The purpose of this study was to test the effect of adolescent dragon boat participation on the above-mentioned psychological characteristics. Adolescent racers were divided into two groups, new racers and veteran racers. The racers and common adolescents from Guangdong and Fujian Provinces influenced by Lingnan culture completed a self-report questionnaire to assess their psychological characteristics. Results demonstrated that there was an interaction between age and training years and significant differences in several dimensions between the racers and common adolescents. The interaction showed there may be a sensitive age for effect of sport intervention. Racers showed more intensive absorption, more action, more preference for accumulated commitment and more disciplined. These findings highlight the importance of sport intervention and we predict that dragon boat participation may act as a positive intervention to reduce the negative influence of regional Lingnan culture on psychological characteristics of regional adolescents.

Research and application on college students’ physical health management
Qi Luo Wuhan Institute of Technology, China
Physical health problems of college students have been increasingly highlighted due to negative events caused by physical health, psychological health, social adaptation and other health problems in an endless stream of college students, and the educational philosophy and methods in the traditional sense cannot meet physical health needs of college students in the period of social transition.
Reasonable, effective, and operable physical education and health management of college students reflecting the characteristics of the college student population has become the focus of educational and academic circles. Based on a large number of studies and works on physical health of college students and taking the indicators of physical health and personalised physical health management system of college students in China as research object, a personalised physical health management model of college students is constructed and tested by using the methods of literature research, interview, questionnaire, mathematical statistics and computer engineering. The conclusion as follows: Physical health management model of college students includes 7 items of physical health indicators and 15 items of psychological health indicators, which are divided into 6 dimensions and 22 indicators in all. The human shape dimension including: height and weight; body functions dimension including lung capacity and pulse; a fitness and athletic ability level of development dimension including strength, flexibility and endurance; a self-dimension including self-esteem, confidence, self-reliance and independence; an interpersonal dimension including teamwork, interpersonal communication, collaboration, awareness and collaboration; a doing-things dimension including focus, persistence, persistency, emotional stability, anti-frustration, adaptability and self-learning.

The linguistic and motivational properties of self-talk predict on-task effort in athletes

Emily Oliver Aberystwyth University, United Kingdom

The frequency and content of one’s self-directed cognition predicts affective and behavioural consequences. However, objective linguistic analyses of self-talk are lacking. In addition, studies which have considered motivational functions of self-speech frequently lack a theoretical basis. Drawing on cognitive evaluation theory (Deci & Ryan, 1985), the present study examined associations between linguistic markers, motivational interpretation, and athletes’ effort in training. Following institutional ethics approval, post-training, 241 team sport athletes (Mage = 23.05, s = 6.78) completed measures of effort and the functional significance of their self-talk (ICSTQ; Oliver, Markland, & Hardy, 2010). Thought-listed self-talk was processed using lexical frequency analysis software (LIWC; Pennebaker, Booth, & Francis, 2001). Quantitative differences in categories of word use were predictive of athletes’ effort during training. Contrary to hypotheses, effort was negatively predicted by the use of 1st person speech (β = -.042; p = .005) and positively predicted by the use of second person pronouns (β = .038; p = .036), perhaps reflecting a reactive role for self-talk in response to effort decrements. As expected, self-talk in the past tense was a negative predictor of on-task effort (β = -.059, p = .017), whereas present tense speech was positively associated with effort. Informational (need supportive) self-talk tended to be briefer and focus less on others, and positively predicted effort (β = .369; p = .001). These findings enhance understanding of the role of self-talk in the regulation of effort.

Psychological acceptance to sports injury in Japanese university elite athletes: Coping free of adhesion, perceived physical recovery, and perceived personal growth

Tatsumi Tomanori Kio University, Japan

In this study, the effect of psychological acceptance to sports injury on athletes’ recognition of physical recovery and personal growth was examined. The subjects were 137 highly competitive college athletes in Japan, who were forced to stop playing for more than one week, owing to injury suffered after they hand entered universities. They were asked to fill out originally developed questionnaires consisting of the following 4 scales: Coping free of adhesion (COFAD), Injury-Recovery, Movement-Recovery, and Personal-Growth scale. The main results were as follows: 1. Significant positive correlations were found between WOSC and PRO-COPE (r=.47, p=.00); WOSC and PS (r=.30, p=.00); and WOSC and PT (r=.49, p=.00). Significant negative correlation were found between WOSC and EMOCOPE (r=-.18, p=.05); WOSC and AV (r=-.34, p=.00). 2. Significant positive correlations were found between ACRE and PRO-COPE (r=.28, p=.00); ACRE and PT (r=.31, p=.00). Significant negative correlation were found about between ACRE and EMO-COPE (r=-.31, p=.00); ACRE and AV (r=-.32, p=.00); and ACRE and CA (r=-.35, p=.00). Consequently, the relation between COFAD factor and active stress-coping was suggested, and criterion-related validity of COFAD scale was demonstrated.

Eye-movement characteristics of judgment of tennis serving position

Yingchun Wang Division of Sport Psychology, China

This study used a Head mounted Eye tracking Device (HED) to track the record of eye movement. 20 general students who have no tennis experience participated in the experiment. The results showed that: (1) In determining the course of tennis serving placement, the participants who watch the rivals’ body will get more scores than those who only watch the ball. (2) There was significant difference on saccade amplitude average between the participants who watch the rival’s body and those who watch the ball.
Influence of experimentally induced anxiety on placebo efficiency in pain experiment
Adriana Banozic, MEFST, University of Split, Croatia; India Morrison; Damir Sapunar

Pain perception is subject to variety of psychological influences. The underlying mechanisms of expectancy play a central role in both placebo analgesia and nocebo responses and are often accompanied by emotional processes. Anxiety relevant to the source of pain can modulate pain perception. Thus, it is possible that expected pain levels, motivation to reduce pain, empathy and anxiety may contribute to the increased efficiency of the placebo effect. The present study investigated whether participants would attribute more analgesic properties to an inert substance and exhibit an increased placebo effect when exposed to a threat of painful stimulation. Participants were previously thresholded in a neutral condition and then randomly exposed to anxiety relevant or irrelevant context. Anxiety was manipulated using previously validated video materials. Results indicated that there was a significant increase in pain expectancy in the anxiety-relevant condition compared with the neutral condition, as well as decrease in VAS ratings after being exposed to the anxiety-relevant manipulation. There was no difference in the level of pain expectancy or in VAS reports in the anxiety irrelevant condition. The expected mediating effect of empathy to the pain levels was not confirmed in this setting, although significant associations were found between pain ratings, expectancy and empathy towards participant in a video. Anxiety results showed significant correlation to the amount of ”placebo substance” used, indicating that highly anxious participants exhibited proportional motivation to reduce pain.

Comparative approaches to delay of gratification
Michael Beran, Georgia State University, United States of America

Individuals often are faced with conflicts between receiving things that they want right now, or waiting to receive something they want even more, but later. When they wait, they exhibit self-control. One of these experiments made use of the idiosyncratic style of Amedeo Modigliani who employed manneristic face elongation. In the first part of the experiment, the pre-adaptation phase (T1), participants were asked to rate their liking of a number of portraits by various artists of a variety of different historical epochs on a seven-point Likert-scale. Each portrait was presented in 11 different versions which differed in the amount of compression or extension in heights. This block was followed by an adaptation-phase in which Modigliani’s paintings were shown. In a succeeding test-phase, the post-adaptation phase (T2), liking of the same paintings of T1 was rated again by the participants. Results revealed systematic changes in aesthetic appreciation for those exemplars that were structurally rather similar in the style to Modigliani (the extended versions). The present paper integrates these experimental findings into a framework of taste development which helps to understand both the stable and the flexible parts of a person’s taste.

Personal determinants of success in the detection of threat conditions in visual displays
Craig Donald, Edith Cowan University - Perth, South Africa; Antony Bridges; Fiona Donald

Security concerns are driving the development of an increasing range of imaging technologies ranging from the depiction of real life still pictures or video, to increasingly abstract electromagnetic imaging including x-rays, millimetre wave, and terahertz based systems. Although extensive attention is paid to technology, settings, structures and procedures in order to increase the detection rate of threats, the nature and contribution of individuals’ psychological approach and image processing skills is poorly understood and recognised. This paper examines the impact on detection success of personality and visual analysis using research findings in two visual imaging areas, aviation x-ray screening and Closed Circuit Television (CCTV) behavioural detection. The contribution of separate studies examining personality (n=300) and (n=16), and visual analysis skills (n=16, n=12, n=42) demonstrate significant and appreciable relationships (up to r=.69) with detection success in x-ray and various types of CCTV environments. The parallel findings in these two types of visual analysis environments indicate that, despite variations in work situations, visual image displays, and target indicators, the way people relate to the process of visual analysis and detection is an important factor in detection success independent of the image content of displays. Personnel with appropriate personality characteristics and visual image processing skills are likely to be higher performers, and more able to adapt to multidisciplinary viewing roles with different types of imaging technologies, including those displaying high levels of abstract or representative content.

The effect of presentation procedure on behavioural measures of hemispheric specialisation
Louise Hansen; James Cook University - Cairns, Australia; Deborah Graham; David Cottrell

The dichotic listening paradigm is the dominant behavioural procedure for measuring hemispheric specialisation in the processing of auditory stimuli. This dominance has been achieved without a direct comparison of presentation procedures. In the studies reported here we compared monaural, dichotic and the distractor noise presentation procedures on the same task using the same target stimuli. The stimuli were simple tonal and atonal melodies and the task was to make an affective (“Is the melody pleasant/unpleasant?”) or musical (“Is the melody in-key/out of key?”) judgement. Significant ear advantages emerged as a function of presentation condition and melody duration. When the stimuli were relatively brief (850 ms) response times differed between the left and right ear in the affective monaural listening task. Reponses were quickest for pleasant melodies presented to the right ear and slowest for unpleasant melodies to the same ear supporting the notion that positive and negative emotions are differentially processed in the two cerebral hemispheres of the human brain. However, when longer versions of the same melodies (2200ms) were appraised, response times were quickest for both pleasant and unpleasant melodies presented to the left ear in the dichotic listening task. This left ear advantage is consistent with the majority of dichotic listening tasks that provide evidence for the right hemisphere’s role in processing all emotions. Given that ear asymmetries depend on stimulus duration and what is being presented in the unattended ear, we question the assumption that dichotic listening tasks reliably measure hemispheric differences in emotional processing.

Perceived direction and depth of an object in visual space versus differences in monocular luminance contrast
Vaitkevicius Henrikas, Vilnius University, Lithuania; Algimantas Svegda; Janus Kuilikis; Rytis Stanikunas; Aludze Dzereviciute; Ausra Daugirdiene; Remigijus Blumius; Villus Vilunas

As has been shown, differences in the monocular brightness contrast of dichoptic images affect the perceived location of the object in 3-D space. But the data obtained by the different authors are contradictory (Fiorentini, 1971; Blake, 1979; Petruskas et al., 1990; Mansfield, 1996). These phenomena cannot be explained by the well-known ‘energy model’ (Ohzawa, 1998). Therefore we address this
problem. Three stimuli generated by PC on the right side of the screen and three stimuli on the left were presented dichoptically. The subject perceived two bars 1 and 2: one above and another below the dark disc, which the subject fixated. The Weber contrasts of the monocular images of bar 2 were kept constant. The contrasts of images of bar 1 were changed within the range of (-1.0 to 1.5), while their location was not changed. Disparity of images of bar 2 was changed randomly (by 1 min of arc). The subject had to say when the depth or horizontal directions of the upper and lower bars coincided (2-AFC). The perceived direction and depth of bar 1 have been calculated. Taking into account both our data and the data of other authors, we reiterate that differences in monocular contrast affect the perception of both the direction and depth, but this impact on the perception of the direction and depth is different and depends on the location of images in the retinas. To explain the obtained data the vector model is suggested.

How does ruminative self-focus modify the influence of control deprivation?

Tomasz Jarmakowski University of Lodz, Poland

This presentation describes research that consisted of two experiments, the aim of which was to examine the role of ruminative self-focus in developing helplessness deficits (experienced after control deprivation). The participants of the 1st and 2nd experiments were 94 and 90 students respectively. In both experiments control deprivation was manipulated with the Informational Helplessness Training method by Kofa and Sadek. After this stage, different types of ruminative self-focus vs. distraction (focusing on emotionally neutral tasks) were induced. Additionally, different methods of ruminative self-focus induction were used in each experiment. The methods were prepared by the author (based on the methods used by Nolen-Hoeksema et al.). The impact of self-focus after experiencing control deprivation was tested with the Linear Order Method by Bedyska and Czajkowski that measured cognitive functions (short-term memory and generative reasoning) and self-report methods gauging emotional functioning and subjective cognitive problems experienced during performance on the Linear Order task. The results of both experiments suggest that self-focus after experiencing control deprivation prevents or, at least, reduces cognitive helplessness deficit (cognitive functions). This effect is independent of the type of ruminative self-focus. The positive effect of self-focus after control deprivation for emotional functioning and subjectively perceived cognitive problems was observed only in the first experiment. The possible explanation for these results, considering the role of emotions for developing helplessness deficit, will be proposed.

Effects of emotion on intertemporal choice

Jing Jiang Peking University, China; Lei Wang Peking University, China

Two studies were conducted to investigate the effects of emotion on inter-temporal choice. In Study 1, Participants (65 employees) were asked to recall and write down related events to prime their emotions (positive, negative, or neutral) and then were measured discounting rates as the index of inter-temporal choice. The results showed that (1) time-delay had main effect on discounting rates such that the discounting rate decreases as the delaying time increases; (2) Emotion valence didn’t have main effect but interacted with time-delay to influence discounting rates, discounting rate in negative emotion condition was significantly higher than in other two conditions only when time-delay was longer than 1 month. In Study 2, participants (22 college students) were asked to imagine and write down related events to prime their emotions (positive, negative, or neutral), dependent variables was measured in the same way as that in Study 1. We found that (1) time-delay again had main effect on discounting rates, (2) the average discounting rate in negative condition was significantly higher than that in positive condition, showing the general impact of emotion valence no matter how long the time-delay was. In sum, the effect of emotion on inter-temporal choice was mixed and largely depends on the context, such as delaying time in the situation and emotion arousal in the process of recalling or imaging. In the future, we should pay more attention on the emotion involvement in different contexts and clarify the primary influencing factor of emotion valence on inter-temporal choice.

Using wasabi for the sensory evaluation of pungent taste in Japanese people

Miwako Kato Aichi Shukutoku University, Japan

Wasabi is eaten with sushi, and it is very popular for its sharp taste, especially among Japanese people. Previous studies have reported a relationship between this pungent taste, the brain and the central nervous system, as well as a person’s physical state. Capsaicin in red pepper is also well known for its pungent taste. However, it is difficult for this ingredient to be tested repeatedly because the test subject continues to experience an aftertaste. Therefore, in this study, wasabi was compared with the taste of red pepper, in order to evaluate the potential of using wasabi in research on the sensory evolution of pungent taste. Healthy volunteer university students (n = 31; mean age 28.6 ± 9.2 years) participated in the study. They were randomly divided into the capscain, or the wasabi groups. Participants sat quietly for 15 minutes. Following this, they performed the first taste test. The second and third taste tests were consecutively performed following two subsequent 10-minute periods of sitting quietly. In the test, participants ate a sample of capscain or wasabi, and then evaluated the degree of the pungent taste. Affect-grid scoring was used to evaluate the emotional states of the participants. An analysis of variance indicated that the pungent rating for red pepper fluctuated more than that of wasabi. In addition, the pleasantness scores of the wasabi group did not change, but that of the red pepper group decreased significantly. These results suggest that wasabi is suitable for the sensory evaluation of pungent taste.

Prospective and retrospective time estimation: A dual task paradigm

Azzuddin Khan IIT Bombay, India

Time is ubiquitous in human lives. Timing is essential to ensure optimum functioning of an organism (Block & Zakay, 1997). People may look both backward and forward in time. Perceived time is not the same as the actual or physical time. The same interval of actual time may be perceived as long or short, as slow or fast. An experiment was conducted using 180 subjects to determine the effects of four factors on time estimation: cognitive load (low, medium, and high), actual duration (short vs. long), method of time judgment (verbal estimation vs. reproduction), and paradigm (prospective vs. retrospective). Analysis of variance was used to analyze the data. Time estimation data were analyzed using directional and absolute error. For directional error, all the main effects and few interactions were significant. For absolute error, the main effects of paradigm and cognitive load between subjects and the main effect of actual duration within subjects were significant; some interactions were also significant. In general, there was overestimation of short duration in all the conditions under the prospective paradigm. Under the retrospective paradigm, there was underestimation of time judgment. Time estimation under the prospective paradigm was more accurate than under the retrospective paradigm. Time judgment was more accurate under verbal estimation as compared to the reproduction method.

The effect of inductive emotion on scientific invention problem-solving

Qian Li Xinan University, China

This study selected the scientific invention problems as material, using the expression pictures to induce emotion, and analyzed the influence of positive or negative emotion on the prototype elicitation effect in insight through the “X vs. X (X=6)” learning and testing experimental paradigm. The results showed that there is no significant difference among the positive, negative, and neutral inductive emotion groups on the grades of self-evaluation emotion post-testing after the experiment. But on the experiment, in solving the high difficulty scientific invention problems, the positive and negative inductive emotion groups got a significantly higher accuracy rate than the neutral inductive emotion group, while in solving the high difficulty scientific invention problems, the positive and negative inductive emotion groups got a significantly lower accuracy rate than the neutral inductive emotion group.

The effects of ease of retrieval on consistent confirmatory information search under organisational change

Bin Ling Zhejiang University, China; Zhongming Wang

Prior research has suggested that individuals prefer standpoint-consistent information to standpoint-inconsistent information in an information search in a systematic manner. The present research project (NSFC70232001) aims at investigating a new mechanism for confirmatory information search (selective exposure) in the ease of retrieval paradigm. That is, individuals are requested to produce or retrieve a high or low number of reasons (easy vs. difficult) for their preliminary decisions. When it is easy (difficult) for participants to generate some reasons for choosing one option, they are more inclined to search consistent (inconsistent) information for it. In three experiments, participants (as a chief manager in the scenario) were presented with
In the mood for risk? An experiment on moods and risk preferences

Theresa Michl, Munich School of Management, Germany; Arnold Picot; Philipp Koellinger

This study investigates moods’ influence on risk preferences. We conducted a large-scale economic experiment (N = 253) on risk preferences that manipulates individuals’ moods, inducing either joy, fear or sadness. Our experiment uses an incentive-compatible measure of risk preferences (Holt and Laury, 2002). In addition, we differentiate between no, low, and very high financial stakes. Our results suggest that a sad mood leads to risk aver- sion compared to a neutral mood. The influence of moods on risk preferences is not dependent of the magnitude of the financial stakes for all observations, but differs between males and females. Within the gender groups, moods’ influence on risk preferences depends on the presence and the magnitude of the financial stakes. Men let their moods guide their risk choices when nothing is at stake, while women are guided by their moods in the context of high stakes. This indicates that the relationship between moods and risk preferences is moderated by more than one variable.

Automated warning improves visual vigilance of individuals with hearing impairment: An exploratory study

Amrita Panda, Calcutta University, India; Mallick Banerjee, Calcutta University, India

An automated warning system is a sensory stimulation meant to reduce errors in highly loaded cognitive tasks. Previous research findings suggest that performance efficiency is uninfuenced by warning (Helton et al., 2008), or a higher error of omission reported in the presence of warning signals (Helton et al., 2011). With the increase in automation, the concept of automated warning had been increasing- ly used in industrial setups. But, how it affects cognitive processes like vigilance, particularly for persons with disability, has rarely been explored. The present study attempts to shed light on the interrelationship between vigilance and automated warning, and purports to reveal whether warning actually reduces performance decrement, or decreases performance accuracy, inducing anxiety. Participants were 40 individuals (Mean age: 17.78 years, SD=7.81) with profound deafness (90%–100% impairment) from the metropolitan areas of Kolkata, India. Participants were given a visual vigilance tasks through a software program (Panda et al., 2011), where they were asked to detect a target stimulus among randomly occurring buffer stimuli on a computer screen. Whenever participants made two consecutive errors in target stimu- lus detection, an automated warning occurred on screen. Results indicate a significant increment of “hit” scores with the introduction of automated warnings in experimental conditions, suggesting an increase in performance efficiency in the presence of a warning signal. The findings of the present study can be used more widely during vigilance tasks or suggestions can be made regarding the more cautious use of automated warning during cognitive tasks.

Resistance to manipulations as a meaningful psychological construct reflecting features of situated identity performance in the experimental context

Michael Quayle, UKZN, South Africa

Manipulation checks have traditionally been used in experimental research to assess in a binary way whether a manipulation has ‘worked’. Often, participants who fail to answer the manipulation checks in the expected way are simply dropped from the study. This is acceptable when the social and psychological processes being explored in the study are completely independent from the social and psychological processes involved in experiencing and responding to the experimental manipulation and manipulation checks, but in many studies this independence is neither considered by the researcher nor assured in practice. For example, in a study of stereotype threat participants may be explicitly reminded of a stereotype that they strongly disagree with and express their disagreement by answering manipulation check questions in ways that reflect their resistance. This response is not independent of the focus of the study and could well be associated with social-psychological processes that are critical to our understanding of how group status works. If that participant is simply dropped from the study on the basis of the manipulation check, then important data about that participant’s orientation to the ex- perimental situation is excluded from the study. This paper (1) proposes a very simple metric for assessing the degree of resistance to manipulations and (2) demonstrates the psychological and methodo- logical value of the metric by showing how it allows us to observe and explore situated and stra- tegic features of identity production in experimental contexts.

Effects of category names and figures of the scale on choice responses in web survey

Takayuki Sagakami, Department of Psychology, Keio University, Japan; Shin’ya Masuda

It is widely known that participants’ response to the bipolar scale (e.g. “2” to “2”) is more right-skewed than the central position compared to the unipolar scale (e.g. 1 to 5). The difference may appear not only at the figures (F) but also at the category names (N) on the scale. If the names on the extreme positions were “absolutely small” and “absolutely big”, these might be bipolar scale (B). But if these were “absolutely not big” and “absolutely big”, these might be unipolar (U). We examined the possibility of this difference using Web survey (Sex: 200 males and 200 females, Age: 15 to 78 yrs old, average 47.5 yrs old. We used only Q1, asking the degree of happiness for this research.). We assigned 400 par- ticipants into four groups, the type of category names of Group A was bipolar, and the type of figures of it was unipolar (N=B, F=U), Group B (N=B, F=B), and Group D (N=U, F=U). Group C was bipolar-names, but attached arrows which were accent the effect of bipolar scale, and F=U. Because the first question and the form of the answer section of Group A were the same as the original National survey, we could compare them to check reliability of the small population using an internet survey. Results showed that there were no differ- ences between the two surveys. The highest scores observed in Group B suggested that the bipolar type of category figures may have mutually potentiated effects with the bipolar category names.

Computerised assessment of attention for children: Divisa-uam and taci-uam test

Jose Santana, Universidad Autonoma de Madrid, Spain; Quiroga Angeles, UKZN, South Africa

Research group designed two objective tasks, which differ in difficulty, to measure attention in children. DivISA-UAM is a test of simple visual discrimination and TACI-UAM is a test to measure category discrimination of an array of figures. Categories have diferent rewards associated to them and performance should be inhibited when the color of the screen turns yellow. Besides these two tests we administered the d2 test of attention of Brick- enkamp and FACES test (test of perception of differences of Thurstone & Yela) to 385 school children from 7 to 11 years old. Tests designed were administered in the school computer rooms. The data obtained show the developmental pattern of each index provided by each test. Reliability coefficients (Cronbach’s alpha) for the DIVISA in- dex (Global index of attention, Commission Errors, Interval between Presses) are higher than α ≥ .80. Reliability coefficients for all TACI variables are higher than (α = .90). The two developed tasks to test attention in school children, from 6 to 12 years old, show some advantages to evaluate attention globally if compared with the available tests. Stud- ies on the relationship between the Divisa-UAM with the other two tests show that the correlation of the Divisa-UAM test with the d2 test is r = 0.547 and with the Faces test is r = 0.637. Relationship between the TACI-UAM test and the the Faces test is r = 0.320, and there is no correlation between the TACI-UAM test and the d2 test.

Duration of micro-expression: An event-re- lated potential study

Xunbing Shen, Institute of Psychology, CAS, China; Xiaolan Fu; Qi Wu

Microexpression is a fleeting facial expression which is discordant with the expressed emotion and usually suppressed within 1/25 to 1/5 of a second. There is much inconsistency about the duration of microexpression. To explore the neural correlates of the duration of microexpression, we employed the Event-related Potentials (ERPs) technique and tried to identify brain regions involved in microexpress- ion processing using standard low resolution brain electromagnetic tomography (sLORETA). We set up four levels of durations (40, 120, 200, and 300 ms) in the experiment and chose N400 as the dependent variable, which can indicate the level of processing of the brain. ERPs were computed...
for each level of durations. The data showed that there were significant differences between pairs of 40 ms and 300 ms, 40 ms and 200 ms, 120 ms and 300 ms, indicating that the proper duration of a so-called microexpression should be 200 ms or so. The sLORETA results showed that the activation was highest in the occipital lobe at 290 ms post-stimulus and the highest activation in the frontal areas at 570 ms after stimulus onset in the pairs of durations with significant differences. In conclusion, the appropriate duration of micro-expression should be less than 300 ms and the brain areas response appropriate duration of micro-expression should be 200 ms or so. The decision and that the rewards would be assigned according to their and their counterpart’s choices, which were clearly stated ahead of time. By combining an ingenious paradigm with the direct measurement of the potential sources, it is able to coordinate logic with empirical evidence. Differing from previous findings, our results consistently revealed a complex mechanism for decision making: 1) none of the agent has the dominating power to prompt cooperation, and 2) the interaction effect between different agents emerged in different groups and functioned in different ways. More details and implications were discussed in the paper.

High trait anger individuals’ inhibition of distraction in negative priming task
Dajun Zhang Center for Mental Health, China

The objective of this study was to investigate high trait anger individuals’ inhibition of distraction to negative emotional stimuli. 46 high and low trait anger college students were subjects and an emotional negative priming task was used for analyzing both groups’ reaction time differences to positive and negative target words in both situations (control and negative priming). Repeated measurement analysis of variance showed that the main effect of experimental conditions is not significant (F=0.889, p=.351), and the interaction effect between experimental conditions and groups is significant (F=7.084, p=.011) at the condition of detected target angry words. Simple effect analysis showed that the reaction time of high trait anger individuals to angry words at the negative priming condition is shorter than at the controlled condition (720.75 ±58.68 vs 739.81±74.00, F=6.50, p=.014). The main effect of experimental conditions is not significant (F=9.05, p=.346), and the interaction effect between experimental conditions and groups is not significant (F=410, p=.525) at the condition of detected target happy words. High trait anger group did not show a negative priming effect (<19.07 ±35.36) and low trait anger low trait anger group showed a negative priming effect(9.09±37.90). The differences between the two groups is significant (t=-2.661, p<.011) at the condition of detected target angry words. High and low trait anger groups both showed a negative priming effect(2.16±45.78/11.06 ±50.40), and the difference is not significant (t=-0.640, p=.525) at the condition of detected target happy words. In conclusion, high trait anger individuals can inhibit positive information in a negative priming task, but the reaction time at the negative priming condition is shorter than at the controlled condition, and the inhibition of distraction to angry words is weak.

Creativity of gifted children: Is it different?
Irena Zukauskaite Vilnius University, Lithuania; Sigita Girdziuskiene; Grazina Gintiliene

Giftedness is usually related with person’s ability to manage effectively conventional problems. Yet the data about relationship of intellectual potential and creativity is ambiguous. The studies show that Fluid IQ correlated significantly with creativity in the high IQ group but not in the average IQ group. Furthermore, the results depend on instruments used for the assessment. The aim of the study was to discover the differences of creativity between gifted children and control group. 52 children from 12 to 16 years randomly selected from standardised sample took part in the study. 26 (13 boys and 13 girls) were from test group (personal score of Ravens APM test was 98 percentile or higher) and 26 (13 boys and 13 girls) were from control group (personal score of Ravens APM test was 50 percentile). They completed Test for Creativity-Drawing Production (TCT-DP) (Urban, 2005) and 14 scores were analysed (Continuations, Completion, New elements, Connections made with a line, Connections made to produce a theme, 2 types of Boundary breaking (fragment dependent or fragment independent), Perspective, Humour and affectivity, 4 types of Unconventionality (manipulation of the material, surrealistic elements, usage of symbols, use of given fragments), Speed). Results show that fluid intelligence is related with creativity, yet the differences were found not in all scales of TCT-DP. The possibilities of additional teaching of creativity for gifted children are discussed.

Session Type: Posters

Agency captures body ownership: Proprioceptive drift toward external agents acting in synchronisation
Tomohisa Asai Chiba University, Japan; Eriko Sugimoto

Our awareness of our own body (sense of body ownership) and action (sense of agency) could be fundamental to our self-consciousness. The sense of body ownership can be realized by the integration between vision and somatosensation. The rubber hand illusion - watching a rubber hand being stroked synchronously with one’s own unseen hand for a short time - causes the observer to subjectively attribute the rubber hand to one’s own body. Their sense of their own hand’s location is captured and drifts toward the rubber hand (proprioceptive drift). We might attribute the external movement to ourselves, as long as it is acting synchronously, because the sense of agency might need to be matched between the desired and the actual sensory outcome of motor commands. In the current series of experiments, we suggested that our body ownership, measured by the index of proprioceptive drift, could be captured by the external agent acting synchronously so that we feel the sense of agency. While participants were clapping and unclapping their left hand for 60 seconds, they focused on video feedback on a monitor in front of them. This visual feedback could be temporally or spatially biased. As a result, the proprioceptive drift was observed only under synchronised conditions, suggesting an essential interaction between the sense of body ownership and agency. These components of "minimal self"
Pavlovian conditioning affects social hierarchy and copulatory efficiency in quail
German Gutierrez Universidad Nacional-Colombia, Colombia; Laura Suarez; Bibiana Montoya
The relationship between male-male competition in sexual selection and learning, in male quail (Coturnix japonica), was evaluated. Groups of three males were observed for 40 days, assessing the relationship of copulatory efficiency, reproductive fitness, and winner-loser status, for each male. Transitive winner-loser relationships within each group, and a positive association between a better copulatory efficiency index and the winner status, were observed. Subsequently, the effect of learning on copulatory efficiency, and reproductive fitness for the loser male of each group, was evaluated. The selected male of each group competed for copulatory access to a receptive female. When the CS was present in the test, the conditioned male copulated first with the female, and his copulatory efficiency index did not show any difference with the other two males’ indices. These results provide further evidence of the adaptive value of learning, and an improvement of the copulatory efficiency in the males that previously had been lowest in the social hierarchy of each group.

Transfer effects and word-class-dependent improvement of foreign language text comprehension: An empirical study using eye-tracking
Laura Nathalie Hiller University of Innsbruck, Austria; Marco Futter; Pierre Sachse; Markus Martini
According to Zyzik (2009) only a few empirical studies have dealt with the use of word classes in terms of the transfer effect from native (L1) to second language (L2). Futtner, Rauthmann, and Sachse (2009) showed that the noun (in the rankings ahead of adjectives, verbs and closed-class words) was most commonly used to increase understanding of another difficult word reading a transposed German text (L1) (“jumbled word reading”). The present study explored whether there are similarities in terms of the importance of word classes in an English text (L2). 141 participants were given an English text with transposed letters and additionally their eye movements were analysed. The results indicate that nouns are again most commonly used to increase understanding of another difficult word. Thus, a transfer effect from L1 to L2 can be assumed. The results are discussed in terms of their theoretical and practical relevance.

Does EMG biofeedback affect the symptoms of depression, anxiety and stress in patients with blepharospasm?
Anis Jahanbazi University of Isfahan, Islamic Republic of Iran; Karim Asgari; Ahmad Chitsaz; Neda Asemi
This study was aimed to investigate the effectiveness of EMG biofeedback on psychological symptoms including depression, anxiety and stress in patients with blepharospasm in Isfahan. 10 patients with blepharospasm were randomly selected from those who have been referred to neurology clinics through clinical examination by a neurologist in Isfahan city. They were randomly assigned into two groups, including an experimental and a control group. Each group consisted of 5 patients. 20 sessions of biofeedback were administered on the experimental group. The control group received no intervention during this phase of study. DASS-42 scale was administered on both groups before and after the intervention, and the data was analyzed by ANCOVA. Statistical analysis revealed significant differences in the scores of depression, anxiety and stress between two groups. Findings of this study suggested that EMG biofeedback can significantly and effectively decrease the scores of depression, anxiety and stress in patients with blepharospasm.

Investigating the effectiveness of medication in comparison to EMG biofeedback on neurological symptoms in patients with spasmodic torticollis in Isfahan
Anis Jahanbazi, University of Isfahan, Islamic Republic of Iran; Karim Asgari; Ahmad Chitsaz; Neda Asemi
This study investigated the effectiveness of medication in comparison to EMG biofeedback on neurological symptoms in patients with spasmodic torticollis in Isfahan city. 20 patients with spasmodic torticollis were randomly selected from those referred to neurology clinics, through clinical examination by a neurologist in Isfahan city. They were randomly assigned into two experimental groups, including a biofeedback and a medication group. Each group consisted of 10 patients. 20 sessions of EMG biofeedback were performed for the medication group, and the other group was kept under drug therapy. The Toronto Western Spasmodic Torticollis Rating Scale was performed on both groups before and after each treatment. The data were analysed by ANCOVA. Statistical analysis revealed significant differences in neurological symptoms between the two groups after each intervention. Findings of this study suggested that EMG biofeedback can significantly and effectively decrease neurological symptoms in patients with spasmodic torticollis.

Exposure to real roses affects work performance and mood
Yasumasa Otsuka Hiroshima University, Japan; Kazuhiro Watanabe
Although it is known that the exposure to artificial floral fragrances can improve work performance and mood, no studies, to date, have used real flowers as the experimental stimulus. We investigated the effects of real flowers on work performance and mood. Healthy university students were randomly assigned to the experimental (10 women and 10 men, mean age was 20.0 ± 1.12), or control groups (10 women and 10 men, mean age was 20.2 ± 1.15). Participants performed the Uchida-Kraepelin test and responded to the brief version of the Profile of Mood States. In the experimental group, about 10 Wishing Roses in full-bloom were placed approximately 50 cm from the participants. A repeated-measures, between-subject, two-way analysis of variances indicated no significant interactions between the placement of flowers and work performance, or mood. A significant main effect of group was found for vigour, suggesting that vigour was higher in the experimental group than in the control group. Additional analyses revealed that among the experimental group, participants who liked roses showed low levels of fatigue 10 minutes after finishing the Uchida-Kraepelin test, compared with immediately after finishing the test. However, this result was not seen among participants who did not like roses. Participants who did not like roses had lower levels of vigour immediately after finishing the Uchida-Kraepelin test compared with before starting the test. We conclude that having roses nearby contributes to recovery from fatigue immediately after a task and to maintaining vigour during task performance, especially among participants who like roses.

Acupuncture therapy for mental disorders
Andrea Mercedes Riegel Germany
The objective of a long term clinical observation was to prove that acupuncture may be helpful in the therapy of mental disturbances. Based on the channel theory and the theory of the five phases we chose points mainly of the Dumai, the heart, liver and pericardium channels (p. ex. Du 14, Du 20, Du 16, Pe 6, Pe 7, Liv 3, He 7 and Pe 7) for the treatment of 12 patients suffering from mental depression, nervousness, and anxiety disorders. The point selection took into consideration the individual condition of every patient. All patients had two sessions per week over three months minimum. All patients showed good reactions, some of them have to continue treatment. In any case life quality improved and pharmaceuticals could be reduced. Though this is not a representative study we may draw the conclusion that the old theories of Traditional Chinese Medicine are worth being applied in modern medicine.

Misattributing speech: Relationship between brain areas active during hearing and imagining hearing and subsequent source memory
Erito Sugimori Yale University, United States of America
Using fMRI, we investigated relations between brain activity during encoding and subsequent source memory for whether words had been heard or imagined. During scanning, healthy young adults heard some words in another person’s voice and imagined hearing other words in that same voice. Later outside the scanner, participants decided, for each word, if they heard it, imagined it, or it was new. An area of left inferior frontal gyrus (BA45) was more active at encoding for items later called “Heard” than “Imagined,” regardless of the source of the item. An area of left supplementary motor area (BA6) was less active at encoding for imagined items participants subsequently incorrectly called “Heard” than items correctly called “Imagined.” These findings suggest that more activity in brain areas associated with speech generation (BA45) and less activity in brain areas associated with cognitive operations (BA6) led participants to later judge items as “Heard.” In addition, left and right superior temporal gyrus (STG: BA22) – an area associated with speech perception – showed greater activity for heard words than for imagined words.
Moreover, scores on the Auditory Hallucination Experience Scale were positively related to activity in STG for imagined words that participants subsequently incorrectly called “Heard.” Together with findings in the literature on brain activity during auditory hallucinations in clinical populations, these results suggest a similarity in mechanisms contributing to auditory source misattributions in healthy participants and those underlying auditory verbal hallucinations.

Effects of larger reward requiring more responses on preference for non-rewarded behaviour

Hiroyuki Tajima, Shokei Gakuin University, Japan; Takeyasu Kawabata

The present study aims to investigate the effects of reinforcement history on preference for non-rewarded behaviour. Twenty-one university students, divided into three groups, were given a series of choices between touching either of two coloured buttons for points exchangeable for money. For all groups, touching of one button was reinforced according to a continuous reinforcement (CRF) schedule with 1 point. For one group, touching of the other button was reinforced according to a CRF schedule with 3 points. For a second group, touching of the other button was reinforced according to a ratio schedule with 36 points, and the response requirement increased from 1 to 12. For a third group, touching the other button was reinforced according to a ratio schedule whose response requirement increased from 1 to 12, and the delivered points per reinforcement also increased from 3 to 36. Next, all participants were given a series of choices between touching either of two same coloured buttons with different letters on them. One button delivered 1 point according to a CRF schedule, and the other delivered no points. The second and third groups chose to touch the button delivering no points more than did the first group. The results suggest that larger rewards requiring more responses increase preference for non-rewarded behaviour.

Differential visual attention to images of dessert or high-fat content food

David Velazquez-Martinez, Universidad Nal Autonoma Mexico, Mexico; Toscana-Zaplen Anna Laura; Velazquez-Lopez Daniel

In the Dot Probe Task, subjects decrease their latency to find a dot that appear after a food image compared to the latency to locate the dot after a non-food image when they are food deprived. We recorded gaze variables as a more direct evaluation of attention to different categories of food stimuli. Subjects were instructed to fixate their gaze to a central point in a screen before being presented a pair of images followed by a colored dot, subjects had to press a key that matched the dot color. Images used were stationary items or images of light, dessert or high-fat content food. Images were presented in pairs of all possible combination-locations in a computer screen and the time to fixation, the pupil diameter and the duration of each gaze at each image presented were recorded. No differences were observed in the fixation times. When the two stimuli presented were alike there was no difference in total gaze time or pupil diameter to each stimulus. When one stimulus was a stationary item or light food and the other stimulus was dessert or high-fat food, subjects preferred to gaze at the dessert or high-fat food. However, no differences in pupil diameter were observed when attending the different kind of images. Results confirm preferential attention to food images of high-carbohydrate (dessert) or high-fat food than to stationary items or light-food when subjects are food deprived.

Focusing on similarity restrains theory of mind performance

Yang Wu, Peking University, China; Yanjie Su; Yue Wang

This study examined whether a mind-set focusing on similarity would restrain theory of mind performance in adults. In Experiment one, 83 Chinese adults completed a picture-comparison task. In this task, each participant was primed with a mind-set focusing on similarity (e.g., two or neither control group). Perceptual theory of mind was then tested with a visual perspective-taking task. The results showed that participants primed with similarity mind-set were less likely to take other-oriented visual perspective than participants in the control group, $\chi^2(1, 54) = 0.5976, p = 0.029$, indicating that focusing on similarity hindered perceptual theory of mind. In Experiment two, 156 Chinese adults were tested in conceptual theory of mind with a false belief reasoning task. Similarity or difference was naturally induced by the nationality of the protagonist's name (Chinese, Japanese, or American name) in the task. The results showed that Chinese participants were more self-centered when reasoning the false belief of a protagonist with shared nationality (Chinese) than those with a different nationality (American), $p = 0.029$. In addition, participants were marginally more self-centered when reasoning the false belief of a protagonist with shared culture (Chinese and Japanese—collectivism), than those with a different culture (American—individualism), $p = 0.091$, indicating that similarities in nationality and culture could result in egocentrism. In conclusion, this study implies that similarity restrains both perceptual and conceptual theory of mind performance.

A psychological study of strong experiences induced by listening to music: Focusing on participant musical training

Shoko Yasuda, Doshisha University, Japan

The phenomenon referred to as strong experiences with music (SEM) is experienced by many individuals, particularly those with musical training. We examined whether a mind-set focusing on similarity restrains theory of mind performance in adults. In Experiment one, 83 Chinese adults completed a picture-comparison task. In this task, each participant was primed with a mind-set focusing on similarity (e.g., two or neither control group). Perceptual theory of mind was then tested with a visual perspective-taking task. The results showed that participants primed with similarity mind-set were less likely to take other-oriented visual perspective than participants in the control group, $\chi^2(1, 54) = 0.5976, p = 0.029$, indicating that focusing on similarity hindered perceptual theory of mind. In Experiment two, 156 Chinese adults were tested in conceptual theory of mind with a false belief reasoning task. Similarity or difference was naturally induced by the nationality of the protagonist’s name (Chinese, Japanese, or American name) in the task. The results showed that Chinese participants were more self-centered when reasoning the false belief of a protagonist with shared nationality (Chinese) than those with a different nationality (American), $p = 0.029$. In addition, participants were marginally more self-centered when reasoning the false belief of a protagonist with shared culture (Chinese and Japanese—collectivism), than those with a different culture (American—individualism), $p = 0.091$, indicating that similarities in nationality and culture could result in egocentrism. In conclusion, this study implies that similarity restrains both perceptual and conceptual theory of mind performance.

Sound predictability facilitates auditory scene analysis

Alexandra Bendixen, University of Leipzig, Germany

Many sound sources in a natural environment emit signals in a predictable manner over time, such as a train passing by that is characterised by a foreseeable sound signature on a likewise foreseeable trajectory? The auditory system is particularly suited for the extraction of such predictability from sequences of events. The major benefit of auditory predictive processing has long been seen in the possibility to prepare for upcoming events. I pro-

Session Type: Invited Symposia

Symposium title: Auditory scene analysis: From sounds to meaning

Convenor: Claude Alain

Experimental
pose that another beneficial aspect of predictive processing consists in its contribution to auditory scene analysis. The auditory system is typically confronted with a mixture of different sounds within which it has to disentangle the various sources before relevant information can be retrieved. Tracking an auditory source over time may help to segregate this source’s activity from signals emitted by concurrently active sources. In line with this hypothesis, I will present behavioural and electrophysiological evidence for the contribution of auditory predictability to sound source segregation. Moreover, I will address the interaction of predictive processing with other cues for solving the auditory scene analysis problem. A consistent picture emerges from these studies, suggesting that predictability supports the auditory system in one of its central tasks: To derive meaning from the complex acoustic mixture arriving at the ears.

**Session Type: Symposia**

**Symposium title: Portuguese-speaking adolescent mental health in Europe and South America**

**Convenor:** Marta Gonçalves

**Implementation and evaluation of a mental health destigmatisation programme in the educational context of Portugal**

Marta Gonçalves Lisbon University Institute, Portugal

Both the European Representation of the World Health Organization (WHO, 2010a) as the European Commission (EC, 2009) state the child and adolescent mental health as a key area of concern in Europe, including Portugal. Mental Illness, especially emotional and behavioural problems and learning difficulties, increase among children and young Europeans. The results of the international research project on social representations of youth aged 12 to 16 years in the area of mental health - The AMHC study: Access to Mental Health Care in Children (Käppler et al., 2004; Aquino, 2008; Gonçalves, 2009; Käppler & Gonçalves, 2010; Moleiro & Gonçalves, 2010; Amparo et al., 2010; Gonçalves & Moleiro, 2011), demonstrate the need to destigmatise mental illness. According to young people, their caregivers and health and education professionals who serve them, the biggest barrier for not seeking help, regardless of whether or not they belong to an ethnic minority, is the stigma.

Through a participatory approach this project aims to design a destigmatisation programme, implement and test it, in an educational context. A cultural change in relation to mental health issues may help to decrease the expectations of the World Health Organization (WHO, 2010b) that points depression as the second cause of death worldwide in 9 years.

**Symposium title: Preference and decision making**

**Convenor:** Kazuhsia Takemura

**Choice and eye-tracking behaviour**

Takayuki Sakagami Department of Psychology, Keio University, Japan

Researchers in decision making fields have long focused on the relationship between choice and eye-tracking behaviour. One of the reasons for tackling this relationship might lie in the endeavour to uncover a process directly resulting in a final choice. We will introduce a couple of examples conducting preliminary choice experiments with the eye-tracker instruments. Usually people show a tendency to choose central items when answering the multiple-items questionnaires. In our first experiment, we tried to understand the exact processes of the eye-tracking behaviours in this situation and to examine the possibilities of final choice prediction from some indices of the eye-tracking behaviour, such as the total gazing duration of an item. The second experiment analysed the eye-tracking behaviours during the binary choice task asking participants’ preference (evaluation) or inference (judgment). We focused on the process of the eye-tracking behaviours during the choice-making process by participants between two objects with multiple attributes and tried to find the different eye-tracking patterns with the different choice modes. The third experiment studied the choice behaviours under a version of the implicit association experiments, such as Implicit Relational Assessment Procedure. People generally showed the long latencies when they tried to figure out a target between two categories which included some distracters in these experiments. We analysed whether the eye-tracking behaviour had specific features related to the implicit relationships or not.

**Preference construction process by choice:**

Eye movement and preference analysis

Kazuhsia Takemura Waseda University, Japan; Yuki Tamari; Takayuki Sakagami Waseda University, Japan; Takashi Ideno; Takayuki Tanino; Tsuyoshi Hatori; Mikiya Hayashi; Shigataga Ohkubo; Satoshi Fujii

Previous investigations examining decision-making have suggested that human choice is highly contingent on the form of information processing such as task complexity, time pressure, response mode, framing, reference point, and other contextual factors. These findings of previous studies of decision-making imply that preference is constructed during the choice process. Cognitive dissonance theory (Festinger, 1964) also predicts that the preference is reconstructed in line with a preceding choice. However, the cognitive dissonance theory does not predict whether automatic repeated choice produces preferences or not. This study was undertaken to examine the effects of prior automatic repeated choice on preference construction using eye movement equipment and a personal computer. The experiment participants were 22 university students. They were asked to choose one of two given alternatives. The chosen alternative was denoted by a triangular sign on a computer display for each trial. The numbers of a certain chosen alternative were controlled in unequal proportions (96 times vs. 32 times). The chosen alternatives, the position of presentation, and the order of presentation were counter-balanced. Results show that 67.4 percent of participants preferred the highly frequent chosen alternative, and that 32.6 percent of participants preferred the less frequently chosen alternative. Eye movement analyses of the choice process suggested that the eye gaze pattern of choice differed from the gaze cascade effect (Shimojo et al., 2003). This finding implies that the preference construction process is made by automatic repeated choice.

**Symposium title: Time perception: Contemporary perspectives on psychological time**

**Convenor:** Simon Grondin

**Saccadic eye-movements alter subjective time in a duration reproduction task**

Trevor Penney National University of Singapore, Singapore

The effect of saccades on interval timing was studied using a duration reproduction task. Participants first learned a 6s target duration demarcated by a visual stimulus, and then reproduced the target duration by terminating the presentation of a visual stimulus, via button press, at the appropriate time. Saccadic eye- movements during target duration reproduction were manipulated by requiring participants to (1) make repeated saccades to peripheral distracters that occurred on an occasional and unpredictable basis (Distracter - Saccade condition); (2) keep their eyes fixed on the center of the timing stimulus and ignore the peripheral distracters (Distracter - No Saccade condition); and (3) keep their eyes fixed on the center of the timing stimulus in the absence of distracters (No Distracter - No Saccade condition). Eye-movements were monitored using an Eye-Link 1000. Reproduced durations in the Distracter - Saccade condition were significantly longer than those in the Distracter - No Saccade condition and the No Distracter - No Saccade condition. Moreover, in the Distracter - Saccade condition there was a significant relationship between reproduced duration on a trial and the total duration of saccades on that trial. Longer saccade durations were associated with longer reproduced durations. Taken together, the results demonstrate that the subjective experience of multi-second durations is modulated by saccadic eye-movements. The results will be discussed within the context of several influential models of interval timing.
Distinguishing single-victim rapists from serial rapists by the crime scene actions in cases of stranger rape
Jelena Corovic Stockholm University; Sweden; Sven Christiansson; Lars R. Bergman

Stranger rape cases are usually the most difficult type of rape for the police to investigate, because there is no natural tie between the victim and offender. This type of rape also tends to be common among serial rapists, who tend to victimise multiple victims before they are caught. This study aimed at examining how single-victim rapists can be differentiated from serial rapists in cases of stranger rape. Data were collected from Swedish police files, court verdicts, psychiatric evaluations, and criminal records. Only cases that led to a conviction were included in the study. A total of 38 crime scene actions were analysed from the first/only stranger rape of 31 single-victim rapists and compared to the first and second stranger rape for 35 serial rapists. Results showed that the serial rapists were overall more criminally sophisticated than the single-victim rapists, during their first as well as the second rape. Single-victim rapists were significantly more likely to engage in the interpersonal involvement behaviour of kissing the victim, and engaging in pre-assault alcohol use before the rape. However, no significant differences in physically violent or sexual behaviours were found. Findings from logistic regression analyses indicate that three behaviours in conjunction: kissed victim, controlled victim, and offender drank alcohol before the offense, predicted whether an unknown offender is a single-victim or serial rapist with a classification accuracy of 80.4%. The findings have implications for the classification of stranger rapists in offender profiling.

A clinical guide to the detection of malingering
Lorise Du Plessis University of Johannesburg, South Africa

Malingering is encountered throughout clinical practice. It is widely believed that malingering is present in more than 60% of assessments for criminal competence, litigation, injury compensation, education and in military and disciplinary contexts. The faces of malingering are protean and can be wilder and humble even the most experienced clinician. Although many models and protocols have emerged to assist the clinician with its detection, they are often very condition-specific and difficult to teach to the novice practitioner. Cognisant of this, the author has proposed a model for the detection of malingering that is generalisable across all of pathology – from orthopaed trauma to psychopathology; has clearly defined parameters of assessment and is easy to learn and apply. The model is distilled from the everyday clinical experience of established experts in the field of forensic psychological assessment and recognises the fact that malingering is merely a form of deceit defined by a medical or psychological context of assessment. The model thus developed, called the Expert Model, approaches malingering as a deceitful communication that interrogates two domains: a subject of deceit and the communication of this deception. In malingering the subject of deceit concerns symptoms and is considered as the Symptomatology Domain; the communication plays out during the assessment, and is conceptualised as the Assessment Behaviour Domain. This paper will focus on the conceptualisation of malingering along the domains of symptomatology and assessment behaviour and provide illustrative examples of each.

Towards a new vision for inclusion of children in custody decision making in Zimbabwe
Gwatirera Javangwe University of Zimbabwe, Zimbabwe

This paper explores the marginalisation of children in family law court proceedings by the very professionals who are mandated to protect them. Premised on the qualitative Interpretative Phenomenological Analysis approach, the study used data collected from in-depth interviews with a sample of 20 professionals (3 psychologists, 7 lawyers, 3 judges, 2 social workers and 5 magistrates). The data were analysed using the guidelines espoused by Smith (2009). The findings revealed the peripheralisation of children in custody decision making, and how controverted this process (aimed at assisting children to cope with parental divorce and post separation arrangements) is in Zimbabwe. The findings of the study indicated that despite a gamut of professionals having been trained to protect children, they seem to marginalise children through their practice. The findings illustrated that custody evaluators need to focus on a number of child vulnerability indicators like geographical dislocation, economic dislocation, manipulative lawyers, manipulative parents, manipulative mental health professionals, poor maintenance awards, the adversarial trap, failing to delink divorce from other issues and the political will of the judiciary. The study concluded by proposing specific approaches for use in child focused and child inclusive custody evaluation and custody decision making. This ushers in a process that encapsulates the formulation of new questions, gathering of new data, sharing observations and making interpretations with a view to formulate further questions and creating insights for the development of new-look custody evaluations.

The woman behind bars: A study on the changing profile of female crime
Ana Paula Moniz Freire UNIRIO, Brazil

This study aims to understand how the construction of the female gender influences the crimes committed by women. The female gender has always been steeped in stereotypes and prejudices regarding the role of women in society. This ultimately influences the crimes of women, and how society views and deals with such crimes. This study was based on interviews conducted in Rio de Janeiro, Brazil, using a qualitative method, literature, and statistical data. Seven women were interviewed, four of whom were incarcerated and three of whom were on probation. Whereas the construction of gender is made in social interaction, analysis of the reports is made under this approach, taking into account how society deals with feminine crime. According to
The third type of accountability shows signs of "being experiencers": A contribution to forensic psychology
Naohisa Mori Sapporo Gakuin University, Japan

Two types of accountability are mentioned in discursive psychology (e.g., Edwards & Potter, 1992). They are criteria of the socio-culturally valid narratives. The first one is about the credibility of contents of narrative and the second one is about the reliability of narrators. They are tacitly applied to the examination of credibility of confession and testimony. But both the types of accountability sometimes malfunction under some conditions. It is often difficult for vulnerable people, e.g., the mentally disabled and children, to construct socio-culturally valid narratives and even possible for normal adults to fabricate them. The author proposes the third type of accountability, a cognitive one. It contains signs of real experiencer that appear on forms of remembering. Practical and empirical studies of the author and his colleagues (e.g., Mori, 2008; Ohashi, Mori, Takagi, & Matsushima, 2002) have suggested that normal as well as vulnerable people can show such signs and we can discriminate narratives rooted in real experiences from fake ones according to these signs. Our studies also suggested that these signs can appear on different levels of communication (utterances, question and answer pairs, etc.), in various forms, and peculiar to a rememberer. We are sure that the introduction of the third type of accountability into forensic practice sheds new light on the examination of the credibility of confession and testimony.

Using laboratory methods to assess the line-up and composites created in the station strangler case
Alicia Nortje University of Cape Town, South Africa; Colin Tredoux

The Station Strangler is one of South Africa’s most infamous serial killers: during 1986–1994, 22 people were murdered, and their bodies were found in the Cape Flats region. The killer was named the Station Strangler by the media, since the victims often went missing near the train station. Norman Afzal Simons was arrested and convicted for one of these murders, and is currently in prison. For eyewitness researchers, this case is interesting, since a number of composites were produced, and the line-up procedure was recorded. Most research on eyewitness memory uses line-ups and composites that are created in a laboratory, where researchers are able to use guidelines and methods that ensure the fairness and quality of such stimuli. Despite using such methods to create fair and well-constructed stimuli, these line-ups and composites have little ecological validity. However, since the line-up and composites that were used in the Station Strangler investigation were available, this provided a unique opportunity to assess this particular case using the same methods that were normally employed in a laboratory setting. These methods are described in more detail, and the results of the assessment are discussed.

Asperger syndrome and crime: A spurious relationship?
Jim Nottestad St. Olavs University Hospital, Norway

Deficits in communication, empathy and socialisation found in people with autism spectrum disorder may represent a vulnerability for becoming an offender. The aim of this study is to describe characteristics of persons diagnosed with AS who have undergone a forensic examination and to explore any possible relationship between the diagnosis and the offence. All forensic psychiatric reports from the years 2000 to 2010 where the diagnoses given by the forensic experts was an autism spectrum disorder were retrieved from the National Board of Forensic Medicine in Norway. Data on crimes, situational characteristics and conclusions of the forensic examinations were also collected. Violent crimes were the most prevalent index crimes, followed by sexual crimes. Less than half of the subjects had previously been convicted. Co-morbid diagnoses were common, both psychotic illnesses and personality disorders. Only two persons with AS were considered legally insane, both had co-morbid disorders influencing the decision more than AS. Twelve persons with AS were considered for mitigation of sentence due to mental illness, only four of these had AS as a single diagnosis. Asperger syndrome plays a minor role within forensic psychiatry, rarely influencing decisions of criminal responsibility. People with AS who undergo a forensic psychiatric examination constitute a heterogeneous group, as with offenders within other diagnostic categories.

Revisiting the Realengo massacre: The juridical psychology through behavioural analysis
Geraldo Silva Junior University of Fortaleza, Brazil; Vanessa Pinho; Ana Paula Buosi; Thais Helena Maia

Legal psychology is an area of intersection between law and psychology. To illustrate this intersection we performed a case study based on the Realengo massacre, held in Rio de Janeiro, Brazil, in April 2011. We analyzed the likely contingencies that allowed the tragedy. The tragedy occurred in a municipal school in the district of Realengo, in which twelve students were killed. The killer was a 23-year old man, also a student of the college. He entered the school and fired at the students. After being found by some police officers and shot in his leg, the killer committed suicide by shooting himself in the head. The likely contingencies that allowed the tragedy would be: The fact that the school was located near his home, proving to be a handy target, the killer was the victim of "bullying", he left a letter with typical speech of psychotics; he lived alone, isolated from friends and family; the crime was premeditated; he would like to become famous; according to his sister, he admired the young terrorists. The contingency formed in this case meant that the killer built his behavioural repertoire from external stimuli. Through the review of the Realengo massacre, in the light of behavioural analysis, we show the various factors involved in the genesis of the crime, from the intricate personal factors in the personality of the murderer, through the events that made possible the premeditation of the crime and the biopsychosocial consequences emerged in this context.

One step closer to the development of an optimal psychological assessment procedure for custody recommendations
Henk Swanepoel South Africa

The Divorce Act of 1979 highlights the responsibility of the Court, as upper guardian of all children within its jurisdiction, to ensure the welfare of minor children when their parents get divorced, but the post-apartheid Constitution set the stage for significant changes in family law with a special emphasis on the best interests of children. These were embodied in the Children’s Act of 2005. The “best interests” of a child has to be established in each individual case of divorce and judged on merit. This should entail an “objective assessment” within the framework of the specific circumstances that pertain to each case. The Honourable Justice King formulated 13 variables which courts could use as a standard to determine what care arrangements would best serve the interests of the child. These were "operationaionalised" from a psychological perspective in order for them to be utilised by a psychologist in an attempt to assist the Court in making decisions. This necessitated a careful definition of the variables, from a psychological perspective, as well as establishing a relatively standardised assessment procedure for the measuring and predicting of these in practice. This formed the aim and objective of the study. A sample of 39 families was evaluated on a pre- and a post-level resulting in significant findings. This study thus took an important step towards the development of a relatively standardised assessment procedure which can be used during custody evaluations in South Africa.

Revisiting the Realengo massacre: The juridical psychology through behavioural analysis
Geraldo Silva Junior University of Fortaleza, Brazil; Vanessa Pinho; Ana Paula Buosi; Thais Helena Maia

Forensic assessments with regard to mental disabilities in the workplace
Magdalene Swanepoel UNISA, South Africa

Mental disabilities are increasingly being recognised as an important cause of impairment, probably because its prevalence is rising and there is, now, a greater awareness of its impact. This paper will provide practitioners with guidelines for distinguishing between impairment and disability, in addition to other key factors, to take into consideration when assessing claimants, specifications for the assessment report on the claimant’s mental health status, and specific mental disorders in relation to disability claims, for example schizophrenia, bipolar mood disorder, and brain injury etc. South Africa is, now, more or less in line with more industrialised countries in terms of the legal environment for people with disabilities in the employ-
ment arena, for example the enactment of the Constitution of the Republic of South Africa, 1996 and the Employment Equity Act 55 of 1998. The interpretation of this type of legislation is often difficult and controversial and will be discussed in this paper. The nature and scope of the basic rules of professionals acting as expert witnesses, as they would apply to psychologists and psychiatrists, with regard to mental disability in the workplace, will be explored. Attention will be given to ethical complexities and pitfalls that psychologists and psychiatrists face, when acting as expert witnesses. Finally, conclusions are drawn, and well motivated recommendations are made, for mental health expert assessors/witnesses in cases where the issue of mental disability within the workplace is raised.

Recent developments in eyewitness research
Colin Tredoux UCT, South Africa; Patrick Chiororo
In this symposium, a number of authors who research eyewitness testimony will present reviews, or original research, outlining recent important developments. These may include the following:
(1) Recent improvements in computing power have spawned technologies for producing sophisticated and highly realistic digital artificial faces. These technologies can be used for a number of policing problems. We will demonstrate how they can be used to assist witnesses in creating better quality facial likenesses from memory, and how they can be used to automatically create fair and unbiased synthetic lineups.
(2) There has been considerable interest in recent years in the common police practice of eliciting facial composites from eyewitnesses. In particular, some recent work by Wells and colleagues suggests that this practice may have profound, contaminating effects on witness memory. We will review, and present new data on the question of whether viewing and constructing facial composites leads to contamination of witness memory.
(3) Eyewitnesses who are asked to identify people from other race or population groups are prone to be mistaken more often than they would be for people from their own group. We will review theoretical accounts of this phenomenon, and consider new original data testing some of these accounts.
(4) The sequential lineup has recently been the subject of considerable controversy in the field of eyewitness research. Although a 2001 meta-analysis claimed that the sequential lineup has a real advantage over the simultaneous lineup, a second meta-analysis argued that this difference is artefactual, and that any reduction in false positive identifications is accompanied by an equivalent decrease in positive identifications. Steblay and colleagues have most recently published a further meta-analysis, extending the original analysis to include newer studies, and using new selection criteria, and claim to show that the difference is real and not artefactual. Evidence will be presented that contests this most recent claim.
(5) The confidence with which eyewitnesses make identifications has long been a vexed issue in the literature. Earlier studies claimed that there is no, or little relationship between witness confidence and witness accuracy, but important work in the 1990s and 2000s have shown that this is not correct as a general proposition. A review of recent work in this area will be presented, as well as new, original data.

An evaluation of the Think First program in addressing offender behaviour in Australian correctional centres
Graham Tyson Charles Sturt University, Australia; Karen Burgoyne
The Think First program targets social problem solving in relation to offending behavior. The program requires offenders to analyze their own offending behaviors as problems that can be solved. Starting in 2003, it was implemented in five NSW correctional centers and this paper presents the results of a longitudinal evaluation of it. Changes in scores obtained on the Social Problem Solving Inventory – Revised (SPSI-R); the Barratt Impulsivity Scale, version 11 (BIS-11); the Locus of Control Behavior (LCB) scale; and the Crime PICS, version II scale) were analyzed for a sample of 135 males who had taken part in the program. Significant change in a pro-social direction was found on the LCB, especially for Aboriginal participants, all of the BIS-II and Crime PICS II subscales and two of the SPSI-R subscales. These changes suggest that completion in Think First may improve impulsivity levels, criminal thinking styles and some aspects of social problem solving ability.

Making sense of the senseless: An exploration into the act of serial murder within South Africa
Chantall Waldeck University of Johannesburg, South Africa; Elsabe Jordaan
The act of serial killing has attracted academic attention within the last two decades from both an international as well as a South African perspective. It was reported by a South African author (Hodgskiss, 2004) that, during the 1990’s, there was a definite increase in serial murder within our country. It was hypothesised that this was due to social and political upheaval experienced in South Africa at the time. However, this increase in serial murder may also be understood from another perspective, a psychological one. The definition of serial killing by South African authors (Pistorius, 2006 and Labuschagne, 2001) has encompassed the act of serial killing to have killed three or more persons, occurring at different times and the murders appearing unconnected. Motives for these crimes are not driven by the need for material gain or revenge, and are intrinsic in nature. The act is fuelled by fantasy which then leads to various acts of torture, mutilation and necrophilia. The definitions of international researchers on serial killing are further explored in this study. The definitions above do not acknowledge the psychological aspect of serial murder and this needs further investigation. The possibility that certain maladjusted (interpersonal and intrapersonal) psychological processes lead to acts of violence and torture are explored in this study. Obtaining information on those who commit these crimes of violence could lead to a clearer understanding of risk factors, and the psychological functioning of each individual case. This study is of a qualitative research design, in which semi-structured interviews with offenders convicted of serial killing is done. A thematic analysis of a semi-structured interview with an offender will be reported upon, where preliminary themes will be discussed.

Session Type: Posters

Juvenile sexual offenders
Gene Berg Chapman/Brandman University, United States of America
A significant percentage of juvenile offenders are sex offenders referred for evaluation in the United States Justice System. Juvenile sexual offenders have unique needs and concerns in contrast to other juvenile offenders. The purpose of this study is to examine common factors found in juvenile sexual offenders relating to personality, intelligence, achievement, peer status, socialisation competence, relationships, and self concept. Ten juvenile sexual offender cases were randomly selected from a pool of adolescent sexual offenders evaluated over a ten-year period. Offenders were male, 12 to 18 years of age. This study was conducted on a small sample which may not be fully representative of the whole population of juvenile sexual offenders. However, the study gave key information relating to variables identified with juvenile sexual offenders. This study raised potential avenues of research for juveniles. Results indicated that juvenile sexual offenders have difficulties with social competence, social sophistication, boundaries, and relating to age appropriate peers.

Confirming feedback effect for confidence judgment on the delayed photograph lineup identification
Satoshi Hara Surugadai University, Japan; Masa-hiro Ohara
We examined the effect of confirming feedback on delayed photograph lineup identification. Participants were shown a videotape of a staged crime event. The participants then were requested to make an identification of the perpetrator on a 7-person photograph sequential lineup and to rate how confident they were in that identification. They then were given the confirming feedback. One week later, they conducted the same identification task again (delayed identification) without the feedback. We found that the confirming feedback increased the delayed identification confidence in both the target presented lineup condition and the target absent condition. This means that the confirming feedback effect maintained for one week. Using calibration, a strong accuracy and confidence relationship was established.

A psycho-legal perspective on competency testing for the child witness
Sharon Kruger University of Johannesburg, South Africa; Gertie Pretorius; Ellette Fritz
The admissibility of children’s evidence in criminal cases is often blocked by abstract and/or inappropriate questioning in order to determine the child’s competency to testify in court. Consequently, the child’s right to participate in any judicial matter concerning her/him is violated and criminals may therefore not be brought to justice. Many of these children are therefore left vulnerable to further abuse because the alleged perpetrator is set free. Other children may suffer from further psychological trauma as they believe that when they did speak up about their experience they were not believed. In this presentation the authors explore age-appropriate methods for assessing a child’s competency to
serve as a witness and propose a standardised procedure for assessing the competency of the child witness. We begin by defining competency and exploring the relevance of existing methods and procedures used to assess the competency of the child witness. Hereafter the importance of matching the methods of questioning to the cognitive skills and emotional development of the child is presented. The authors then argue that while competency testing remains a requirement in South Africa, there is a need to standardise the method of questioning used during competency testing. The presentation concludes with the assertion that while the legal arena demands uniformity regarding psycho-legal information gathering, psychologists have the necessary psychological expertise to offer a framework in which standardised, competency-testing guidelines can be developed for psycho-legal purposes.

Ownership of firearms: Its effects and security challenges in the Nigerian context
Abiodun Lawal University of Ibadan, Nigeria
People have mixed views on the crime rate in Nigeria. Their views can be influenced by reason of whether they can, or cannot, own firearms to control crime. This study investigated people’s attitudes toward liberalisation of ownership of firearms, and its perceived effect on the crime rate. The study used ex-post facto design and an accidental sampling technique to sample three hundred (300) respondents across a population sector of uniformed and non-uniformed individuals. The participants responded with regard to their attitude towards liberalisation of ownership of firearms, and perception of the crime rate scale, which was developed by the researcher for the purpose of this study. Four hypotheses were tested in the course of the study, using independent t-test analysis. The results of the tested hypotheses showed that attitude toward liberalisation of ownership of firearms influenced respondents’ perception of crime rate (t=4.01; df=298; P > .05, age: t=-.04, df =298, =P>.05 and type of respondents: t=.059, df =298, =P>.05), respectively. The implication of this finding is that respondents’ attitudes toward liberalisation of ownership of firearms are important for regulating firearm control policy in Nigeria. The findings of this study were discussed in accordance with existing related literature.

Future time perspective and satisfaction with life in a sample of parolees
Isabel Mikulic University of Buenos Aires, Argentina; Melina Crespi
Future time perspective can be understood as the mental representation of objects located in the future. Under the relevance of this variable in the study of social reintegration of persons who have regained their freedom, is proposed in this research to analyse the Future Time Perspective in a sample of parolees. It also seeks to assess the degree of association between time perspective and level of life satisfaction experienced by this population. A descriptive-correlational has been developed. The sample consisted of 140 adults on parole. Were administered: a) A questionnaire to assess future time perspective, specially built in this study. c) Satisfaction with Life Scale by Pavot and Diener (1993). The average number of goals mentioned by participants is 2 (SD = 1). The goals are largely concentrated in the categories of personal accomplishment and material possessions (obtaining property such as cars, housing and money). A temporary extension of the proposed goals focuses on the open present (from now on) rather than in the distant future. Regarding the planning of goals, the results show a low degree of knowledge about how to achieve them and a small amount of shares effectively mobilised for obtaining. The temporal analysis of attitudes shows a predominantly negative attitude toward the past and present, and positive toward the future. Data also show the existence of association between temporal attitude and satisfaction with life. It is interesting to continue investigating the role these variables have in terms of adequate social reintegration or recidivism in the crime.

Development and validation of the Penny Beliefs Scale – Weapons (PBS-W)
Helen Penny King’s College London, South Africa; Julian Walker; Gisli Gudjonsson
Weapons carrying, and use, is an area of increasing concern and frequent media attention. Despite this, there is a distinct lack of psychological research into the reasons that people carry and use weapons. At present there is no adequate measure of beliefs that facilitate carrying and using weapons, and the present investigation sought to develop and validate such a tool: the Penny Beliefs Scale – Weapons (PBS-W). The PBS-W was developed using themes identified in a literature review, and through consultation with experienced Forensic Psychologists. The factor structure, reliability, and validity were ascertained by administering the PBS-W to 212 school pupils in South Wales, who were aged between 16 and 18 years. The final version of the PBS-W comprises of 36 items that measure young people’s beliefs about carrying and using weapons, and load onto one factor named Potency. The new scale has excellent internal reliability (Cronbach’s alpha of .92), extremely good test-retest consistency (ICC = .833), male participants scored significantly higher on the PBS-W compared with female participants, and the PBSW is significantly positively correlated with self-reported delinquency.

Early developmental psychopathology and its link with criminality and self-harm
Mohammad Rahman Princess Marina Hospital, Bangladesh; Vonile Tladi; Mitu Shultana
Is there a hidden psychopathology behind criminal activity? Review of literature and professional observation reveals that negative early developmental factors have great impact on criminal activity in later life. Faulty parenting is one of the factors that has a major influence on a person’s lawless activity. For example, indulgent or inconsistent parenting might cause children and adolescents to be impulsive. On the other hand, deprivation by parents might give rise to suppressed emotions in early life. Due to continuous suppression of feelings, these children can become emotionally and socially mal-adjusted, lack of empathy for others, and can act out against people to express their anger, or to punish them as compensation for their hidden and suppressed pain. This pattern of behaviour does lead to criminality, but in some cases, some adolescents and adults from similar circumstances act out against themselves by self-harming that can lead to suicidal attempts. In special cases where there is an emotionally explosive situation, such as being rejected in love, a person can do both – passion killing as an act of criminality, and an attempted or actual suicide. This paper aims to establish the link between criminality and suicidal phenomena to early life deprivation, through case studies from secondary sources and professional experiential observations. The analysis of the results will lead to the recommendations on strategies for early interventions for repairing and correctional work, for restoring the balance in the self-pattern for prevention of criminality and suicidal or self-harm tendencies, during childhood and adolescence.

Dynamic factors of recidivism of drug-dependent prisoners in therapeutic community
Victoria Ramos-Barbero University of Burgos, Spain
We have seen on research conducted with Spanish inmates that many of the variables associated with recidivism are static, aspects of the offender’s background (such as age and criminal history) that can not be changed with treatment. This research aims to highlight the dynamic variables. Dynamic variables are modifiable and are themselves targets of a treatment program, such as time spent in treatment or to have work habits. The objective of this research is to identify the dynamic variables associated with the conduct of criminal recidivism in a population of drug dependent prisoners released from the penitentiary in Burgos (Spain) (N=120). These inmates were in a drug free unit in prison and were released to one therapeutic community to finish their prison sentence. Therapeutic community is an alternative-to-prison substance abuse treatment client. The documentary sources consulted for collecting information were the prison record, the classification and treatment protocol and the social record. The method used is a nonparametric inference technique called chi-square (χ2) for qualitative variables. For the bivariate analysis, the criminal recidivism variable has been related to other variables that have been considered theoretically relevant for recidivism. The characteristics of the variables that showed higher percentages of recidivism were: Lack of work habits, HIV disease, higher scores in extraversion, finalising the treatment in therapeutic community with expulsion or abandonment and shorter stay in the therapeutic community. These results suggest that the prevention of recidivism can have positive results, if we can influence these variables through prison treatment.

Intellectually disabled sex offenders and non-intellectually disabled sex offenders: A comparison of phallicometric test results
Rebekah Ranger Institute of Mental Health Rese, Canada; Paul Fedoroff; Susan Curry
This study examines the sexual arousal (phallicometric) test results of three groups of individuals. The first group is comprised of intellectually disabled adult men who have committed a hands-on sex offence against a child less than 12 years of age. The second group is comprised of non-intellectually disabled adult men who have committed a hands-on sex offence against a child less than 12 years of age.
The third group is a control group of adult men who reported never having committed a sexual offence, but have been tested phallometrically for research purposes. Each group had been matched on age, gender, number and age of victim(s) as well as degree of sexual act and degree of violence (when applicable). In line with current research on intellectually disabled sex offenders, higher levels of overall arousal and a lower level of arousal discrimination were expected to be found in the group of intellectually disabled sex offenders when compared to the other groups. Phallometric test results to child, adult and child coercive audio stimuli were compared for each group. Contrary to what was hypothesised based on previous literature, the intellectually disabled and non-intellectually disabled groups were not significantly different in their sexual arousal patterns. Further research is needed on larger samples, using medications at time of assessment as a covariate, as some medications can impact sexual arousal. Additionally, further research should focus on differences in sexual orientation of intellectually disabled sex offenders with respect to arousal patterns to child, adult and child coercive stimuli.

Competency restoration programmes and practice guidelines in forensic psychiatric settings

Jason Smith Carlos Albizu University, United States of America; Enna Taylor; Ted Collliff; David Landry

Competency restoration is based on historical conceptions of fairness, accuracy and dignity of the trial process. Hence, the primary justification for competency restoration programs is to ensure that defendants receive relevant treatment for incompetence. However, there is a significant lack of reliable, valid and empirically based structured treatment options in the competency restoration literature. At the present time, treatment commonly entails the administration of psychotropic medications and didactic training programs in psychiatric settings. Although these approaches to competency restoration have been at the forefront of treatment for the past five decades, concerns persist about their effectiveness. In the present literature review, current empirical findings on competency restoration are examined and recommendations provided toward the establishment of empirically validated treatments for incompetence. Specifically, the authors highlight the need for structured manualised treatment regimens and the significant void of empirically supported treatments in the current literature. Since competence to proceed and the concomitant competency restoration treatment currently comprises one of the most frequently occurring referrals for forensic psychologists and forensic psychiatric facilities, providing clinicians with information regarding this present issue is important in the interests of enhancing the effectiveness of competency restoration around the world.

Forensic utility of the Rorschach Inkblot method

Jason Smith Carlos Albizu University, United States of America; Enna Taylor; David Landry; Carl Gacano

The Rorschach Inkblot Method (RIM) is a measure that is valuable to forensic assessments. However, the Rorschach has been criticised to the extent that a moratorium on its use has been suggested (Garb, 1999). Careful examination of these criticisms indicates a lack of knowledge of the scientific and empirical research supporting the Rorschach's utility. The Rorschach's psychometric properties are comparable to other personality measures commonly used in forensic settings. As such, psychologists should not be intimidated by the critics and otherwise should remain confident when using the Rorschach in forensic settings. Education is paramount in debunking misconceptions about the Rorschach's clinical utility.

Developing an optimal psychological assessment procedure for determining parental responsibilities and rights

Henk Swanepoel South Africa

Post-apartheid changes gave rise to the adoption of a new Constitution for South Africa, causing changes in family law resulting in the Children's Act, 2005. Psychologists working within the psycho-legal field are faced with the demanding task of assisting the court in determining the best interests of the child. This study aimed to develop a psychological assessment procedure for determining parental responsibilities and the rights and primary residency allocation of children. The basis of the 'best interests' of the child in the South African context was set out by Honourable Mr. Justice King where he formulated a list of 13 criteria which courts could use as a standard to determine what care arrangements would best serve the interests of the child. These criteria form the cornerstone of this study, as the contextualisation of the data is based on this set of variables. The study was conducted in two phases. The first phase focussed on the qualitative operationalisation of the 13 identified variables into an assessment procedure. The second phase was quantitative, where 39 families (26 treatment-group and 13 control-group families) were evaluated on a pre- and a post-level by means of ANOVA and MANOVA. It is recommended that the Professional Board of Psychology in South Africa consider including the results of this study in the training of students under the new category of forensic psychology.

Female partner serial sexual offenders: Using the brace character profile to form a typology

Joan Swart Eiser Institute, South Africa

The question of the behavioural expression of female sex offenders is an important one from the perspective of prevention, treatment, and legal options. Modern models of typology favour a dichotomy of predisposition and coercion in female partner-related sex crimes. The objective of the study is to test the assumption that offender types are indeed non-overlapping as held in other studies, and further qualify profiles using the BRACE Character Profile® method. The BRACE Character Profile® is a validated tool that provides a detailed and nuanced behavioural and personality profile of a known, or unknown, subject based on a 75-item questionnaire. A generic profile for each offender type is generated and tested against 40 known female partner serial sex offenders. Measures of psychopathy are used to determine the role in offender behaviour, and regard is given to victim characteristics, nature and course of offences. The results of the study will assist in the behavioural analysis of female serial sex offenders to determine the most appropriate penal and rehabilitation response in each case.

Direct confession bias in suspect interview

Kotaro Takagi Aoyama Gakuin University, Japan

Direct confession bias is a phenomenon in which an interrogator gives credibility to a suspect's confession, not through its contents and relation to other evidence, but through the fact that the suspect confessed his/her guilt to the interrogator. This kind of biased judgement must be eliminated because it might increase the potential risk of false confessions. The purpose of present research is to examine the generating mechanism of this bias through analysing an audio recorded interrogation by a prosecutor in Japan. The case occurred in 1990, and involved the sexual abuse and murder of a 4 year old girl. This case was known as the first criminal case in Japan which was proved to be a false accusation based on the retesting of DNA. Verbal interaction between the suspect and the prosecutor was analysed based on the theoretical framework of the Gibsonian approach to memory in which the act of remembering was defined as a type of "exploration of environment" (Reed, 1994). The analysis showed that the occurrence of direct confession bias is closely related to the emergence of an interaction structure, in which an interrogator jointly explores past criminal events with a suspect, instead of listening to the suspect's explanation of the event.
Deception often is accompanied by facial expressions simulated or concealed to be consistent with the false message. Darwin hypothesized that some facial muscle actions beyond voluntary control may leak genuine emotion or reveal falsified expressions. In this presentation, I describe the results of laboratory and field studies to examine this assertion. We found that emotional leakage is most likely to occur during masking (attempting to conceal one’s felt emotion with a simulated expression), particularly when the to-be-concealed emotion is strongly felt. Careful attention to the face can also reveal deceit in high-stakes, emotional, real-world situations. Televised footage of a large international sample of individuals \( N = 78 \) emotionally pleading to the public for the return of a missing relative was meticulously coded for emotional presentation. Half of the pleaders eventually were convicted of killing the missing person based on overwhelming physical evidence. Failed attempts to simulate sadness and leakage of genuine happiness revealed deceptive pleaders’ covert emotions and, in combination with verbal cues, differentiated honest and dishonest pleaders with unprecedented accuracy in the study of deception detection.

Symposium title: Recent developments in research on eyewitnesses

Varying facial similarity: An automated lineup generator

Caitlin Grist United States of America; Colin Tredoux

Lineup bias poses a large problem to the criminal justice system as innocent suspects are often wrongly identified. Two methods used to select lineup foils have been shown to introduce lineup bias, and they can result in different levels of identification accuracy. We propose an automated lineup generation tool, which constructs lineups by synthesising face images of a specifiable similarity to the perpetrator. The lineup generator tool may serve as a third method for foil selection. Experiment one showed that the tool can create artificial faces that are difficult to distinguish from real faces. Experiment two showed that foil-suspect similarity could be varied through manipulation of the synthetic faces in ways that resulted in predictable similarity-contingent recognition rates. Experiment three extended the methods of experiment two to include suspect-perpetrator similarity in the manipulations. In overall terms, the results from the three experiments suggest the utility of the synthetic lineup generator.

What big teeth you have! Red Riding Hood and face recognition failure

Kate Kempen University of Cape Town, South Africa

Law enforcement typically relies on the testimony of eyewitnesses. These eyewitnesses are usually required to construct a composite of the perpetrator. Research has found composite construction to have a negative effect on later recognition (e.g. Wells, Charman, & Olson, 2005). This hampering effect may occur because composite programmes utilise a featural selection strategy, in opposition to the configurial and holistic processing that may be used on encoding. We report a series of experiments aimed to investigate the featural aspect of composite construction. Two types of lineups were used in Experiment 1: Whole-face, and feature lineups. Participants in each group encoded a target face and were asked to select the whole target from the lineup, or to identify the correct features. Participants in the featural lineups could only select the correct features at chance levels. This suggests that participants are unable to identify correct features, thus participants may not be able to accurately select appropriate features in composite systems. Experiments 2A and 2B attempted to separate the featural process of construction. Participants selected composite features one at a time, and did not assemble features. A featural-assembly group selected the individual features and assembled them once all the features were chosen. Results indicated that the isolated-featural group obtained significantly fewer hits than the control group. However, the isolated-featural group rejected the lineup, and did not incorrectly select fillers. When forced-choice results were analysed, all participants performed at the same level as the control group. This offers evidence towards a criterion shift which is discussed.

Face typicality, recognition, and affective evaluations of own and other group faces

Colin Tredoux UCT, South Africa

We are better at recognising faces of our own group than faces belonging to another group (Own-Group Bias). The present work investigated the hypothesis that within-group variations in physiognomic appearance might affect recognition of faces of the own and other racial groups. Repeatedly, research on prejudice and stereotyping has demonstrated that a greater extent of stereotyping and more negative evaluation occurred towards black persons high in typically for their racial group. The present work assessed participants’ recognition performance for faces high and low in racial typicality. Additionally, affective-evaluative responses were assessed by facial electromyographic activity and collection of ratings for each face on how positive, likable and emotionally arousing it was perceived to be. Forty-one white, German students participated in the experiment. Participants’ recognition performance was better for faces of the own than of the other racial group. Recognition performance for highly typical faces of the own racial group was marginally superior to recognition performance for own-race faces low in racial typicality. EMG data did not reveal any significant results. However, a significant Race x Typicality interaction effect was found on positivity and likability ratings. Additionally, other-race faces were reported to elicit higher arousal than own-race faces and cross-race faces high in typicality were rated to elicit higher arousal than less typical other-race faces. The results will be discussed in the light of current approaches towards both an own-race and a phenotypicality bias in face recognition and in person evaluation.

The cognitive resources framework: How eye-closure improves eyewitness memory

Annelies Vredeveldt United States of America

Recent research has shown that eyewitnesses instructed to close their eyes during an interview remember significantly more accurate information than eyewitnesses not doing so. Furthermore, although eye-closure improves recall of auditory details of the witnessed event, it is particularly effective for recall of visual details. Based on previous findings, the Cognitive Resources (CR) framework is proposed, which aims to explain how eye-closure improves eyewitness memory. The CR framework holds that, during an investigative interview, the eyewitness needs to devote cognitive resources to the retrieval task, but also to the task of monitoring the current environment. Blocking out visual distractions in the interview environment can therefore improve retrieval performance by freeing up cognitive resources. The framework specifies both general and modality-specific pools of cognitive resources.

An experiment was presented in which mock witnesses were assigned to one of two high-distraction conditions (visual or auditory distractions), or to one of two low-distraction control conditions (eye-closure or looking at a blank screen). Exposure to any type of distraction was found to impair recall performance, compared to the low-distraction conditions. Moreover, visual distractions particularly disrupted recall of visual details, whereas auditory distractions particularly disrupted recall of auditory details. The data was fitted to the CR framework to gain insight into the extent to which the disruption was general versus modality-specific in nature. It is concluded that auditory distractions take up predominantly general cognitive resources, whereas visual distractions take up general and modality-specific cognitive resources to a similar extent.

Symposium title: The state of psychology in Zimbabwe

Convenor: Gwathirera Javangwe

Forensic psychology new kid on the block in Zimbabwe

Gwathirera Javangwe University of Zimbabwe, Zimbabwe

The paper traces the historical development of the field of forensic psychology from a Zimbabwean perspective. Specifically, it uses the metaphor of a marriage between psychology and law, from courtship, marriage, the pregnancy, offspring, the developmental milestones reached, obstacles, and the future of the marriage and the possibility of a divorce. The paper concludes by focusing on the path to be taken in an attempt to preserve the marriage.
Adolescent boys in an HIV context
David Blackbeard University of KwaZulu-Natal, South Africa; Graham Lindegger
This study explored masculinity self-construction among adolescent boys who were members of an HIV support group. Dialogical self-theory was chosen as a perspective from which to identify how the boys positioned themselves and were positioned by dominant masculinity ideals and imperatives. Multiple data sources and multiple methods of analysis afforded a view on the dialogues among the material, spatial, dynamic, and temporal contexts in which the extended self was instantiated and innovated. These dialogues suggested how masculine selves were positioned, created and maintained both corporately, and at an individual level, with implications for the development of alternatives to problematic forms of masculinity and the development of theory in the psychology of gender. The study was qualitative, involving an extensive process of participation in the data, and analysis, with a small purposive sample. Reflexivity practices facilitated an opportunity to explore dialogues within a research team along with the benefits of having differing perspectives among multiple interviewers. The study had potential relevance for policy, prevention and activism for problems associated with dominant forms of masculinity as sets of embodied ideals, standards and practices. These included not only HIV interventions, but other areas such as physical risk taking, health protective behaviour and gender-based violence. Across several areas, identifying positioning processes in relation to masculine hegemonies offers possibilities for alternative ideals and practices.

Understanding frameworks of medical intervention and biomedical discourses within the HELLP syndrome experience
Michelle Andipatin University Western Cape, South Africa
HELP Syndrome (characterized by haemolysis, elevated liver enzymes and low platelet count) is a maternal condition of pregnancy potentially fatal to the mother and/or baby. Nested within a feminist post-modern epistemology, and drawing on a material-discursive theoretical framework, my study examined the role that frameworks of medical intervention and biomedical discourses play in South African women’s understandings of their experience with HELLP Syndrome. Eleven participants who had pregnancies with HELLP Syndrome were interviewed. A discourse analysis revealed that women’s talk was embedded within ideological frames such as technocratic medicine, patriarchy and the South African health care system. Participants’ discourses about their encounters with the medical context was located within, and shaped by, the structure of health care in our country. In this regard binaries like private versus public health care, women versus men and nurses versus doctors were erected. Furthermore their hospital stay reflected two discrete technological cultures, namely, the mothers’ own pregnancy and body (ICU), and the baby (NICU). Biomedical discourses that filtered through in the participants’ talk were: medicine is science; body as machine; doctor as God and the fetus as super subject. Discourses of risk were inevitably taken up as participants tried to make sense of both their current pregnancies and the potential ones to follow.

Telling stories of childbirth across race/class divides
Rachelle Chadwick University of Cape Town, South Africa
Since the 1970s a substantial body of social science, psychological and feminist research has analysed women’s childbirth experiences. This work has predominantly focused on middle-class women, with the childbirth narratives of poor, marginalized women remaining relatively unexplored. This paper addresses this gap and presents results of a narrative study of South African women’s childbirth stories told across race/class divides. The birthing stories of poor, ‘black’ women and middle-class, mostly ‘white’ women are contrasted and compared. The paper shows how historical and contemporary race/class politics continue to mark South African women’s bodies and delineate spaces of/o to birth according to race/class positions. While sharply inscribed by race/class dynamics, a powerful national medical hegemony over childbirth and deeply entrenched forms of gender normativity also materialized as powerful modes of inscription and discipline which worked to produce a local politics of birth in which women across colour and class divides remained subject to potentially dehumanizing birth experiences, albeit in very different ways. The different modes of power/domination operating on poor, ‘black’ women and middle-class, ‘white’ women in relation to childbirth are explored. Different modes of resistance to this local geo-politics of birth are also considered.

Interpersonal relationships with gay and lesbian peers among male and female university students in Taiwan
Te-Sheng Chang National Dong Hwa University, Taiwan, R.O.C.; Shew-Wen Huang; Jia-Sheng You; Tsai-Wei Wang
The purpose of this study was to investigate male and female university students’ interpersonal relationship with lesbians and gays. The sample consisted of 1164 male and 1186 female students in Taiwan. The research included three instruments: the Interpersonal Relationship with neutral, gay, and lesbian peers. Each survey consisted of 10 items, divided into three subscales: Friendship, Love, and Sympathy. The split-plot factorial design was adapted to find the interaction between students’ gender (male and female) and their attitudes toward peers (neutral, gay, and lesbian) for Friendship, Love, and Sympathy respectively. The results show that the interactions between student gender and types of Forms (attitudes toward neutral, gay, and lesbian peers) are statistically significant in Friendship, Love, and Sympathy factors. Female students score significantly higher than their counterparts regarding to three factors across different forms. Male students report more acceptable attitudes toward neutral students than both gay and lesbian peers across three factors. In addition, male students report more acceptable attitudes toward
Co-parenting alliances assessment in heterossexual and same-sex parents triads

Salvatore D’Amore University of Liege, Belgium; Nicolas Favez; Seth Pardo

Co-parenting is defined as the alliance of mothers and fathers in their roles as parents including cooperation, support, and reciprocity in the triadic processes with their child. Despite decades of co-parenting research, little is known about non-heterosexual co-parenting. This study examines differences in co-parenting in 10 lesbian family triads compared to 30 heterosexual family triads. We hypothesise that there are no group differences in co-parenting behaviours. Heterosexual mothers’ mean age was 31.2 years (SD=2.3) and fathers’ was 32.6 (SD=3.5). Lesbian biological mother’s mean age was 34.4 years (SD=5.85) and female partners’ was 36.6 (SD=7.69). Both groups were of middle- to upper-middle socio-economic status. Co-parenting was observed with the Lausanne Trilogue Play and measured with the Family Alliance Assessment Scale. Results demonstrated that there were no between group differences in co-parenting behaviours across 14 of the 15 sub-scales examined. A significant group difference was only observed in coparenting structure, t(9)=-6.74, p<.001; lesbian parents did not adhere as well to the expected interactive structure of the LTP. However, lesbian and heterosexual parents demonstrated similar postures/actions, inclusion, roles, co-construction, scaffolding, warmth, validation, authenticity, mistakes, support, conflict, involvement, and self-regulation. These results support a similarity hypothesis for heterosexual and same-sex parenting, and fill a necessary gap in the literature regarding same-sex co-parenting. Presentation will discuss implications for future research on non-heterosexual families and child development.

A study of women in atypical careers

Daniel Du Toit North-West University, South Africa; Jolene van den Berg

The primary objective of this research was to explore the constructs that are outlined in the model of Young and Hurlic (2007) within the South African context and to establish the influence of gender and gender-related behaviour to person-group fit, person-organisation fit and career decision making of South African women in atypical careers. The constructs in Young and Hurlic’s model that are considered to have an effect on career decision making of employees with atypical careers include: Gender enactment, gender based micro-culture, skills and education, person-group fit, person-organisation fit, perceived stress, self-efficacy, gender based macro-culture, and person-organisation fit (Young & Hurlic, 2007). A qualitative design was used and a purposive sampling method was applied to select the sample (N=10). The sample of female employees consisted of electricians, millwrights, steel-makers, technicians and engineers. Participants who were selected all did physically demanding work, previously viewed as unsuitable for women, under harsh work conditions on the factory floor of the organisation in which this study was conducted. Unstructured and semi-structured interviews were conducted to collect research data. Results indicated that awareness, group acceptance, person-group fit, perceived stress and person-organisation fit are the factors with the most influence in the career decision making of South African women in atypical positions. Recommendations include steps organisations can take to enhance awareness, assist new employees to fit into their work groups and manage stress.

Gender relationships in Brazilian carnival music in the 1930s to 1940s

Ronald Ericerei UFRPE, Brazil

This research weaves together the repertoire of carnival music and gender studies. Examining musical compositions of Lamartine Babo, João de de Barrio and Ari Barroso, we aim to identify social views on women in Rio de Janeiro during the years of 1930 to 1940. We estimate discussions on gender relations are far from exhausted, especially since our discussion proposes to launch a psychosocial look on this theme by analyzing the discussion of carnival music. The work departs from the conception of the category of woman as a common place and a synonym for female identity. We understand the concept of gender as a social construction with different meanings in the world. In this argument, we believe that concomitant to the process of production and circulation of various discourses on the social roles of men and women, the composers of carnival music inserted carnival language as another meaning varies and changes with each context. In these terms, we express the desire to insert the carnival music as a privileged place for understanding a portion of a Brazilian social thought regarding the status of being a man or woman in the country. We tried to uncover social views on women in letters of carnival music through Bakhtinian reflections on psychology, which continually allowed us to establish a close relationship between the socio-historical context of Rio de Janeiro in the 1930s and 1940s and the social messages contained in the carnival music of that period.

Desiring to be unique: Female secondary school learners’ construction of gender and sexual identities

Elron Fouten Rhodes University, South Africa; Tammy Shefer

This paper explores the construction of gender and sexual identities among a group of female secondary school learners at a school in Cape Town’s northern suburbs. This study is grounded on the social constructionist premise that gender identities, i.e. masculinity and femininity, are continuously being created and recreated through social interactions. The study used qualitative methodology including a series of paired interviews with 17 girls between 16 and 17 years of age. In addition to this method of data collection each participant received a 35mm exposure camera for the purpose of taking pictures that would depict stories of what it meant to be a young girl in Africa from their point of view. Interview data was discursively analysed while photographic images where interpreted and understood for the stories they conveyed. This study confirms that gender, like other identity-creating practices is dependent on social context and that its meaning varies and changes with each context. Findings further show that in certain spaces girls conform to the dominant feminine ideal of their context but in others, at home, at school, or when socialising, they may intentionally and unintentionally challenge and resist prescribed socially acceptable ideals of femininity, as evident through various articulations of the self in dress, behaviour and desires.

The significance of gender in the abortion debate: A content analysis of South African newspaper articles

Tracey Feltham-King Rhodes University, South Africa

We report on a content analysis of South African newspaper articles written about abortion from 1978 to 2005 in order to ask two questions: ‘What is the gender of those called upon to comment on abortion issues?’ and ‘From what position do these commentators contribute to the discussion on abortion?’ South Africa provides a particularly pertinent context given the fact that both the media and legislation pertaining to abortion underwent significant transformation over the last three decades. Results indicate that women are represented as commentators more frequently in articles about abortion than in the media generally. This representation reached its height around the politically charged court challenges to the Choice on Termination of Pregnancy Act of 1996 which legalized abortion on request to 12 weeks of gestation. The alignment of commentators is balanced between pro-life and pro-choice however; there is a swing in the dominance of pro-life versus pro-choice alignments at various points. The gender of the commentators referred to in each article and their alignment to the abortion debate was cross-tabulated with the 28-year time period. This was done in order to measure the impact of the descriptive representation of women (i.e. the presence of women commentators) on the substantive representation of women (i.e. presence of positions that promote gender equity) in newspaper articles about abortion. The findings provide evidence of the relationship between female commentators and their alignment with the pro-choice position, highlighting the differences women representatives make practically to the representation of abortion in the media.

Women ministers’ discourses in relation to gender discrimination in the Lutheran Church

Ursula Froschauer University of Johannesburg, South Africa

The aim of this research study was to uncover women minister’s discourses in relation to gender discrimination in the Lutheran Church by using a discourse analysis. Three female participants, who are involved in ministry in the Lutheran Church in South Africa, were interviewed regarding their
experiences and perceptions of gender discrimination. The resultant texts were analyzed using Parker’s (2005) steps to discourse analytic reading. The discourses that were discovered indicate that power struggles are prevalent in the context of gender discrimination. Furthermore, the extent to which an individual opposes gender discrimination is informed by contextual, educational and historical factors. In addition to this, gender discrimination within the church is easily legitimized — to a large extent by women — through discourses, such as Biblical texts. The analysis indicated five discourses, namely patriotism, patriarchy, silence, visibility and trust, which women utilize in justifying or opposing gender discrimination. An awareness of the abovementioned findings is useful in promoting gender equality in institutions.

Patterns of adolescent coping with domestic violence
Svetlana Gridneva Southern Federal University, Russian Federation; Anna Tashcheva
During 2009–2011 scientists of the Southern Federal University examined 397 Rostovite-teenagers of 12–17 years old who had experienced domestic violence. The revealed patterns of reaction of teenagers were: “change of self-attitude” (99.2%); “bad state of health” (93.7%), “a sharp need to pour out his/her soul” (91.2%), “to distract with something” (85.9%), “an attempt to improve the situation” (73.5%), “a reciprocal aggression” against the rapist (61.7%), “without external changes” (36.2%). 97.5% victims acquire their family “norms” of communication and reproduce them during communication with people around or retire into themselves. The latter respondents characterise themselves as reserved, close, excessively timid, having serious difficulties in a choice situation when they have to take responsibility. The victims using violence reproduce the kinds and forms of violence which they have experienced in 96.9% cases. Not only relatives, but also people from the nearest social environment, casual persons, animals and plants become victims of such “secondary violence”. Teenager-victims designate motives of their aggressive actions as a demonstration of their force, superiority (98.0%), revenge (42.3%). 74.3% of the examined teenagers want to have confidential communication with their parents, 23.2% with close friends. 63.7% teenagers wanted and 3.8% actively searched for professional psychological help and only 2.0% preferred to cope with their difficulties independently.

Gender differences in emotional intelligence and the effects of a negative mood induction
Laura Nathalie Hiller University of Innsbruck, Austria; Klaus Riedmuller; Katharina Reiter
Former studies showed gender differences in emotional intelligence, in which women score higher than men (MacCann, 2010; Extremera et al., 2006). According to Chepennik et al. (2007), a negative mood induction decreases emotion recognition. Our study assessed gender differences in emotional intelligence, how negative mood affects emotion recognition, and the interaction between these measures. This was achieved by asking fifty-nine participants to complete the Wong and Law Emotional Intelligence Scale (WLEIS), followed by either a negative or a neutral mood induction by a short film sequence. For the emotion recognition task we used fifty pictures displaying basic emotions from the Facial Expressions and Emotions Database (FEED). Self-reported Emotional Intelligence did not show a significant gender difference concerning the global factor, but in the sub-factors “Regulation of Emotions” and “Others-Emotions Appraisal,” where men had higher scores than women. In contrast to that, the objective measure of emotion recognition showed, that women were better in “Others-Emotions Appraisal.” These results illustrate that men estimate their “Others-Emotions Appraisal” ability higher than it actually is. After a negative mood induction, the participants showed, in comparison to a neutral mood induction, lower abilities in recognising other’s emotions. In this context, women reacted more sensitively to the negative mood induction than men. The results of the study will be discussed in terms of theoretical and practical relevance.

Identity construction of gay men through masculinity perspectives in Turkey
Yasin Koc Bogazici University, Turkey; Hande Eslen-Ziya
This study investigates how gay men construct their identities through their perspectives of different masculinities in their society. Although the study

Relational and social aggression amongst girls from pre-school age to early adulthood has been the focus of researchers and concerned adults alike, but surprisingly little research has systematically investigated relational and social aggression among adult women. Electronic communications technologies create new means for the expression of aggression in forms such as electronic bullying, cyber-bullying, or online social cruelty. Research increasingly identifies girls as the instigators and perpetrators of these forms of aggression. Similarly, access to electronic communications technologies has seen the rise of “mommy blogging”. Mothering blogs represent an intersection where women make use of electronic communications media and where adult women’s relational and social aggression can be explored. This study investigates women’s social and relational aggression in a sample of mothering blogs and forums. Content analysis identified gender-related themes in the data. The identified themes contain messages regarding the “rules” that define acceptable mothering and femininity. As within adolescent peer culture, power comes from the ability to invoke these norms. We call into question how expressions of social and relational aggression in mothering blogs and forums are associated with women’s agency and the good mother/bad mother discourse.

Gendered dimensions of marital conflicts and psychological distress in India: Implications
Aparna Joshi Tata Institute of Social Science, India
The present article is based on experiences of a psychotherapeutic centre housed in an Indian Family court. The centre was the first of its kind and offered individual and couple therapy to litigants in psychological distress. Couples come to family court to access legal solutions to marital conflicts. This is often a last resort for many in the Indian setting. Marital conflicts contribute to psychological distress; and gender appears to be one of the critical determinants of mental health and distress in many of these cases. Narratives of men and women litigants bring out the gendered nature of stressors experienced and of manifestations of mental distress. Relational and social consequences of the resulting mental distress are also gendered in nature. All of these are closely linked to the gender roles prescribed by the larger and dominant socio-cultural narratives, and to the power differences between both the genders. Prevalent legal and medical discourses also seem to reify these gendered roles and power differences. Using referral data, litigants’ narratives and therapists’ experiences, this article offers a gendered analysis of mental health concerns presented by the litigants and suggests implications for a gender sensitive psychotherapy. The article underscores the fact that gender issues need to be addressed for effective therapeutic interventions.

Similarities in correlates of relationship commitment across gender, sexual orientation, and cultures
Charles Hill Whittier College, United States of America; Loredana Ivan; Rodrigo Carucedo Gonzalez; Claudia Brumbaugh; Maria Barros; Jose Canto y Rodriguez; Mie Kito; Guillermo Macbeth & Eugenia Razumieczyska; Silvia Mari
Correlates of commitment in intimate relationships were analysed using data from an on-going cross-cultural study of intimate relationships in multiple languages at web.whittier.edu/chill/ir. Measures include social background, attitudes and values, current intimate relationship (if any), and well-being. Students and non-students were recruited in countries in North America (United States, Canada, and Mexico), South America (Argentina and Colombia), and Europe (Spain, Italy, and Romania), plus others responded from elsewhere. Among the 2738 in these preliminary results, 70% were women, 72% were students, and 74% described a current relationship, of which 70% were opposite-sex and 30% were same-sex, including 11% opposite-sex marriages and 11% same-sex marriages. For both sexes, relationship commitment was positively correlated with measures of love, self-disclosure, expressions of affection, certainty of partner’s affection, parents and others knowing and approving of partner, relationship benefits, investment, communication frequency, closeness, and relationship satisfaction. This was true for students and non-students, opposite-sex and same-sex relationships, married and unmarried, and for samples in each of the eight countries with rare exceptions. Similarity on willingness to have children was generally correlated with commitment as well, except for gay men and married lesbians. Correlations between commitment and sexual activities were less consistent. In sum, the dynamics of relationship commitment were surprisingly similar in spite of presumed differences relating to gender, sexual orientation, and culture. Future data collection will include countries in Asia and elsewhere.

Saccharine mommies: The aggression hidden in mothering blogs
Elisabe Jordaan University of Johannesburg, South Africa; Chantal Waldeck

Implications for the study of social and relational aggression among adult mothers. Social and relational aggression in mothering blogs and forums is explored. Content analysis identifies gender-related themes in the data. The identified themes contain messages regarding the “rules” that define acceptable mothering and femininity. As within adolescent peer culture, power comes from the ability to invoke these norms. We call into question how expressions of social and relational aggression in mothering blogs and forums are associated with women’s agency and the good mother/bad mother discourse.
of masculinities has recently been popular in Turkey, the scope has mostly been on heterosexual masculinities. Little is known about the masculinity construction of gay men and its relation to identity formation processes. This project is designed accordingly to fill this gap in the literature and aims to propose a different and novel understanding of the concept of masculinities by focusing on gay men in Turkey. Within this scope, our research aims to understand how the perception and construction of gay masculinities relate to identity formation processes, and how these processes are experienced within the Turkish gay society. For this purpose, in-depth interviews were conducted with 15 Turkish gay men from various backgrounds, and questions related to the core issues of the masculinity perception and homosexual identity formation were addressed. Our findings revealed an interesting relationship between homosexual masculine identity and its actual experience in a Muslim society showing both overlaps and contrasts with internalised gender roles. These findings, by bridging the gap in the existing literature, are expected to contribute to masculinities studies and other related disciplines such as social psychology, cross-cultural psychology and gender studies.

Girls are to be seen, not to be heard: Linking child attachment, gender and poverty in understanding social trauma of Kutchi girls in post-earthquake Gujarat

Manasa Kumar, University of Nairobi, Kenya

The focus on children under vulnerable conditions in the context of everyday life offers great promise for enriching our understanding of how disputes over culture and forms of belongingness are enacted repeatedly and undramatically: here culture takes a living form rather than a fixed one. This paper is a part of a larger project that examines the psychological and social trauma of child survivors of the 2001/2002 Gujarat earthquake and riots. Interactions with Kutchi girls from the villages of Lodai, Khengarpur, Khavda and the outskirts of Bhuj enabled the researcher to explore the diverse ways in which gender structures the notions of childhood, and household work and domesticity define their identity. ‘Inhibition’, ‘absence’ and ‘invisibility’ of a certain kind were emblematic of their personalities. Keeping these themes in mind, a critical commentary on the narratives that emerged in Child Attachment Interviews (CAIs) with girl survivors of the 2001 Gujarat earthquake is offered. Attachment (‘anaclisis’ in Greek meaning ‘dependence’/‘leaning on’ and in Freudian ouevre often linked with the problematic of need vs. drives) is understood as a basic human survival need, embedded within a dialectical intra-psychic/inter-subjective matrix that pervades culture and socialization. Girls’ impoverished responses during the interviews were marked by long pauses, and socialization. Girls psychic/intersubjective matrix that pervades culture and forms of belongingness are enacted repeatedly and undramatically: here culture takes a living form rather than a carbon copy of the other. At one level the interviews try to tap into the nature of the ties between the children and their families; on another level these act as testimonies where differentiating narrative modes of thought from narrative discourse (Bruner, 2004) allows an exploration into the psychic vicissitudes of this language of absence and everyday existence marked by painful endurance. The paper develops these observations further to argue that trauma in the case of these girls is a continual disenfranchisement of their voices, needs and desires. Attachment trauma in these young girls is this inability and failure of their families to adequately nurture (psychological and social) capabilities (Sen, 1982; Robeyns, 2003) in the (girl) child and this ‘lack’ trauma has an intergenerational transmission and import (Lasub & Felman, 1992; Grubich-Simitis, 1994). The paper illuminates the symptoms the girls have become (being mute, stoic – multiple/ongoing – trauma survivors), and behind this symptom lies social deprivities such as gender discrimination and child-rights violations where the mother (and remaining family) is not only implicated but caught in the same rigmaole of patriarchal hubris.

Social gender perspective on women’s football in China, USA and Germany: Progress and problems

Bin Liang, CTBU, Chongqing, China

Society has accepted the variety of sports, in which both male and female athletes compete, regardless of the traditional gender sports notions of the past. But social stereotypes for male-dominated football have changed very little and fans, football players and clubs, football governing bodies, and massive media, eagerly pursue more and more physically completed football performances. The social stereotype for football has never been physically prevailed like today and labelled with speed, power, physical competition and match dominance. The stereotype is essentially masculinised and makes women’s football subordinate. The essay covered research on the history of women’s football in China, USA and Germany, and statistically analysed the population of women’s football. The three nations were important in women’s football, and there were different major reasons for their booming period. China benefited from earlier professionalisation. USA took advantage of Americans’ indifference to men’s football and successfully promoted women’s football stars like Mia Hamm. German should thank the popularity of women’s football at school level. However, like other countries, women’s football in the three countries faces a obstacles. The ways in which women’s football is packaged, played and supported, in the three countries showed that the social stereotype for football negatively influenced women’s football in cultural recognition, people acceptance, mass media attitude and professionalisation. The gender preference of social stereotype for football causes major obstacles to further development of women’s football.

Women who bear children through rape in Goma, Eastern Congo

Helen Liebling, Coventry University, United Kingdom; Henny Slegh

This paper outlines research assessing the role of stigma, justice and health provision for rape survivors that bore children in Goma, eastern Congo. Seventy-six woman survivors were interviewed regarding their rape experiences and of bearing a child from rape and the service responses. Thirty semi-structured interviews were carried out with police, legal and health officials and non-state providers. The findings were triangulated in discussion with key informants and survivors. Young women described rape, gang rape and sexual violence and their experiences of conceiving children. They disclosed rape by military forces, rebels, soldiers and civilians; many of whom had weapons. There was untold suffering and numerous untreated health problems. High levels of traumatic effects including stigma and shame were exacerbated by the complex emotion of bearing a child and rejection and abuse by families, husbands and communities. Despite the apparent end of the conflict, sexual violence continues at very high rates in eastern Congo. The numbers of adolescent women who require health and justice responses are very high. However, there exist very minimal services to respond to their needs and those of their children. Participants reported low levels of health care access with several challenges including limited treatment, lack of health facilities and infrastructure and lack of support and training for staff. Likewise there were severe weaknesses in the justice system and overwhelming challenges including logistical problems, bribes, threats to safety and impunity. Specific policy and service recommendations are made.

Development of the Chinese sex role inventory and comparing representations of sex roles between eastern and western cultures

Dianzhi Liu, Soochow University, China; Huxin Huang; Haoyang Cheng; Qi Huang

Due to the culture, region and time differences, there are concerns regarding the validity of Bem sex role inventory (BSRI) in measuring sex role perceptions in Eastern culture. This study constructed a Chinese sex role inventory. Based on social desirability for males and females, 90 items were selected by frequency analysis. With a sample of 351 Chinese college students (179 males, 172 females), 50 out of 90 items were retained via discrimination analysis and exploratory factor analysis. The sex role inventory includes 16 positive items for masculinity, 16 positive items for femininity, and 18 neutral and negative items. EFA indicated four dimensions (leadership, masculinity, rationality, generosity) under masculinity and three dimensions (empathy, femininity, thrift and careful) under femininity. Confirmatory factor analysis was conducted on a sample of 233 (106 males, 127 females) randomly selected from a pool of 5008 college students. The CFA successfully replicated the dimension structure identified above and the fit indices indicated a satisfactory goodness-of-fit. The Cronbach alpha coefficients of the Masculinity and the Femininity were 0.89 and 0.84, respectively. The test-retest reliability was 0.82 for the Masculinity and 0.80 for the Femininity, suggesting a good criterion validity. Comparing to BSRI, this research reflects differences in representations of sex roles between Eastern and Western cultures. Rationality in Chinese masculinity traits is distinct from individualism in Western masculinity traits. Apart from expressiveness, Chinese femininity traits are also influenced by traditional characteristics such as thrifty and carefulness.

Public service motivation: A gender perspective

Bangcheng Liu, Shanghai Jiao Tong University, China; Xiaohua Zhou
Public service motivation (PSM) refers to “an individual’s orientation to delivering services to people with a purpose to do good for others and society” (Perry & Honda, 2008a, viii). From a gender perspective, what are the differences of PSM between female and male individuals? Surveys of 730 master of public administration (MPA) graduates from a university located in Eastern China suggest that in general the PSM of male public servants is higher than the PSM of their female counterparts. However, when analyzing the specific dimensions of PSM, there are mixed results. Results indicate that male public servants score higher in attraction to public policy making and commitment to public interest and there is no significant difference in compassion and self-sacrifice between the female and male groups. The implications for the future research of PSM and human resource recruitment and selection in the public sector will be discussed.

‘Adolescent pregnancy’: A feminist issue

Catriona Macleod Rhodes University, South Africa

Pregnancy and mothering are enduring and central concerns of feminisms across a range of contexts. Despite this, there has been surprisingly little direct engagement by feminists in the area of ‘adolescent pregnancy’. In this paper I argue that both the relative lack of engagement of feminists in ‘adolescent pregnancy’ and the manner in which some have engaged with the issues surrounding early reproduction must be seen as strengths. Refusing to acknowledge ‘adolescent pregnancy’ as a separate reality from the reproductive lives of women who find themselves in similar socio-economic, cultural and racialized circumstances must be balanced with the fact that ‘adolescent pregnancy’ has become a real phenomenon in the sense of being a socially constructed reality that is taken up in social policy, educational reforms, sexuality education initiatives, health and welfare interventions and public concern. In light of this, the question that this paper addresses is how feminism(s) should respond to research, practice and policy regarding ‘adolescent pregnancy’. Utilizing a post-structural, postcolonial feminist framework I argue for a twin approach to ‘adolescent pregnancy’: vigilance with respect to the power relations that the very notion of ‘adolescent pregnancy’ and the associated research and interventions, allow; advocacy for pre-, ante- and post-natal care and interventions that are attuned to localized gendered dynamics and that are aimed at empowering young women.

Love and happiness in young Black men’s lives

Mandisa Malanga UNISA-Medical Research Council, South Africa; Kopano Ratele

South African literature shows that, relative to other groups, Blacks, specifically Black males, are at heightened risk of various psychological, social and economic problems. Two problems with these studies are that they tend to approach Black men from a risk and deficit perspective, and the models of masculinities uncritically applied in assessing Black men’s behaviour are imported from the West. A few studies have gone beyond a risk approach, calling attention to alternative discourses of manhood and questions related to how good Black men are built.

In the present study, which centralises a critical and transformative approach in understanding the making of generative masculinity in African traditions, we delve into the significance of positive emotions in the construction of masculinities. The study examined the place of love and happiness in constructions of masculinities. Participants in and outside of steady heterosexual relationships were recruited. In order to understand the influence of traditions on meanings men give to their emotional and gendered lives, we looked for subjects who had recently moved from rural to urban areas to compare with those born in urban areas. Adopting feminist qualitative methodology, men were interviewed individually as well as in focus groups. A culturally-informed critical discourse analysis was used to analyse the material. We present some of the findings as to how love and happiness are understood, whether they are seen as important, and what role they play men’s lives and constructions of masculinity.

Puberty experiences of Xhosa males from two universities

Nyameka Mankayi University of the Western Cape, South Africa

The paper explores how a group of young Xhosa men construct their masculinity and sexuality. It further explores the meaning of masculinity and the narratives of puberty and initiation into adulthood. The findings presented here emerge out of a larger study which explores how Xhosa males construct their puberty experiences and how these concepts impact with their risky sexual practices. This study uses a retrospective life story method to describe the connection between reported bodily changes during puberty and constructs of masculinity and sexuality. The sample was drawn from two universities, one in the Eastern Cape and the other in Kwa-Zulu Natal. Individual interviews were conducted with 18-25 year old Xhosa men enrolled for undergraduate studies. There were 20 men who were purposefully drawn from the list of students registered in the School of Psychology from the two universities. Each of the interviews was analysed using a discourse analysis framework informed by a social constructionist approach. The findings from this study illustrate how these young men’s responses and perceptions of the puberty stage intersect with contemporary and shifting constructs of hegemonic masculinity and are mediated by cultural rituals, particularly circumcision. An association between masculinity, puberty stage, circumcision and risk-taking behaviour has emerged.

Women overcoming barriers in science and technology careers: A social cognitive perspective

Marinda Maree University of Pretoria, South Africa; David Maree

This paper briefly discusses structural and individual barriers responsible for the under-representation of women in Science, Engineering and Technology (SET). However, it is pointed out that the focus on the removal of structural barriers does not guarantee success for women in SET careers. The paper emphasises social-cognitive factors, such as self-efficacy, that contribute to the success of women in SET. The results are briefly illustrated with reference to a study done with a sample of 29 women in successful ET careers in South Africa. These women experienced some form of gender discrimination at some stages of their development from school to career. They also struggle with family and work-life balance and similar issues. The women attributed their success to personal characteristics and strong self-efficacy beliefs. Aspects such as a drive for achievement, strong goal orientation, passion for their work, determination and perseverance were identified. Strong self-efficacy beliefs which can be associated with resilience seem to contribute to success despite structural and some individual barriers.

Indenturing the body: Masculine role norms, body image discrepancy, and attitudes towards masculinity in South African Indian school-going boys

Jarred Martin SANDF, South Africa; Samantha Tornell

The authors investigated the relationship between traditional masculine role norms, body image discrepancy, body appearance schemas, and sociocultural attitudes towards appearance in a sample of 495 South African Indian school-going boys, between the ages of 13 and 18 years old. Employing self-report surveys, the constructs were measured using the Masculine Role Norms Inventory, Lynch and Zellner’s Body Figure Drawings (1999), the Appearance Schemas Inventory, and the Sociocultural Attitudes Towards Appearance Scale-3. The findings showed how a sample of South African Indian boys is (re)defining a localized masculine sense of self within the broader interplays of South African gender relations and masculinities. Analysis revealed traditional masculine role norms of status-seeking, heterosexism, anti-femininity, emotional stoicism, and nontraditional masculine attitudes shared significant positive correlations with body image discrepancy. Sociocultural attitudes towards appearance and investment in body appearance were key ingredients for participants positioning an athleticism toned and muscular male body as their ethnomorphological ideal. This body ideal also coincided with participants’ perceptions of the muscular male physique in Bollywood cinema and the body perceived to be most desired by the opposite sex. Further, steroid and muscle-supplement use were identified as risk behaviors associated with support for a masculinised, traditionally masculine subjective and normative agenda. The authors recommend continued qualitative and ethnographic research which extrapolates the complex trajectories of ethnomorphology as a central reference point for masculinities in gendered and racialised South African identity.

Queering gender: An exploration of the subjective experience of the development of a transgender identity

Christine Mclachlan Fort Napier Hospital KZN Health, South Africa; Graham Lindegger

This study aimed to explore transgender people’s experience of the development of their transgender identity. The research used a phenomenological approach to explore the lived experience of five individuals who believe that they are the opposite gender than their birth anatomical sex. Critical turn-
ing points in their gender identity were identified, and the influence of spirituality/religion on the development of their transgender identity explored. The findings showed the uniqueness and complexity of the transgender participants’ lived worlds. The findings suggest that the research participants experienced themselves not only as marginalised, but also between the feminine/masculine gender categories and the female/male sex categories. Their dominant lived experience is of being in an in-between state. Religion/spirituality were found to have a varying impact on the development of a transgender identity. Sex reassignment surgery emerged as only one possible phase in the treatment of the transgender individual. Further therapy and support are necessary as not all the problems are alleviated through surgery, and new psychological challenges emerge during the transitioning and post-transition phase. The lived experience of these transgender individuals challenges the Western dichotomous view of sex and gender and the discourses that are constructed in order to uphold the gender binary. The findings suggest that a distinct space in society needs to be created for the transgender individual. Re-visionsing gender as more fluid and variant than the binary structure acknowledges the possibility of much more than two genders and the possibility of in-between states of gender.

Do successful women politicians maintain more feminine values and traits compared to their male colleagues? 
Minou Ella Mebane Università La Sapienza, Italy; Michele Vecchione; Donata Francescato
Women are still greatly under-represented at the top of political institutions (Stokes, 2005; Stevens, 2007). Personality theorists have suggested that in this era of personalisation of politics dispositional characteristics of politicians may contribute to political success (Jewell & Whicker, 1994; Caciagli & Corbetta, 2001; Rosenthal, 2004; Barisone, 2000). Theorists of politics of presence hypothesise that it is especially important to have women politicians because being females they bring a different set of values and characteristics. These values come to shape party manifestos and political issues (Phillips 1995). According to the critical mass theory, when women politicians are only a minority, successful political women, tend to accept the culture of dominant group (Kanter, 1977b, p. 231). Our research aimed to investigate whether in the Italian political context, which is male dominated: the minority of women elected to Parliament and local offices continued to hold feminine values and traits compared to their male colleagues or had similar values and personality traits. Two hundred women and men members of the Italian Parliament and the three-hundred local politicians completed standard questionnairenaires, aimed to assess their basic personality dimensions (BFQ, Caprara et al. 2003) and personal values (PVQ, Schwarts, 2005). Results are evaluated and will be discussed at the convention.

Gender equality as a maturation process 
Patricia Mercader Université Lumière Lyon 2, France
Recently, a sociologist colleague confided in me that she has always asked herself how one can be both a psychologist and a feminist. As this is how I define myself, as well as many colleagues, I was quite astonished. It is not that difficult, I argued, if we admit that integrating the idea of gender equality requires a certain degree of acceptance of alterity. That is to say, a level of psychic maturation difficult to attain in any case, but especially difficult within a social environment where this idea is far from being obvious and within a political system that renders this maturation process particularly difficult. And yet, this sociologist did not have it all wrong. The relationship between psychology and feminism sure enough gives rise to a number of problems, particularly when psychology leans towards a psychoanalytical meta-theory. Between a feminist analysis of society and a clinical interpretation of the future of the individual, their compatibility is not self-evident. Within a contemporary feminist perspective, gender is not only defined as the psychosocial side of the differences between the sexes but also as a system of differentiation that produces social identities that serve relationships of domination. In this way, gender precedes sex which is before anything a sign which renders visible the dominant from the dominated. However, for psychoanalysis, the difference between the sexes, in its material corporeal fundament, is first a psychic feat which signifies loss, incompleteness, and castration in the sense that no human can be ‘all’ for another or themselves, nor be, by default, absolutely identical to others. Indeed, psychoanalysis advances an essentially tragic idea of human development: Confronted with the necessities of our maturation in conditions that are more or less desirable, we unknowingly make choices that determine our psychic future. These choices are always creative and always imply sacrifices. In other words, here, being a man or a woman, masculine or feminine is not political but rather libidinal and proper to childhood. How can one articulate the disjunction between biological sex and political gender with the psychoanalytical distinction between anatomical sex, unconscious sexuality and the dynamic of identifications? By showing which processes, albeit full of obstacles, allow individuals, like societies, to access equality between men and women, I will attempt to propose some preliminary answers to this question.

A discourse analysis of young men’s engagement with popular representations of brotherhood 
Sibongiseni Mkhize Rhodes University, South Africa
This paper presents an analysis of the discourses employed by young, South African black men when they engage with popular representations of brotherhood. In particular, participants in this study were shown extracts from episodes of the popular soap opera ‘Generations’ that depicted the relationships of two fraternal dyads, one representing men who were raised during the Apartheid era, the other being men who were raised during the post-Apartheid era. A focus group discussion was then facilitated in which the men were asked to comment on the depictions of brotherhood and to compare and contrast their own experiences of brothering with those shown on TV. The focus group discussion was analysed using discourse analysis. In particular, the analysis is interested in the discourses the men employ in constructing brotherhood and how these discourses enable and also subjugate particular masculine subject positions. Emphasizing the discourses at work around ‘doing brother’ and around ‘doing man’ can be taken to other men through avenues such as the media to be used in working with social action groups that work with men and aim to bring about social change in men.

Trauma of the transgender family 
Carol Muskashan UNISA, South Africa
The subject of the paper that will be presented, is the trauma experienced by transgender family members, and how they cope with this trauma. Semi-structured interviews were conducted with various family members (immediate family and care givers) of the transgender person, in order to ascertain what trauma they experienced during the disclosure, and transition, of their transgender child/sibling/grandchild, as well as how they managed to overcome, or deal with, their specific trauma. The number of families interviewed are 10 families consisting of two or more members each. There is also a focus group of six members. The types of trauma that transpire, from this disclosure, are also highlighted as well as what influence religion, cultural and socio-economic situations have on either creating, maintaining, increasing or maybe even overcoming this trauma. The fact that the researcher is also the mother of a transgender child, contributes to the richness of this research paper. This research is conducted within Family Systems Theoretical framework. Sampling is purposeful sampling, interpretative phenomenology and content analysis are used in order to interpret information obtained.

Sex differences in the manifestation of aggression on internally displaced Nigerian children 
Agatha Ogwo Nasarawa State University Keffi, Nigeria; Solomon Mumuh; Chinwe Iheach
The study was carried out to determine the role played by sex differences in the manifestation of aggression among internally displaced male and female children. Participants (N=445) aged 10-15 years and drawn from two communities in Nasarawa State, Nigeria, namely, Bassa and Igbirra, were involved in the study. Aggression in children was measured by a 19-item questionnaire developed by the researchers to test the hypothesis that there will be no statistically significant difference in the manifestation of aggression between internally displaced male children and their female counterparts. A 3-way between groups ANOVA was used to establish the differences. Results indicate that Nigerian children did not show significant difference in their manifestation of aggression based on gender. These findings seem to suggest that armed conflict and its consequences, like internal displacement is a threat to children’s general well-being because of the disruption of the environment in which they are socialised. The unfavourable conditions which children are subjected to irrespective of their sex make sexual affiliation irrelevant in the way children react to situations.

Skateboarding boy vs rugby jock: Queering hegemonic Afrikaner masculinity 
Qui Leong Pun University of Johannesburg, South Africa
This paper aims at exploring gender within gender “othering” based on the lived experience of a young male student in the context of hegemonic Afrikaner masculinity. The paper further aims to understand how this gender within gender “othering” may have impacted on the father-son relationship and the developmental consequences on the individual. Queer theory and Social Capital theory informed this study. A phenomenology case study design was used. A Queer phenomenology research approach informed the design and research. Data were collected through two in-depth qualitative interviews and therapeutic process notes. Data analysis will be conducted using an Interpretive Phenomenological Analysis.

Subordinate men without fear
Kapano Ratele University of South Africa/MRC, South Africa

Studies on homicide in South Africa indicate that young black and coloured males are the most vulnerable. Among the explanations offered for the preponderance of these groups in homicide high-lights is the role of a certain form of masculinity. The argument mounted in this essay is that while programming against violence victimisation and perpetration has to incorporate amongst others issues socioeconomic justice and gendered sexual rights to be effective, levels of fatal violence remain high because interventions still have to confront the historical and contemporary emotional health concerns affecting young black and coloured men. Foregrounding the relationship between young men’s emotional lives and deadly violence I tease out the critical role of emotions as an underappreciated consideration. I particularly explore the interplay of fear and fearless in the construction of masculinity. In conclusion I recommend that programmes on emotion regulation and connectedness be developed and tested with a view of incorporating them in intervention frameworks.

Male ballet dancers’ gender identity construction: Sexuality and body
Megan Reeves University of the Witwatersrand, South Africa; Lynlee Howard-Payne University of the Witwatersrand, South Africa

Male ballet dancers are often constructed as being feminine or homosexual (Bailey & Obershneider, 1997; Phillips, 2008), attributes that do not conform to the broader social ideas of what it means to be a masculine male in South Africa. Therefore, the space occupied by male ballet dancers in South Africa is one that contradicts the patriarchal ideas of masculinity and is one that provides further insights into constructions of masculinity that do not conform to essentialist understandings. Therefore, the aim of this research report was to investigate the ways in which male ballet dancers construct their gender identities, sexualities and bodies within this contradictory space. A purposeful sample of four classically trained male ballet dancers over the age of 18 from Johannesburg, South Africa, were invited to participate in the study by means of snowball sampling. Data was collected using a semi-structured interview, and examined using narrative analysis. These results contributed to a better understanding of gender in an alternative domain, where the ways that male ballet dancers construct their gender identities are challenged.

Gender perspectives in care services treatment of Brazil’s child and adolescent mental health users
Alberto Reis Universidade de São Paulo, Brazil; Camila Muyloert

The paper analyses the gender determinations in diagnosis construction and the composition of populations receiving care at Psychosocial Care Centers (CAPSi). The research involved all CAPSi’s of Sao Paulo state (23% of Brazilian CAPSi’s). The research is a cross-sectional study, based on a random sample of records, during the period September 2008 to February 2009. The inclusion criterion in study was: Active records registered in the Health Ministry, until three months before the date of collection. To obtain the data record, a protocol was prepared with 58 questions. A questionnaire was given to CAPSi managers to complete. Of the group of children and adolescents attended to in CAPSi, 69.7% (634) are male and 30.3% (275) are female. Female users of CAPSi tend to be older than male users. More frequent diagnoses for boys refers to behaviour disorders and emotional disorders (29.5%), psychological development disorders (23.2%) and retardation disorders (11.7%). Diagnoses for girls are mood disorders (16.7%), retardation disorders (14.6%) and psychological development disorders (12.0%). The consultant’s reasons are homogenous for both sexes, with the exception of differing aggressiveness variables and social behaviour problems (82.49% for boys and 71.64% for girls). Data was analysed with reference to Winnicott, and Gillingan theories about gender moral development. The diagnostic construction and the sexist composition of the CAPSi population (which reflects the gender bias) are in synergy with the “ invisibility” of the psychological distress of girls. The study emphasizes the importance of disorder in school and behaviour associated with male children and adolescents.

Photographic representations of masculinity by young men
Nivedhna Singh University of KwaZulu Natal, South Africa; Graham Lindegger

Young masculinity has become a research priority by young men and women. The paper provides a rich description of what it means to be a brother for young men in South Africa today through the use of in-depth individual interviews. The data is subjected to a thematic narrative analysis (Riessman, 2006) in order to interrogate how brothering is informed by constructions of masculinities and how, in turn, the brother-brother relationship constructs young men’s masculine identities.

The impact of employment in the mental health of Hispanic women
Valerie Stipes Carlos Albizu University, Puerto Rico; Jose Martinez; Jessica Robleda; Aida Jimenez

Puerto Rico is presently in a period of economic depression, which has instigated an increasing rate of unemployment. Many studies show that the stressors created by unemployment have negative consequences on mental health, but few studies have evaluated the psychological impact of employment status in women. This study explores the relationship between employment status and depressive symptomatology among Puerto Rican women. Depressive symptomatology was assessed with the Center for Epidemiologic Studies Depression Scale (CES-D). This ex post facto design study acquired a sample of 113 employed, as well as unemployed women. The results showed that unemployed women had a statistically significant higher mean of depressive symptomatology and a higher mean of prior diagnosis of depression, than their employed counterparts. The majority of women in the sample were the primary support and caregivers in their family, and unemployed women,
more often, carried on the same responsibilities without a domestic partner. Unemployed women had higher dropout rates and less education. Although employed women had more years of preparation and had statistically significant higher earnings, only five thousand dollars separated one group of women from the other in terms of classifying under the federal poverty line. This study is a stepping-stone for further research in trying to understand the impact of employment for Puerto Rican women and how are they being affected by the current economic crisis in Puerto Rico. This work is also oriented towards government activation to service the mental health needs of unemployed women.

**Homo-motherhood: One among other ways to be family**

Marlene Strey; PUCRS, Brazil; Teresa Cristina dos Santos; Yoolara Palma; Aline Piasson

The advent of feminism and LGBT movements reinforced the existence of families composed of plural identities, showing other ways to be family in the present. Among them, we highlight those formed by two women who identify themselves as lesbians and their daughters and sons, considering that the present study has as its main objective to know then, homomotherhood and its implications. From the perspective of gender studies, we aim to understand how lesbians are experiencing motherhood in their conjugal relations. Therefore, we analyzed the experiences in the process of motherhood, family dynamics and lesbian marital relations associated with motherhood. Of qualitative stamp, were heard, for the research, eight women, through narrative interviews. After the interviews were recorded (by signing the Free and Clear Consent Term), the contents were subjected to discourse analysis considering the feminist theories of gender. The results showed the existence of a family dynamic quite similar to a heterosexual one, even equal in a couple of cases. Furthermore, we found that homomotherhood families are living satisfactorily their relationships of lesbian maternity, but, despite the progress of human rights in the quest for a society with greater respect and justice, we even realize that compulsory heteronormativity is something strongly present. Finally, we consider an expansion in the way of being and thinking about families, but many roads still have to be traversed.

**The impact of gender harassment on job-related behaviours in the Japanese workplace**

Ken’ichiro Tanaka; Graduate School of Nihon Univ., Japan

The present study examined the effect of gender harassment on Japanese females’ job-related behaviours (i.e., organizational citizenship behaviour, OCB and organizational withdrawal behaviours, OWB) in the workplace. The online survey was conducted using a web system. Participants were 500 Japanese female workers as respondents in this study. Results of SEM linking the frequency of experiencing gender harassment to job-related behaviours indicated as follows: (1) The more frequently Japanese female workers experienced gender harassment, the more they performed both OCB and OCB. (2) The higher female workers evaluate interactional justice, the more they would perform OCB. (3) The hypothesis, that the more frequently female workers experienced gender harassment the less they evaluated interactional justice, was supported on the model of the omission of the dimension of gender harassment, but not supported on that of the commission one. (4) The hypothesis, that the lower female workers evaluate interactional justice the more frequently they would perform OWB, was supported only on the commission model.

**Boys are like rocks: Negotiating masculine identities in a co-educational secondary school.**

Leigh Andrea Adams Tucker; HEARD, South Africa; Kaymarlin Govender

An ethnographic approach was employed to describe the way in which early adolescent males construct, and enact, their masculine identities within the co-educational secondary school. Observational and reflexive field notes were supplemented with four focus groups conducted with 20 Grade 8 male learners. Issues of group belonging and identity are particularly heightened amongst the Grade 8 population following the transition from primary school. Within these friendship groups, the young men identified multiple spaces in which masculinities are policed and challenged, and bullying tactics are normalised in the struggle for hegemonic masculinity. Through the emergent discourse of the embodied self, value was assigned to the male body as a tool to inflict or withstand violence. Signifiers of physical strength and performance were aligned with desirable masculinities and identified through sport, bullying, initiation and corporal punishment. As with school policy, sport remains the primary acceptable space for exercising masculine ideals. In the context of these restricted school spaces and expanding ‘sexless’ cyber technologies, young men also described a growing sense of displacement fuelled by a perceived female advantage and a fear of racial insensitivity. In response to this anxiety, reactionary and defensive positions were enacted with repeated accounts of objectifying, splitting and othering. Recommendations generated from the findings include a need to facilitate productive spaces within the school for the critical discussion and negotiation of gendered identities for all learners.

**Sex differences in mating strategies: A biological or a social phenomenon?**

Wim Waterink; Open University of the Netherlands, Netherlands; Janes Eshuis

Men usually report a higher preference for short term mating strategies than women. Explanation of this phenomenon is debated, with evolutionary psychologists claiming it to be the result of a difference in sex drive between the sexes, explained by theories of sexual selection and parental investment. An alternative hypothesis is that these differences are the result of social structures. According to this hypothesis, women pursue short term mating strategies less than men, because they enjoy less autonomy. This study aims to contribute to clarification of this debate by empirically testing these hypotheses against one another. A random sample of people from the Netherlands was invited to take an online survey measuring mating strategies, sex drive and autonomy. 206 people responded; 44% were male, 56% female; age ranged from 21-65 (m = 36). Men pursued a short term mating strategy more than women. Multiple mediation analysis revealed that the effect of sex on short term mating was completely mediated by sex drive, with the direct effect vanishing once sex drive was introduced into the model. Autonomy had no such effect. In general, these results support the hypothesis that sex differences in mating strategies are primarily a biological phenomenon. This study is not entirely conclusive, since the sample used is not universal, and because social factors other than autonomy have not been taken into account. However, within these limitations the evolutionary account seems the more likely explanation.

**Relationships among work family conflict, gender role attitude and job burnout**

James J-M Sun; Remnin University of China, China; Yuan Li; Jian-Min Sun; Rui Wen

This study investigated the relationship between work family conflict and job burnout as well as the moderating effect of gender role attitudes among them with the on-site survey data about white collar workers in different organizations. Questionnaires including standardised scales (validated with Chinese samples) were distributed to 350 employees and 310 were returned, 275 of which are valid (138 are male). The sample is a good representative of employees in the workplace in terms of gender, age, and education level. Descriptive, correlation, and hierarchical regression are conducted to test the research hypotheses. Results demonstrated that: (1) Work-family conflict positively predicts emotional exhaustion and cynicism and negatively predicts reduced personal accomplishment, (2) Family-work conflict positively predicts the three dimensions of job burnout, emotion exhaustion, cynicism and reduced personal accomplishment, (3) Gender role attitudes moderate the relationship between work family conflict and job burnout. Specifically for those with more traditional gender role attitudes, the negative effect of family-work conflict on reduced personal accomplishment is stronger. The positive effect of work-family conflict on emotional exhaustion and cynicism is greater for those with more equal gender role attitudes. However, for those with more equal gender role attitudes, the positive effect of work-family conflict on reduced personal accomplishment is stronger. Tentative explanations for the results are provided. Both theoretical and practical implications and the limitations of the study are discussed and future research directions are pointed out.

**Perfectionism and values: Professional and gender aspects**

Julia Babaeva; Lomonosov MSU, Russian Federation; Nataly Rotova; Yuliya Briseva; Marina Markina

Despite perfectionism and values being considered to be important personality traits influencing professional efficiency, data revealing their relationships and determinants are insufficient. We hypothesized that these relationships are mediated by gender and professional factors. Given this as
Gender wage difference has been increasing in China recently. In this study, we focus on occupational stereotype and its influence on the wage assigned to masculine and feminine jobs. One hundred and ninety-three undergraduate students (86 male, 107 female, average age: M = 20.11, SD = 9.2) participated in the study. And then, we used 2 × 3 between-subjects design to examine whether participants would assign different wages to different types of jobs: gender assigned to target job (masculine, feminine) × income level of job (high, medium, low). The result revealed that the salary allocation on the “masculine” domain jobs was significantly higher than those perceived as “feminine” domain jobs. This result is on the straight line with the shifting standards model, and can be interpreted from Chinese contemporary occupational gender stereotype.

**Girls and boys’ choices of courses in higher education in France**

Christine Fontanini University Montpellier 3, France

There are still differences in the selection of courses of girls and boys in higher education in France. Nevertheless, for the last 20 years or so girls have chosen several more subjects that were previously mainly chosen by boys. In order to attempt to explain the ‘new’ choices of courses and careers of girls, we have taken veterinary studies as an example. Currently, women represent 72.6% of the students enrolled in the professional training programs (EACEA, 2009). What are women’s motivations for this course of study leading to a veterinary career? Why are men leaving this profession even though in France, forty years ago, it was mainly the domain of males? In order to attempt to answer these questions, we carried out a questionnaire-based survey in 2008 with 119 students (90 women and 29 men), enrolled in scientific preparatory classes biology, chemistry, physics and earth sciences with the objective to enter a veterinary school. We can consider that this female choice is partially based on the fact that compared to boys, girls have ‘acquired’ a certain knowledge of the veterinary profession through training with professionals. We can readily speak of ‘early’ professional socialization for girls. We have noted that girls wish to steer themselves towards these studies for “sentimental reasons as well as a passionate personal interest” whereas boys show motivations which are “technical or financial”. The latter can be found in other professions whereas caring for animals for “sentimental reasons and passionate interest” could be observed in few professions.

**The influence of occupational stereotype on gender wage difference**

Gender wage difference and the socialisation of girls towards animals in France

Christine Fontanini University Montpellier 3, France

The aim of this research is to measure the correlation between the aspiration of female riders to practice a veterinary career and equestrian riding, the reading of magazines and novels with equines. However, equestrian riding conveys more than just a good relationship with horses. It leads to the caring of the animal which can instigate a professional vocation oriented towards animal or horse care. I can esteem that equestrian clubs are true breeding grounds for future veterinarians. Considering that for the past twenty years there are more girls than boys that ride, it is logical to ascertain that girls are more attracted to the veterinary profession. If I add to these results, the socialisation of girls towards animals through toys, games, magazines, and books, there are grounds to believe that there will be more and more women signing up for veterinary school entrance exams.

Mate choice and marital success in a modern Japanese society

Yasuyuki Fukukawa Waseda University, Japan

The purpose of this study was to examine age and sex differences in mate choice strategies, as well as their relationship with lifetime marital success, through analysing survey data of a modern society. The original source of the data was the National Family Research of Japan: Special Survey 2001 (The National Family Research committee of the Japan Society of Family Sociology, 2001). The study sample was composed of 3,309 Japanese middle-aged and older women (mean age 53.9 ± 12.5 years old). Results show that women (i.e., the participants) preferred men (i.e., the participants’ husband) who are, on average, 2.9 ± 3.6 years older. The later men got married, the larger was the age difference, regardless of whether it was the first marriage or third marriage for them. In females, on the other hand, it was only the first marriage that followed the strategy; there was no decreasing nor increasing age difference between them and their mates in the case of remarrying. In addition, a woman who married a man younger than herself was at a higher risk of divorce compared to a woman who married an older man than herself (odds ratio = 2.1, p < .01). Thus, age preference in the mating of an older man and a younger woman would be adaptive as a reproductive strategy in both sexes in general, so that marital success could be related with preference. Remarrying women, however, might follow other mate choice strategies for reasons other than reproduction.

Sexual script and sexual double standard: A study from four tribes in Sumatera and Java, Indonesia

Matriussy Hermita Gunadarma University, Indonesia; Wahyu Rahardjo Gunadarma University, Indonesia

Sexual script and sexual double standard are concepts that are constructed by culture and values in the society. It is very interesting to see sexual script and sexual double standard in people from different tribes. Indonesia has many different cultures and tribes and might have different points of view in terms of sexual script and sexual double standard. The aim of this research is to measure the correla-
tion, contributions to the literature, and comparison of sexual script and sexual double standard in Batakense, Melayu-
nese, Betawinese, and Javanese tribes. The partici-
pants in this research were 205 people from Medan, 
Samosir, Jakarta, Yogyakarta, and Klaten. The sam-
ple was compiled using incidental sampling. The re-
sult showed that sexual script has a positive cor-
relation and has a significant contribution to the 
sexual double standard. There is a significant sexual 
double standard differentiation based on tribes and 
confession to having a past affair, but not in sexual 
script. There is a significant sexual script differen-
tiation based on educational background. On the 
other hand, differentiation of the two variables was 
found based on gender and the city of residence. 
Furthermore, males scored higher than females. 
This result indicates many interesting factors. The 
city where participants live has a more significant 
impact in influencing sexual script and sexual dou-
ble standard than does ethnicity itself. Furthermore, 
marital status has no influence on sexual script and 
sexual double standard.

Gender-role conflict and the media 
Jarrod Israelstam University of the Witwatersrand, 
South Africa
The media has always been an institution inseparable 
from the rest of society. Where there have been soci-
ties, there have been ways of discussing and 
representing information that is key to constituting 
them through media. It has been argued that gender 
identities are informed by such representations in 
the media, but relatively little research has focused 
on male gender identities. This study aimed to invest-
igate what effects exposure to short video clips taken 
from popular media had on young, urban South 
African men’s gender-role conflict. This was so as 
to gain a better understanding of ‘snapshot’ media 
effects. A within-subjects and between-subjects, pre-
experimental research design obtained ethical clear-
ance to gather a sample of 77 undergraduate students, 
who completed the Gender-Role Conflict Scale 
(GRCS) in a pre-test. 52 completed a post-test 3 
weeks later after watching 3 video clips that repre-
sented non-hegemonic forms of masculinity. Analy-
sis of Variance and t-tests were used and it was found 
that religion, race and mother’s education had an 
effect on scores on the GRCS. The findings indicated 
that further investigation should be conducted regard-
ing theories of hegemonic masculinity, as well as 
theories of media effects on gendered identities. The 
study may also inform university gender-education 
campaigns. There are several university societies for 
which the results would be useful, such as the LGBTI 
society, Wits Activate. National social programmes 
which may be able to act on these results include the 
Brothers for Life campaign, which seeks to change 
masculine stereotypes.

Exploring the relationship between hopeless-
ness and suicide risk in male homosexuals 
Ummi Habiba Jasmine Scottish Livingstone Hospi-
tal, Bangladesh; Rofajul Royal; Shamsul Haque; 
Muhammad Mozumder; Md. Ashikul Haque 
Suicide risk is quite common in male homosexuals. 
Studies suggested that hopelessness as measured by 
Beck Hopelessness Scale (BHS) predicts the 
chances of attempting/committing suicides in a 
number of Western cultures. The present study was 
an attempt to examine the relationship between 
these two variables in male homosexuals. The study 
included 102 male homosexual participants taken 
from an NGO based at Dhaka, Bangladesh. History of 
suicide attempt was reported by 32% of the 
participants while 47% reported history of suicidal 
ideation. BHS score indicated 34% MSM at risk of 
suicide (using 9 as cutoff score). Although associ-
ation was found between ‘BHS indicated suicide 
risk’ and ‘history of suicide attempt’ was found (c2 
= 4.35, a = 0.05) but closer inspection of the 2X2 
matrix revealed that BHS was able to identify only 
49% of 33 suicide attempters as at risk of suicide. 
However, BHS also identified 28% as at risk of 
suicide among those who never attempted suicide. 
Finally it can be concluded that in relation to history 
of suicide attempt, BHS was correct in 65% of 
cases. No relation was found between ‘BHS indi-
cated suicide risk’ and ‘history of suicide ideation’.

Gender differences in knowledge of male 
cancers among university students at Mon-
ash, South Africa 
Ravayi Marindo Monash South Africa, South Africa; 
Geoffrey Setswa Are female students more knowledgeable about 
causes and symptoms of male cancers than male students? Our study used a quantitative questionnaire 
and explored gender differences in knowledge of 
neutral cancers among 1,000 male and female students at Monash South Africa. Preliminary results showed 
that females significantly higher levels of knowl-
edge of symptoms and causes of male cancers than 
males. However, understandably, males had more 
detailed knowledge of what a testicular self exami-
nation reveals than females. Results also showed that 
female students relied more on health professionals 
as sources of information on health and disease, 
while male students relied on internet and magazines. 
Results however must be treated as preliminary until 
more detailed analysis has been completed.

Making muscle junkies: Investigating tradi-
tional masculine ideology in South African 
adolescent males 
Jarred Martin SANDF, South Africa; Kay Govender 
The authors investigated the relationship between 
traditional masculine ideology, body image discrep-
ancy, self-esteem, and the pursuit of muscularity in a 
traditional masculine ideology, body image discrep-
ancy is more severe than their Black and White coun-
trateens in the sample. Further, there was a significant 
use of muscle supplements and steroids by school 
going boys. The authors recommend that the perva-
sive use of muscle and fitness supplements, and the 
destructive use of steroids, should be further investi-
gated to explore boys’ motivations for such behav-
ior, as well as to extrapolate race differences in 
steroid abuse. The evidenced use of steroids by school 
boy rugby players should also hold interest for au-
thorities to monitor more closely accurate dietetic 
information that is made available to these boys and 
regulation drug-testing at school boy level rugby.

Gender biases in the perception of 
aggression 
Shradha Mathur University of Delhi, India
The study was conducted to understand the opinions 
and attitudes of young males and females toward 
aggression and gender biases in the perception of 
aggression. The sample was incidental and purposive 
and data was collected from 12 participants (N=6 
Males; N=6 Females), University of Delhi students, 
within the age range of 21-23 years, using the tech-
tique of interviewing. Participants were asked ques-
tions on issues related to gender and physical char-
acteristics, media projection of gender, social display 
of aggressive behavior, situational factors, parenting 
and attraction and anger provoking situations. Results 
indicate that the groups believed that men are 
more likely to engage in acts of physical aggression 
and violence, whereas women involve themselves in 
threaten, verbal abuse and rumors. In addi-
tion, both the groups associate characteristics of mas-
culinity, power and strength with male action heroes, 
and would prefer watching a male hero in lead action 
role as compared to a heroine. Participants agreed 
that parenting differences exists between the two 
groups regarding the expression of aggression in 
shaping the behavior of children where mothers are 
seen as emotional and scolding and fathers as aggres-
sive, firm and focused to the problem in hand. Fe-
male participants believe that men engage in aggres-
sion to overcome feelings of emotional insecurity 
and showcase their physical strength, which is masculin-
ity for them. Male participants believe that women 
are emotional by nature and should avoid hostile and 
aggressive actions since they are not expected to be 
physically aggressive and must safeguard themselves.

Gender based violence attitudes and prac-
tice: Study in Tzaneen municipality, 
South Africa 
Violet Mathye University of Venda, South Africa
The crime statistics released by the South African 
Police (SAP) in 2009, indicated an increase in sexual 
offfences which stood at 71,500 cases in the 2008/ 
2009 financial year. From July 2009 to June 2010, 
close to 40,000 cases of rape were enrolled for the 
first time in magistrate courts around the country. The 
research focused on assessing the knowledge, atti-
uides and practices related to gender-based violence, 
which informs developing appropriate empowerment 
strategies. The objective of the study was to deter-
mine knowledge, attitudes and practices about gen-
der-based violence. Methods included in the study 
were the selected two villages, Mariveni and Mbam-
bamencisi, where a door-to-door campaign was con-
ducted. Domestic violence, sexual abuse including 
incest, assault, and rape are rife. An exploratory 
qualitative approach was used. Two focus groups 
were conducted and information was recorded, and 
later transcribed. Thematic analysis was used to an-
alyse the data. Participants generally had an under-
standing of violence, but acknowledged it was diffi-
cult to report it. They showed good knowledge on the 
types of abuse, including sexual abuse of children
and the elderly. Lack of confidentiality in the community, rose as a challenge in accessing help. Lack of information on how the government systems operate, reduces trust on the services rendered by the state, like the clinics and police. The study highlighted the strengths and gaps related to the knowledge, attitudes and practices.

Tackling transition: Exploring the experiences of first year male psychology students
Pilot Mudhovozi University of Venda, South Africa; Angelina Maphula

Students entering university from high school often experience difficulties as they adapt to tertiary life. In particular, male students in a female dominated psychology field of study need to adjust to the new social, physical and teaching and learning environment. A study was undertaken to explore the adaptation experiences of male first year psychology students. Purpose sampling was used to select participants for the study. Thematic content analysis was used to determine the transitional experiences of the participating students. The study found that male psychology students experienced several challenges. The findings of the study assist University Faculties and Heads of Department to understand the transitional experiences of minority groups.

Weight a minute: An investigation of weight bias
Megan Myers Penn State Erie, United States of America; Victoria Kazemirs; Stephanie Cattron

Weight discrimination occurs in a variety of domains, e.g. offices, schools, and hospitals. Weight discrimination is almost as prevalent as race and age discrimination (Swami, et al., 2008). The consequences of weight bias can be immense, resulting in negative impact on psychological health (Carpenter, et al., 2000), fewer education and career opportunities, and cruel victimisation by peers. In this study, we investigated weight discrimination in helping and bullying scenarios using images of people from each of five body mass index (BMI) categories. In experiment 1, participants read scenarios and then had to select the picture of the woman they were most and least likely to help or bully. Participants completed self-report measures of empathy, aggression, anti-fat attitudes, and BMI. Images of obese women were picked least often in the helping condition, followed by emaciated images. Images of emaciated women were chosen as the targets of bullying most often followed by obese women. Anti-fat attitude predicted weight bias. In experiment 2 we added male images. Weight biases were strongest in the bullying situations for both male and female images. The only significant predictor of weight bias was the anti-fat sub-scale related to dislike of overweight female images. No significant predictors were found for weight bias of male images. These results suggest that gender does indeed play a role in differences of weight bias as females were subjected to greater discrimination based on weight.

Attitudes towards fathering: A South African perspective
Vellie Notshulwana Nelson Mandela Metropolitan University, South Africa

Children who have an ongoing positive connection to their fathers do better in school and get along better with peers than children without such a relationship. Those children whose father plays a positive role in their lives also tend to stay out of the criminal justice system. Unfortunately, the latest figures demonstrate that over 18 million children in South Africa have absent fathers (South African Institute of Race Relations, 2009). This report estimates that 18 percent of these children were of Indian descent, 20 percent were White children and 48 percent and 71 percent were Colour and African children respectively. Clearly, father absence is a serious and multifaceted social problem. Moreover, the situations of South African fathers today are highly diverse and increasingly problematic; many are very young, many are divorced, many have never married, and many confront multiple problems from racism to poor education, to joblessness, to drug addiction. This paper reports on the 134 fathers’ on the attitudes towards fathering. The research report focuses on the themes that play an important role in engaging fathers in the South African context, highlighting some of the challenges and promise of this work with fathers, as an opportunity for a development of a new body of knowledge.

Gender-sensitive strategies to curb school-based sexual violence at selected special schools in South Africa
Doris Nyokangi University of South Africa, Kenya

The paper presents school-based sexual violence of female learners with intellectual disability at selected special schools in South Africa. The study followed a qualitative research methodology, and data was collected by in-depth interviews conducted with 18 participants (16 learner participants (5 males & 11 females) aged 16-24 years and 2 school personnel (school nurse & social worker). School documents such as incident records, and code of conduct books were also observed and analysed. Data was analysed from participant’s interview responses word-by-word which formed categories that were developed to themes. The findings revealed that learners with intellectual disability are not immune to school-based sexual violence in their schools. Sexual violence behaviours which females were frequently subjected to were reported, and certain school practices that reinforced school-based sexual violence were identified. The findings, contradicted misconceptions that people with intellectual disability do not understand what is happening to them. Participants in this study however, gave their intervention suggestions in addressing sexual violence in their schools including: Promotion of sexual violence awareness; intensification of school supervision; countering male peer pressure; and appointment of peer leaders. More significantly teacher training was identified as important in order to successfully handle reported incidents. Finally, it is recommended that the implementation of gender-sensitive strategies will cater for some of the sexuality needs of both female and male learners in order to curb sexual violence in sampled, and other special schools.

Gender perspectives in insertion and treatment in care services of child and adolescents mental health
Alberto Reis Universidade de São Paulo, Brazil; Camila Muylaert; Moacyr Bertolino

The paper analyses the gender determinations in diagnosis construction and composition of a population from Psychosocial Care Centers, CAPSi. The research involved all CAPSi of São Paulo state (23% of Brazilian CAPSi). It is a cross sectional study, based on a random sample of records, for the period of September 2008 to February 2009. The inclusion criterion was all active records registered in the Health Ministry until three months before the date of collection. To obtain the data record a protocol was prepared with 58 questions. A questionnaire was applied for CAPSi managers to complete. The set of children and adolescents attended in CAPSi, 69.7% (634) are male and 30.3% (275) are female. Female population users of CAPSi tends to be older than the male population. The more frequently diagnosis for boys refer to the behaviour disorders and emotional disorder (29.5%), psychological development disorders (23.2%) and retardation disorder (11.7%), while for girls mood disorder (16.7%), retardation disorder (14.6%) and psychological development disorders (12.0%). The consults reasons are homogeneous for both sexes, just differing in terms of the aggressive- ness variable and social behaviour problems (82.49% for boys and 71.64% for girls). Data was analysed from the Winnicott perspective and Gilligan theories about gender and moral development. The diagnosis construction and the sexist composition in CAPSi population, whose root is the gender bias responsible, are in synergy with the invisibility of the psychological distress of girls. The study emphasises the importance of disorders in school and behavior associated with the male universe.

Infidelity, anxiety and depression in couples
Sofia Rivera-Aragon UNAM, Mexico; Pedro Velasco-Matus; Gerardo Villanueva-Orozco; Rolando Diaz-Loving

When people find out about their partners’ infidelity, the offended party feels a realm of negative emotions which includes sadness, anger and jealousy (Buss, 2000; Shakensfeld, et al., 2000). There is also evidence that some show behavioural responses such as divorce, alcohol and drug abuse and suicide attempts, that lead to severe anxiety and depression, somatic illness and diminished mental health (Sweeney & Horwitz, 2001). Within an ethnopsychological framework, the aim of the present research was to explore the relationship between sexual infidelity and anxiety and depression in a sample of Mexican couples. A total of 903 voluntary participants responded to the Multidimensional Infidelity Inventory (Romero, Rivera & Diaz Loving, 2007) developed for Mexican people, and validated Spanish versions of the State trait Anxiety Inventory (IDARE,Spielberger, 1976) and the Depression Scale (Beck, 1979). Results show that infidelity motives, actions and motives relate positively with anxiety in both sexes; however, correlations are significantly higher for males than for females. Discussion will centre on the effects of infidelity on mental health (Hickey, Carr, Dooley, Guerin, Butler & Fitzpatrick, 2005) and the effects of traditional Mexican cultural norms on how males and females experience their sexuality and its derivatives.

An explorative study into the psychological experiences of HELLP syndrome in South African women
Rizwana Roomaney South Africa; Michelle Andiapatn
HELLP Syndrome is a high-risk pregnancy condition that could be fatal to mother and/or baby. It is characterized by haemolysis, elevated liver enzymes and low blood platelets. This study explored South African women's psychological experience of HELLP Syndrome. Six participants who previously experienced HELLP Syndrome were interviewed. Using a grounded theory theoretical framework and analysis, themes emerged and a model illustrating the psychological experience of HELLP Syndrome was constructed. The major themes that emerged were the perceived lack of information, a need to assign blame and a shift in focus. Themes of not knowing and trance/surreal experience underpin the cognitive aspects of the HELLP Syndrome experience. Themes that expressed feelings of no control, whirlwind/rapid pace and support acted together to bind the experience. Finally, emotions such as anger, ambivalence, disbelief, anxiety, guilt, loneliness and fear were present throughout the experience.

Entanglements in relationships between males and females in school: A study from the design of students of the 8th and 9th years of basic education
Leila Salles Depto Educação, UNESP/RC, Brazil; Maria Oliveira Lima

The text discusses the meanings assigned by groups of young people to issues of gender, and attempts to understand how these meanings manifest themselves in school life. We sought to investigate and characterise the concepts of male/female and sexuality, present in the discourse and practices reported by young people. We also examined their perceptions regarding the role of educators in the classroom, according to gender, and investigated the contours of relationships between educators and students according to gender, in addition to characterizing and analysing stereotypes present in the perceptions of respondents. For this purpose, we organised three focus groups which were distinguished on the basis of gender. One group was made up of only girls, the second only boys, and the third girls and boys. Each group comprised between 8 and 12 persons. Data were analyzed qualitatively. The analysis indicated that stereotypical ideas of gender are present in groups, and occur mainly when referring to relationships between men and women in the school routine. However, the results also indicate the presence of concepts and positions that are less crystallized, and stereotypical about gender and sexuality when the reference is the relationship between young people. Thus, the study showed that the conceptions about gender seem to be in a transition process, in which gender studies and queer studies it analyses the reasons why the thinness is among the female body and the possible relations between fashion and beauty standards in Vogue Brazil in that same period. Using the gender studies and queer studies it analyses the gender experiences of being included or excluded in the school system, social scientists, non-governmental organizations, social activists, and the community at large, including parents and youth. Further, the study bears on future research in this field focusing on the need to conduct similar research studies on different communities with special reference to caste structure, socio-economic and educational background and also physiography of the region, etc.

Thinness as beauty: The building of beauty standards in Vogue Brazil
Marlene Strey PUCRS, Brazil; Fernanda Heinzlmann; Kelly Kohn; Ana Luiza Julio

In this paper we intend to investigate the building of beauty standards by the fashion industry. It proposes a discussion about the aesthetic standard for women established by Brazilian fashion in the first decade of 21st century, through an observation of images published in the fashion editorials of the magazine “Vogue Brazil” in that same period. Using the gender studies and queer studies it analyses the reasons why the thinness is among the nationals’ beauty imaginary. It approaches the implications of being included or excluded in the thin standard set by fashion. The aim of this discussion is to investigate the implied beauty standards, the transformation that have been proposed to the female body and the possible relations between fashion and beauty standards in Vogue Brazil’s fashion editorials, from 2000 to 2010. The methodological strategies come from Roland Barthes’ semiological studies.

Similarity and differences in gender violence by adolescent males and females
Silvia Ubillas University of Burgos, Spain; Goibur Elder

The aim of this study is to analyse the differences and similarities in gender violence in adolescent males and females. The sample was comprised of 2,283 Spanish students (45% boys, 54% girls) with a mean age of 14.98 years. A descriptive and analytical cross-sectional design was applied. Variables included in the study were: socio-demographic data, a measure of Ambivalent Sexism, Beliefs and Attitudes towards violence against women in relationships, gender role attitudes and violence against women in couples. The instruments used in the study were: Ambivalent Sexism Inventory (Glick y Fiske, 1996), Double Standard Scale (Caron et al., 1993), Distorted Thoughts on Women and Violence Inventory (Echeburúa & Fernández Montalvo, 1997), Conflict in Adolescent Dating Relationships Inventory (Spanish version Fernández-Fuertes, Fuertes & Pulido, 2005). Results show that boys are more sexist than girls and they commit more sexual, relational and threat violence. Nevertheless, boys receive more sexual, relational, physical and threat violence. These results, similar to those found in other studies, may be reflecting a change in the role of women in intimate partner violence. This result should be taken into account when implementing future social intervention and educational programmes.

Gender issues in children’s literature: Which discourses are presented to children?
Bruna Von Muhlen PUCRS, Brazil; Marlene Strey; Andressa Bottor; Marília Saldanha

This research stemmed from an interest in discussing the sexual binary based on biological determinism that defines that if born girl/woman, or boy/man, with two opposing and exclusive universes mutually relatives, one to another, besides the concern with the ways of exercise that is called masculine and feminine taught from childhood, based on sexist and patriarchal social structures and according to the sex of the child and their corresponding gender. As a focus for analysis, we used feminist theories of gender bias in a post-structuralist research design, and to focus the questions in childhood, we performed the analysis of ten children’s books: Award-winning by the National Book Foundation for Children and Youth (FNLJ – Fundação Nacional do Livro Infantil e Juvenil), responsible for encouraging reading among children and adolescents. The specific objectives were to understand how gender issues are shown in these works and if or how they contribute to the maintenance of gender stereotypes and attitudes of subsequent submission of women in relation to male domination. For the texts and illustration analysis, we used, respectively Discourse Analysis and Semiotic Analysis of Snapshots. In our view, the large presence of traditional gender stereotypes associating the female figure to marriage, motherhood, movement in private settings and dependence on men, while male figures are characterised by activity, virility, courage and bravery, having free will to express opinions on the public scene. We also observed that the discourses that break these stereotypes appear sparingly and often succumb to an end according to traditional gender stereotypes.

Gender differences in sex drive, exposed in masturbation not in partnered sex
Wim Waterink Open University of the Netherlands, Netherlands

One distinct difference found across studies is the gender differences in the prevalence of masturbation. Men masturbate more than women. For heterosexual men, it is suggested that masturbation represents a substitute for partnered sex. For heterosexual women, it appears to be part of the wider repertoire of sexual fulfillment. The differential rates of masturbation may reflect gender differences in sex drive: women having a lower sex drive than men. In this study, the effect of sex drive on masturbation and partnered sex was investigated among

Gender issues in children’s literature: Which discourses are presented to children?
Bruna Von Muhlen PUCRS, Brazil; Marlene Strey; Andressa Bottor; Marília Saldanha

This research stemmed from an interest in discussing the sexual binary based on biological determinism that defines that if born girl/woman, or boy/man, with two opposing and exclusive universes mutually relatives, one to another, besides the concern with the ways of exercise that is called masculine and feminine taught from childhood, based on sexist and patriarchal social structures and according to the sex of the child and their corresponding gender. As a focus for analysis, we used feminist theories of gender bias in a post-structuralist research design, and to focus the questions in childhood, we performed the analysis of ten children’s books: Award-winning by the National Book Foundation for Children and Youth (FNLJ – Fundação Nacional do Livro Infantil e Juvenil), responsible for encouraging reading among children and adolescents. The specific objectives were to understand how gender issues are shown in these works and if or how they contribute to the maintenance of gender stereotypes and attitudes of subsequent submission of women in relation to male domination. For the texts and illustration analysis, we used, respectively Discourse Analysis and Semiotic Analysis of Snapshots. We also observed that the discourses that break these stereotypes appear sparingly and often succumb to an end according to traditional gender stereotypes.
The influence of motherhood on the promotion of women

Fangfong Wen School of Psychology, China; Bin Zuo School of Psychology, China

This article examined the influence of the occupational gender stereotype on women (especially the maternal identity) in job promotion. Fifty-five working people (24 male, 31 female) participated in the study. We used a 2 × 2 repeated-measure design, with parental status of the applicant (no children/children) and gender of the applicant (male/female) as the two independent variables. Ratings of anticipated job commitment, achievement efforts, ability, agentic behaviour, and recommendation, were the dependent variables. The results showed that mothers were evaluated the lowest in variables such as anticipated job commitment, achievement effort, ability, agentic behaviour, and recommendation than non-fathers. Male applicants who were non-parents were evaluated significantly higher in anticipated job commitment, achievement efforts, ability, agentic behaviour and recommendation than female non-parents. These findings suggest that occupational gender stereotype has a potential impact on women especially for mothers in promotion decisions.

Effects of gender, occupational level and type of industry on job satisfaction among Nigerian workers

Andrew Mogaji Benue State University, Makurdi, Nigeria

This paper examined the effects of gender, occupational level and type of industry on job satisfaction among Nigerian workers. Data were collected from 600 workers randomly selected from the shoe, food and textile manufacturing industries in Lagos, Nigeria. The sample included 200 subjects from each industry. Altogether, there were 450 junior workers, 90 supervisors and 60 managers. Categorising the subjects according to gender, there were 495 males and 105 females. Analysing the data with T-statistics, showed a significant gender difference in job satisfaction among the workers at p < .01. Moreover, the analysis with one-way ANOVA also showed significant differences as a result of occupational level and the type of industry at p < .01 respectively. The results have implications for developing a favourable work environment where personal needs of employees and organisational needs are satisfied.

Narratives of sex work: Sex worker stories of entry into sex work

Joni Halland University of Cape Town, South Africa; Floretta Boonzaier

Studies exploring the reasons for why women enter sex work have commonly ascribed entry to perspectives of choice or constraint. Choice perspectives attribute entry into sex work to reasons such as female agency and empowerment; and social and financial independence; while constraint perspectives attribute entry to reasons such as economic necessity; drug/alcohol abuse; childhood sexual abuse; lack of education and job opportunities; and homelessness and truancy. Such perspectives have been criticized for constructing a dichotomous understanding of entry, and for neglecting to explore the reality of women’s lives. This paper records the ways in which 14 street-based sex workers framed their presence in the sex work industry by providing account of the stories they told about how and why they decided to become sex workers. Through the findings of a qualitative thematic narrative approach to the research, it was found that most sex workers constructed their entry into sex work from a perspective of constraint; maintaining that they did not choose to enter sex work. And yet while most participants framed their entry from a perspective of constraint, they communicated a sense of agency and choice in the decisions they made to better their circumstances through entering sex work. The findings suggest that it is largely simplistic to view entry into sex work from perspectives of choice/constraint alone, and thus argue for the necessity to explore the social and cultural contexts informing the realities of sex workers in South Africa if one is to understand the psychology of sex work.

Exploring prostituted women’s experience of a South African exit intervention

Tessa Heiberg South Africa; Despina Learmonth

Prostitution is the oldest form of oppression. Many prostituted women in South Africa wish to exit sex work, but are unable to because they have no other means of earning money. There is a dearth of research available on assisting prostituted women to exit sex work in South Africa. This study explored the effectiveness of a Cape Town-based NGO’s – Embrace Dignity – exit intervention for prostituted women. Using semi-structured interviews it investigated the experiences of eight prostituted women in Cape Town. The research goal was to be able to inform improvements to the intervention for exit. An interpretative phenomenological approach was used to analyse interviews of women’s experiences of the intervention. Findings revealed that attempting to exit prostitution in South Africa is an incredibly difficult and deeply complex process. An exploration of women’s experiences of Embrace Dignity suggested that whilst it provides emotional and social support to prostituted women, it does not address their physical needs, most importantly that of employment. This study reveals that although emotional support plays a crucial role in assisting prostituted women to exit, it is second-ary to the urgent physical support needed to satisfy the basic survival needs of prostituted women living in extreme poverty in South Africa.

Women’s experiences of harm in prostitution: A feminist inquiry

Monique Huysamen University of Cape Town, South Africa; Floretta Boonzaier

Street-based prostituted women can be found on the major roads of every city in South Africa. The issue of prostitution raises complex questions around its nature and implications for prostituted women, an issue on which feminists are vehemently divided. This qualitative study explored prostituted women’s subjective experiences of harm in prostitution. Unstructured face-to-face interviews were conducted with 15 poor black South African women working as street-based prostitutes. Data was analysed thematically. The findings of the study reflect a client-prostitute relationship, based on unequal power relations and male dominance, which serves to subjugate, disempower and exploit prostituted women. The findings suggest that prostitution is...
The meaning of corrective rape: Experiences of Black South African lesbians
Lisa De Wee University of Johannesburg, South Africa
South Africa has high levels of sexual violence perpetrated against women and children. In particular, raping of women has become exceedingly common. There is, however, a sub-type of rape that appears to be unique to the South African context. This is called corrective rape, perpetrated against Black lesbian women. Corrective rape is considered to be a curative measure to return women engaging in ‘deviant’ sexual practices to a heterosexual lifestyle because such a ‘deviant’ lifestyle is un-African. In South Africa, however, corrective rape is not considered a hate crime and is not protected by law. Black lesbian women who experience corrective rape are therefore subject to triple discrimination. This includes identity-based discrimination, intersectional discrimination and cultural discrimination. In this paper the authors explore the lived experiences of three Black African women who experienced corrective rape. An interpretative phenomenological research design was used in this study. The participants were sampled using purposive and snowball sampling and data was collected using semi-structured interviews. There are currently no results available as the data are still under analysis. The authors will present the results of the analysis in the context of race, gender, culture and legislation in the South African context.

Group therapeutic healing for female adult survivors of child sexual abuse
Hester Gertrude Pretorius University of Johannesburg, South Africa
South Africa is a society in transition from an Apartheid regime to democratic governance. Erstwhile discriminatory policies and practices have led to unprecedented levels of sexual crime. Sexual violence perpetrated against women and children has, in particular, taken on pandemic proportions. The effects of child sexual abuse are not confined to childhood. It continues to impact on adult survivors’ personal functioning, relationships and parenting styles. It further extends to the macro-level of society where it exacerbates an already overloaded health care and judicial system. In this paper the authors (1) present a group therapeutic intervention used for counselling adult survivors of childhood sexual abuse and (2) provide evidence of its effectiveness as a treatment modality. A sample of 25 South African women who experienced sexual abuse in their childhood participated in the intervention. Process research congruent with an action research strategy was used to explore the impact of the intervention. The results indicate that the participants experienced personal healing, consisting of shifting from a state of disempowerment to empowerment, an augmented sense of self-worth, enhanced relationships with their intimate partners and with their children, and that a process of forgiveness toward the perpetrators of the abuse was facilitated. The authors conclude with a discussion on how a group therapeutic intervention can empower adult survivors of childhood sexual abuse. Recommendations for practice and research are then made.
The purpose of this paper is to explore the biographical and psychological factors that are related to women who kill their intimate male partners. The author reports on two studies that investigated incarcerated women who murdered their intimate male partners. The first study used a survey research design where a biographical questionnaire was administered to 60 incarcerated women in five prisons across South Africa. The data were analysed using descriptive statistics. The second study used a multiple case-study design. Three incarcerated women from the Western Cape were interviewed. The interviews were analysed using thematic analysis. The results of the first study indicate that women who kill their intimate male partners tend to be between 35 to 45 years of age, have limited education, experienced childhood abuse and/or domestic violence, were socially isolated from other people, and were subjected to verbal, physical, sexual and economic abuse. The second study found four themes that were common across the three participants. These were Post-Traumatic Stress Disorder symptomatology, coercive control, substance abuse and inter-relational conflict. The author uses the results of the two studies to create an over-arching biographical and psychological profile of women who murder their intimate male partner. The implications of these findings for research and practice in relation to children of women who have killed their intimate partner, the role of society in this phenomenon, and for interventions to prevent the murder are then presented.

Gender violence in South Africa: A symposium on violence perpetrated against women and men

Hester Gertrude Pretorius
University of Johannesburg, South Africa

South Africa is a society that is characterised by high levels of violence. Violence perpetrated on the basis of race, sex and class was common during the erstwhile Apartheid government. However, violence did not cease with the transition into the new democratic dispensation. In particular, South Africa is facing a pandemic of violence against women and children in the form of sexual abuse, rape, and domestic violence. The purpose of this symposium is to present five papers on violence in the South African context. The first paper explores the biographical and psychological profiles of abused women who murdered their intimate male partners. The second paper investigates the experience of Black African women who are abused by their male partners and who have chosen to remain in the relationship, from an African cultural perspective. The third paper interrogates corrective rape of Black African women who are lesbian. The fourth paper presents a group therapeutic intervention for women who were sexually abused during their childhood. The final paper explores the experience of male rape for male rape survivors and discusses the meaning of male rape for the survivors. The symposium concludes with the author’s reflections on gender and violence in South Africa and the implications of the paper presentations for research and practice.

Symposium title: Going beyond: Reimagining stories of violence against women in South Africa
Convenor: Floretta Boonzaier

Going beyond masculinities in violence against women: Violent men’s life stories through the lens of intersectionality
Anna Aulette-Root
South Africa

Men who use violence against intimate partners are increasingly a focus of research in the field of violence against women. Current research draws on masculinities in particular as an explanation for men’s violence. Theorising however, remains underdeveloped in its attention to the complexity of masculinities especially with regard to marginalised men and masculinities in the global South. While masculinities are understandably foregrounded in the study of violence against women, the essential fact that gender is inextricably linked to other social oppressions such as race and class, is largely ignored. Taking a broader look at the whole lives of South African men who have been violent towards women that includes attention to multiple systems of social-structural oppression, is crucial in light of our high rates of gender-based violence in South Africa, in the context of a legacy of violence and injustice through slavery, colonialism, and apartheid. This study provides greater insight into the events that have shaped violent men’s lives and identities by using a life history approach in the collection of data rather than focusing on specific violent events in men’s lives. Important themes in these narratives include: Hero, survivor, and victim stories, and a missing element in all of these stories; women. Framing the analysis by intersectional theory offers enhanced understandings of the complex interaction of race, class, gender, and other forms of oppression which emerge in the autobiographical narratives of marginalised men who have abused intimate woman partners.

Talking against dominance: South African women resisting dominant discourse in narratives of violence
Floretta Boonzaier
University of Cape Town, South Africa

This paper explores how women resist dominant discourses about their positioning in violent intimate relationships. The cultural positioning of women, particularly within a patriarchal context such as South Africa, leave little room for women to take up positions of resistance against victim-blaming and other stigmatising discourses. Women who are marginalised by poverty, race and other factors have been shown to be vulnerable to experiencing intimate partner violence and their options for responding to violence against them are fundamentally limited. The cultural scripts available to women, poor women in particular, have important implications for the ways in which they are able to recount experiences, construct subjectivity and imagine possibilities for action. However, to simply recount the ways in which women are constrained by cultural scripts would be to tell just half of the story. This ‘half-story’ would also work to conceal the ways in which women respond to and resist dominant gender discourses about intimate partner violence. This paper draws on qualitative interviews with abused women to show how their narratives about violence from an intimate male partner are authored in ways that might involve ‘talking against dominance’. The work is informed by feminist poststructuralist theory in its exploration of subjectivity, meaning and language. It also draws on narrative theory, showing how women make meaning of their experiences of violence through the method of storytelling and how, through narrative, women take on agentic roles in re-authoring stories about violence.

Re-imagining identity: Exploring the psychological impact of a culture of violence against women
Sarah Gordon
University of Cape Town, South Africa

Violence against women is extremely prevalent in South Africa. South African women could be considered a ‘high risk’ group and it is argued that all women are affected by the presence of gender-based violence in their community and as a result are subject to insidious trauma. Women are expected to actively avoid gender-based violence and these precautionary strategies become instrumental to their identities. This study focuses on the ways in which women’s lives and identities are transformed by this culture of violence. Focus is placed on how women in South Africa are affected by living in a society where violence against them is prevalent; trivialised, eroticised and tolerated and the impact this has on the identity construction of women. The theoretical framework of the psycho-social subject and a biographical-interpretive methodological approach were used to frame this research study. Free-association, narrative interviews were conducted with female, University of Cape Town (UCT) students and interpretive analysis was utilised. This paper explores the complex dynamics of identity construction in the midst of this violent context, highlighting how all women are affected by living in a country with abnormally high levels of violence against women.

‘People you love – you hurt them’: Men’s representations of their own violence against women
Taryn Van Niekerk
University of Cape Town, South Africa

It is of national emergency to understand why the prevalence of intimate partner violence (IPV) against women in South Africa remains high, despite intervention efforts to address the problem. South African research has shown that IPV is a social phenomenon that may be encouraged or guarded against within specific social groups. However, studies on men perpetrators of IPV and their social networks have still received little emphasis as a crucial route to understanding men’s violence in context. This paper seeks to address this necessary area by exploring the social representations of IPV that emerge in men’s narratives of violence against women. This paper draws on a larger research project that investigates representations of IPV amongst men and their social networks. Interviews were conducted with 10 men who were recruited from a Cape Town NGO that provides programmes for battering men. A preliminary narrative analysis unravelled stories that suggest that shared beliefs, within men’s social groups, that normalise violence against women may impact on men’s individual beliefs about their own violence. Furthermore, the findings illustrate the complex nature of social representations and individuals’ beliefs of violence against women. The findings from this paper serve to contribute to the development of theories that examine the causes of IPV in the South
African context, and may also work to clarify what strategies work best for intervening in particular communities.

Symposium title: Impact of gender and ethnicity stereotypic expectations for women’s leadership and political candidacy
Convenor: Natalie Porter

What we want vs. what we are able to do: Impact of gender and ethnic minority status on leadership
Jean Lau Chin Adelphi University, United States of America

With the growing diversity within countries internationally, leaders are finding themselves in increasingly heterogeneous contexts. Gender and racial/ethnic disparities still exist within the ranks of leadership across private and public sectors. Theories of leadership typically omit the discussion of gender, feminist values, or principles of diversity. While the literature has identified differences and similarities between men and women leaders, it has largely ignored that organisational cultures remain male dominated. Although “new” styles of leadership, such as transformational leadership, are considered important for today’s leaders and favour the leadership of women, the inattention to context misses key influences on how women lead - e.g., follower expectations or the leadership-member relationship. While men and women leaders often behave similarly, leadership for women remains a different experience because of underrepresentation and gender bias. In this study examining leadership style, leadership identity, and lived experiences of diverse women leaders, we found that all leaders (women and men, US white and racial/ethnic minority groups) embrace transformational and collaborative leadership styles consistent with cross-national data from the GLOBE studies (House, et al). We also found that ethnicity and gender identity significantly influenced the exercise of leadership; women and racial/ethnic minority leaders find these dimensions of identity intricately interwoven with their leadership whereas white male leaders do not. These results have implications for today’s global diversity context and the perceptions and expectations associated with gender and ethnicity.

An international journey in academic leadership: Triumphs and pitfalls for a Liberian woman in two contexts
Elizabeth Davis-Russell WVS Tubman University, United States of America

This presentation will focus on one woman’s leadership in higher education in two very different countries, on two very different continents. This presentation will highlight and augment the issues raised by the previous presenters and their research and provide a more personal context to the leadership issues discussed. The presenter was born and spent her early years in Liberia, West Africa, educated and began her career in the United States, and now is back in Liberia building and leading an institution of higher education. The presentation will underscore the influences of her early life which in turn shaped a philosophical perspective which guided her leadership and the challenges confronting her leadership. It will examine the status of women in higher education in the United States and Liberia. The historical circles of power will also be examined in those contexts, and the role of race and gender will be compared and contrasted. In each country the barriers to advancement for women in higher education will be highlighted with examples of how these can be overcome. The presentation will conclude with some observations and advice from women leaders in higher education. The implications of this narrative and the previous research presentations for women across global leadership contexts will be discussed.

Stereotypes, prescriptions, and proscriptions for women in politics
Natalie Porter Alliant International Universit, United States of America; Dalia Ducker

Research on women leaders shows that sex biases persist in the United States. Women who assume roles that counter to gender stereotypes are penalized: rated as less likeable, lacking “feminine” attributes, are interpersonally derogated, and are less likely to be recommended for hiring or career advancement. The social mandate requires that women adhere to gender prescriptions. Women who are seen as competent are perceived as lacking in communal qualities. Some women may avoid being penalized for possessing positive male gender-role attributes (competence or leadership) by concurrently demonstrating female gender positive behaviors (compliance or helpfulness) and not manifesting negative male behaviors (arrogance or aggressiveness). We investigated how these findings apply to two controversial female political leaders in the United States, Hilary Clinton and Sarah Palin. The purpose was to determine the relationships among people’s attitudes about women’s roles, with gender role prescriptions and proscriptions and ratings of likeability, desirability, and competence. In two studies, 200 adults were asked to rate Hilary Clinton and Sarah Palin on aggregated scales of likeability, competence, desirability, and on gender-prescriptive and gender-proscriptive attributes. Participants also completed the Ambivalent Sexism Inventory. The results demonstrated the persistence of stereotypes and provide a framework for discussing the double bind for women. Although there are differences, both political figures evoked responses that pertain to our own attitudes about women in power more than to their actual attributes. Implications of the studies will be discussed.

Remembering and evaluating US political candidates: Impact of gender schemas
Natalie Porter Alliant International Universit, United States of America; Michele Haley; Matthew Harris

Women in the U.S. are underrepresented in political office, although they graduate from college more than men. Gender stereotypes affect how we view women as leaders; this research examined how gender schemas impact perceptions of women leaders. This study examined how stereotypes impacted the retention of male and female candidates’ political platforms, their evaluation on competence, likeability, and desirability for office. 200 participants were shown a video of a male and female candidate running for political office. They presented positions on 4 issues, 2 representing stereotypically masculine and 2 feminine topics. Videos were counterbalanced for order, for masculine or feminine topics, and political ideology. Retention of material was measured, and candidates were rated on competence likeability, and desirability for the office and were administered The Ambivalent Sexism Scale. Findings indicated that women accurately retained equal amounts of information about both candidates, whereas men recalled significantly more about the male candidate. Both men and women attributed more of the hard political issues to the male candidate and the soft political issues to the female candidate. All rated the female candidate as more desirable. The contradiction between recall and evaluation highlights the importance of using implicit and explicit measures to capture gender stereotyping. Social desirability may influence our conscious choices, but implicit measures tend to capture more unconscious phenomena. Implications for leadership are discussed.

Symposium title: Increasing necessity of a global perspective on psychological research: Stand point of Pan American Psychologists
Convenor: Aluisio Lima

The development of instrumental and expressive traits through education
Aluisio Lima Universidade Federal do Ceara, Brazil

In order to construct an ethnopsychologically valid measure of the instrumental and expressive, socially desirable and undesirable attributes of Mexican people, a 117 adjective questionnaire was constructed. The questionnaire was developed based on the original list of 323 adjectives obtained by Diaz-Loving, Rivera-Aragon y Sanchez Aragon (2001), who initially used focus groups to obtain the instrumental and expressive attributes, and then applied the list of descriptors to a large sample of subjects who indicated how typical and ideal these attributes were of males and females in Mexico. Results from the psychometric analysis yield 3 conceptually clear and statistically robust instrumental socially desirable and 3 undesirable factors, 2 socially desirable expressive and 3 socially undesirable factors, both in males and females. Considering there are some critical periods in which the psycho-socio-cultural development of these attributes are emphasized, creating the rules and the social expectations related to their differences through specific socialisation and interaction practices, in the present study, 100 males and 100 females from 5th grade, 200 more from 6th grade and in equal numbers grades 7th through first year of college, responded to masculinity and femininity scales. Mean differences show consistent differences by sex and educational level in which more equalitarian and androgynous orientations appear specially in females and all subjects with more formal education. The results are discussed in terms of the impact of culture on the definition of gender.
Creating sex-perfect genitals: Medicalisation, sex, and bodies in the case of female genital cosmetic surgery
Virginia Braun The University of Auckland, New Zealand

Medicalisation, a trend that has grown since the 1970s, affects western individuals across multiple domains of everyday existence. In a sometimes dual-process of problem-definition and problem-creation, numerous aspects of life have been reframed as issues of health, as problems and their solutions have been defined in terms of medical or pharmaceutical interventions. Women’s minds, bodies, and sexuality are key domains in which medicalisation has flourished, offering particular understandings of, and solutions to, bodies/selves that don’t look, feel, think or respond in the way they ‘should’. For example, coinciding with an apparent western liberation and even valorisation of women’s sexuality and sexual pleasure, lack of sexual desire and certain sexual response/pleasure for women have become target problems to be fixed: Pharmaceutical giants are spending millions racing each other to create the perfect product, the perfect ‘fix’. Yet one ‘solution’ already exists: Female genital cosmetic surgery (FGCS). FGCS, which emerged in the late 1990s, refers to a cluster of procedures framed as providing easy, quick, relatively risk-free and effective solutions to genital-related psychological and sexual distress. These ‘solutions’ can also be analysed as creating a new pathology – undesirable genital morphology – to which they offer the solution; the creation of sex-perfect genitals, creating a psychological and sexual transformation of the woman. This talk will critically interrogate this aspect of the medicalisation of the female body, and consider the implications for women’s subjectivity, sexuality and embodiment.

This paper is intended to be part of a symposium titled “The Wrong Prescription: Effects of Medicalisation on the Psychology of Women” chaired by Varda Mulhauer, Ph.D. with Suzanna Rose, Ph.D. as discussant.

Aunt Flo is (not) visiting: Curing the curse with continuous oral contraceptives
Joan Christer Connecticut College, United States of America

The process of menstruation has long been thoroughly medicalised in many countries around the world. For centuries women have been considered ill during their menses, and even, in some cases, capable of making others ill. During the 1980s, changes in the body that signal the onset of the menses became known as “premenstrual syndrome” (i.e., PMS), an illness in itself. This means that women are now considered to be ill for nearly two weeks of every month during their reproductive years. As PMS became accepted, and self-diagnosed, by increasing numbers of women the notion that the menstrual cycle itself is bad for women’s health became established. Brazilian gynecologist Elsimar Coutinho’s international best selling book: Is Menstruation Obsolete?, solidified this notion, as he made the argument that evolution never intended for women to menstruate as often as modern women do and suggested that too many menstrual cycles leave women vulnerable to all manner of ailments. He suggested the use of the contraceptive Depo-Provera to suppress the menstrual cycle. The book provoked a media frenzy, and, a few years later, pharmaceutical firms began marketing continuous oral contraceptives (e.g., Seasonale) for menstrual suppression. Many adolescents and young women were attracted to the idea that they could be “period free”, but is menstrual suppression safe? Does it really protect women’s health? How does seeing oneself as ill for half of one’s reproductive years and altering nature’s design affect women’s self-concept and body image? These are some of the questions this presentation will address. This is intended as part of a symposium titled “The Wrong Prescription: Effects of Medicalisation on the Psychology of Women” chaired by Varda Mulhauer, Ph.D. with Suzanna Rose, Ph.D. as discussant.

The wrong prescription: Effects of medicalisation on the psychology of women
Maureen Mchugh Indiana University of Pennsylvania, United States of America

Fueled by corporate funding, medical ‘experts’ have developed new labels that pathologise women’s sexual behaviour (e.g. FSD and hypothalamic sexual disorder) or render it inadequate. Women, especially aging women, may be impacted by constructed expectations and norms regarding sexual desire and behaviour. To the extent that women report levels of desire or behaviour that are different from those of males, women’s experiences are frequently viewed as problematic or pathological. Feminists (e.g. the New View Campaign) work to resist the pathologizing and profitiering of the pharmaceutical industry and criticise the medicalisation of female sexuality as presenting sexuality from a reductionistic, mechanistic, androcentric and essentialist framework. The author critiques the medicalised perspective of women’s sexuality focusing on the issues of desire and dysfunction in young women, women at midlife and aging women. This presentation examines the processes by which the language/discourse of medicalisation impacts women’s sense of their bodies and their sexual behavior as adequate and pleasurable. For example, sexual function and sexual activity are often linked to health and vitality, and ‘sexiness’ has been depicted as an important means of distinguishing oneself as ‘not old’.

I only care about your health: The war on fat women’s bodies
Christine Smith University of Wisconsin, United States of America

The idea that there is a global ‘epidemic’ of obesity, which threatens not only individual health but also entire healthcare systems, is deeply entrenched in popular, medical and policy discourse (James, Leach, Kalamara, & Shuyeghi, 2001; World Health Organization, 2000). One argument in support of the obesity epidemic is that obesity has been correlated with a variety of medical problems including diabetes, coronary heart disease, and some types of cancer (Centers for Disease Control, 2010). Considering issues of gender, women tend to have more body fat than men (Jackson, Stanforth, Gagnon, Rinkinen, Leon et al., 2002). Because women bear children, their bodies store fat for fertility, fetal development, and lactation (O’Sullivan, 2009). Women are also more likely than men to be obese (Wang, Colditz, & Kuntz, 2007). In Western culture being large-sized is more stigmatising for women than for men (Oliver, 2006). Some cultures have valued plumpness in women, but that view is increasingly disappearing with influence of Western media and culture (Jaeger, Ruggiero, Edlund, Gomez-Perreta, Lang et al., 2002). Thus, the “war on obesity” is largely a war on women’s bodies. Meanwhile, women around the world are living longer (World Bank, 2001) and research suggests that for optimum longevity, having a large body may be potentially beneficial for women (Flegal, Graubard, Williamson, & Gail, 2005). In this paper, I discuss weight, health, and longevity in women, the research on weight stigma, and the ways in which women’s bodies are often stigmatised under the guise of “concerns about health”. This paper is intended to be part of a symposium titled “The Wrong Prescription: Effects of Medicalisation on the Psychology of Women” chaired by Varda Mulhauer, Ph.D. with Suzanna Rose as discussant.

Symposium title: Women of color leaders in psychology: Context and experiences
Convenor: Jessica Daniel

Women of colour, leaders in psychology
Jessica Daniel Children’s Hospital Boston, United States of America; Adelaide Magwaza; Yuwanna Mivanyi; Elizabeth Nair; Ubolwanna Pavakalanun; Melba Vasquez Children’s Hospital Boston, United States of America

Psychology is the behavioural science that addresses all aspects of the human experience. It is a broad and multi-layered discipline. The theories and empirical findings generated by practitioners and scientists can increase our understanding of human behaviour. It intersects with other disciplines as well. The current focus on the mind-body connection is an example of its utility in creating interventions that can sustain adherence and consequently generate better health outcomes, both physical and mental. Persons who are leaders in psychology have the potential to impact policies and practices in many contexts, from the local to the international. In the past, leaders in the discipline have often been male. The more recent emergence of women leaders in psychology may broaden the scope, and consequently the influence of psychology in various countries around the world. Women of colour psychologists who are or have been leaders in psychology in their respective countries have been invited to participate in this symposium. Their presentations will focus on the identification of skills and strategies that contributed to their successfully assuming leadership positions and that helped them to manage the inevitable challenges that emerge when one is a leader. These include: Negotiation skills, understanding the culture of an organisation in terms of power, national traditions, race/ethnicity and gender, and creating a leadership agenda. The presentations will provide a rich array of challenges and triumphs from a range of women from five different countries.

Leadership as a woman and a member of a minority group: Building bridges
Jessica Daniel Children’s Hospital Boston, United States of America
Since earning my PhD in 1969, I have held numerous leadership positions in psychology. I am an African American woman. African Americans constitute only 2% of psychologists in the United States. Stereotypic images of African American women are not consistent with images of leaders in psychological organisations and yet over the years I have held those positions. One African American women’s organisation has as its mantra ‘Lift As You Climb’. Mentoring has been an integral part of my career as a psychologist as well as instruction and training. The integration of mentoring, instruction and training while being a leader has been a challenge. But such an approach has led to inclusion and building bridges to a range of groups of psychologists. Sustaining such alliances has resulted in successful initiatives as well as effective professional and positive personal relationships. Knowing when to advocate with a focus on race and ethnicity and when to have a broader perspective has been a challenge as balance is needed to maintain the leadership role. The presentation will provide leadership strategies used to keep multiple identities in perspective as a leader of multicultural organisations. My leadership positions have included Chair of the Massachusetts Board of Registration of Psychologists, president of a the Society for the Psychology of Women in the American Psychological Association and member-at-large of the American Psychological Association Board of Directors.

**Growth and leadership in a heterogeneous and acculturated Nigerian society**

*Yuwanna Mivany*  
*Kaduna Polytechnic, Nigeria*

From an academic status of a lecturer in 1984, I rose to the position of Acting Rector in 2011 and have now applied for the post of the Rector (Chief Executive) of Kaduna Polytechnic. Made up of five campuses, the Institution has a history of multiple ownership by the Northern states, constituting of nearly 200 ethnic groups. It is Nigeria in miniature. Growing through the ranks as a woman required me to be daring, using faith and industry. Preceding these two statuses, I was elected Dean, having been appointed Examination Officer. The Kauna state Government and UNICEF, engaged me in very important committees and periodic research, at the same time while being the national President for promoting quality education in Nigeria. Sharing my experiences with other women will be of encouragement to those who are facing cultural and political challenges as I did, and hopefully they will not relent as well.

**Psychology leadership from the little red dot:**  
*Woman waving the victory flag*  
*Elizabeth Nair*  
*Work & Health Psychologists, Singapore*

In various contexts, at home, school, and in my adult working life, I found myself in positions of elected and appointed leadership. On reflection, these positions may have come my way because of a perception that I was a responsible and capable person, who can be trusted to do the right thing, and fearless in speaking up where there were issues that needed to be addressed and set right. In the Singapore Ministry of Defence, I was the first woman Chief Psychologist, a position not easily attained in a military context especially by a civilian woman. My entry to international psychology leadership was determined by the successful delivery of the IAAP XXV ICAP in Singapore in 2002, in my capacity as Organising Chair, and Scientific Program Co-Chair. My country, Singapore, has been variously described as the mouse that roars, and the little red dot on the world map. The Singapore Psychological Society was established in 1979, and I have served four non-consecutive terms as President. I have had the privilege of a leading role in establishing the ASEAN Regional Union of Psychology Societies (ARUPS) in 2006, thus institutionalising a collaborative union for psychologists in the ten South East Asian countries of ASEAN. This was possible through my appointment as National Capacity Building Chair, IUPsyS, where I served as the first South East Asian psychologist on the Executive Board from 2000-2008. My leadership style, honed through trial and error is inclusive, consultative, collaborative, evidence driven, timely, decisive, and considerate.
Empathy and learning how we impact others

Natasha Ali New Mexico State University, United States of America; Michael Waldo

Interpersonal learning is a term used to refer to people’s ability to gain insight about the impact they have made on others (Yalom, 1995, p. 42). It has been identified as a critical skill for conflict resolution (Guerney, 1977). However, interpersonal learning does not always occur during conflict when people may feel too defensive to learn how they are being perceived by others (Yalom, 1995). Empathic understanding is the ability to understand what someone else is feeling and doing from their unique point of view (Rogers, 1961). When people are able to understand the impact they have made on others, they are able to adjust their interaction style to promote constructive conflict resolution (Guerney, 1977). This study sought to test this hypothesis, that people who exhibit higher empathic listening exhibit higher levels of interpersonal learning. Using participants who underwent divorce mediation in a family court located in the Southwestern region of the United States, 66 participants’ empathic listening skills were measured using the Written Interaction Task (Waldo, 1989). Their interpersonal learning was measured using an abbreviated version of the Therapeutic Factors Scale (Yalom, Tinklenburg & Gilula, 1968 in Yalom, 1995). Results indicated a significant correlation between participants’ empathic listening and their interpersonal learning at the .01 level (r = .3, p < .01). This result can serve humanity because it suggests that helping people increase their empathic listening can increase their interpersonal learning and consequently their conflict resolution skills.

Psychology and the human right to enjoy the benefits of science: Report from an interdisciplinary focus group study

Clinton Anderson American Psychological Association, United States of America

The purpose of this presentation is to increase psychology’s role in the United Nations (UN) process of defining the human right to “enjoy the benefits of scientific progress and its applications,” Article 15 of the International Covenant on Economic, Social, and Cultural Rights. Because it is one of the least understood human rights, the UN has called upon the scientific community to help to elucidate the meaning of the right. This presentation will report on preliminary results from psychological participants in a US focus group study of how members of different scientific, engineering, and health disciplines interpret the language of the right. Two psychological associations—the American Psychological Association and the Society for the Psychological Study of Social Issues—have sponsored focus groups in the study, involving 8-12 participants in a two-hour discussion of questions derived from the text of Article 15. The presentation will include results from the two psychology focus groups with some comparisons with the results of focus groups from other disciplines. In addition, the presentation will report on plans of the Science and Human Rights Coalition of the American Association for the Advancement of Science to convey the results of the focus group study to the UN and to bring the perspective of scientists to bear on the UN’s process of monitoring states’ performance on this human right. Lastly, the presentation will suggest ways that psychologists and psychological associations may become involved in advocating for the right to benefit from psychological science and science in general.

The unification of psychology

Ruben Arldia National University of Colombia, Colombia; Isaac Prilleltensky

The lack of unity of psychology has been an obstacle for theoretical coherence of the discipline and for improving its role in society. A research programme for the unification of psychology is presented, called the Experimental Synthesis of Behaviour (ESB). This paradigm places special emphasis on complex behavioural issues such as social behaviour, language, cognition, emotion, contextual variables, history of reinforcement and cultural determinants of human behaviour. The requirements of this paradigm for the unification of psychology are: (1) Its level of explanation, viz. behaviour and its relation to the environment, (2) its method, viz. experimental, but based on other methods if it is necessary for a comprehensive understanding of psychological phenomena, (3) an emphasis on learning, (4) the range of behaviours that ESB attempts to explain, (5) the importance given to the environment, both physical and social, (6) the technology derived from research and based on scientific evidence. ESB is a research programme for the unification of psychology, based on current research and theory.

Suppression as an effective emotion regulation strategy in the context of anger and economic risk taking

Marina Astahova University of Konstanz, Germany; Birgit Wimmer; Thomas Goetz; Matthias Spoerri

Experiences of uncertainty and loss of control have become an integral part of our daily life in the face of rapid technological developments and increasing complexity of modern societies. Dealing with these experiences in a functional way is vital for an individual’s adaptability. Perceptions of loss of control influence emotions and subsequent decision making. This study thus focuses on the moderating effect of trait emotion regulation strategies (suppression; Gross, 1998) on behavioural consequences (risk taking) of anger induced by subjective loss of control. We hypothesised that the effect of anger on risk-taking behaviour is reduced by enhanced dispositional suppression. Results of a laboratory experiment (z-Tree; Fischbacher, 2007) with N = 135 Chinese students confirmed that the influence of induced anger on risk taking is moderated by suppression (Beta = .18, p < .05): Only in participants with lower degrees of suppression, the positive effect of anger, causing increased risk-taking behaviour is shown (Beta = .29, p < .05), whereas this is not true for participants with medium (Beta = .11, ns) or high levels (Beta = -.07, ns) of dispositional suppression. Individuals habitually using suppression as an emotion regulation strategy are less prepared to take risks under anger following subjective loss of control. This effect on behaviour might be due to the suppression of the expressive component of emotions. These results on their moderating effect in the context of risk-taking behaviour highlight the relevance of self-regulatory skills and challenge the view of suppression as a generally maladaptive emotion regulation strategy.

The influence of religiosity on perceived trust among university of Lagos undergraduate students

Oyeyemi Ayeni University of Lagos, Nigeria; Ke-Ahinde Ayeniowu; Esther Ayeni

The study examined the effect of religiosity on perceived trust among undergraduates. A total of 122 undergraduates participated in the study. 58 of them were males while 64 were female. Six stories depicting two characters (a male and a female) each of low, moderate and high religiosity were used to assess perceived trust. Participants were requested to determine the extent to which they would trust the characters in the stories. In addition, a religious trust scale was administered to the participants to assess their level of intrinsic religiosity. The results show a significant positive relationship between the participants’ level of intrinsic religiosity and their perceived trust of the highly religious (r = .82) and the moderately religious characters (r = .76) at P < 0.01. It also revealed that level of trust increased slightly with the level of religiosity of the character being assessed. The highly religious characters were assessed as more trustworthy (mean = 65.23; SD = 11.29) than the moderately religious (mean = 62.57; SD = 10.26) and the non-religious (mean = 56.82; SD = 15.53) characters. However the differences are not significant. The results did not also show any significant differences between the male and the female participants in religious trust and intrinsic religiosity. The findings underscore the role of similarity and stereotype in interpersonal relationships.

Reflexive game as a means to prevent extremism among youth

Karine Babiyants Southern Federal University, Russian Federation

The relevance and purpose of the study was early psychological prevention of youth extremism, individual development of reflective capacity in situations of frustration, and awareness of their cultural and mythological stereotypes. The method used was Babiyants K.A. “Addressing the causes and facts of the growth of extremism” and Manuilova O.W. “Reflexive game as the prevention of extremism.” Techniques studied in a situation of frustration and threat of terrorist extremism, individual-typological characteristics of the respondents, the types and directions of possible reactions. Only 84 people participated (Christians), women 16-30.
Non-linear influence of the gnostic emotional orientations on parental feelings
Mikhail Basimov Kurgan State University, Russian Federation; Elena Padurina
By results of research of features of positive parental feelings and their influence on formation of an adequate self-appraisal of the preschool child (50 parameters, 6 diagnostic techniques), it has come to light that there is non-linear influence of a gnostic emotional orientation (within the limits of 10 component models of an emotional orientation) on other parameters of research (for calculations M.Basimov’s method was used). Dependences of following types (calculation for explanatory variable triads) are revealed: 1. With the symmetric maximum two parameters depend on a gnostic emotional orientation (X): "The emotional component of positive parental feelings" and "Positive feelings to the child" (Y) from parameter "A gnostic emotional orientation" (X) as comparative weightiness of parameter Y for triads on scale X: X1(Y=652); X2(Y=4109); X3(Y=908). Factor of the connection strength=0.66 (feedback is weak = 0.28). Coefficient of correlation=0.03. 2. With the maximum cut off at the left (the general decrease) two parameters depend on X: "Aspiration to corporal contact" and "Rendering of emotional support". 3. With the maximum cut off on the right (the general increase) four parameters depend on X: "Satisfaction relations with the child"; "The behavioural component of positive parental feelings"; "Positive feelings to the child caused by its advantages and achievements"; "The estimation of the child the parent".

Knowledge and attitudes towards domestic violence in North Cyprus
Fatos Bayraktar Eastern Mediterranean Univ., Cyprus; Senel Husnu; Ugur Maner; Biran Mertan; Faith Bayraktar; Gozde Pehlivan; Duriye Celik
Domestic violence victims usually first apply to police stations or hospitals (McMullan, Carlan & Nored, 2010). Therefore law enforcement and health care professionals can play a vital role in cases of violence. One of the aims of this study was to assess how knowledge and attitudes toward domestic violence against women would differ between professionals and students from different disciplines. The second aim was to assess whether knowledge and attitudes toward domestic violence against women would vary as a result of previous training and contact with a domestic violence case. The final aim was to investigate whether knowledge and attitudes toward domestic violence against women would change based on varying demographic characteristics of the participants. A total of 305 participants (170 law, nursing and psychology students and 135 police officers) were included in the sample of the study. A Domestic Violence Attitudes Scale (DVAS) was developed by the authors to measure knowledge and attitudes toward domestic violence against women and a demographic information form was administered to obtain personal information regarding the participants. Results indicate that knowledge and attitudes toward domestic violence against women are related with the area of study or occupation and previous training and/or previous contact with a domestic violence case, but not with age, gender, nationality or marital status.

The psychologist in the process of organ and tissue donation
Marcos Cavalcante Faculdade Integrada Tidentes, Brazil; Arlina Dias
The growing demand in organ transplant procedures has caused physicians to adopt psychological criteria in evaluating candidates for these procedures to identify those who have a higher chance of success, reducing risks and optimising benefits. The psychological evaluation is part of this procedure, where after the medical evaluation it is considered whether or not the individual is a transplant candidate. BOOK REPORT through other publications, visit the Transplantation Center of Macedonia and interviews with psychologists of this institution, we can verify the performance of counseling in the pre, during and post-treatment factors that may cause shock and influence on their emotional state and their decision-making, but also how this intervention occurs. The study shows a whole process and follow-up of a multidisciplinary team where the main difficulty is the psychologist’s awareness of the family for the donation of organs and tissues, where the final verdict belongs to first-degree relatives. The knowledge in thanatology helps professionals involved in the process of overcoming this barrier, putting it into a new perspective for family members.

Behavioural correlates of coping strategies in close relationships
Belanger Claude University of Quebec, Montreal, Canada; Stephane Sabourin
The main objective of this study was to investigate the relationship between specific coping strategies and problem-solving/communication behaviours in close relationships. The sample consisted of 72 couples who completed the Dyadic Adjustment Scale and the Marital Coping Questionnaire and who also participated in a filmed 30-minute discussion where they had to solve a relational problem. Observed behaviors were coded using a macrosopic coding system for dyadic interactions. For both men and women, results show significant relationships among coping strategies, marital interaction, and marital adjustment. For women, coping strategies and behavioral dimensions independently accounted for observed fluctuations in marital satisfaction scores. Theoretical implications of these results are discussed.

History and growth of international psychology: A record from psychological abstracts
John M. Davis Texas State Univ-San Marcos, United States of America
The historical development and geographic expansion of scientific disciplines can be charted from various indexing and abstracting services. In the discipline of psychology, PsycINFO, the abstract database of the American Psychological Association, provides the most comprehensive and accessible of these services. Using this database, several researchers have conducted comparisons of psychological research outside the United States with research in the U.S. (Brozek and Siegler, 1989, 1991; Bauserman 1997). Rosenzweig (1992) reported that psychology is growing faster outside the U.S. than within the U.S. International representation of psychological literature in PsycINFO has also been reported by Imada (1996) and by Imada, Overmier, and Davis (2009). The present study examined two questions: (1) To what extent is psychological research from outside the US represented in the PsycINFO indexing and abstracting service? (2) What trends are evident from 1975 to 2010? PsycINFO records were searched, country-by-country, for blocks of five-year periods between 1975 and 2010. Countries were identified in the IN (institution) field of PsycINFO. Countries were grouped into the following geographic regions: United States, Canada, Western Europe, Eastern Europe, East Asia, Southeast Asia, Australia/New Zealand, Middle East/North Africa, Sub-Saharan Africa, Latin America.

What is new psychology?
Shukran Dadayev Baku State University, Azerbaijan
Please consider these questions: 1. What does psychology study? 2. Why does psychology have various definitions in different countries? In various countries, psychology has various definitions. This is the international crisis of psychology. Psychology is foremost a science about the psyche, (ancient Greek: psychology = psyche + logos). Psyche is the original subject, the real foundation of psychological and psychological Sciences. It's the primitive historical-scientific reality. We should not be afraid of the difficulties inherent in researching the psyche. Since the psyche is the original subject of psychology, the determination and study of the human psyche enables us to create foundations of new fundamental, real psychology. This should refer to a new psychology as a discipline rather than as a psychological direction or school within psychology. This new psychology is unlike former soviet psychology and modern Western psychology. It's a new scientific approach. It's a science free from policy, political ideology and is fundamental, original psychology. This psychology is the true and original psychology that whole world needs and is expecting. This science is the professional psychology formed on the basis of its true subject and foundation: psyche. Thus, I propose the following as the new common definition of psychology: the study of the psyche and all living peculiarities.

General
in America. Results showed that the percentage of articles in PsyCINFO has increased in countries outside the United States from 1975 to 2010. Continuing the trend reported by Bauserman (1997), Western Europe, Australia, Japan, and Israel have increased their international representation. Developing nations continue to be less well represented in the psychological literature and particularly in basic research areas. However, international growth in the psychological literature as represented in PsyCINFO is likely to continue.

The social relationship between adolescents through the digital media in two Brazilians cities

Fabricio De Souza Federal University of Bahia, Brazil

The technological advances and the digital apparatuses that have constituted an interactive media produce social changes leading people’s actions to be marked by the reality of the cultivation of what is new; of renewal and ruptures of some social structures. The culture of mobility, flexibility, transition and temporariness in societies marked by information technology impinges in people the need to act in agreement with the demands created by these societies. It is opportune to study the effects of this technological change upon adolescence, the adaptation of adolescents to the digital technologies and its utilisation in the establishment and maintenance of social connections. This work aimed to investigate blogs and other profiles kept by adolescents in two Brazilian cities, Vitória/ES and Salvador/BA, and collected information concerning the social changes established through the mediation of the digital media. 16 blogs and orkut profiles have been selected, eight of young females and eight of young males. The results were analysed in accordance with Evolutionary Psychology and indicated that certain patterns of off-line interactions orientated the establishment of on-line relationships and revealed evolutionary patterns typical of sex typed behaviour, such as the demonstration of affection, praises, the expression of longing and the search for contacts. The digital media was considered an efficient tool in the sociability as it is important in the favouring of aptitude in the life in group.

Research into legal consciousness constructs

Davlet Duisenbekov Kazakh National University, Kazakhstan

Legal consciousness is the background of righteous stands and helps us to comprehend own rights, self and their respect or humiliation. Human legal consciousness arises as an inner system of person-centred legal constructs reflecting various aspects of righteous reality, regulating our own behaviour and developing personal righteous notions. The activity of a person’s legal consciousness is considered as realisation of one’s free activity not only as determined by necessity but as capable of going through its frontiers. 354 adult subjects were involved and distributed into three exclusive groups according to their mentality (lawyers – judicial-normative, naturalists – natural-scientific, humanitarians – humane) with the application of the analytical method, original technique of detecting legal consciousness’ attributive signs, data processing and interpreting, content-analysis and data quality analysis. Basic factors represent peculiarities of righteous preferences in different exclusives. Factor 1 - a “right-norm” unites common-legal and normative legal constructs with traits of civil identity and righteous protectiveness. Factor 2 - a “right-social value” unites social-valuable and communicative constructs with personal identity and social protectiveness. Factor 3 - a “right-culture” unites cultural-righteous and cultural-valuable constructs with cultural-ethnic identity or cultural liberty. Factor 4 – a “right-Me” unites personal-righteous and individuval-valuable constructs with traits of subjective-personal identity and possession of one’s vital and legal activity. Research allowed to us differentiate three forms of legal self-consciousness – empirical, rational and metaphorical.

The marital adjustment in dual career families of state university’s employees in Isfahan

Leila Esmaili Dkhorsgan (Isfahan) Branch, I.A.U., Islamic Republic of Iran; Mohammad Reza Abedi; Mohammad Sadeghi; Iran Baghban

This study aimed to examine the marital adjustment in dual career families of state University’s employees in Isfahan, 2010. The study was descriptive and the population included all employees of the state University in Isfahan. A random sampling method was used: After distributing 600 pairs of questionnaires (1200), 473 pairs were returned, 200 pairs were related to dual career families and 200 pairs were related to single-earner families. The assessment tools were World Health Organisation Quality of life Standard Questionnaire (WHOQOL-100) and Revised Dyadic Adjustment Scale (RDAS) which have a desirable reliability and validity. The result of Independent t test analysis and regression analysis with the stepwise method showed that: The difference of score of marital adjustment between the two groups, dual career and single-earner families is significant (P = 0.002). Also, from 25 factors of quality of life, only seven factors have respectively significant roles in the prediction of marital adjustment: Sexual activity, pain and discomfort, Work capacity, Social support, Physical environment, Positive feelings and Opportunities for acquiring new information and skills.

The impact of occupational field of expertise on intention to pirate software

Ameetha Garbharran University of the Witwatersrand, South Africa; Andrew Thatcher

The objective of this study was to explore the impact of occupational field of expertise on intention to pirate software using social cognitive theory as the theoretical paradigm. The sample consisted of 233 individuals from IT/technical occupations and 223 individuals from non-technical occupations drawn from a database of consumers of technology-oriented products and services from a large telecommunications organization. Data were collected using a 21 item questionnaire (measuring past behaviour, moral disengagement, self-efficacy, outcome expectations and software piracy intention) deployed on an online survey tool. Data were analyzed with SAS using independent sample t-tests, Fisher’s Z transformations and multiple-group path analysis to test for occupational field of expertise as a moderator in the proposed structural model of social cognitive theory. Significant differences were found between the groups on the self-efficacy and intention to pirate software variables, with individuals from the IT/technical occupations group reporting higher scores. A significant difference was found in the association between outcome expectations and intention to pirate software with a higher correlation obtained for individuals from IT/technical occupations. Occupational field of expertise did not act as a moderator in the model. Thus, while there were some differences between individuals from IT/technical occupations and those from non-technical occupations in terms of individual social cognitive constructs and the associations between them, the social cognitive model for explaining software piracy intention was equally predictive for both groups. Implications of these findings will be explored.

A comparison life satisfaction and meaning of life: Art and non-art students at Tehran University

Mohammad Hakami Islamic Azad University, Karaj B, Islamic Republic of Iran

The aim of present project is the comparison life satisfaction and meaning of life in the field of art university students and non-art students of Tehran University. Samples include 159 university students (75 university art students - 29 men and 49 women - and 84 university students in non-art fields; sport, microbiology and computer engineers - 43 men and 41 women). The simple accidental sampling methodology was used for selecting art students and several stage branch sampling for selecting art students. For analyzing data, the MANOVA method and t-exam have been used. The result of this analysis show that there isn’t any significant relation between university students’ life satisfaction and meaning of life and their study of art or not. Other findings also show that there isn’t any significant relation between university students’ life satisfaction and meaning of life between men and women. It is observed that there is significant relation between meaning of life of men and women university students and this difference advantages men. There is no significant relation between meaning of life and satisfaction for university students in the fields of art and non-art.

The emerging new success DNA - new challenges for psychologists

Brenda Hattingh South Africa

We are hardwired for success and need not settle for anything less. Current scientific research has revealed the existence of a new, emerging, human DNA. What once were perceived as physical junk genes, are now turning out to be biological material with inherent higher emotional, mental and universal potential. These keys to new levels of healing, happiness and success are waiting for us to become conscious, reconnect, and access this universal gift. However, most people are disconnected from the true self and their inherent potential to be happy and fulfilled. The tasks of psychologists are to fully understand emerging new success DNA, enhance the healing and re-connecting process and fast-forward a new success process for all. Few professionals however have been trained in New Success DNA and activation, as it has not yet become part of main stream Psychology. This is igniting new personal and professional challenges. This paper...
Focuses on: (1) The results of seven years of research and the emerging New Success DNA (2) Consciousness, mindful living and the new face of success, (3) Counselling, coaching, therapeutic intervention and DNA activation (4) Guidelines for training professionals in this new emerging awareness and new success DNA.

Power intelligence: Activating new success DNA
Brenda Hattingh South Africa
A new human consciousness and a new Success DNA is emerging in order to harness this potential, we need to develop a new mindset, even a whole new intelligence. The term Power Intelligence (PI) was coined to describe this process. Power Intelligence is defined as the conscious ability to utilise our infinite potential and create success and prosperity for all. Power Intelligence is the conscious ability to activate New Success DNA. A research project was undertaken to identify the challenges of the future, quality living, aging, levels of consciousness and methods for activating New Success DNA. A Power Intelligence Success Profile (PISP) was developed in order to assist individuals, groups and organizations in developing awareness, self mastery and New Success DNA. This poster presentation includes: Results from the research; Methods for activating New Success DNA; The Power Intelligence Success Profile (PISP); Case study. We have the responsibility to secure a safe transition into the future. Power Intelligence and DNA activation will therefore need to become part of our training. The time to join hands has come.

Prevalence and correlates of adolescent substance use: A study among 13- to 18-year-old students in Sri Lanka
Anne Ismail University of Colombo, Sri Lanka
There is much concern about the increasing burden of substance-related deaths and disease rapidly shifting to developing nations, especially among their youth. Epidemiology of substance use by adolescents in Sri Lanka is scarce. Reliable and valid data on substance use by adolescents would guide the allocation of prevention resources in the country. This study was conducted to determine the prevalence and identify correlates of substance use by adolescents attending school. A cross-sectional survey was conducted among 3,454 13- to 18-year-old students in the Colombo district (the main commercial hub of Sri Lanka). The validated self-administered Adolescent Substance Use Student Questionnaire, Adolescent Substance Use Correlates Questionnaire and the Sinhala Substance Use Risk Factor Profile Scale assessed the use of various substances and correlates. Descriptive and multivariate analyses were carried out to determine prevalence and identify correlates of the occurrence of ever using substances. Overall 16% have used at least one substance in their lifetime. Prevalence of ever use of cigarettes, alcohol, marijuana and other drugs was 6.1%, 13.6%, 25% and 1% respectively. Boys were significantly more likely to report use than girls. Use increased with age of the adolescents. Age at first use varied with each substance. Nearly 70% have used only one substance. Ever use of cigarette, alcohol and other drugs is best explained by a unique combination of demographic and psychosocial correlates. Identified correlates indicated areas for substance-specific interventions. This study contributes to the knowledge base of preventive professionals and forms a foundation for further research and national and cross-cultural comparisons.

A study of college students’ personality, self-compassion and anxiety
Kai Jing Jiangxi Normal University, China
As a new form of self-view, self-compassion is put forward based on numerous studies of self-esteem. Many studies showed self-compassion included many psychological advantages related with self-esteem such as self-acceptance and self-affirmation, and self-compassion connects self with others. So it’s necessary to explore the relationships between self-compassion and other aspects of the individuals. Due to the difficulty to change the personal- ity of the individuals, the objective of this investi- gation was to explore the role of self-compassion between personality and mental health, which would provide us with the way to improve the level of mental health by improving self-compassion level. 942 students in four grades from 8 universities of Nanchang were randomly chosen as the partici- pants. The Big Five Inventory (BFI), Self-Compassion Scale (SCS) and Self-Rating Anxiety Scale (SAS) were used to study the relationship of college students’ personality, self-compassion with anxiety. The enter multiple regression statistics method was used to analyze all collected data by SPSS13.0. The results revealed that the global state of self-compassion is in good shape. Its score was 3.22 ±0.46, which showed they would understand and be kind to themselves when they faced with failures and setbacks. College students’ five factor personality, self-compassion and anxiety were significant- ly correlated. Meanwhile, self-compassion and per- sonality were the distinct predictors for anxiety, and self-compassion was a mediator between personality and anxiety.

A web-based mother-daughter communication strategy
Mary Katsiklis University of the Sunshine Coast, Australia; Christian Jones; Melody Muscat
This study introduces an intervention designed to bring mothers and daughters together to discuss and explore several issues, including interpersonal com- munication and parenting style, conflict resolution and risk-taking behaviours, such as binge drinking. The study has 2 stages. Stage 1 consisted of meeting with 2 separate focus groups, one with mothers and a separate one with their adolescent daughters. These issues (above) were all identified as pivotal to the mother-daughter relationship at this stage of the developmental cycle (for both mothers and daugh- ters). In Stage 2, we designed a web-based inter- vention, using technologies such as Facebook and SMS to support our programming. The intervention provides a new opportunity to provide supportive, positive experiences that meet the developmental needs of both groups. The intervention involves activities that mothers and daughters do together, once a week, for a period of 3 weeks. Evaluation of the intervention includes, mother-daughter communica- tion, parenting style, parental confidence in parenting and self-esteem of both parties. Results and a demonstration of the web-based intervention will be provided.

An investigation into developmental dyslexia: a cross linguistic study
Azizuddin Khan IIT Bombay, India; Smita Desai IIT Bombay, India
A commonly accepted hypothesis is that dyslexic children encounter difficulties in reading and writing because they are impaired in their abilities to discrimi- nate basic sound units of spoken language. Thus, dyslexia may be a consequence of a deficit in the conversion between sounds (phonemes) and let- ters (graphemes). Dyslexic children would be im- paired in their abilities to segment and discriminate the sequence of sounds in a spoken language, that is, in their “phonological awareness” (e.g., Wise et al, 1999). The degree of mapping between sounds and letters largely vary between Western languages such as English, French, Italian and Spanish. For instance, English comprises 40 phonemes and 1120 gra- phemes, and is consequently a complex, opaque, language in terms of phonemes to graphemes map- ping. Most interestingly for the present project, there are even larger differences between Western lan- guages and Eastern languages such as the major languages of India (Hindi, Marathi, Tamil), which are said to be “the most perfectly transparent” lan- guages. Linguistic differences in terms of transpar- ency are known to have important consequences for the first stages of reading acquisition. In a large scale study, Seymour et al (2003) have demonstrated that the highest the degree of transparency in the pho- neme to grapheme conversion, the highest the read- ing skills of the children. The present paper is an attempt to explore cross linguistic differences be- tween western and oriental languages and its impact on dyslexic symptoms.

Relationship of attachment styles with empathy in nursing students
Mohamad Reza Khodabakhsh University of Tehran, Islamic Republic of Iran
Attachment styles of nurses as caregivers and mem- bers of healthcare teams are considered to be an important topic worth studying. This study exam- ined the relationship of attachment styles with em- pathy in nursing students. A sample of 260 univer- sity students (130 males, 130 females) was included in this study. All participants completed the Attach- ment Style Questionnaire (ASQ), and the Interper- sonal Reactivity Index (IRI). The results showed that secure and insecure attachment styles had sig- nificant positive and negative correlation with em- pathy, respectively. The results of regression analy- sis revealed that secure attachment style is shown to be the predicting 53% of the variance empathy variable, whereas insecure attachment styles are shown together, explaining up to 76% of the vari- ance empathy variable. The meaning and limitation of this study and the suggestion for the further study are discussed.

Relationship of narcissism with self esteem in tendency to forgive
Mohamad Reza Khodabakhsh University of Tehran, Islamic Republic of Iran

General
Researchers have begun to examine how personality relates to forgiveness, regarding the importance of examining the determining and effective variables in forgiveness. The purpose of the present study was to examine the relationship of narcissism with self-esteem in the tendency to forgive. A sample of 324 university students (160 males, 152 females, 12 unknown) was included in this study. All participants completed the Narcissistic Personality Inventory (NPI; Raskin, & Terry, 1988), Heartland Forgiveness Scale (HFS; Thompson et al., 2005); and the Rosenberg Self-esteem scale (RSE; Rosenberg., 1965). The results showed that narcissism had a significant positive correlation with self-esteem. The results of regression analysis revealed that narcissism and self-esteem are shown together, explaining up to 76 percent of the variance in forgiveness variable. The meaning and limitation of this study and the suggestion for the further study are discussed.

The future of psychology in the Arab world: The need for an Arab framework
Brigite Khoury American University of Beirut, Lebanon

One of the main challenges faced by psychologists in the Arab world is applying Western theories and training to an Arab population. Most of the psychologists in our societies are Western-trained, and when faced with working in their communities they realise the difficulties and challenges they have when trying to apply Western theories and therapies to Arab clients. Examples will be given from my own work for the past 10 years in Lebanon and the difficulties faced in therapy as well as in the training of young psychologists. Hence, the need and importance of creating an Arab psychology arises, with its own framework which stems from our own culture, value system, traditions, and social context. Discussion will be focused on the adaption of Western psychology into our Arab societies and the creating of an ‘Arab psychology’, which will be the optimal goal psychology needs to reach in the Arab world in the years to come.

Implications of psychological control theory
Ruiguang Liu Department of Psychology, China

Much of what we know about human thought and behaviour has emerged due to various psychological theories. As an illustration of the breadth of its applicability, the basic construct of control theory, the discrepancy-reducing feedback loop, is presented, and certain implications for theory in 3 areas of human psychology are also discussed. It is contended that control theory provides a model of self-regulation that is useful in the analysis of human behaviour. Glasser claims that all behaviour is made up of three components: What we do, what we think, and what we feel. He also identifies five needs, which are deeply interpreted in the paper. According to Glasser, all human behaviour is an attempt to satisfy powerful forces within. He specifies that control is a way in which humans must function in order to fulfill their needs, in other words, it is the predominant need of most individuals.

Experiences of mothers caring for schizophrenic children in Elim village, Makhado

Solomon Mashegoane University of Limpopo, South Africa; Aziwhangwisi Negota

Mothers who care for schizophrenic children go through various personal experiences and face enormous challenges. The aim of this study was to explore their experiences. Eight mothers from Elim Village, Makhado were interviewed at their homes, using in-depth, phenomenological interviews. Analysis began as soon as the process of data collection itself commenced. It included, inter alia, reading and re-reading the transcripts to identify meaning units, which in turn were constituted into themes. The authenticity of the themes was established and verified with the participating mothers. Eight themes emerged from the participating mothers’ articulations. They were labelled (i) poverty and unemployment, (ii) mothers’ emotional reactions, (iii) blaming witchcraft, (iv) dealing with the children’s violence and destructiveness, (v) financial support, (vi) social support, (vii) effect of schizophrenia on mothers, and (viii) the loss that mothers go through. The study reconfirmed that caring for individuals with schizophrenias is not an easy task for most mothers. Recommendations were advanced on the basis of the findings.

Protection of maternity and newborn life: An empirical intervention to promote the anonymous birth and develop culturally competent care
Laura Milani Iulm University, Italy; Vincenzo Russo; Barbara Ghiringhelli

The incidence of unintended pregnancy remains high in Italy, where induced abortion is permitted and is often the only choice that women have. Official statistics, and nationally representative surveys, show that there is a decline in the abortion rate in Italian women and an increased rate of abortion in immigrants. The aim of the project is to promote anonymous birth and to develop culturally competent care (social and health workers). The present research is promoted by the Consortium “Preferring Life” and the Presidency of the Council of Ministers. A literature review on psychosocial databases was carried out. The qualitative phase consisted of spot analyses, broadcast in Italy and abroad, in-depth interviews within the professional community, and women who had terminated a pregnancy. The quantitative phase consisted of a questionnaire within professionals across Italy. It has emerged that there is a lack of information and communication on the issue at a national level. Training about the alternatives to abortion (anonymous birth) and about the development of culturally competent care is needed. A training course is implemented within public and private professionals and volunteers (health and social) across Italy. It is designed for the acquisition of cultural knowledge and skills to integrate cultural and religious differences, and is essential to improve local service provision throughout migrant-friendly services. A spot campaign is being prepared to be launched at a national level.

Mental health, school performance, and Internet addiction
Eliehe Naseri Islamic Republic of Iran; Jaril Fatkhabadi; Fatemeh Bagherian; Fatemeh Bagherian

Studies show that people’s personality or mental characteristics and school performance are related to their amount of Internet use. The purpose of this study was to investigate whether excessive use of the Internet can affect mental health and school performance. In addition, the relation between demographic characteristics and excessive use of Internet was measured. A sample of 200 university students participated in the study according to convenience. The students answered to Young Internet Addiction Questionnaire, Mental Health Questionnaire, GHQ, and a few questions about their school performance. The results of analyzing data showed that 8% of physical problems, 6% of stress signal, 7% of social performance disorders, and 9% of depression can be predicted by excessive use of Internet. There was no significant relation in total between excessive use of Internet with mental health and school performance. However, school probation can predict 23% of addiction to the Internet. Correlation between excessive use of Internet and mental health problem was 39%, indicating a significant relation between the two factors. In conclusion, addiction to the Internet can probably predict poor school performance and mental health problems.

What is God able to do? Iranian children’s views and the effect of experiencing loss
Raziyeh Nasirzadeh Shahid Beheshti University, Islamic Republic of Iran; Mohamadali Mazaheri

The purpose of this study was to investigate children’s perception of God’s deeds (what God is able to do), and the impact of experiencing loss. The sample consisted of 122 children from 8 Iranian elementary schools (55 girls and 67 boys, ages 6-11). They are from three categories of family (divorced family, dead parent and without a loss experience) and were selected through multistage stratified random sampling. In this investigation, children were interviewed individually and they were asked to free-associate what they think about God’s deeds (what God is able to do). The answers children gave to these questions were recorded and in the next step, the responses were categorised by the researcher. Frequency, frequency percent and chi-square were used for data analysis. The results show that during free association, children mentioned omnipotence more than other deeds, were significantly different depending on the child’s age and there was a significant difference between children with the experience of parents’ divorce and children without a loss experience. Children who experienced the death of a parent in expressing the works that God is able to do, tend to report that God is able to do anything, and children with the experience of parents’ divorce tend to report positive works for God.

Iranian childrens’ perceptions of family relationships
Raziyeh Nasirzadeh Shahid Beheshti University, Islamic Republic of Iran; Narjes Erfanmanesh

The House-Tree-Person test (HTP) is one of the most commonly used methods to gather data regarding interpersonal connectedness. The purpose of this research was to investigate childrens’ perceptions of family relationships using the House-Tree-Person test. According to the Handbook of
Psychological Assessment (Marnat, 1975) is a symbol of the mother, a tree is a symbol of the father and the person is a symbol of the self. The study sample included 117 Iranian children, (62 boys and 55 girls, 6–11 years old) selected using multistage stratified random sampling. HTP tests were administered to children individually. Data analysis was conducted using descriptive statistics and chi-square testing. The findings of this research showed that children in Iranian elementary schools drew the house larger and earlier than two other objects (the tree and the person) in addition they drew the person nearer to the house rather than to tree. Thus findings of this study showed that in children between the ages of 6 to 11 years, in Iran, the mother figure is perceived as more powerful and more important than the father and self figures. Also, they feel more comfortable with their mothers.

Parasocial relations and creative internet activity
Lyubov Nasyonova ISSP, Ukraine
Parasocial relations are the normal element of daily life in the digital age. Virtual heroes created by mass media are part of the person’s social relations network, especially for young people. Parasocial relations cause an emotional attachment, similar to friendships. The depth of parasocial relations is defined by reflexion (situational, attachment, self-definition forms). The main research question is the connection between parasocial relations and creative Internet activity. An All-Ukrainian survey for mediaculture monitoring during 2009-2010 is the method we used. Samples are 1997 adults, 399 schoolchildren (14-17 years old), 410 university graduate students (representative by gender, education level, city/village home places and regions). We employed a questionnaire of parasocial relations (Hartmann et al., 2008). Results showed that 32% graduate students, 50% both school students and adults demonstrated the situational level of parasocial relations (in negative modality) and 11%, 15% and 18% - attachment level (in positive modality). The existence of inverse connections between parasocial relations and Internet creativity is confirmed. Positive modality of parasocial relations (situational and attachment levels) occurred at least two times less if respondents have their own blog or webpage. We found a positive connection between parasocial relations (positive modality) and wanting to make video films. We conclude that parasocial relations specifically, must be taken into account for media education programmes. The recommendations were made for an experimental media education project started in 82 Ukrainian schools in Ukraine from 2011.

Community development worker perception on wellness at an HIV/AIDS organisation in Nelson Mandela Bay
Joshua Ndlela NMMU, South Africa
The general aim of the study was to explore and describe the community development workers’ perceptions of wellness at an HIV/AIDS organisation in Nelson Mandela Bay, South Africa. The population of 36 community development workers at the Nelson Mandela Bay office of this organisation participated in this study. Focus group interviews with community development workers revealed seven common themes in the experience of working in an HIV/AIDS organization: participants’ understanding of wellness; organizational factors that impact on wellness; personal factors that impact on wellness; family and community factors that impact on wellness; participants’ wellness; personal coping strategies; and suggestions regarding organizational strategies. These themes are supposedly guiding the development of an employee wellness programme. In this study, the sampling technique employed can be described as a census as it involved sampling an entire finite population that included everyone in the organization. These workers are predominantly Xhosa-speaking adults between the ages of 21 and 60 years, and include both males and females. Qualitative data was gathered by means of audio-recorded focus groups, utilising semi-structured interviews. Tesch’s method was used to analyse the data, while Guba’s model was used to enhance the trustworthiness of the research. It is envisaged that the research findings of this study will be used in future to direct interventions that will be most beneficial for the short- and long-term planning for the wellness of the community development workers of the HIV/ AIDS organisation and those around them. It is recommended that the organization have to develop a workplace wellness program, increase management support towards the wellness of the staff and to increase the staff capacity.

Psychology in the context of health policy
Eva Neu; Klara-Stephen Molnar; Michael Schratz; Penka Fassova Germany; Silvena Tarpananova; Rumen Stainov; Michael Michailov; Detchko Christoff; Stanka Burova; Dimitrinka Michailova Inst. Umweltmedizin/ICSD e.V., Germany

On interdisciplinarity of psychology: Long-term project anthropology and integrative medicine

Experiences of senior students involved in the orientation programme of first year university students
Sisanda Nkoso NMMU, South Africa
Well-documented evidence shows that “having the skill and academic capacity for achievement at university and the appropriate habits of an effective student are generally not a sufficient pre-condition for success” (McInnes et al., 1995). Therefore creating and delivering appropriate support systems, like a successful how2buddy programme, is crucial to student success. The main objective of this study was to investigate how the NMMU how2buddy programme has contributed to the holistic development of the how2buddies as senior students. That means their development in various different dimensions, including academic, leadership, social and personal. The sample of the study was a group
Experiences of inner city Black youth living with depression: A phenomenological study
Mirian Ofoneda Kennedy Krieger Institute, United States of America
Diagnosing depression in adolescents is frequently challenging. Depression is often under-identified, and misdiagnosed, especially in youth from under-represented ethnic and racial groups who live in urban environments. Depression may best be understood by directly asking individuals about their experiences. We employed a qualitative phenomenological design to examine the subjective experience of ten African American adolescents, within the age range of 13 to 17 years, who had a DSM-IV-TR diagnosis of depression. Five super-ordinate themes emerged from the study analysis: (a) difficulty describing the depth of the experience, (b) life events and experiences as root base, (c) the emotional sense of self, (d) the survival self, and (e) the healing self. These themes formed the essence of the adolescents’ experience of living with depression. Findings demonstrate the essence of the lived experience of being depressed as including both externalizing and internalizing strategies for coping. The adolescents in this study condemned suicide as an ultimate means of escape from their inner distress and found anger as a means of coping with the ‘pains’ of depression, suggesting the need to acknowledge anger as a construct that may lead to a more informed understanding and identification of depression among African American youths. The findings also revealed that the meaning of depression remains unique to the individual experiencing it. Methodological limitations and recommendations for future research are addressed.

The causal relation between children’s materialism and life satisfaction and the role of advertising exposure
Suzanna Opree ASCor, Netherlands; Moniek Bijlzen; Eva van Reijmersdal; Patti Valkenburg
As many as nine out of 10 parents worry that children’s frequent exposure to advertising makes them materialistic. In this study we not only aim to investigate if children’s advertising exposure indeed affects their materialism, but also how it affects their materialism (i.e., by studying the mediating effects of advertised product desire and perceived reality of advertising). The study investigates 8- to 11-year-olds, because these children are in the midst of consumer development. Unlike previous studies, it focuses on the longitudinal rather than the cross-sectional relations. A sample of 466 children (ages 8-11 years; 55% girls) participated in a two-wave online survey with a one-year interval. We asked children questions about material possessions, life satisfaction, and advertising. We used structural equation modeling to study the relationship between these variables. For the children in our sample, no effect of materialism on life satisfaction was observed. However, life satisfaction did have a negative effect on materialism. Exposure to advertising facilitated this effect: We only found an effect of life satisfaction on materialism for children frequently exposed to advertising. It was concluded that among 8- to 11-year-old children, life satisfaction leads to decreased materialism and not the other way around. However, this effect only holds for children who are frequently exposed to television advertising. It is plausible that the material values portrayed in advertising teach children that material possessions are a way to cope with decreased life satisfaction. It is important to reduce this effect, because findings among adults suggest that materialistic children may become less happy later in life. Various intervention strategies are discussed.

Children’s advertising exposure and materialistic orientations: A longitudinal study
Suzanna Opree ASCor, Netherlands; Moniek Bijlzen; Eva van Reijmersdal; Patti Valkenburg
The purpose of this study was to investigate the relationship between these variables. Findings demonstrate the essence of the lived experience of being depressed as including both externalizing and internalizing strategies for coping. The adolescents in this study condemned suicide as an ultimate means of escape from their inner distress and found anger as a means of coping with the ‘pains’ of depression, suggesting the need to acknowledge anger as a construct that may lead to a more informed understanding and identification of depression among African American youths. The findings also revealed that the meaning of depression remains unique to the individual experiencing it. Methodological limitations and recommendations for future research are addressed.

The study of marital satisfaction in mothers of intellectually-disabled children
Seyed Reza Poospeyery University Esfahan, Islamic Republic of Iran; Vahide Mojarrad
The purpose of this study was to determine the marital satisfaction of mothers with intellectually-disabled children. This is a descriptive-analytical study through which 100 parents with intellectually-disabled children studying via remedial education, were selected through random sampling in Abarkoo. They were studied using the ENRICH marital satisfaction questionnaire. For data analysis, T-test and F-test were used. The results showed that parents with intellectually-disabled children live in an undesirable status in terms of marital satisfaction and its four sub-scales (idealistic distortion, marital relationship, marital conflict and conflict resolution). To cope with psychological problems and marital conflicts, organizations such as Welfare and Rehabilitation center, remedial education system, and IRIB are required to offer classes for these parents.

The effectiveness of parent training programmes to reduce bullying
Seyed Reza Poospeyery University Esfahan, Islamic Republic of Iran; Antonio Fuertes; Eva Gonzalez; Jose Martinez; Rodrigo Carcedo; Shole Amiri
The aim of the study was to investigate the efficacy of parent training programmes to reduce bullying among fifth grade elementary students. The statistical society was the fifth grade elementary male students of Abarkooh city. After doing sociometry and administering the questionnaire of PRQ (some parts of which measures bullying among children) the data were analysed. 20 children who were se-
Theoretical foundations.

Bullying. Results have been explained based on control groups in post test and follow up stage, it seems that the parent training programme can reduce bullying behaviour among children, therefore it can be used as an effective method to reduce bullying. Results have been explained based on theoretical foundations.

Management competencies in higher education: Perceived job importance in relation to level of training required

Ingrid Potgieter UNISA, South Africa

The increasing changes and demands placed on higher education institutions in the 21st century impact on the roles and responsibilities of heads of department (HODs) and have led to an increasing emphasis on the development of core HOD management competencies. The aim of this article is to determine the relationship between a specific set of HOD managerial competencies identified as being important for the job and the level of training required in terms of these competencies. Research has provided evidence that HODs are often ill-prepared for their managerial role, which requires the development of specific management competencies to enable them to fulfill their roles effectively. A non-experimental quantitative survey design approach was followed and correlational data analyses were performed. A cross-sectional sample of 41 HODs of 22 departments from various faculties of a higher education institution in Gauteng participated. The Management Competency Inventory (MCI) of Visser (2009) was applied as a measure. The Pearson product-moment analysis indicated that there is a significant relationship between the competencies indicated as being important for the job and the level of training required. Training needs of HODs should be formally assessed and the depth of training required in terms of the identified management competencies should be considered in the design of training programmes. The information obtained in this study may potentially serve as a foundation for the development of an HOD training programme in the South African higher education environment.

Gratitude toward God, happiness, stress, depression, anxiety and health in middle life

Fariba Pourjali Payamnoor University, Islamic Republic of Iran; Shanggui Song Payamnoor University, Islamic Republic of Iran; Maryam Zarnaghash

The purpose of this study was to see if feeling grateful to God reduces the deleterious effects of stress, depression, and anxiety on health in middle life. In addition, an effort was made to test for gender differences in this process and also the relationship between gratitude toward god and happiness was surveyed. In this study 12 adults aged 40 to 65 completed the depression, anxiety, stress scale (DASS), mental health check list (MHC), Oxford Happiness Inventory (OHI) and Gratitude toward God scale (Emmons et al. 2003). By using multiple linear regression analysis, it was found that gratitude toward God was a significant predictor of happiness and reduces negative effects of stress, depression, anxiety towards mental health in middle life. It was also found that gratitude toward God correlated with happiness. The findings were discussed in light of the literature.

Wilderness serving psychology serving humanity

Jeffrey Rink South Africa

Ecopsychology, the synthesis of psychology and ecology, utilises psychotherapeutic principles in wilderness to promote physical, emotional and spiritual wellbeing. The ecopsychologist facilitates a return to nature-the word nature coming from the Latin word 'natus' - to be born. Ecopsychologists facilitate a process in which clients connect with the Earth. Mother Earth provides the setting where one can be 'rebom' and 'suckle' at her breast. Nature nurtures, new life is born. Africa is where we all come from; it is the cradle of humanity. The ecopsychology retreats discussed, take place in primordial, African wilderness. African culture is utilised. "All things are connected" Chief Seattle tells us, "whatever befalls the Earth, befalls the sons of the Earth". Wilderness teaches us about the interconnectedness of life. Similarly, in this presentation, the interconnectedness of psychotherapy, clinical hypnosis, meditation, drumming, traditional African music, healers and shamans, symbol and metaphor, hiking, adventure, and humour, is illustrated - all leading to a multifaceted healing experience. Wilderness alters consciousness, as does meditation enhanced by clinical hypnosis, all serving as a catalyst to naturally alter consciousness. The external journey leads to an inner destination. In this process, wilderness serves psychology and in so doing, serves humanity. This ideally is a reciprocal process, and humanity through benefitting from wilderness, can contribute to the conservation of wilderness which in its own way, is stressed and threatened, like humanity, to the point of extinction. Filmed material will be used to illustrate concepts.

The feasibility and acceptability of an intervention to reduce burnout in radiation therapists

Arthee Roopnarain University of Witwatersrand, South Africa

Oncology has been described as an exciting and challenging specialty for those who work in it. For many caregivers the ability to be directly involved in the care of cancer patients and the desire to help those who are chronically ill serves as motivations for choosing this specialty (Le Blanco, Hox, Schaufeli, Taris, & Peeters, 2007). However the cost of caring may deplete this initial excitement and ability to care which may ultimately culminate in burnout (Le Blanco et al., 2007, Le Blanco & Schaufeli, 2003). This study incorporated the Trials of Improved Practice (Tips) and aimed to identify recom-

I looked for something more than just the physical

Candice Rule Human Science Research Council, South Africa; Kopano Ratele

What specific things do individuals look for in choosing a romantic partner? In a historically, and largely still, segregated context like South Africa, attraction and intimate partner choice are especially interesting topics of inquiry because extra-individual factors may play as large a role as psychosocial ones, but also because of the multicultural traditions of society. However, there seems to be a general neglect of the psychological study of love in South Africa. Although there is continuing debate regarding what both men and women perceive as a perfect mate, studies on attraction have found that there are several things that play significant roles in the partners we choose, such as physical features, proximity, affective states, and similarity. Using a qualitative approach, and critical discourse analysis, we explored young adult Coloured heterosexual men’s preferences in partners who are in racially homogenous relationships. Men’s accounts indicated that, in order of reported importance, personality was most important in establishing a steady relationship, followed by physical attraction, and then similarities in background and upbringing. Further analysis of the data also found the contribution of culture, religion and race (which was usually denied), to be important in men’s partner choice. Our findings thus indicate that both psychological influences, and not always acknowledged social ones, play a significant role when men choose a long-term intimate partner. Further research is recommended with other male and female groups as well as couples in racially similar and dissimilar intimate relationship.

Understanding why individuals choose to become tattooed

Carolina Saccaggi University of Johannesburg, South Africa; Adil Prinsloo

Set against the backdrop of the rapid rise in the popularity of tattoos and other forms of body modification, this qualitative research project set out to explore the language of tattoos and to position this language within a framework of understanding. The study focused particularly on trying to understand why individuals choose to become tattooed. Tattoos have long been associated with pathology and deviance, but their increasing popularity suggests that these associations are fading and that new meanings are being attached to the process of embedding ink.
in the skin. Through a discourse analysis of online accounts of being tattooed and getting a tattoo three key ways of speaking were identified in connection with tattooing. These ways of speaking were linked to (1) a sense of bodily completion, (2) a sense of community and belonging, and (3) the creation of a position of authority. Through a presentation of extracts from these online accounts this presentation discusses these ways of speaking and shows how they are supported by powerful societal discourses, including Western discourses surrounding individuality, self-actualisation and ownership.

Broadening access for under-represented groups using social media

Birgit Schreiber University of the Western Cape, South Africa

In South Africa, there are about 48 million cell phone subscribers, providing a platform for deep penetration into the 15-55 year old population, including student population at Higher Education where this pilot study was conducted. This study describes the findings of a pilot study of an online support service via mobile technology using chat facilities at a Higher Education Institution in South Africa. The online support service, accessible via cell phone and computer chat facility, augmented a face-to-face counseling service in a Student Development and Support Department at a medium size university in South Africa. The participants were 729 first year students who were part of a voluntary self-select peer support program. Data was gathered on the numbers and gender of students utilising the service, the range of presenting concerns and the type of responses provided by the counselor. Key findings indicate that this online support service presented a lower barrier to help seeking behaviour for male students, compared to the total gender distribution of the university and more specifically, compared to the gender distribution of students who had utilised the face-to-face counseling during the same year. Issues presented to the online support service were similar to the presenting concerns listed at the face-to-face counseling service of the university. The paper concludes with recommendations about exploring innovative practices for service provision especially around broadening access. Ethical challenges and scope of practice issues are briefly discussed.

A comprehensive analysis of psychopathology development among college students

Amrita Sen University of Calcutta, India; Hadi Farhadi

Psychopathology refers to the study either of mental illness or mental distress. It refers to an aberrant or dysfunctional way of functioning, where functioning is defined in terms of behavioral, interpersonal, emotional, cognitive and psychological patterns. The present study probes into the domain of whether or not psychopathologies (depression and state-anxiety) are consequences of attachment style, irrational belief, total number of coping and number of life events in last one year faced by the college students. Two hundred college students were assessed on the above mentioned variables, by applying the Relationship Structure Questionnaire, Irrational Belief Scale, Presumptive Stressful Life Events Scale, Coping Checklist-I, Beck Depression Inventory and State-Trait Anxiety Inventory. The data were analyzed using t-test, product moment coefficient of correlation and Stepwise Multiple Regression Analysis (SMRA). Since significant differences between male and female students did not emerge, further statistical treatments were done combining male–female groups together. However, findings of the present study reveals that students’ anxiety-related attachment style and avoidance-related attachment style, irrational belief and number of life events in last one year were positively correlated with depression. Further, irrational belief was positively correlated with state-trait anxiety. Again anxiety-related attachment style was positively correlated with trait anxiety, whereas total number of coping along with irrational belief were found to be contributory factors in depression.

The functions of deliberate self-harm among a student population

Christiaan Van Rooyen University of Pretoria, South Africa; Ingrid Lynch

This cross-sectional study aimed to generate an exploratory functional model of deliberate self-harm (DSH) occurring among a South African student population (n = 603) using Principle Component Analysis (PCA). A battery of instruments, including the Deliberate Self-Harm Inventory (DSHI) and the Functional Assessment of Self-Mutilation (FASM) were administered to students. Following Nock and Prinstein’s (2004) four-factor model on the functions of DSH, self-reported reasons for DSH on the FASM were conceptualised in light of the reinforcement mechanisms of social learning theory. PCA revealed a four-factor model for the reasons students engaged in DSH, constituent of the following components: social positive reinforcement, social negative reinforcement, automatic reinforcement, and reinforcement regarding self-image. A unique factor manifests in the self-image reinforcement component, suggesting divergence in the functions of DSH between student and adolescent populations.

Counteracting negative body perceptions in adolescent girls by information labels on media models

Jolanda Veldhuis VU University Amsterdam, Netherlands; Elly Konijn

Previous research showed that thin and beautiful media models evoke body dissatisfaction and negative body perceptions, and may lead to distorted eating behavior and wishes to change one’s body, especially in (pre-)adolescent girls. However, could the very same medium also be used to counteract (Western) media’s thin-body ideal, or, to promote a more realistic norm? Along the lines of social comparison mechanisms and media psychological theorizing, the present study included pragmatic weight information labels and systematically combined these labels with attractive media models. That is, we designed a 3 (media model’s body shape: extremely thin vs. thin vs. normal weight) x 3 (information label: 6kg-underweight vs. 3kg-underweight vs. normal-weight) between-subjects experiment including three different age groups (9-10, 12-13 and 15-16 year olds; N=184). Multi-variate tests and contrast analyses showed that weight information labels and media models’ body shape interacted to affect the adolescent girls’ body perceptions. As expected, weight information labels instigated a normalization effect: exposure to an extremely thin body shape labeled to be of ‘normal-weight’ lead to the highest levels of body dissatisfaction, objectified body consciousness, and social comparison with media models. Moreover, weight information labels showed a counteracting effect when they appropriately confirmed the actual (under)weight status of the media model (e.g., an extremely thin media model with a corresponding 6kg-underweight label induced less body dissatisfaction). Additionally, results showed that pre-adolescent girls (aged 9-10) responded less strongly than older adolescent girls, indicating a critical criterion age between pre-adolescence and adolescence in responding to media models’ body shape.

Resilience in intimate relationships

Nerine Venter South Africa

This is a qualitative study that aims to explore and define resilience in intimate relationships. A constructivist perspective and a systemic approach ground the study, and the literature review highlights useful definitions of resilience. This study uses three sources of information to explore relational resilience: Three family therapists shared their experiences and insights about couples in distress, excerpts from five films provided information regarding couple interactions and were used as visual stimuli, and three participant couples viewed these excerpts and discussed their responses and personal experiences in semi-structured interviews. The themes arising from the participants’ responses were analysed by means of thematic network analysis. In view of the participants’ experiences a definition of resilience in intimate relationships not only includes the ability of the couple to endure adversity, but also involves the relational capacity to adapt, grow, and recover from adversities, and includes the relational processes that allow the couple as a system to rebound from shared difficulties and become more resourceful.

Characteristics of marital relationship in southern Brazil: Marital satisfaction, conflict resolution strategies and violence

Adriana Wagner UFRRGS, Brazil; Clarisse Mosmann; Denise Falke; Luciana Grybowsk

The presence of conflict is an inherent aspect of the marital relationship, but the strategies used to resolve conflicts differ between couples. Couples use a variety of options for conflict resolution, from the most effective to the most dysfunctional strategies – the latter may even culminate in violence. This study aimed to analyse how marital satisfaction, conflict resolution styles and the presence of indicators of violence between partners are associated in a sample of 730 couples from southern Brazil. Spouses responded separately to a 172-item questionnaire designed to assess sociodemographic data, levels of marital satisfaction (GRIMS), conflict resolution strategies (CRBQ; CRSI), and indicators of violence (CTS2). A Pearson correlation analysis indicated associations between almost all variables, demonstrating the complex interactions inherent in the marital relationship. We highlight the correla-
tions of positive problem solving—CRSI (p<0.001; r=0.377), seeking partnership agreement—CRBQ (p<0.001; r=0.510) and negotiation—CTS2 (p<0.001; r=0.361) with the level of marital satisfaction. Attack strategy was positively and significantly (p<0.001) correlated with the categories physical assault and psychological aggression. Our results indicate that high levels of marital satisfaction result from the absence of indicators of violence and from the presence of functional strategies of conflict resolution. Corroborating findings from the literature, we conclude that marital satisfaction, rather than the absence of conflict, is the result of how couples manage their conflicts.

We have something to say too: Inpatient survey in KwaZulu-Natal of people with intellectual disability

Andrea Zank Umgenvi Hospital, South Africa

The rights of minority groups within the general population of people, such as those with intellectual disabilities, are often overlooked. In the last few years the South African State Health Department has initiated a national drive in an attempt to improve the core standards of the State’s public health services. These investigations have focused on general hospitals through the consultation of service users, to whom health services are provided, at the exclusion of the unique needs to the intellectually disabled population. The following study was developed on the premise of inclusion, that this population has the right to express their experiences too. The objective of the study was to attempt to measure their awareness of their rights including their understanding of the procedure to submitting complaints. It was also to examine the level of these patients’ experienced satisfaction with the services rendered. These services included amongst others, social and stimulation programs as well as basic self-care. A patient friendly survey appropriate to this specific population was developed and applied amongst the patients of a state institution in the KwaZulu-Natal midlands region that provides residential care for patients with a range of intellectual disabilities. Outcomes are discussed with an emphasis on issues specific to representing the voice of the intellectually disabled population. In addition, difficulties in implementing research with this specific population are explored, such as dealing with varying capacities of understanding and communicating.

Study of the effect of family communication patterns on self esteem in high school students of Shiraz

Maryam Zarnaghass Shahid Chamran University, Islamic Republic of Iran; Hadi Farhadi; Azadeh Alavi pour

The goal of the present study was examining the effect of family communication patterns, included consensual, pluralistic, protective and laissez-faire, on self esteem. The sample group included 200 students – girls (100) and boys (100) - selected from different high schools of Shiraz city. A revised version of the Cooper Smith Self Esteem Questionnaire and a revised version of Koerner-Fitzpatrick Family Communication Patterns Questionnaire were used. The Cronbach alpha coefficient was calculated in order to determine of reliability of the measures. For testing validity of the instruments factor analysis methods were used. The results showed acceptable reliability and validity of the instruments. By using two way ANOVA the effect of communication patterns on self esteem, regarding gender as a moderator, was verified. Results showed that consensual and pluralistic patterns in comparison to protective and laissez-faire patterns have higher scores on the self esteem scale. The conversation aspect of family communication, in comparison with conformity, especially in boys, is the powerful determinant factor of self esteem.

Effect of group teaching of self-control on children’s improving social skills

Seyed Ali Abyar Hosseini Qom Payame Noor University, Islamic Republic of Iran

The purpose was to consider the effect of group teaching of self-control techniques on improving social skills in children suffering from Hyperactivity and Attention Deficit. This research has been administered according to semi-experimental method, with the intervention program. The study sample included 120 children divided into two groups, both of which took the pre-test. The Experimental group learned self-control techniques during 10 sessions in groups. The post-test was then administered, and again, after 2 months. The data were considered with the variance analysis method, by frequent measurement. The results indicate that teaching self-control techniques dramatically increased children’s social skills in the sample and these changes were stable after 2 months. According to the results, teaching self-controlling techniques has a positive influence on improving social skills.

The prevalence and comparison of alexithymia in male and female undergraduates

Afroz Afshari University of Isfahan, Islamic Republic of Iran; Maryam Esmaeili

The aim of present study was to investigate the epidemiology of alexithymia and comparing male and female students of Shahid Chamran University in this construct and its subscales. The sample consisted of 841 undergraduate students in second semester of year 1386-87. This sample was selected by multi-stage random sampling method and the 20 items version of Toronto Alexithymia Scale was administered to them. The results showed that the rate of alexithymia in the whole sample was 16.2%, in females it was 16.1% and in males it was 16.3%. There was no significant difference in prevalence of alexithymia between males and females. Comparison of the two genders in the total score and three subscales showed that there was significant difference in total score (p<0.017) and External Oriented Thinking style (p<0.001) and both averages were higher in male students.

A comparison between forgiveness and its components in normal couples and divorced spouses in Isfahan

Asghar Aghaei Jeshvaghi Khorasan (Isfahan) Branch, I.A.U, Islamic Republic of Iran; Maryam Fatehizadeh; Samayeh Karimi; Hossein Vasefpour

The purpose of this study was compare forgiveness and its components in normal couples and divorcing couples in Isfahan city. The statistical population consisted of couples who lived in Isfahan city in 1387 (2009). Therefore, 100 normal couples were selected randomly from four parks, and 100 at-divorce couples were selected randomly from couples who were referred to divorce centers in Isfahan. Forgiveness and its components were measured by means of the Forgiveness scale (FFS). The results of a one-way analysis of variances showed that forgiveness and its components (recognition, reparation, restitution, resolution) were significantly more evidenced in normal couples than divorcing couples (p<0.01). It is concluded that it is important to consider the role of forgiveness in couples who are going to divorce.

Relationship and comparison between spiritual intelligenc and mindfulness high school students

Hamid Arab University of Isfahan, Islamic Republic of Iran

The purpose of this study was to examine the relationship between Spiritual intelligence and mindfulness in a sample of high school students and compare the variables between boys and girls. The method of the study is correlational and based on comparison. The statistical community was isfahan high school students selected through random sampling: 90 second grade students (45 boys and 45 girls) from a high school in Isfahan (Iran). The Inventory Spiritual Intelligence of Abdollahzade (1387) and the Kentucky Inventory of Mindfulness skill of Bear Amith and Allen (2004) were used as measurement instruments. The study hypotheses were: 1) there is a relationship between students’ spiritual intelligence and their mindfulness. 2) there is a difference between girls’ spiritual intelligence and that of boys. 3) there is a difference between girls’ mindfulness and that of boys. The results indicated that girls obtained higher scores than boys in both variables, however these scores were not reasonable. The other findings showed that as the spiritual intelligence increased in both genders the mindfulness also increased, i.e. these two variables are interrelated. The study suggests that these two variables be studied in other levels of education.

The relationship between attachment styles and aggression among university students

Hamid Arab University of Isfahan, Islamic Republic of Iran; Roghayeh Ahmadi; Mohammad Naghavi

The aim of the present study was to examine the relationship between attachment styles and aggression. The test subjects were 150 female and male junior college BA students studying at Sheikh Bahae non-profit university who were selected according to random sampling. To measure attachment styles, Hazen and Shiver’s (1987) attachment style scale and for measuring aggression, Zahedifar, et.al’s (2000) aggression questionnaire was applied. The achieved data were analyzed through Pearson correlation and multivariate regression method in order to predict the changes of criterion variables according to predictive variable factors. The results
Effectiveness of forgiveness intervention training on marital satisfaction, anger reduction, and family forgiveness
Fatemeh Bagherian Shahid Beheshti University, Islamic Republic of Iran; Ali Arab; Shahriar Shahidi
There has been an increase of interest in forgiveness training as an intervention strategy by a wide range of psychologists and psychotherapists. But in Iran, despite a relatively long history of theoretical interest in the field (Shamloo, 2004), virtually no clinical or training intervention has been reported to date. This study can be considered the first training intervention in this field. The present study evaluated the effectiveness of a 6-week forgiveness training on marital satisfaction, state and trait anger, and family forgiveness. The forgiveness training was based on Luskin’s (2006) theoretical framework. 140 married adults (54 men, 86 women), aged between 22-45 years, participated in the study and were randomly assigned to either a forgiveness training intervention or a no intervention group. Information was collected through Enrich Marital Satisfaction Questionnaire, Spielberger State-trait Anger Expression Inventory (STAXI-2) and Family Forgiveness Scale (Pollard et al). Measures were obtained at pre-test, post-test, and four months follow-up. Results of a mixed ANOVA revealed that forgiveness and marital satisfaction significantly increased and that both trait and state anxiety decreased at post-test. These effects were largely maintained after four months.

Facilitating working alliance: Does gender matching make a difference?
Kuldhir Bhati The University of Akron, United States of America
Matching clients and psychologists on the basis of various heuristics, including gender, is common in clinical practice. Considerable research has been conducted to examine the impact of gender matching on the therapeutic alliance, but the results have been equivocal. Previous studies, at best, have examined only pre-treatment measures at the end of therapy to evaluate the impact of gender matching. This study sought to further examine gender matching in a naturalistic setting and proposed that perhaps gender matching varies in importance depending upon the stage of counselling. It is hypothesised that gender matching impacts alliance significantly initially and then tapers off in impact, as other factors that affect the development of working alliance come into play. This study examined the impact of gender matching on alliance at different stages of therapy. The results indicated that gender matching does not have a significant impact on the alliance, even at the early stages of therapy. Interestingly, results indicated support for a general “female effect.” Across all stages of therapy, female - female client therapist dyads tended to report the highest alliance ratings, followed by the dyads with at least one female member, and male - male dyads consistently reported the lowest alliance ratings. Implications of these results and future directions are discussed. Recommendations are made regarding factors to consider when assigning clients and ways to do so effectively.

An exploration of the relational experiences of an older woman’s effective relationships in an intergenerational context
Madalene Botha North-West University, South Africa
This presentation aims to explore an older woman’s relational experiences that she describes as effective in her intergenerational relations. The theoretical framework that informed this presentation, is that relationships which promote a caring relational environment are effective for members of both generations. The relational qualities informing a relationship are important to promote the caring environment between generations. A case study design was applied to gain insight into the relational experiences of an older woman (aged 67), who reported that she experiences effective intergenerational relationships. Data collection methods included a visual clay presentation produced by a projective data gathering instrument, the Mnemosphere model™ (Roos, 2008, 2012), as well as verbal expressions and personal journal reflections. The visual and textual data have been thematically analysed and the following themes emerged: spirituality is used to deal with ambiguities in an empathetic manner. She was able to adopt a meta-reflective position in her intergenerational environment. She also demonstrated flexibility by adopting various roles in her different relational contexts. A caring intergenerational relationship seemingly consists of empathy, meta-reflectivity, and flexibility. In order to obtain a more complete understanding of intergenerational relationships, future studies need to approach this subject from various generational and cultural perspectives.

Captured by music and dance: Melholistics and performance in sports
Annalisa Cangelosi AIO-AEO-FOIL, Italy
Studies have been conducted in movement activities which, by focusing on aspects related to motion, investigated the possible effects that music might have on relieving athletes’ pressure. In the first part, the authors illustrate the main theories in this area. In particular, they dwell on Hernandez-Peon’s theory whereby music might improve athletic performance, or the emotions accompanying physical exercise, thus decreasing the psychological backlash associated with physical strain. In the second part, they illustrate the innovation at the foundation of the theory of Melholistics (A. Meneghetti). Specifically, they address a) theory, applications and materials used; and b) possible influence on the mental attitude of gymnasts before a performance, especially in relation to the way they view such engagement before, during and after the work performed during Melholistics sessions.

The effect of text messaging in the family relationship: A sample of Puerto Rico
Michelle Cordero-Soto Carlos Alibizu University, Puerto Rico; Celsie Hiraldo; Gladys Rodriguez; Rosana Rivera; Angeli Crespo; Aida Jimenez
During the past decade, text messaging has become a popular phenomenon among mobile phone users. Statistics prove that the use of text messages (TM) is becoming common among family members, expanding communication methods. Studies reveal that the use of TM has positively contributed to parent-child communication. However, there is scarce scientific literature validating the effect of text messaging in the family context. Using qualitative methodology, this study explores participant’s verbalisations regarding the impact that texting has on the family. The sample consisted of 111 participants selected by availability in Puerto Rico. Each participant was asked to answer five open-ended questions regarding the benefits and problems of communicating through TM, and identify if family communication and cohesion were affected. Results were analysed by four independent coders, which developed common themes around issues of communication and cohesion. Results showed that TM were considered a positive tool towards communication among family members. Family members agreed that the use of TM helped them communicate with each other when communication was difficult. Moreover, the majority expressed that TM facilitated communication when it was hard to express their feelings towards each other. Results show that benefits associated with texting surpassed the negative aspects, increasing family communication and cohesion. Considering the verbalisations of the participants, and based on the principles of Family Systemic Theory, we concluded that the use of TM may contribute to the development of less rigid and healthier boundaries among family members.

A study of structural relations of some psychological risk and protective factors of addiction potential
Iran Davoudi Shahid Chamran University, Islamic Republic of Iran
The purpose of this study was developing, testing and refining a model to understand the relationships between some psychological risk and protective factors of addiction potential. This study used structural equation modeling (SEM) to evaluate the associations between parenting styles and potential addiction mediated by novelty seeking, behaviour problems and coping strategies in a sample of 572 third grade high school students (male: 328, female: 244) in Mashhad, Iran. The participants were selected through multistage random sampling. Data were collected by questionnaires including Parenting Style Questionnaire, Temperament and Character Inventory, Coping Inventory for Stressful Situation, Achenbach Youth Self-Report Scale and Iranian Addiction Potential Scale. Amos-16 model program software was applied for structural equation modelling. The modified model had a good fit with the data (CFI = 90, RMSEA = .07) after deleting the coefficients without significance, and considering covariance between some of error variables. The present study found many of the predicted relations between parenting styles and potential addiction mediated by novelty seeking, behaviour problems and coping strategies, although most of the purposed paths between permissive parenting style and other variables were not significant. Based on standard coefficients emotion-oriented, problem-oriented, avoidance-oriented coping
strategies and problem behaviours, have more effect on addiction potential, respectively. The clinical and applied implications of results and the model presented in this study are discussed.

The elicitation of young people’s emotions through the Mmogo-method as a projective technique
Monique Delport North-West University, South Africa
Projective techniques enable us to discover innermost beliefs and emotions that are hidden. The Mmogo-method™ is a visual data gathering method that can be viewed as a projective technique that entails the making of visual images of certain experiences by means of clay, beads and straw as material. In this instance it was used to reflect on their relationships with members of the older generation (people older than 60 years). The aim of the study was to describe the relational experiences of young adults, aged 21 to 30, male and female, who participated in the Mmogo-method™ as part of an inter-generational project at the North-West University, South Africa. The participants were requested to construct a visual image by using unstructured material. The data that was collected consists of observations of the emotions of participants as well as journals after the completion of the Mmogo-method™ and reflections of the participants about their experiences in this projective technique. Data analysis through thematic analysis, made it observable that participants displayed different emotional reactions such as crying and frustration. The young adults cried when they realised the losses they have experienced in relation to their grandparents. By using projective data gathering instruments, emotional content is elicited which should be helpful if dealt with in an empathic and ethical manner. It is recommended that the Mmogo-method™ be explored in terms of its value as an intervention and research instrument regarding emotion and emotional reactions.

Ethical individuality as an issue of integral personality theory
Davlet Duisenbekov Kazakh National University, Kazakhstan; Almat Nuradinov; Bizhan Sheraly
Personality as a system of individual traits and features ought to be considered on the ground of historical-ethical concept developed by professor M. Mukhamedov, renowned founder of psychological science in Kazakhstan. Human individuality is considered as an issue of ethically centered psychological study that takes into account cultural-historical conditions of ethnicity and peculiarities of personality growth and socialization. Ethical individuality may be revealed as a system of "measured and unmeasured constructs" (a notion developed by L. Burlachuk) and in structural aspect it can be described (following A. Shmelov) by macro-level of global cross-situational traits represented in the national character, meso-level of generalized skill traits determined by socialisation and by micro-level of situational personal-traits reflecting human social-ethical identity. Measured and unmeasured constructs of ethical individuality can be shown by inter-relation of regulative and reflective aspects representing content of human consciousness coincident with group and social experience of certain ethnics. Ethno-psychological content of integral individuality can be revealed by three versions of archetypes which are characteristic of the Central Asian region: (1) European-centered type with predominant Western values, (2) orthodox-Asian type with predominant Moslem values, and (3) intermediate-mixed type. The practical significance involves recommendations accounting for ethical individuality traits, expert and diagnostic procedures of various directions and also psychological examination of individuals in inter-ethical relations in conditions of the social crisis and variable cross-cultural influences. Psycho-diagnostic techniques in ethical research, social-psychological observation were used.

Psycho-linguistic aspects of modern Kazakh language development
Davlet Duisenbekov Kazakh National University, Kazakhstan; Kulyash Bassybekova
There are two sides of research analysis connected with language users, natural mechanism of sensual cognition and social-cultural mechanism of the word origin. A person’s sensory-perceptive system is an entire functional system consisting of sense-motor subsystems. It’s a complex multi-level organisation with intra- and intermodal connections and subordinate-coordinative parameters of managing and regulating. Revealing managing mechanisms of this system allows to create means of language acquisition and to clear up its psycho-energy-informational essence. As a model of intra- and intermodal mutual connections there is selected “eye – hand” system. This research deals with psychological peculiarities of modern Kazakh language development and consist of general-psychological, ethnospsychological and psycho-linguistic fields of analysis. The general-psychological part examines personal features of Kazakh as state language acquisition and everyday usage by Kazakhs and representatives of other nations. From this point some social-economic and political issues are taken into consideration. The ethnospsychological part indicates a wide spectrum of specific regional peculiarities of Kazakh language and a lot of foreign borrowings, especially from Russian and English. The psycho-linguistic part reveals inner peculiarities of modern Kazakh language on the basis of interrelation of “linguistic competence” and “linguistic performance” (by Ch. Osgood and others) and tendencies of literal Kazakh language development in modern social-economic, political and multi-cultural situation. The empirical study had shown significant differences of the Kazakh language usage in urban and countryside conditions, in official and non-official practice among different persons, social and professional groups, ethnic subgroups and minorities.

Impact factors on religious attitude and its relationship with adjustments (social, educational, emotional)
Javad Ghanbari Technical University of Zanjan, Islamic Republic of Iran; Akbar Mahdiloo Technical University of Zanjan, Islamic Republic of Iran
Measuring religious attitudes, determining factors and their impact on religious attitude was related to aging status. Also religious attitude was related to aging of students so that students of ages 16-17 years were more religious than other students.

Two sampling method was used: multi-stage cluster sampling and stratified sampling (within clusters). Sample size was 381 people who estimated using Krjsly and Morgan’s method. They filled the religious attitude scale (includes 42 questions with five options in Likert’s method), adjustment questionnaire (includes 55 questions with 2), and personal information questionnaire. Findings of the research showed that there was a significant relationship between religious attitudes and educational level in students. In addition, there was a significant difference in religious attitudes between boys and girls: boys had more religious attitudes than girls. There was significant relationship between religious attitudes of students and their mothers’ educational level, students whose mothers had primary education levels scored higher in religious attitudes, whereas there was no relationship between religious attitudes of students and their fathers’ educational level. Comparing the means among students showed that there was no relationship between religious attitudes and their parents’ occupational status. Also religious attitude was related to aging of students so that students of ages 16-17 years were more religious than other students.

Measuring marital adjustment for Chinese couples
Ying Han Peking University, China; Lei Wang Peking University, China
This research measured Chinese couples’ marital adjustment by combining and revising Marital Adjustment Test (MAT) and Dyadic Adjustment Scale (DAS), which are commonly used in marital adjustment measurement, in the purpose of examining its prediction validity, as well as its prediction for Chinese couples’ marriage quality. A total of 159 married couples participated in the survey. Two factors emerged in exploratory factor analysis, namely, "living things" and "intimate dyadic". The results showed that participants with a bachelor’s degree had significantly lower scores than undergraduates and postgraduates in "intimate dyadic", couples with children had less time and frequency in "intimate dyadic". In the meantime, hierarchy regression analysis showed that marital status was only significantly influenced by "living things", where higher scores were related to the greater differences between couples and the lower evaluation of marital status. These results provide beneficial references for measuring and understanding Chinese couples’ marital adjustment. It also makes for some insight in understanding and regulating couples’ behaviour and interaction mode.

Implicit attitude is positively associated with immediate enhancement and rebound effects in thought suppression tasks
Ming-Chou Ho Chung-Shan Medical University, Taiwan; R.O.C.; Ren-Hau Li; Fan-Ting Chang; Tze-Chun Tang
Betel nut is a common stimulant in Asian countries. We ask whether the hyperactivity due to suppressing thoughts of betel nut is associated with the habitual chewers’ implicit attitude. Seventy-seven habitual betel nut chewers and 19 non-chewers completed a thought suppression task and the single-category implicit attitude test (SC-IAT). In the thought suppression task, participants thought of
anything including betel nut, then they were asked not to think of anything related to betel nut, and finally they thought of anything as beginning. The immediate enhancement effect was computed by subtracting number of intrusions in the baseline from the number of intrusions during suppression phase. The rebound effect was computed by subtracting number of intrusions in the baseline from the number of intrusions during expression phase. In SC-IAT, participants were asked to categorise the betel nut pictures to the label "pleasant" as quickly as possible, and then to the label "unpleasant". Error responses were replaced with the session mean plus a penalty time of 400 ms. The mean RTs in the session "betel + pleasant" were subtracted from the mean RTs in the session "betel + unpleasant". This value was divided by the SD of all correct RTs within both sessions. Higher SC-IAT scores indicate more positive associations with betel nut. In habitual chewers, but not non-chewers, their implicit attitudes positively correlated to intruding thoughts within both sessions. Higher SC-IAT scores indicate more positive associations with betel nut.

The individual difference of intelligence level: The contributions from both the difference of structure and factor’s function
Zhong Jianjun Educational Science College, China; Chen ZhongYong; Fang Fuxi
The aim of this study is to determine whether individual difference in IQ is closely related to intelligent structure and factor function. 256 students, aged between 14 years and 1 month to 14 years and 12 months, were assessed by means of the WISC-CR, then divided into the following three groups, based on IQ scores: 70-85; 86-115 and 116-130. The results are as follows. As the intelligence level increases, the inter-correlation from WISC-CR, verbal and operational subscales become lower. Although there is the same factor structure and the g explains ratio on the full scale, there are more factors on operation subscale in the higher IQ group than the lower. As for the variation of g loading on subtest, there is more consistency in the subtest with higher g loading than lower g loading among three groups. Some conclusions are drawn as follows: although there are the same intelligence factors in the three groups, the individuals who have the bigger g function and more differentiated structure in operational intelligence, tend to get higher IQ scores. Some factors leading to undifferentiated structure are discussed.

The difference between males and females regarding the effect of children on relationships
Sarah Kadzomba UNISA, Zimbabwe
Children can either make or break a relationship between parents, with varying degrees of impact on males or females. Five aspects of children have been identified as contributing to the life of a relationship: availability or unavailability, nature of children, number of children, child-rearing practices and the decisions the children take in life. All can impact an adult relationship, and this can differ between males and females. The principal aim of this exploratory qualitative study has been to investigate the difference between males and females with regard to the effect of children on relationships in Nyanga, North, Zimbabwe, through answering these exploratory questions: What are the effects of children on a relationship? What aspects of children affect relationships? How does society view children in a relationship? and, How can relationships survive these effects? Participants (n=10, 5 males and 5 females) whose ages ranged from 35 to 75 years. Data were gathered using unstructured interviews and were analysed through interpretive analysis. The findings revealed that there are indeed differences between males and females regarding the effects of children on relationships. Participants needed support and intervention especially tailored for their unique needs. The findings of the study recommended counselling, education and social support.

Well-being in a Czech population sample
Vladimir Keblka National Institute of Public Health, Czech Republic; Miloslav Kadi; Iva Solcova; Vera Kernova
An empirical survey of well-being in a representative Czech population sample was conducted. A sample of the Czech population (N = 1321,18 - 74 years, 674 women, 647 men) provided data concerning the level and structure of subjective well-being, self-reported health, locus of control, and general self-efficacy. General self-efficacy and socio-demographic data. Subjective well-being was employed as dependent variable. Independent variables were: sex, age, education, self-reported health, locus of control, and general self-efficacy. General self-efficacy, locus of control, self-reported health, and education were determined as predictors of well-being within this survey. Our findings speak to the growing literature on well-being research, which has documented that no relation of well-being to sex and age was determined.

An action plan for building a successful Psi Chi chapter
Maria Lovoo Florida Institute of Technology, United States of America; Martha Zlokovich
Psi Chi, one of the largest academic honor societies, was founded in 1929 to advance the science of psychology. As a federation of over 1100 chapters (Psi Chi members at a particular university), Psi Chi recently became an international organisation. As the number of international institutions submitting applications increases, so, too, do the questions and concerns with regard to comparing US and international psychology curricula and grading schemes. This poster addresses the “nuts and bolts” of applying for a Psi Chi chapter and ensuring that it will succeed and flourish. While chapter faculty advisors face a number of challenges, one of the most important ones for chapter success relates to recruiting officers. This is an important challenge because the student officers will “set the tone” for the coming year. It is a difficult one because many students believe the responsibility of leadership will be overwhelming or too time-consuming. Another challenge is finding the right time and place for meetings. If this can be successfully resolved, it will significantly increase membership and attendance. Other issues addressed are developing an action plan for recruiting new members and officers, providing information relevant to conducting meetings, sharing ideas for invited speakers, arranging volunteer projects, and discussing Psi Chi grant and award opportunities. Additionally, information will be shared about chapter involvement beyond campus activities: Society voting and service, and attending and presenting at regional, national, and international conferences.

Workplace bullying: The victims’ experiences
Bolutelelo Maja UNISA, South Africa
This study aimed to explore the lived experiences of the victims of bullying in the workplace. There are studies that reveal that there are prolonged effects on bully victim’s health, social functioning and work performance. These studies also provide a broad description on how bullying negatively impacts on the victim’s normal functioning. The focus of this study was on exploring five aspects that can provide a clear description of bullying in the workplace. These aspects included: low self-esteem, lack of motivation, the victim’s mental health, the bully’s typical tactics and the role that Human Resources (HR) can play in combating the prevalence of bullying. A descriptive-interpretive approach was applied which showed that bullying has negative impacts on the normal functioning of the bullied. Data were collected from individuals who previously experienced bullying in their place of work. The selection of the sample was purposive. From each participant’s response there were common themes that were identified, and there were also commonalities in their experiences. Furthermore, it was clear from the findings that HR needs to focus on, and deal with, bullying within the workplace, as it not only affects the victims, but the entire organisation.

Differences in definitions of infidelity between romantic partners and relationship satisfaction
Magdalena Mijas Jagiellonian University, Poland
The purpose of the research was to investigate the connections between differences in definitions of infidelity between romantic partners and relationship satisfaction. Individualised definitions of infidelity were measured with the Perception of Infidelity Scale (PIS) (Mijas, Szpitalak, 2010), that allows measurement of both quantitative differences in perception of infidelity (conceptualised as restrictive vs. liberal definitions of infidelity), and qualitative differences (conceptualised according to three factors that analysis revealed – Emotional infidelity, Sexual infidelity and Impersonal infidelity). Relationship satisfaction was measured with the Quality of Relationships Inventory (QRI) (Pierce, Sarason, Sarason, Solky-Butzkel, Nagle 1997), and the Relationship Assessment Scale (RAS) (Hendrick, Dicke, and Hendrick, 1998). Among other measured variables were: Attachment Styles (RSQ, Griffin, Bartholomew, 1994). History of Relationship (History of Relationship Scale designed for this study), and various demographic data (brief questionnaire designed for this study). The study involved 20 couples (including same-sex couples) who had formed intimate relationships for more than 2 years. As expected, analysis revealed that the larger the discrepancy in the definitions of infidelity between partners (conceptualised as restrictive vs. liberal), the lower the levels of satis-
faction with the relationship were revealed by both partners. Analysis also revealed interesting associations between other measured variables, all of which will be presented and discussed during the presentation. Possible applications and limitations of the presented research as well as directions of future studies in this area will be discussed too.

Developing and validating the Psychological Well-Being scale for children (PWB-c)

Suzanna Opree ASCoR, Netherlands

After conducting a thorough review of the literature into the theoretical foundations of psychological well-being, Ryff and Singer (2008) distinguished six core dimensions of psychological well-being: purpose in life, environmental mastery, positive relationships, personal growth, autonomy, and self-acceptance. The goal of this study was to use these insights to develop the Psychological Well-Being Scale for Children (PWB-c). A literature search was conducted in order to determine how purpose in life, environmental mastery, positive relationships, personal growth, autonomy, and self-acceptance have previously been measured among children. These existing measures formed the inspiration for the PWB-c. The PWB-c consists of 28 items. It was administered twice within a 2-week interval to 166 9- to 11-year olds in order to test its internal consistency, test-retest reliability, and construct validity. Both the internal consistency (αTime1 = .816; αTime2 = .832) and test-retest reliability (rtime1-time2 = .800, p < .0001) were high. In conclusion, the PWB-c performs well in terms of reliability and empirical usefulness.

The use of text messaging and its effect in a family system

Ramon Perez Carlos Albizu University, Puerto Rico; Tamara Martinez; Celsie Hiraldo; Mariangie Lugo

Studies show that texting has been conceived as a contributing factor to how families engage in communication and relate to each other (Devitt & Roker, 2009). However, the amount of scientific literature discussing this topic is scarce. Therefore, this cross-sectional survey explores the perceptions regarding the use of text messaging among family members. The questionnaire developed by the researchers gathered social demographic information, text messaging usage, frequency, and family members' perception of its usage and impact. The sample consisted of 111 Puerto Rican residents, selected by convenience. Results showed that 45% of the participants send text messages from one to ten times daily, often employed in order to receive immediate responses (46%) and when the target family member is not available, to answer calls (35%). Sixty-seven percent usually send text messages in the presence of other family members, and 72% reported not having family problems while texting. Only 20% reported having family problems with the use of texting, mostly mothers who indicated difficulties with their children. However, the overall results showed that the use of text messages have more advantages than disadvantages among family members. The frequent use of text messaging among family members suggests that families are becoming accustomed to new ways of communication, contributing to less rigid and healthier boundaries. These results are consistent with other studies demonstrating that the use of text messaging, rather than causing problems, is beneficial for immediate communication, and family cohesion (Hakouma & Hakoyama, 2011).

Maternal substance use among women attending midwife obstetric units in the Cape metropole, South Africa

Petal Petersen Williams Medical Research Council, South Africa

Maternal substance use in pregnancy poses health risks for women and their unborn babies. There is increasing evidence in South Africa of substance use among women (and in particular women of childbearing age) and the burden this places on the health and social development of mothers and their infants. The objective of this study is to describe the nature and extent of substance use among pregnant women attending Midwife Obstetric Units (MOUs) in the Cape Metropole. A cross-sectional survey was conducted and intervention was attended by 11 MOUs in greater Cape Town. In total 5231 pregnant women were screened for drug and alcohol use and 684 completed an interviewer administered survey and provided a urine sample. Among the 5231 pregnant women screened 34.4% and 3.6% respectively self reported drinking alcohol and using illicit drugs during their current pregnancy or in the 3 months before they knew they were pregnant. However, biological testing highlighted the levels of under reporting. Among the sub-set of women who reported that they have not used drugs in their current pregnancy, 9.2% tested positive for one or more drugs, mainly amphetamines and cannabis. Findings point to the fact that there are high levels of substance use among pregnant women attending public sector antenatal clinics in the Cape Metropole. Pregnant women however, are not always truthful about their use of alcohol and/or other drugs. This indicates a need for early identification and intervention with substance using pregnant women using biological markers such as urine.

Monitoring the prevalence of methamphetamine-related presentations at psychiatric hospitals in Cape Town, South Africa

Andreas Pluiddemann Medical Research Council, South Africa; Ian Lewis; Claudia de Clercq; Sipho-kazi Dada; Charles Parry; John Parker; Henk Temmingh; Surita van Heerden; Rehana Kade.

This study aimed to determine a demographic profile of methamphetamine (MA)-related admissions to major psychiatric services in Cape Town, obtain a substance-use profile from admitted patients, a profile of common MA-related admitted diagnoses on methamphetamine-related admissions between July and December 2008 using a one-page record review form. The data collection form consisted of the patient’s demographic details, presenting symptoms, previous admission details, current MA and other substance-use information, and DSM-IV diagnosis. A total of 235 forms were completed. Most patients were male (69%) and the mean age was 25 years. The most common presenting symptoms were aggressive behaviour (74%), followed by delusions (59%) and hallucinations (57%). Males were two times more likely to present with aggression as compared to females, while females were significantly more likely to present with depressed mood or euphoric/elevated mood. The majority of patients had substance-induced psychotic disorder (41%), followed by schizophrenic disorders (31%). Twelve percent (12%) had bipolar mood disorder. MA-related psychiatric admissions pose serious challenges to all health services dealing with these patients. Further training and treatment protocol development and distribution is indicated.

The effect of education play training on motor development of educable mentally disabled boys in preschool

Seyed Reza Poorseyed University Esfahan, Islamic Republic of Iran; Areezo Shahmive Isfahani

The purpose of this research was to determine the effect of education play training on motor development of educable mentally disabled boys (age 5 to 7 years old). The statistical population of this study included all boys in preschool who, although mentally disabled, were educable. The sample included 20 boys who were randomly selected from 3 special schools in Isfahan city. Then they were randomly split into 2 groups: the experimental and control groups. The instrument used in this research was, Lincoln Osersetky Test of Motor Proficiency and Education Play Training. A pretest was administered to both the experimental and control groups. Then education play training was employed on the experimental group in 12 sessions, over a month. A post-test was administered to both groups at the end of training. The results showed that there was a significant difference between the mean scores of Lincoln Osersetky Test of Motor Proficiency in the experimental and the control groups in the post test (p<0.01). Finding showed that educable play training could increase motor development in educable mentally disabled boys(p<0.001).

Happiness understanding and its dependence of sense formation features

Aidana Rizulla Kazakh National University, Kazakhstan; Zuha Ismagambetova; Fatima Tashimova

Happiness understanding is one of the important phenomenon defining sense, and a feature of the self-realisation of the person. According to our hypothesis the understanding of happiness depends on features of sense formation. The process of sense formation we understand as a result of correlation of personal requirements defined by values of set of virtual subjects. A method of incomplete offers, a technique of “Values of relations” and a projective technique (Actual sense) were developed by authors. 252 students were investigated and divided into four groups. Group 1 (mobile), in sense formation process values of following virtual subjects have essential value: the value of the father, which stimulates values of the superiority; idols (authors of favourite books, the Internet), stimulating on achievement. In the process of sense formation defining are cognitive components which provide success in self-realisation and promote understanding of happiness as achievements. However, they have problems in personal relations. Group 2 (harmonious), in process of sense formation...
values of the father and mother through which prism all other essential values refract. Their happiness is defined by them as harmony creation. Group 3 (egocentric), in sense formation process values of virtual subjects (authors and heroes of telecasts and cinema, and Internet) from different points of the world have essential value, ignoring of values of parents. At students of group 4 (socio-centric), in sense formation process values of virtual subjects are important. Where their closest environment and idols have happiness, they have essential value and that is defined by them as pleasure.

A description of older persons’ perceptions of younger people
Carmine Schmitz North West University, South Africa
The goal of this presentation is to describe the perceptions of older persons about younger adults (aged 25 and younger). Perceptions assist people to make sense of the world and to compare new information with existing frameworks. Thirteen white Afrikaans-speaking older people (five male and eight female, ages ranging from 65 to 85), participated in the research. A narrative research design was chosen and the Mnogo-method (Roos, 2008:2012), a visual projective data gathering instrument, was used to gather data by using clay, straws and beads to construct the perceptions of their relationship with younger people. The data gathered were analysed by identifying themes. The findings indicated that the older people compared their life experiences to those of the younger people, from their own perspectives. They regarded the younger people as people who are more likely to be faced with challenges such as drug use. Younger people are perceived as people who have privileges such as further educational opportunities, and that money is an asset they can use limitless. Younger people are also perceived as having less time to spend with the older people. The younger generation are perceived as people who attach less meaning regarding their family and who they are. It can be concluded that the perceptions of the older generations might not be in line with how younger people are in reality. It is therefore recommended that individual interactions between the older and younger people be facilitated to create more awareness of one another.

Portrayal of older people in the print media: Implications for intergenerational relations
Samiera Sedick North West University, South Africa; Vera Roos
This study explored the perceptions of older people in a residential care facility, regarding how they are portrayed in the print media and the implications of such portrayal for intergenerational relations. Twenty-one older residents in a residential care facility participated voluntarily in the study (men = 9; women = 12; age range 60 to 85 years). Data were collected using exploratory interviews and focus groups followed by the thematic analysis of the data. The findings suggest that older people perceived their portrayal in the print media as minimal, marginalised and stereotypical. Such portrayals could negatively influence younger people’s perceptions of older people and consequently compromise sound intergenerational relations. The older people in the study recommended that the print media should also portray older people who display agency in interpersonal relations as well as positive aging.

Prediction of criteria of mate selection based on big five personality trait
Sofaora Sepehri Shahid Beheshti University, Islamic Republic of Iran; Mohammadali Mazaheri; Fatehmel Bagherian
One of the issues studied in mate selection area is personality effects that have been considered less than other issues like sex differences or social similarity. This research studies the power of predictability of big five personality trait on criteria of mate selection in two genders. Instead of questionnaire, a computer program was made to determine the criteria of mate selection by providing a virtual space. Participants were 295 single persons. Multi-parametric logistic regression was used for data analysis: Factors of personality were defined as independent, and criteria of mate selection as dependent variables. Results showed personality traits effect on mate selection. In the male group, openness predicted the temper of chosen wife, openness, agreeableness and extraversion predicted religiosity, openness and extraversion predicted sexual relationship before marriage, openness, agreeableness and extraversion predicted age, agreeableness predicted importance of family similarity, neuroticism predicted loyalty and openness, extraversion and conscientiousness predicted dependence of chosen wife on her family. In female group, openness predicted importance of amount of love of chosen husband, conscientiousness predicted importance of being in love, openness, conscientiousness and neuroticism predicted responsibility, neuroticism and openness predicted age, neuroticism predicted importance of family similarity, neuroticism, agreeableness and extraversion predicted loyalty and openness predicted dependence of chosen husband on his family. In conclusion, through the virtual space, as a new method in gathering data, it shows criteria of mate selection were predicted by personality trait in two genders in different ways.

Parenting styles and mental health of Chinese adolescents: The role of general self-efficacy
Jing Shi Chinese Academy of Sciences, China; Jing Yang; Miao Liu
The main purpose of this study is to examine the parenting styles and mental health of Chinese adolescents as well as the role of general self-efficacy in this relationship. The current investigation examined these issues in a sample of 10th, 11th and 12th grade (n=334, 55.4% female) Chinese students by EMBU, GSES and SCL-90. The findings showed that 57% of Chinese adolescents had mental health problems and 7.76% of them were serious. Significant differences in parenting styles for gender were observed, parents took more negative raising styles for male students (t = 3.835). The parenting styles were significantly different between the mentally healthy group and the group with mental health problems, where the parents of the mentally healthy group took more positive parenting styles (t = 3.701) and the parents of the group with mental health problems took more negative parenting styles (t = -3.967). General self-efficacy was the partial mediator of positive parenting styles and mental health. Findings illustrated that parenting styles and mental health were closely related for adolescents, and general self-efficacy played an intermediary role between parenting styles and mental health.

Dot.com glasses: How older people perceive social media
Aida Terblanch-Greeff NWU, South Africa; Vera Roos
The birth of the World Wide Web changed the way people communicate and interact. Social media (Facebook, Twitter, etc.) enables people to interact, despite distance. The theoretical framework of this research is that humans have a basic need to relate. The purpose of this presentation is to describe the perceptions of older people regarding the use of social media. A purposive, voluntary sample of four older persons (65 to 85 years) was taken from an intergenerational research project where students assist older people to use social media, at the North-West University, South Africa. Qualitative research and the phenomenological research design were used in this study. Data were collected using multiple in-depth interviews and thematically analysed to identify the “essence” of the phenomenon. The older persons initially expressed suspicion about the use of social media and suspected the unethical use of information; that their privacy and confidentiality won’t be protected if they use social media; and access to social media is limited to the specific computers at the University. Despite these initial misperceptions, most of the older persons were optimistic to learn about technology as a medium to maintain contact with family and friends who have relocated. Older person’s limited use of social media can be due to a lack of information. It’s recommended that older persons be introduced to social media in a clear and accessible manner because social media can play an important role to maintain contact with significant others.

The missing link: An exploration of the experiences of loss of a grandparent(s) by young adults
Stefanus Van Zyl North West University, South Africa; Vera Roos
Loss of a loved one is perhaps the only certain thing about life and it is inevitable that everyone needs to deal with it at some time in their lives. Loss of a grandparent can be experienced in different ways by young adults, since grandparents are usually part of their relational network. Losing a grandparent is conceptualised as the loss of a meaningful relationship. Relational theories and object-relation theory informed this study. This presentation explores the experiences of loss by young adults whose grandparent(s) has died. Qualitative research was conducted and narrative design was used. Young Afrikaans-speaking adults (aged 20-30; 1 male; 10 female) were selected to participate in the study. Data collection consisted of the Mnogo-method™ (Roos 2008; 2012) which is regarded as a projective visual data gathering technique. It requires people to make visual constructions after an open prompt to make a visual presentation of their relationship with an older person. Individual representations
the truth of their universal psychology against claims for alternative truths by newcomers from the “Rest”. Premised on colonial history, they divide psychological knowledge into a “universal” part and a collection of indigenous psychologies with “local” meaning only. Re-reading psychology’s history helps recognizing that scholarly work from 20th century Europe and North America was and is equally indigenous as that from elsewhere. The world’s expanding psychological community is unlikely to accept a “universal psychology” rooting in colonial relations and requiring mastery of English language to be understood and used. A viable alternative is recognizing and respecting indigenous psychologies regardless of their origin and seeking common ground and exchange. It will change ways of sharing knowledge, and alter research, education and practice, making global psychology more congruent with its environment and more valuable.

Developing resources to support expanded research and effective practice
Norman Anderson American Psychological Assn, United States of America
The APA is a major psychology publisher, releasing more than 75 books per year and publishing more than 60 scholarly journals. Since 1965, APA has also been a major database producer, including PsycINFO, PsycEXTRA, PsycARTICLES, and PsycBOOKS. Two new APA databases, PsyCTESTS and PsyCTherapy, will be described, and their use in expanding research and improving clinical practice will be illustrated. PsyCTESTS is a research database that provides access to complete psychological tests, measures, scales, and other assessments as well as descriptive and administrative information for each instrument. Essential for libraries that support those involved in practicing, studying, or teaching in the helping professions, PsyCTherapy is a database of streaming therapy demonstrations featuring clinicians working with participants that offers synchronised, searchable transcripts, and allows users to create individual playlists.

APA policy and guidelines inform professional practice
Katherine Nordal American Psychological Assn, United States of America
The APA’s important role in the development of policy and guidelines for professional practice will be discussed. These guidelines not only inform practitioners but also serve to educate other health professionals as well as policy makers at the national and state level. Examples include: Evidence Based Practice in Psychology; the Model Licensing Act; the APA Code of Ethics; Record-Keeping Guidelines; Guidelines for Child Custody Evaluations; Guidelines for Evaluating Dementia in Older Adults; Guidelines for Practice in Healthcare Delivery Systems; and practice guidelines regarding certain populations such as LGBT clients, Older Adults, Persons with Disabilities, and Girls and Women. Currently the APA is developing new practice guidelines in the areas of Telepsychology as well as clinical treatment guidelines for depression and obesity.

Session Type: Invited Symposia
Symposium title: PANEL: Round table on psychology and policy-making
Convenor: Robert Roe
Round table on psychology and policy-making
Robert Roe Maastricht University, Netherlands
This round table is meant for officials of national and regional psychology associations and for other leading psychologists from all over the world. The starting point for the discussion is that psychology can and should do more to influence policy making for the benefit of people. The aim is to share needs, experiences and best practices, and to identify possibilities for future action at the local, national and international level.

Psychology in Malaysia
Chee-Leong Goh HELP University College, Malaysia
This Focal Symposium, presented by the leadership of the Malaysian Psychological Association, aims to provide an insight into current developments, challenges and applications of psychology in Malaysia. The convenor will provide an overview of psychology in Malaysia to set the tone for this Focal Symposium. This will then be followed by presentations exploring two critical areas for psychology in the country: Clinical psychology and youth development and intervention. There will be adequate time for discussion, during which it is hoped some of the answers to key challenges facing psychology in Malaysia may emerge.

Session Type: Invited Addresses
We have always been indigenous
Robert Roe Maastricht University School of, Netherlands
Since the earliest, scholars in psychology have assumed that people’s thinking, feeling and behaving follows universal principles. This “uniformity of nature assumption” made them believe that their findings and ideas have universal validity, even though their observations and theories were produced under unique, path-dependent societal and historical conditions. Having remained intact for almost a century, the notion of universal psychology was ultimately challenged as new generations of scholars from emerging economies produced congruent evidence and discordant ideas. Two notions characterise the status-quo: cross-cultural psychology and indigenous psychology. Both reflect a response among scholars from the “West” to defend

Historical perspectives in phenomenological psychology: Ratio-vitalism and human life
Carpintero Hielo UDIMA, Spain
This paper describes in greater detail the historical perspectives in phenomenological psychology. Psychology built according to a phenomenological point of view takes into account the conscious experience of the subjects in order to analyse its psychological processing. Such experience is always determined historically, according to the place and time framework in which the subject is placed. The examination of these historical dimensions needs the introduction of some methodological perspectives, upon which this presentation focuses. Special attention is paid to the analysis of the

The relational repertoire of young people in interaction with an older person
Roelien Visser North West University, South Africa
Relationships between people, related or unrelated, occur in social contexts. The theoretical framework that informs this research is the intergenerational approach and it is conceptualised that interactions take place in a relational context, which is continuously created and co-created. The purpose of this presentation is to explore how the relational repertoires of young people inform their interactions with an older person in an intergenerational research project. This is a qualitative research study which used an instrumental case study design. Data were collected through individual in-depth interviews with an older male (83 years) as well as self-reflections and group reflective discussions with two younger females (aged 23 years) and analysed thematically. The two younger people’s relational repertoire developed from their exposure to either a limited or a broad intergenerational network. A limited relational repertoire with older people and the interaction was described as frustrating due to unfamiliarity with age-specific developmental issues of older people. In the case of a broad intergenerational relational repertoire the younger person described a familiarity with age specific behaviour and was more accepting of the person. Although individual preferences in interactions with people are acknowledged, it is proposed that the type and nature of exposure to intergenerational relations be explored to understand how it informs young people’s relationship with older people. These findings may be used to develop programmes to create awareness.

Setting and situation: Tracing behaviour to where it actually occurs

Michael Knowles Monash University, Australia; Kurt Pawlik

While psychology’s spectacular development over the past 100 years can safely be attributed to its grounding in laboratory-based research, this symposium draws attention to certain issues complementary to this approach that need to be addressed theoretically, methodologically and educationally. The symposium begins by focusing upon the particular need for psychology to study human behavior under everyday life conditions in the field or in situ, and describes the contributions of Ambulatory Assessment in this respect. The second paper describes developments in the phenomenological approach to understanding behaviour that concentrate upon peoples’ conscious experiences, while the third paper discusses the need to study human behavior from a perspective wider than phenomenology. Given that human behaviour develops and finds expression in an ethnocentric context, papers four, five and six discuss the insights gained from studying psychology from a cross-cultural perspective. If the development of psychology is to be furthered by the kind of changes just described, this will have implications for the way psychology is taught in universities. So the seventh paper considers teaching methodologies available to facilitate the learning of practical skills for successfully conducting research in real-life situations. The symposium concludes with a discussion of some of the distinguishing characteristics of psychology as a science compared with other sciences such as physics, and discusses fundamental questions that confront both disciplines and which remain unanswered to the present day.

Teaching methodologies for conducting research in real-life situations

Michael Knowles Monash University, Australia; Mike Knowles

While the teaching of psychology is widely accepted as being of a high standard, in keeping with the persuasions argued above, there is a need in university curricula for it to be broadened so as to make provision for teaching methods that enable research in real-life situations to be conducted. Drawing upon experience in teaching organisational behaviour on MBA programs, this paper outlines the value of teaching methodologies including lecture/discussions, syndicate work, process analysis, and organisational analysis.

Ambulatory psychological assessment: Studying behaviour in its natural ecology

Kurt Pawlik University of Hamburg, Germany

This paper lays focus upon the importance of studying psychological phenomena in their natural environments. This complementary alternative to purely laboratory-based research has in fact a long, albeit tenuous history which will traced briefly in an introductory way. The main part of the paper describes recent developments in Ambulatory Assessment involving the monitoring of behaviour and conscious experience, of psychophysiological functions and their psychometric assessment outside of the laboratory. These advances have now established a viable route into the domain of real-life behaviour and have provided the discipline of psychology with a novel approach to ecologically representative designs sensus Brunswik.

Psychological research efficacy and the three "logies"

Piotr Trzesniak Universidade Federal de Itajubá, Brazil

Browsing literature and attending conferences in Psychology one can easily identify the huge amount of the human and financial capital invested in research in the area. But looking back at other fields which already reached a higher context of abstraction and theorisation, would it be possible to learn anything that can change the above overview? The answer may well be yes. Psychological research is strongly methodologically oriented, in the sense that to do good research, it is enough to do something methodologically correct. Actually, it cannot be that way. To optimise the ratio between advancement of knowledge and research effort, there are two other "logies" (besides methodology) to be taken into account: Epistemology, to establish the nature of investigation; which is most likely to bring the largest contribution to advance knowledge, and terminology, which favours the exchange of research results among the several "rope contestants", allowing them to start to pull in the same and most fruitful direction. Epistemology tells us whether it is better to do just descriptions of processes, or analysis, or conceptualisation, or development of measuring instruments, or synthesis, or modelling, or model extensions, or formulation of general principles, and so on. Terminology is to enunciate and refine concepts, to make them agreed upon and accepted by the whole research community (what should be culturally independent), and to develop and standardise measuring instruments (which can eventually be culturally dependent). Concrete proposals to enhance the role of these two "logies" are suggested.

Session Type: Symposia

Symposium title: An advocacy model for professional psychology

Convenor: Jennifer Kelly

Disaster response: Helping communities plan for, respond to and recover from disasters

Ellen Garrison American Psychological Assn., United States of America

APA’s Disaster Response Network (DRN) is a national network of more than 3000 licensed psychologists with disaster training who share information and expertise and help communities to plan for, respond to and recover from disaster. To engage in this work, the DRN works closely with the American Red Cross and government agencies. Over the past twenty years, DRN psychologist volunteers have been reaching out to communities to offer training to disaster responders, join coalitions of community disaster organisations, participate in planning meetings, respond to local disaster incidents, and provide psycho-educational programming to help communities rebuild and prepare for future disasters. Through its supportive disaster services work, the DRN program supports APA’s mission to benefit society and improve people’s lives.

An advocacy model for professional psychology

Jennifer Kelly United States of America; Elaine Levine; Katherine Nordan

In this symposium we will discuss the American Psychological Association (APA) Practice Directorate’s model for multifaceted advocacy on behalf of the professional psychology community. Through its Practice Directorate, APA, along with its companion organisation known as the APA Practice Organisation (APAPO), promotes the practice of psychology through multifaceted advocacy initiatives. The Practice Directorate advocacy model spans several interrelated areas, including legislative, local/regulatory, public education, disaster response and the employer/business community. Current legislative priorities include Medicare reimbursement for psychologists, and including practitioners, in incentives related to the use of electronic health records. APA’s Mind/Body Health Campaign educates the public about the link between physical and emotional health. Our Psychologically Healthy Workplace Programme (PHWP) is designed to help employers optimise employee well-being and organisational performance. PHWP provides connections between the business and psychology communities. The Disaster Response Network (DRN) is a national network of licensed psychologists with disaster training who share information and expertise and help communities to plan for, respond to, and recover from disaster. The success of all the Practice Directorate’s advocacy work depends on close collaboration with state, provincial and territorial psychological associations and the active involvement of grassroots psychologists throughout America.

Federal advocacy network: Harnessing the power of citizen psychologists

Jennifer Kelly United States of America

Grassroots mobilisation - harnessing the power of citizen psychologists to communicate legislative priorities to members of Congress - is critical to success on Capitol Hill. The Federal Advocacy Network, which consists of Federal Advocacy Coordinators for each state and territory as well as many APA divisions, is the APA Practice Organisation’s primary mechanism for mobilising grassroots support for professional psychology’s top legislative advocacy initiatives. Priorities include Medicare reimbursement for practitioners and psychologists’ inclusion in incentives related to the purchase and use of electronic health record keeping systems. When grassroots advocacy is needed, APAPO’s Government Relations staff works with field consultants to prepare Federal Advocacy Coordinators to deliver Action and Information Alerts to practicing psychologists across the country. Grassroots psychologists respond to these calls to action by sending a message to their legislators through APA-
PO’s online Legislative Action Centre, as well as with phone calls, constituent meetings and in-district town halls.

Public education campaign network: Community engagement about mind/body health
Elaine LeVine New Mexico State University, United States of America
A grassroots cadre of more than 1000 psychologists known as the Public Education Campaign (PEC) Network is an integral component of APA’s Mind/Body Health Campaign, which educates the public about the link between physical and emotional health. Through community outreach efforts including health fairs, free mental health screenings, interviews with local media outlets and a visible presence in schools, PEC Network volunteers promote messages about stress, lifestyle and behaviour, resilience and disaster prevention and management within communities throughout the US. The widespread community engagement increases the public’s awareness of psychology and the many ways in which psychologists can help individuals and communities develop skills and implement strategies to enhance health and well-being. PEC Network members also support partnership activities involving APA and Y-USA – for example, by conducting workshops that provide families with resources for healthy living.

Workplace Network: Helping to build connections with business and employer communities
Katherine Nordal American Psychological Assn, United States of America
The Psychology in the Workplace Network of more than 50 psychologists works to strategically position psychology in a leadership role within the marketplace by developing strong collaborative relationships with the business and employer communities and educating them about the roles and value of psychology in the workplace. The network is an integral component of the APA and APA Practice Organisation’s Psychologically Healthy Workplace Programme, which is designed to help employers optimise employee well-being and organisational performance. PHWP and the Psychology in the Workplace Network provide connections between the business and psychology communities at the national and local levels. Their activity includes supporting programmes implemented by state, provincial and territorial psychological associations as mechanisms for driving grassroots change in local business communities.

Symposium title: Career development in India - The formation of the India Career Development Association
Convenor: N.K. Chadha

Need for professionalism in career counseling and guidance in India
N.K. Chadha University of Delhi, India
The Career Development Facilitator Curriculum aims to provide a platform for the career advancement of human resources and to professionalize career counselling in India. This curriculum incorporates numerous career advising specialties. Firstly, it can be modified for post-secondary school graduates to assist children and secondary school students in learning about various job opportunities. Secondly, it can be a basis for the specialization of people interested in social work, psychology and other human services professions at an undergraduate level. Thirdly, trained career advisors will provide help to underprivileged individuals and workers in rural areas to become better employed. Fourthly, this curriculum can be used as a graduate level course, training program and certification for those in counselling psychology, social work and related professions. Training will be provided to career counsellors employed in direct service, as well as to instructors, employment and labour market specialists and human resource professionals using context specific training methods both for functional and soft skills development. They would also be involved in academia, government and private sector business. Various methods will be employed to assess the value of the curriculum including both short term assessments, like feedback from students, job seekers, trainers and professionals themselves, and long term assessments like the extent to which the objectives of the curriculum have been achieved. This would include tracing the career advancement of human resources over a period of time or return on investment, and looking at national indices like per capita income, gross domestic product and poverty index.

Career and Indian workforce
Bir Priya University of Delhi, India
Career planning and development are at the core of any vital economy. As India continues its growth and takes its rightful place among major industrialized economies, employment must be a primary concern. While education and training are often touted as the means to individual and national economic security, without employment opportunities, the critical knowledge and skills acquired can be lost. For at least a decade, India has been a leader in computer systems, bio-technology, engineering, and financial services support. Online and through call centers, India provides the world with a variety of support services from administrative and accounting to medical diagnosis and treatment recommendations. Currently, career planning and employment programs for secondary school and college students are growing in India. Career development programs, as well as job placement and recruiting services are becoming more common. However, many in the Indian workforce are being underserved.

Symposium title: Close relationships in one low-income South African community
Convenor: Elsien Lesch
Low-income fathers’ constructions of being a father to a daughter
Adiela Balim South Africa; Elsien Lesch
ULittle research has been conducted on how fathers define and give meaning to their experience of being fathers. In South Africa, research on fatherhood - especially the focus on fathers’ relationships with their daughters - has been limited. Where studies did include low income communities, the studies focused on the absence or presence of fathers. This study therefore explored the constructions of fathers of adolescent daughters who lived in one such a low-income Coloured, semi-rural Western Cape community. Multiple, semi-structured interviews were conducted with five father and Braun and Clarke’s method of inductive thematic analysis was used to analyse the resulting narratives. This method entails generating themes out of the narratives depicting father’s experiences that are close to the data itself. Three main themes emerged: Firstly, participants’ recollection of their own fathers’ parenting indicated that their own fathers informed their constructions of fatherhood. Secondly, our findings confirm other local research which found that traditional gender roles and relations are dominant in economically disadvantaged, historically disenfranchised Western Cape communities. Thirdly, it appeared that fathers and daughters had limited emotional and affectionate interactions with each other which may imply that they had limited opportunities to get to know each other and develop closer bonds.

Exploring closeness in parent-adolescent relationships (PAR)
Olivia Bosmer Helderberg College, South Africa; Elsien Lesch
The research objective was to explore closeness in parent-adolescent relationships (PAR) in one semi-rural, low-income Coloured community in the Western Cape Province of South Africa. This study was exploratory in nature, making use of a cross-sectional survey research design and semi-structured interviews. Fifty families (67 parents and 50 adolescents) participated in the quantitative part of this study, while 12 families (19 parents and 12 adolescents) took part in the Western Cape Part of the study. For the empirical investigation into close PAR, the following questionnaires were administered to parents: Mother and Father Versions of the Inventory of Parent Attachment (IPA), Revised Inventory of Parent Attachment (RIPA), and the Relationship Closeness Inventory (RCI). Thematic analysis was used to analyse the qualitative data and to explore the participants’ constructions of close PAR. General findings were that most female participants reported close mother-daughter relationships while most male participants reported relatively close father-son relationships. Overall, mothers generally spent more time with their adolescent children. Fathers and daughters generally reported less close relationships with one another. Although fathers were relatively more involved in their children’s lives compared to fathers in prior research studies, mothers and adolescents reported to have a closer bond.

The importance of studying father/adolescent daughter relationships in low-income communities: A literature review
Freda Conje South Africa; Elsien Lesch; Cronje Freda
Three completed studies in our project highlight the importance of studying fathers and fatherhood in our participating research community. Our literature searches, however, show that few studies have been
Constructions of intimacy in heterosexual, longterm relationships in a South African farmworker community

Arlene Kleinhans  South Africa; Arlene Kleinhans; Elmien Lesch
This study aimed to generate context-specific knowledge regarding intimate longterm, heterosexual relationships in one low-income, farmworker community. The aim was to specifically explore if and how intimacy is constructed, and to explore how partners experience intimacy in their relationships. The study used Charmaz’ social constructionist grounded theory method. Semi-structured in-depth interviews were conducted with fifteen adult couples (older than 23 years). A structured questionnaire with 67 items was utilised to collect relevant demographic and relationship information such level of education, work status, financial status, number of children, type of dwelling/housing, and the number of people in the dwelling/house. The relationship questions determined the status and characteristics, age and number of relationships of current partner and others. Four categories emerged from qualitative analysis. Firstly, the participants attached various meanings to the word “intimacy”. Secondly, the participants’ expressions and experiences of intimacy appeared to be shaped and informed by traditional gender roles. Thirdly, family of origin seemed to play an important role in how participants expressed and experienced intimacy in their current relationships. Lastly, it was found that alcohol featured prominently in the participants’ experiences of intimacy in their relationships. These categories and how they coalesce in a core category will be presented and discussed.

Introduction: Close relationships in one low-income, South African community
Elmien Lesch Stellenbosch University, South Africa
Close relationships play an important role in people’s general resilience, and their ability to overcome physical and mental difficulties. Most close/intimate relationship studies, however, have been conducted with White populations in developed countries, and tend to neglect the importance of social and cultural context in understanding how people relate. Due to these limitations, we have an inadequate understanding of the close relationships of people living in Western Cape, Coloured communities. Since these communities have unique histories, and often very specific psychosocial problems, the generation of community-specific research therefore appears paramount if we heed the urgings that problematic human behaviour should be contextualised to understand it adequately. This symposium will present some of the completed studies in a project that aims to provide such contextual understandings of relationships by exploring various close relationships and relationship constructs in one South African, Western Cape, Coloured community. “Coloured community” refers to a geographical area largely populated by “Coloured” people. The term “Coloured” is a term that was used under the Apartheid system to refer to a heterogeneous group of people of mixed racial descent and is still used today to refer to self-identify/race/ethnicity. We use it to acknowledge a history of political and economic differentiation between groups in South Africa and indicative of a certain social-cultural context.

Symposium title: Help for psychologists in distress
Convenor: Bjornhild Stokvik

Empathy, impaired practitioner, and ethical support in professional psychology in South Africa
Umesh Bawa United States of America
The objective of this presentation is to share the experiences of the Ethics Committee’s approach to queries on ethical matters from its members. This approach is aimed at offering guidance and support in cases of serious ethical concern, that require collegial and collective oversight. South African psychologists are governed by the Health Professions Act and are required to be statutorily registered in order to practise. The Health Professions Act deals specifically with the category of “Impaired Practitioners”. It stipulates the manner and process required to manage and support practitioners unable to offer professional services through impairment. This presentation will outline the approach adopted by the Psychological Society of South Africa in empathetically engaging with colleagues who may require assistance. It will offer views on how the association supports the “impaired practitioner” in maintaining professional and personal integrity in times of distress.

Quality service in psychology for the general public must include care for psychologists in distress
Boila Ephraime Jr Mozambique
The aim of this paper is to examine the need of a support system for psychologist in distress. The Mozambican Association of Psychology, MAP, has not yet established a formal support system for psychologists in distress. Currently the support for those colleagues is done on a collegial basis. Additionally MAP has been piloting training in a psychotherapy and supervision programme, since 2010, together with the Pedagogical University of Maputo. This project to assist colleagues in distress is part of it. MAP is also part of another project headed by the Ministry of health called “Health markets,” an event that is part of a health workers’ well-being programme, aiming at promoting self-care. Starting this year, the MAP will develop a better-structured assistance programme for psychologists in distress, as part of establishing the Psychological Chamber of Mozambique. The main goal of this Chamber is to guarantee the quality of psychological services offered to the general public. The MAP understands and lobbies for a better service for psychologists in distress as part of guaranteeing a quality service for the general public.

APA and colleague assistance
Katherine Nordal American Psychological Assn, United States of America
The objective of this paper is to present the colleague assistance programmes of the APA. APA’s work with psychologists in distress and collegial support is done through the Advisory Committee on Colleague Assistance (ACCA). ACCA was founded in 1988 when concern focused on the "troubled psychologist" and focused mainly around issues of substance abuse and boundary violations. The focus of ACCA evolved in the mid-1990s to focus more on problems of professional competence rather than the impaired psychologist. Today ACCA emphasises the importance of promoting wellness and self-care. ACCA’s role in APA is to assist with the development of Colleague Assistance Programmes (CAPs) in every State, Territorial and Provincial Psychological Association (SPTA). At this time there are nine formal CAPs which provide services such as confidence call-in lines for psychologists, referrals for therapy, workshops and resources on self-care, and peer consultation. Some CAPs are affiliated with their Boards of Examiners of Psychology while others are not. One of the main challenges to developing a CAP is the SPTAs concern about confidentiality and liability. ACCA is working with CAPs to address these concerns so that these SPTAs can move forward in developing programmes to assist psychologists in their state, territory or province who are struggling with substance abuse, depression, burnout or other forms of emotional distress.

Help for psychologists in distress
Anders Skuterud Norwegian Psychological Association, Norway
Associations for psychologists often have different arrangements of support on offer, giving advice and guidance to members who are in a difficult situation. Legal/practical advice regarding work situation/business activity. Advice on ethics, often in connection with a complaint filed against the member. A variety of professional continuing education courses and guidance aiming at developing professional knowledge and competence. These are assumed to have an effect in preventing professional problems. Collegial support and guidance. This could be either an informal talk between colleagues, or an organised open/free offer to members of the association. This last form of support is often given by respected colleagues appointed by the association. They give advice on how the psychologist may best get out of a situation when he or she as a professional finds him or herself in distress. The
objective of this symposium is to present different ways of organising such arrangements for collo
gial support and guidance in four different countries:
Mozambique, Norway, South Africa and the US.
The different arrangements and their experiences
will be presented and discussed.

That which I do not share with anyone: Col
genial support in Norway
Bjornhild Stokvik Norwegian Psychological Associ
ation, Norway
In addition to different other types of support The
Norwegian Psychological Association organises col
genial support to members in distress via its local
associations. The local association appoints three to
four respected members who are available for con
sultation with the psychologist in need. This positive
ly utilises the strength we know is generally found in
peer support. It combines practical/actual support with
an important mental support for the person in
distress, this in turn being a powerful acknowledge
ment and confirmation that the troubled psychologist
is still a peer and part of the professional community
at large. Collegial support in this way is easy to
organise and may be performed at a low cost. It is
partially founded on psychologists’ strong sense of
professional identity as well as the degree of general
respect and trust the appointed collegial support
enjoys in the psychological community. The objec
tive of this paper is to present the organisation and
experiences of collegial support in Norway.

Symposium title: Models of successful in
ternational research collaborations
Convenor: Merry Bullock
Fostering research collaboration: Programmes
at the German Research Foundation
Merry Bullock American Psychological Association,
United States of America
The DFG supports cooperation with international
partners in all of its funding programmes and with
a multitude of instruments. In general, it is possible
to apply for the funds needed for cooperation, in
addition to the project funding itself, regardless of
the specific type of project funding involved. Co
operative projects with foreign partners are gener
ally supported on the principle of reciprocal respon
sibility. Those researchers working in Germany
interact with the DFG, while their cooperative part
ners working abroad liaise with the funding bodies
in their own country. Research fellowships enable
researchers at an early stage of their scientific career
to carry out a clearly defined research project at a
place of their choice abroad or to acquaint them
selves with new scientific research methods. All of
the DFG’s programmes are also open to young
postdoctoral researchers from abroad, provided that
they intend to continue their scientific work in
Germany following their award. International Re
search Training Groups provide an opportunity for
joint doctoral training between a group at a German
university and a partner group abroad.

Models of successful research collaboration:
Views from around the world
Merry Bullock American Psychological Association,
United States of America
Although most would agree with the value of inter
national collaboration in psychology research, find
ing, beginning and carrying out international re
search collaboration requires more than good ideas and methodological skill. This symposium will
present three examples of programs to facilitate research collaboration and will invite audience
questions and examples to begin a discussion of
developing a range of best practices to encourage
appropriate, collaborative, equitable and interna
tional collaboration.

Symposium title: Obama’s global identity
Convenor: Dinesh Sharma
Obama and Africa
Saths Cooper ICP, South Africa
In the conclusion of this panel, we will organise the
discussion by focusing on Obama’s roots in Africa and
his perceptions and results for the African nations, who had very high hopes of his election.
What is Obama’s image in Africa and how well
does it match with reality? What can Obama do for
Africa in the short and long term? These are some of
the questions the discussion will deal with.

Barack Obama’s hybrid identity and the glob
al 21st century

Uwe Gielen St. Francis College, United States of
America
Coming from a multinational, multiracial, multicul
tural, and multi-religious family with roots in North
America, Africa, Asia and several Pacific islands,
Barack Obama is his country’s first global president
and the first to endorse a fully hybrid identity. My
paper, which has been prepared in response to
Dinesh Sharma’s psycho-cultural biography, Barack
Obama in Hawaii and Indonesia, focuses on Oba
ma’s attempts to create a more inclusive identity not
only for himself, but also for his country. Given
ongoing immigration trends in the United States,
the rapidly changing demographic composition of
its population, and the accelerating pressures to
globalise its economy and culture, a more inclusive
identity would seem to be highly desirable. More
over, Obama’s childhood in Hawaii and Indonesia
guided him towards a better understanding of global
identity-processes that are increasingly influenced
by ongoing economic and cultural developments in
Pacific Rim countries. In contrast, conservative po
litical groups in the United States favour a more
narrowly conceived and traditional Euro-American
Caucasian identity. Employing an Eriksonian
framework of identity construction and identity
change, this paper argues that Obama’s earlier strug
gles for a more inclusive and cohesive identity,
the ongoing political and cultural struggles in the
United States to create a more inclusive and less
reactionary identity, and worldwide attempts to cre
ate an evolving global identity exhibit significant
psychological similarities.

Introduction: Obama’s global identity
Roy Moodley University of Toronto, Canada
Introduction will outline the purpose and aim of this
panel. The focus of the panel is Barack Obama’s
global identity and his standing as the first multi
cultural head of a Western democracy. Papers will
discuss evidence and theory about Obama’s global
genealogy, political identity and social popularity.

Obama at the crossroads of globalisation
Dinesh Sharma IICP St Francis College, United
States of America
The Obama presidency represents a paradigmatic
moment in the history of the United States of
America and the emerging global world, given that
it is the first time that an African American politi
cian has reached the highest office in the US and
possibly the most powerful executive position in the
world. His election may have been driven by “the
Bush fatigue”, electoral and demographic changes
in the US population, and new forms of social and
information technologies. Indeed, it can be argued
that Obama is the first internet and post-genomic
president with newly formed social networks and
transmuted notions of race and ethnicity, respective
ly. While Pew research has shown that Obama’s
political effectiveness and image have weakened in
the United States, the surveys also show that he
remains a far more popular American president in
most parts of the world than his predecessor. What
are the reasons for this global popularity? In this
panel, scholars from around the world analyse how
the present American president, Barack Hussein
Obama, is viewed internationally by the public,
by academics, and the political establishment in
various parts of the world within the context of cultural and technological globalisation. Scholars from around the world analyse how and why the Obama image and perceptions have emerged significantly in a broad range of sociopolitical contexts, gained political currency, and the impact they are having or will have on our global future.

Barack Obama’s cross-border seduction
Rinaldo Walcott Canada

In this paper I will look at how Canadian multiculturalism and party politics have made use of questions of race and ethnicity to advance an anti-Black agenda. At the same time the paper will attempt to make sense of the Canadian electorate’s overwhelming support of and admiration for US President Barack Obama within the context of Sharma’s book, “Barack Obama in Hawaii and Indonesia: The Making of a Global President”. Putting Obama’s very favourable ratings among Canadian voters alongside their electoral decisions – electing one of the most conservative governments in recent memory – opens up a set of contradictions about race, Blackness, multiculturalism that raise significant questions about Obama’s significance and symbolism for impacting questions of global anti-Black racism. The paper will attempt to demonstrate how Obama’s deployment in the Canadian context by conservatives is ironically an anti-Black deployment.

Education in psychology: Preparing for the future
Cynthia Belar American Psychological Assn., United States of America

This presentation will address current needs and trends in the US relevant to the teaching of psychology, the preparation of psychologists and the application of psychology to education. With respect to the preparation of psychologists, it will examine changes in the US higher education system and how that is impacting on graduate education, as well as workforce needs for the nation’s future. With respect to precollege and undergraduate education it will report on new APA policies on high school and undergraduate education that are designed to promote quality in psychology education and psychological literacy in the public. It will also address issues in promoting psychology as a core STEM discipline, and efforts to include more psychological science in elementary and secondary education. Finally, it will address trends in the professional development sector of lifelong learning in psychology.

Psychology addressing social issues
Gwendolyn Keita American Psychological Assn., United States of America

Psychology has an important role to play in addressing societal problems and improving people’s lives. This presentation will describe the APA Public Interest Directorate and how it achieves its mission, “to apply the science and practice of psychology to the fundamental problems of human welfare and social justice and the promotion of equitable and just treatment of all segments of society through education, training, and public policy”. I will do this by describing the directorate’s organization, activities of committees and task forces, examples of projects, federal advocacy and training efforts to engage members, as well as some of the challenges. Special attention will be paid to how best to disseminate the information and have an impact.

Symposium title: Psychology in the United States: Current and future directions
Convenor: Norman Anderson

Interdisciplinary science and health care teams: Preparing psychologists for the future
Norman Anderson American Psychological Assn, United States of America

Two major components of APA’s strategic plan include (1) increasing recognition of psychology as a science and (2) expanding psychology’s role in advancing health. To meet these strategic goals, US psychologists must become members of interdisciplinary science teams addressing complex society problems that no single scientific discipline can solve. Similarly, US health care is moving toward patient-centred care where all of the patient’s needs - both medical and psychological - are met by a collaborative team of experts. This will require US psychologists to deliver services in new ways and settings, as members of health care interdisciplinary teams.

Advancing psychology as a stem discipline
Norman Anderson American Psychological Assn, United States of America

Psychology in the US is not consistently recognised as a STEM (Science-Technology-Engineering-Mathematics) discipline. This has important consequences for education, policy making, and the allocation of research funding, where emphasis is currently placed on the recognised STEM fields. In education, students do not learn that social and behavioural phenomena are subject to scientific scrutiny. In policy circles, psychology is not fully utilised in developing solutions to pressing societal concerns. In research funding, psychology comes up short because it is the recognised STEM disciplines that currently receive priority for support. Discussion will focus on what psychology can do to improve the situation, and how society will benefit as a result.

Symposium title: Setting and situation: Tracing behaviour to where it actually occurs
Convenor: Michael Knowles

Ecological and cultural perspectives in cross-cultural psychology
John Berry Queen’s University, South Africa

One of the basic perspectives of cross-cultural psychology is that all human behaviour develops and is expressed in cultural contexts. The examination of these contexts has traditionally been carried out using ethnocentric methods, largely adopted from cultural anthropology. Related to these cultural contexts are the ecological settings within which human populations have constructed their cultural systems, including their material, social and ideational culture. This concern with these two contexts has given rise to the field of ecological anthropol-ogy in the social sciences, and to the eco-cultural approach in cross-cultural psychology. In these approaches, features of cultures are seen as long-term and accumulated adaptations to features of the ecological contexts in which they have evolved. And the development and display of human behaviour are seen as being nurtured and constrained by features of both the ecological and cultural contexts.

In cross-cultural psychology, the focus has been on natural and cultural contexts (rather than on artificial ones) in the search for the roots of human behaviour in all its variety.

Addressing global problems grounded in local contexts
Judith Gibbons Universidad del Valle Guatemala, Guatemala

This paper addresses the need for the discipline of psychology and psychologists to investigate and attend to the world’s problems. To do this requires both a global perspective and the recognition that problems are embedded in particular local and cultural contexts. A new journal, International Perspectives in Psychology: Research, Practice, Consultation has taken up the mission of addressing global issues, including inter-group relations, disaster response, societal and national development, environmental conservation, emigration and immigration, education, social and workplace environments, policy and decision making, leadership, health care, poverty and economic justice, and the experiences and needs of disadvantaged groups, as those issues are instantiated in local contexts.

Indigenous psychologies and societal development
Janak Pandey Central University of Bihar, India

Psychology’s preoccupation with covert mental processes in a de-contextualized manner and its commitment to individualism has drastically limited its engagement with macro-level societal problems. This paper traces the increasing realization of the relevance and historicity of social and psychological knowledge as well as the necessity not only to develop alternative epistemologies but also to increase interaction with allied disciplines to pave the way for the emergence of socially situated psychological perspectives. Over the decades, the meaning of development has undergone changes. The experience of equating economic growth with development is no longer found appropriate and Western modernization is not seen as the solution to all problems. Therefore, endogenous development incorporating social and cultural characteristics of the people is considered as a more real approach for societal development leading to realization of the full potential of a society. Accordingly, conceptual tools and theories of cultural and indigenous psychologies facilitate greater understanding of people in their socio-cultural milieu and their participation in development processes. This understanding is critically important in the creation of a sense of power in collectivities and individuals for solving their problems. These indigenous and cultural approaches are discussed in the context of societal
development particularly in African and Asian countries.

**Symposium title: The Association of Black Psychology**
**Convenor: Cheryl Grills**

The Association of Black Psychologists (ABPsi) will provide insight into the relevance and need for an African-centred professional psychology organisation. The convener will provide a brief overview of the historical context surrounding the birth of ABPsi to set the tone for this focal symposium. This will then be followed by presentations exploring the association’s formation, mission, challenges, relevance and future in the United States and throughout the diaspora. Time will be allotted for discussion of the above facilitated by the convener. ABPsi’s present and future will be discussed particularly as they relate to the issue of identity, Africanism, indigenisation, and relevance. Current efforts to expand the scope of the organisation’s involvement in public policy, research activities, collaboration with other national and international black organisations, and community programmes, opportunities and challenges will be discussed as well as lessons learned.

**Symposium title: The state of psychology in Zimbabwe**
**Convenor: Gwatirera Javangwe**

The rebirthing psychology in Zimbabwe: Yesterday, today and tomorrow
Gwatirera Javangwe University of Zimbabwe, Zimbabwe; Florence Ngwenya; Tinashe Muromo; Kwadzi Nyanungo; Samson Mhizha; Edwin Nharirire; Mphikelelo Maseko; Debra Machando; Mags Beksinska

An analysis of the Zimbabwean worldview of psychology, misconceptions, appreciation, opportunities, and application of the discipline of psychology clarifying theory, reality and the desired outcome is done. The papers present how Zimbabwe is pregnant both with challenges and solutions underlining the potential of psychology to redress Zimbabwe’s problems. The paper endeavours to illustrate how most psychological problems can be tackled and how positive psychology can be the miracle drug required to shorten the long labour pains and induce the awaited birth of the baby called psychology. In the Zimbabwean culture, a baby belongs to everyone, and is there to serve everyone. Recommendations are made to facilitate the efforts to resuscitate the discipline and broaden opportunities, rebirthing psychology. This involves a paradigm shift, restructuring, collaborative work, dedicated research, publication and bringing psychology to the people of Zimbabwe. The paper concludes by calling upon the local and international community to participate in this process.
Research Area: Health

Session Type: Papers

Type D personality and quality of life in patients with irritable bowel syndrome
Reza Bagherian Isfahan University of Medical Science, Islamic Republic of Iran; Hamid Afshar; Peyman Adibi

The aim of this study was to determine the association between type D personality and HRQoL in patients with IBS. In a cross-sectional study, 194 consecutive patients with IBS referred to two referral gastro-intestinal clinics affiliated with Isfahan University of Medical Sciences were selected regarding inclusion and exclusion criteria. The patients completed type D personality (DS-14), IBS quality of life and the IB severity scoring (IBS-SSS) scales. The patients were divided into two groups with and without type D personality using DS-14. The data was analysed using ANCOVA and multiple regression. The findings indicated that 40.7% of the patients had type D personalities. The results of ANCOVA with controlling for the influence of severity of IBS and treatment duration showed a significant difference between the two groups in health related quality of life (F = 11.89, p < 0.01). Multiple regression analysis indicated negative affectivity (β = -0.283, p < 0.01), severity of symptoms (β = 0.279, p = 0.000) and duration of treatment (β = -0.189, p < 0.05) as the significant predictors for HRQoL in patients with IBS. Type D personality may be an important determinant of individual differences in HRQoL among IBS patients. Negative affectivity as one of type D dimensions may have an adverse effect on HRQoL in patient with IBS. Therefore, additional attention is needed in IBS patients with type D.

A qualitative exploration of the experiences of adolescents during pregnancy
Wilna Basson Medunsa, South Africa

Many adolescent girls in South Africa fall pregnant whilst they are neither economically nor emotionally ready to deal with parental responsibilities. The aim of this study was to explore and describe the experiences of pregnant adolescents by focusing on their thoughts and feelings about their pregnancies and future prospects. The study followed a qualitative research approach, utilising a phenomenological design. Nine adolescents in their second and third trimester of pregnancy participated. Data was analysed using thematic analysis. Results noted that many of the experiences narrated described fear of parental reaction to the pregnancy, unpreparedness for the challenges of motherhood, strained family relationships after disclosure of the pregnancy, uncertainty about the future, and feelings of anger, regret and anxiety. It was concluded that counselling and debriefing should be accessible at hospitals and clinics to provide pregnant adolescents with the support they need.

Forum participation moderates the relationship between coping-styles and wellbeing in cancer patients
Anika Batenburg VU University Amsterdam, Netherlands; Enny Das

Studies indicate that online contact with peers (i.e., online forum/support group participation) is beneficial for the psychological and physical wellbeing of breast cancer patients (e.g., Lieberman et al., 2003). However, to date no study dealt with the effects of important differences between patients in this relationship. This cross-sectional study is focused on participants’ coping strategies. Studies indicate that the way patients deal with their illness affects wellbeing (e.g., Kim et al., 2010). 184 breast cancer patients filled out a questionnaire assessing online contact with peers, coping styles (Mini-MAC, Watson et al., 1994), and wellbeing (depression, Irwin, Arin & Oxman, 1999; breast cancer related concerns, Spencer et al., 1999; emotional wellbeing, FACIT-B, Brady et al., 1997). Results showed that passive coping styles were negatively related to psychological wellbeing, and active coping styles were positively related to wellbeing. In addition, forum participation moderated the relationship between patients’ coping style and wellbeing. Patients who actively dealt with their emotions and thoughts, seemed to benefit from participation. Online writing may reinforce the effectiveness of their active coping-style. In contrast, patients using passive coping styles may be harmed by participation, active participation was negatively related to their wellbeing compared to passive patients who were less active on an online forum. For patients who cannot cope with their emotions and thoughts, negative stories may be overwhelming or confronting. A second data wave is needed to confirm causality. At the moment we are collecting this data. Results will be integrated in the presentation.

An investigation of condom use intention in a sample of men who have sex with men
Jaco Brink Stellenbosch University, South Africa

The aim of this study is to determine the extent to which the theory of planned behaviour (TPB) is applicable in explaining condom use intention among a sample of student men who have sex with men (MSM). A sample of 50 sexually active student MSM were recruited through convenience sampling to take part in an online (baseline and follow-up) survey, three months apart. Only attitude and perceived group norms could significantly predict intention to use condoms. Attitudes regarding condom use were found to have an inverse relationship with intention to use condoms. The results from the hierarchical multiple regression analyses revealed that the linear combination of the TPB variables could significantly account for 68% of the variance in intention to use condoms when the predictors were considered together. The present study questions the applicability of the TPB in understanding and predicting intention to use condoms among a sample of student MSM attending a South African higher education institution (HEI). The findings advocate for additional research to be undertaken on the applicability of the TPB in informing sexual health interventions that aim to reduce HIV transmission risk among student MSM at South African HEI. A need to further investigate the following was identified: (1) The inversely significant relationship between attitudes and intention to use condoms, (2) the predictive utility of the perceived behavioural control construct, and (3) the relationship between intention and actual condom use.

Sense of coherence and quality of life of elderly persons living with diabetes mellitus
Ottilia Brown Nelson Mandela Metropolitan University, South Africa; Melody Knight; Diane Elkonin

In South Africa, non-communicable diseases such as diabetes mellitus (DM) are responsible for 84% of deaths in elderly people over the age of 60. The World Health Organisation-Quantitative Life Group (1995) defined health as a state of complete physical, mental, and social well-being. As a result, there has been a movement towards a salutogenic orientation with its emphasis on health promotion and stress management for well-being. The primary aims of this study were to explore and describe the sense of coherence (SOC) and quality of life (QoL) of elderly people living with DM, and to generate information on the relationship between SOC and QoL of these people (n = 72). An exploratory-descriptive and correlational research design was used. A Biographical Questionnaire, Sense of Coherence Inventory (SOC-29) and WHOQOL-100 were administered to 72 elderly individuals aged 60 years and above living with diabetes mellitus. Results from the study indicated that the average person in the current sample has a fairly strong SOC and perceives themselves as having a good QoL. The correlational analysis revealed a significant positive relationship between these two measures for the current sample. These findings support the need to focus on elderly diabetics’ resources and capacities as well as their perceptions of efficacy, esteem and autonomy in the management of their DM.

Advantages to men attending perinatal classes: Clinical outcomes, the fathering role and parental relationships
Paul Campbell Paul Campbell Psychology, Australia; Dulcie Ryalls

This presentation outlines the clinical and social benefits both for early intervention and ongoing treatment for parents in the perinatal time, after participation in 5 workshops. The workshops were targeted at new parents, totaling 60 participants, in the second and third trimester, at several health facilities throughout North-West Tasmania. The workshops focused on Perinatal Depression (early identification, treatment, and resources, as well as depression in men); support, along with attachment, fathering and the male role. They also focused on early identification of perinatal depression; support of the partner through treatment; the importance of roles; and the long-term impact of being a father on the family dynamics; relationships; feeding and parenting. The workshop participants undertook a pre- and post-workshop assessment directed at knowledge- and skill-acquisition. Data focused on referral numbers was provided to the Tasmania Medicare Local clinical team for perinatal issues (pre- and post-natal). Results show an increase in knowledge due to the programme, attitude changes to fathering, changes in the fathers’ roles, parenting, and relationships, and finally, a significant increase in presentation for Post-natal Depression intervention at a clinical service in the North-West of Tas-
Depression and quality of life for patients attending diabetes specialist clinics in Barbados

Michael Campbell University of the West Indies-Cave Hill, Barbados; Michael Krimholtz; JaDon Knight; Carlisle Goddard; Anders Nielsen; Susanne Petersen

Anderson, Freedland, Clouse, & Lustman (2001) demonstrated that the presence of diabetes doubles the odds of developing co-morbid depression. Depression increases the overall health burden (Ludman et al., 2004) and likelihood of comorbidities, particularly cardiovascular risk factors (Katon et al., 2004) in persons with diabetes. Few Caribbean publications address the relationship of depression and diabetes. The present study recruited 132 participants (96 % Afro-Caribbean; 61 % female) attending specialist diabetes clinics in Barbados, a Caribbean nation of 280,000. Participants completed the Beck Depression Inventory-II (BDI-II; Beck, Steer, & Brown, 1996) the Diabetes Quality of Life Brief Clinical Inventory (DQOL-B; Burroughs et al., 2004), and the Veterans SF-36 Health Status Questionnaire (YSF-36; Kazis, 2000). Internal consistency for each instrument was excellent (α > .84 for all). Clinical data including blood pressure, lipid status, and glycosylated hemoglobin, weight, and lifestyle factors were recorded. 25% of patients had BDI-II scores at or above 14, the recommended cutoff score for mild depressive symptoms; only 3.3 % scored above 29, the cutoff for severe depression. Depressive symptoms were associated with lower quality of life (DQOL: r = -.73, p < .01) (YSF-36: r = -.77, p < .01), increased diastolic BP (r = .37, p = .01), and increased cholesterol levels (r = .41, p < .01). Quality of life measures did not correlate with any clinical measure. This study suggests that clinical implications of depressive symptoms in Barbadian patients with diabetes are similar to those reported previously.

Increasing physical activity in older adults: Walking by prescription in primary care setting

Claudia Carvalho ISPA-Instituto Universitario, Portugal; Vera Morais; Osvaldo Santos; Jorge Encarnado

Health literacy in Portuguese senior citizens

Claudia Carvalho ISPA-Instituto Universitario, Portugal; Vera Morais; Osvaldo Santos; Jorge Encarnado

Health literacy is the degree to which individuals have the capacity to obtain, process and understand health information to make appropriate health decisions. Individuals with limited health literacy have less knowledge about their health problems, more hospitalisations, higher health costs and poorer health status than those with adequate literacy. Awareness of patient’s literacy is a matter of importance on doctor-patient level because it may be the case that it can be used to alert physicians to focus on their communication with patients with limited literacy. On a health promotion level it is important to tailor health information in a format that people can understand. However there are limited studies on health literacy in Portugal, and none conducted with senior citizens. The Newest Vital Sign (NVS) is a 6-item test based on the ability to read and apply information from a nutritional label, which takes approximately 5 minutes to administer. English and Spanish versions are available both with good psychometric properties, demonstrating that NVS is a high sensitivity measure for detecting people with limited literacy. This communication presents preliminary data of the NVS’s Portuguese version in senior citizens. We examined health literacy in a group of patients aged above 65 years old, from a health care center in the Lisbon area, Portugal. Clinical data and measures of functional well-being and health status were also collected. Results are discussed in relation to the psychometric properties of NVS for this population and its association with the other assessed health status indicators.

Quality of life (QoL) coping strategies and coping effectiveness of female adult survivors of cancer

Nadisha Coelho IIT Bombay, India; Shobhana Subramanian; Nirmala Almeida

A dearth of Indian research prompted the study which addressed the QoL, coping strategies and coping effectiveness of male cancer survivors and ascertained the relationship between age, education, income, years of survival and QoL and coping effectiveness. The sample consisted of 24 male survivors of cancer (head and neck, gastro-intestinal and bone) with a mean age=46.7 years (SD=9.613) and post-diagnosis period from 5 to 24 years. Four tools were employed - an interview schedule which examined the QoL and coping strategies and 3 rating scales (QoL, types of coping strategies and coping effectiveness). Mean QoL score of the survivors was high, overall (M=405.96, SD=41.719, theoretical range=120-540) and in all domains - physical, psychological social and spiritual. Coping strategies used to a large extent were acceptance (M=7.38, SD=1.44), active coping (M=6.90, SD=1.58), religion (M=6.63, SD=1.81) and positive reframing (M=6.75, SD=1.871). Coping effectiveness score was very high (M=91.0, SD=7.489, theoretical range=25-100). A significant positive weak relationship was found between QoL and education (r =0.427, p=0.019), QoL and monthly family income (r=0.481, p=0.009), coping effectiveness and monthly family income (r=0.405, p =0.025) and coping effectiveness and number of years of survival (r=0.410, p=0.024). This study attests to the resilience of male cancer survivors.

The development of an inventory to assess structural barriers to adherence to antiretroviral therapy

Bronwyne Coetzee Stellenbosch University, South Africa; Deon De Bruin; Ashraf Kagge

Adherence to antiretroviral therapy (ART) is critical for viral load suppression and the maintenance of
optimal health among persons living with HIV. Despite a growing body of literature on the structural barriers to adherence to ART, there has been little research aimed at measuring the salience of these barriers among persons receiving ART. The aim of the study was to develop and identify the underlying factor structure of two scales measuring adherence. The two scales measured adherence to clinic attendance and adherence to pill-taking respectively. In Phase 1 of the study we collected qualitative data from health care workers and patients to identify the salient barriers to optimal adherence. In Phase 2, we constructed an item pool for inclusion in the two scales with the purpose of constructing. We recruited a sample of 300 ART users from a peri-urban hospital and a non-government organization in the Western Cape. Exploratory factor analysis (EFA) and second-order factor analysis indicated good alpha reliability (0.89 and 0.87 for the two scales respectively). Second-order factor analysis revealed that the items on each of the scales were dominated by a single underlying factor. It is anticipated that the scales may be useful to health care workers in identifying patients experiencing barriers to ART adherence and develop psychosocial interventions to assist them in negotiating and overcoming these barriers.

Sexual and reproductive health services for female street and hotel based sex workers operating from Johannesburg City Deep
Jenny Coetzee WITS, South Africa; Brett Bowman
Sex work is a crime in South Africa. With the prevalence and deleterious social and economic effects of HIV, sex work has often been understood in relation to the transmission of the epidemic. Inadvertently, this positioning of sex work stigmatises the sex worker who is often cast outside the rights-based discourses that characterise South Africa’s post apartheid democracy. In addressing this, this study assessed the barriers and facilitators to accessing sexual and reproductive health (SRH) services as well as the gaps in the current service offerings of SRH in Johannesburg, South Africa. Semi-structured interviews were conducted with 11 female sex workers. The study shows that various structural and individual level barriers prevent access to SRH. Together these present formidable challenges to sex workers’ understanding themselves within a human rights discourse. This is of particular importance to rethinking legislation criminalising sex work, as well as healthcare initiatives geared both towards sex workers and women in general.

Engaging the body-self relationship in healing anorexia/bulimia: A qualitative study
Joan Elizabeth Collett University of South Africa, South Africa
Treatment strategies for anorexia/bulimia often seek bodily repair and overlook the critical dimension of the embodiment of the condition in the life of the patient. By placing emphasis on the renewal of the relationship between body and self, the study aimed at achieving healing by examining the condition from the patient’s perspective. The study employed phenomenology as the overarching epistemological framework, using a qualitative research design and social constructionist approach to explore the experiential meaning of spirituality as lived experience in daily life. Three young women receiving treatment for anorexia/bulimia, provided narrative accounts of developing, living with, and recovering from the illness. Semi-structured interviews, audio-taped and transcribed, were subjected to interpretative phenomenological analysis. The study emphasises that for those challenged by anorexia/bulimia the struggle is not primarily about food. The illness manifested itself as vulnerability in the human condition, a wounded or empty self, harbouring a dis-enabling spirituality. Properties characteristic of obsessive, ritualistic behaviour, bordering on addiction, maintained illness symptoms. The process of healing emphasized the subjective or spiritual, to better understand the ill person’s situatedness in such illness or addiction. This highlights the importance of a holistic approach in treating anorexia/bulimia: it is the individual, rather than the illness itself, that should be the subject of scientific study.

Quality of life in patients with fibromyalgia: Groupual treatment
Maria Isabel Comeche UNED, Spain; Mafe Rodriguez; Jose Ortega
Fibromyalgia (FM) is a chronic syndrome characterised by generalised pain that is a source of great suffering for most patients. The impact that this complex and disabling syndrome has on many aspects of daily life increases and aggravates the negative effect on quality of life (QoL), a fact frequently reported by the literature. Cognitive-Behavior Therapy (CBT) constitutes one of the most successful treatments for FM. This study (long term, randomised clinical trial) tries to analyse the short and long term efficacy of CBT group therapy on QoL in a sample of FM patients. 44 FM patients (100% women) were randomly assigned to one of two conditions: (1) Standard control group, or (2) CBT group therapy. The outcome variable was the Fibromyalgia Impact Questionnaire (FIQ), measured at pre, posttreatment, and follow up at 3, 6 and 12 months. After therapy, the total score (general impact) and some items of the FIQ (anxiety, physical function, fatigue and morning tiredness) improved significantly. During the follow-up physical function remained significantly better and the other items of FIQ returned to pretreatment values or worsened. This result suggests that CBT group therapy is effective in improving clinical manifesta-
tions in FM patients but not for long periods of time. This result points out the need to continue monitoring of these patient’s processes in order to remember the content of the CBT program and maintain the improvements.

Fertility and partnership issues in young childless women with breast cancer
Roslyn Corney University of Greenwich, United Kingdom; Jane Swinglehurst
With many women delaying the birth of their first child, a proportion of young women diagnosed with breast cancer will be childless. Fertility can be impaired by treatment and women may have to wait for a number of years before pregnancy is advised. In this qualitative study, 20 young childless women and 5 partners were interviewed. The women had all received a diagnosis of first episode breast can-
cer at least 6 months before interview and 18 had received chemotherapy. They were recruited by a range of methods and asked to tell their story, with an emphasis on fertility issues, from first discovery of symptoms to the present day. Transcripts were analysed using the thematic method developed by Braun and Clarke. In many cases, women were given inadequate information on the impact of treatments on their fertility. The focus was on treat-
ing the cancer and few were given the opportunity to undergo assisted reproductive techniques beforehand or to choose less toxic treatments. Many women were distressed and worried about their future fertility. Single women had additional concerns about their ability to attract a partner. Few women indicated that they had received emotional support from health professionals or counseling. More holistic care should include emotional support and more detailed information on fertility. Support groups specifically for young women are vital to reduce the prevailing sense of isolation associated with being a young woman with this disease.

Coping with inflammatory bowel disease and the role of social networking sites
Neil Coulson University of Nottingham, United Kingdom
This study aimed to explore the experiences of those patients who had joined IBD-related Facebook groups. There were three main research questions: 1) Reasons for accessing an IBD-related Facebook group, 2) advantages and disadvantages of seeking support online, and 3) how participation has helped patients. An online survey link was posted to a range of IBD-related Facebook groups which included both quantitative measures and open-ended questions. A total of 87 patients participated in the survey (73 female) aged 17 to 53 years (Mean =32.7). Based on their ratings of 15 possible reasons to access an IBD-related Facebook group, the most popular were: ‘To find others in a similar situation’ (87.7%), ‘To learn new information about my condition’ (70.4%), and ‘To share experiences’ (67.9%). Qualitative thematic analysis of the open-ended responses revealed a number of advantages of support via SNS: 1) convenience, 2) connecting with similar others, 3) up to date medical information, and 4) advice, support and understanding. These were considered helpful in coping with IBD and for some, their online activities appeared to contribute to a more positive adaptation to IBD and symptom management. The present results suggest there may potentially be clinical benefits attached to the use of SNS, however there is an urgent need to undertake more methodologically robust research which considers how and why participation in social networking sites for IBD may be beneficial.

Putting the social back into bio-psychosocial models of pain
Kenneth Craig University of British Columbia, Canada
Severe, uncontrolled acute pain, pain related to terminal illness, and chronic pain are serious global public health challenges. These have destructive psychological, physiological, social and economic consequences. Most inadequately controlled pain can be characterized as needless, as a broad range of empirically-supported interventions are avail-
A comparison of dysfunctional beliefs, personality traits and history of serious illness between teachers with and without health anxiety

Iran Davoudi Shahid Chamran University, Islamic Republic of Iran; Mahnaz Mehrabizadeh Honarmand; Farideh Nargesi

The aim of the present study was the comparison of dysfunctional beliefs, personality traits, and history of serious illness between teachers with and without health anxiety in Andimeshk, Iran. The sample consisted of 60 participants with health anxiety and 59 participants without health anxiety. The variables were evaluated in two groups by the Health Anxiety Inventory (HAI), Cognitions About Body and Health (CABAH), NEO–FFI and researcher developed Inventory of history of serious illness. The MANOVA showed there is difference (p=0.001, F=20.56) between groups. Differences between two groups were significant, in CABAH and beliefs relevant to catastrophizing interpretation of bodily complaints, automatic sensations, bodily weakness, intolerance of bodily complaints, and health habits, also neuroticism, extraversion, agreeableness, conscientiousness, and history of serious illness. The scores of Catastrophizing Interpretation of Bodily Complaints, Automatic Sensations, Bodily Weakness, Intolerance of Bodily Complaints, Health Habits, Neuroticism and History of serious illness scales of participants with health anxiety were significantly higher, whereas their scores of Extraversion, Agreeableness and Conscientiousness scales were lower. The two groups were not different on openness scales.

Suicide prevention in rural primary care
Tamara Dehay WICHE Mental Health Program, United States of America; Mimi McFaul

In the United States, suicide rates in rural counties are higher across demographic groups than in urban areas. This pattern holds true for many other countries as well. Due to cultural and workforce factors in rural areas, Primary Care Providers (PCPs) are frequently the sole providers for many patients with mental health concerns. Research has shown that, in the U.S., approximately 66% of individuals who complete suicide have visited their primary care physician within one month of their death. Primary care providers in rural areas are thus uniquely positioned to conduct focused suicide prevention practices. The Western Interstate Commission for Higher Education (WICHE) Mental Health Programme, in collaboration with the Suicide Prevention Resource Centre (SPRC), has developed a Suicide Prevention Toolkit for Rural Primary Care to assist rural PCPs in effectively identifying and intervening with suicidal patients. The purpose of the Toolkit is to bring the best practices in suicide prevention to rural primary care and to offer physicians, patients, and rural communities the tools and support they need. This presentation will include an educational overview of suicide prevention in Primary Care, including epidemiology, prevalence, warning signs, risk and protective factors, suicide assessment, and crisis intervention. The Suicide Prevention Toolkit will be introduced and data from its pilot testing in the U.S. will be presented. It is expected that participants will learn about effective assessment, identification, and intervention for suicidality through the innovative and comprehensive suicide prevention Toolkit developed by the WICHE Mental Health Programme.

Using humour to manage stressful situations
Lucia Dimeo University of the Virgin Islands, Virgin Islands, United States of America

Daily struggles and unexpected situations can escalate stress to dangerous levels adversely affecting an individual’s emotional, cognitive, and physical functioning. Humour has been found to de-escalate stress and provide a safe respite from overwhelming events. Its mind/body benefits can literally lighten the mood, the spirit, and the body, allowing for better coping strategies, as well as increased energy, motivation, and camaraderie. A review of the literature provides support for the therapeutic use of humour to manage stress. This presentation examines the impact of stress on physical and psychological well-being, and how humour can serve as a protective factor in mediating stress. It explores published research on humour and stress, and discusses the use of humour to enhance overall mind/body wellness and resiliency during stressful situations integrating a mindfulness framework.

Health climate predicts affective commitment in the context of workplace health promotion
Anna Ernsting Freie Universitat Berlin, Germany; Ralf Schwarzer; Aimee Ferreira; Sonia Lipke; Michael Schneider

Health climate reflects a specific aspect of organisational climate referring to employees’ shared perception of organisational health-related priorities and practices. Inspired by the job demands–resources model, we examined whether health climate may operate as a beneficial job resource, supporting employees’ affective commitment to an organisation. Associations with long-established workplace health promotion programmes and the two concepts were explored. A sample of 851 longer term employees of a German company participated at two measurement points in time, five months apart. RM-ANOVA, cross-legged panel correlations and mediation analyses were conducted to investigate the longitudinal relationship between health climate and affective commitment, and the associations with workplace health promotion programmes, controlling for age and gender. Preliminary RM-ANOVA revealed health climate and affective commitment as rather stable and general reactions to the organisation (p>0.05). Cross-legged panel analysis showed that both concepts were cross-sectionally and longitudinally correlated (p<0.05). Those who perceived their company as caring about their well-being, showed higher levels of affective commitment five months later. The results support the idea that health climate operates as a beneficial job resource, supporting employees’ affective commitment. Organisations should create and cultivate a healthy work environment.

Psychological well-being and mental distress in a city in Ecuador
Jose Luis Gonzalez-Castro University of Burgos, Spain; Carrera Darwin

Mental distress is a pervasive feature in most modern societies. It affects not only the individual
but the whole social fabric of a community, and constitutes a factor which may disrupt social relationships. Many psychological, social and political factors may influence the appearance of this distress. In this study we will focus on the impact of demographic variables (age, sex, income), life expectations, health indexes (times hospitalized, medical treatments, Body Mass Index), and psychological well-being (Ryff, 1989). The sample consisted of 401 participants from Ambato, a middle-sized city in Ecuador. The dependent variable, mental distress, was measured using the GHQ-12 (Goldberg, 1978). Analyses conducted include crosstabs, t-tests, correlations and logistic regression using GHQ-12 cut off points to include case- ness and non caseness. Results show that there are important gender differences (more distress in women), and that maintaining stable social relationships, being independent and self-regulating one’s behaviour leads to less mental distress. Results will be discussed on the basis of how social and educational interventions should take into account gender differences, and how fostering social relationships may decrease the possibility of suffering from mental problems which will have positive consequences not only for the individual but for society at large.

Experiences of palliative caregiving in a community setting
Tanya Graham University of the Witwatersrand, South Africa; Sarah Uren University of the Witwatersrand, South Africa
Despite the importance of community-based palliative care in South Africa, there is little research on the experiences of formal caregivers in low-income settings, and the contextual and emotional challenges they encounter in providing caregiving services. This study investigated the subjective experiences of palliative caregiving among 11 formal caregivers within a community setting in Gauteng. In depth interviews were conducted with participants that explored the perceived role of the caregiver; the emotional experience of caregiving; personal and social factors influencing the caregiving experience; motivation for caregiving; support mechanisms and the perceived effectiveness of coping strategies employed. The data were considered from an interpretive phenomenological perspective and content analysed into themes that converged around the contextual influences on caregiving experiences. The data was considered from an interpretative phenomenological perspective. The themes provided insight into how caregivers construct their role as a formal caregiver, in comparison to the informal caregiver, and in relation to the community they serve, and highlighted their perceptions of the importance of knowledge within caregiving. The themes also provided an understanding of the coping mechanisms and the contextual factors that interrelate with a caregiver’s ability to manage the difficulties within caregiving and their emotional reactions. These findings illustrated that community-based caregiving, although subject to significantly more stressors, also has significant positive aspects that could be fostered to operate as protective mechanisms. The findings also suggest that contextual factors are an integral and neglected component of understanding the experience of caregiving.

Predictors of self care and mental health outcomes among youths with type 1 diabetes in Victoria, Australia
Naomi Hackworth Parenting Research Centre, Australia; Zvездана Bucalo; Susan Moore; Victoria Hamilton; Elisabeth Northam; Fergus Cameron
Type 1 diabetes (T1D) is a chronic illness, which requires a strict daily regimen of medication and monitoring to avoid short and long term health complications. Adolescents with T1D face considerable physical and psychological demands at a time when they are also negotiating major developmental changes and the transition to independent self-management. Research suggests that this places them at heightened risk of mental health problems. While the link between self care (adherence) behaviours and metabolic control in T1D is well-documented, the specific predictors of self care and the link between diabetes management and mental health outcomes are less well understood. This paper reports findings of a questionnaire study conducted with rural and urban-dwelling youths with T1D (aged 13 – 25) in Victoria, Australia which aimed to explore the psychosocial predictors of self-care, negative affect, and metabolic control. While no rural/urban differences were detected on any outcomes, structural equation modelling revealed that high diabetes self-efficacy, lower engagement in risky behaviour and more conservative risk attitudes predicted better self-care, which in turn predicted better metabolic control and mental health. The study has significance because both diabetes self-efficacy and propensity toward risky behaviour are potential targets for educational and counselling interventions.

Mental health status of Chinese: A progress report
Buxin Han Institute of Psychology, CAS, China
The mental health status of the Chinese was outlined by reviewing related studies over the last 30 years. The review indicated the following: (1) There were two definitions of ‘mental health’, with one based on mentally-ill patients and another one based on normal people in China. (2) The classic measures, such as SCL-90, SDS, SAS, were often inappropriately used as index of mental health, with implicit mismatching of negative emotion with mental health. (3) The samples in most of the related studies were either too small, or focused on rural and urban inhabitants. (4) A recent nationwide investigation, with over 15,000 individuals involved, indicated that 15-18% had excellent mental health, 65-70% had good mental status, 11-15% had some signs of negative mental health, and 2-3% participants showed poor mental status. (5) The mental health status of some specific samples, such as children in the countryside left behind because their parents were working in urban areas, the aged population, survivors of natural disasters, governmental officers, and religious believers, were also investigated and reviewed. Both positive and negative indexes of mental health status were significantly higher than normal control for some populations. For example, SCL-90 scores of school students increased during the past 30 years. It was concluded that the mental health status of the Chinese - a key component of a harmonious society - was a result of the recent economic development in China. However, more culturally-sensitive measures need to be developed based on a clearer definition of mental health.

Cognitive dysfunction and burnout syndrome among nurses: The effects of long term rotating shift work
Hajar Hasani Ardakani Islamic Azad University, Islamic Republic of Iran; Ghassem Naziry Islamic Azad University, Islamic Republic of Iran
The present study was carried out to assess the impact of long term shift rotation, especially night shifts, on cognitive dysfunction, and on the emergence of burnout syndrome in nurses. In a cross-sectional study, a convenience sample of Iranian nurses working at Shiraz hospitals (n=100) were evaluated using the Stroop Test, Weckslor memory test and Maslach Burnout inventory. Cognitive functions (reaction time and memory performance) in rotating shift work nurses, especially those who were assessed in the morning after night shifts, were significantly lower than those who worked in fixed and daily shifts. In addition, the burnout inventory score was positively related to years and hours of work, and there was a difference between daily and night shift nurses. The findings indicate that night shifts have an effect on the quality of work of nurses and their well-being. These results emphasize the need to design proper nursing manager interventions that help nurses to improve nursing care quality.
An exploratory study into the experiences of caregivers of children with cerebral palsy
Rayhanah Hassim
University of the Witwatersrand, South Africa
The birth of a child can fundamentally change the dynamics in many families, more so if the child has a disability. This also has particular influences on the caregiver. This qualitative study explored the experiences of ten primary caregivers with regard to parenting a biological child diagnosed with cerebral palsy using semi-structured interviews. The data followed a thematical framework which highlighted aspects such as the emotions involved in being a caregiver, the challenges faced, support structures, as well as the impact that caring for a child with CP has on the caregivers’ health, well being and relationships. This was then analysed in an interpretive phenomenological manner. From the results, it was evident that caregivers experienced both negative and positive aspects associated with parenting a child with CP. These experiences are discussed in relation to findings from other studies. The need for intervention programmes for this group of people will be highlighted.

Enhancing self-management of depression risk through the integration of mindfulness practice and personal music usage
Christine Hsieh
MIT, United States of America
Relapse rates for clinical depression can be as high as 50% two years post-treatment. Mindfulness and music therapies have been deployed in various clinical settings. This paper examines the possibilities of teaching personal music usage in a psychologically powerful way that incorporates the personality and lifestyle of the individual. Individual and social factors have increasingly been seen to play a substantial role in the success of long term health care, especially when patient self management is crucial. There exists few scientifically supported, self-practiced therapies that take this into account. The purpose of this study was to combine music usage with mindfulness to test whether this bolsters the adherence and efficacy of a music protocol designed to improve well being in healthy subjects. We implemented a six week, six session study with daily 30-minute home practices, using three kinds of audio, in randomised two week blocks, for 24 subjects. Dropout decreased significantly from pre- to post-study, and average in-session mood increased significantly across all subjects. Practice reactions and minutes completed, revealed a favourable response; nearly all indicated that the practice was worth doing each day they completed it. The decrease in rumination is key because it is a symptom and predictor for depressive episodes. From this evidence it is promising to explore interventions of this type further, as it has shown a favourable outcome and, moreover, is a first step towards better psychologically informed self-practices for therapeutic use.

The influence of challenge stressor-hindrance stressor on university staffs’ physical reaction and subjective satisfaction
Ping Hu
Psychology Department, China; Zhang Qiang
This study aimed to investigate the influence of challenge stressor-Hindrance stressor on the university staffs’ physical level and subjective satisfaction. The procedure was divided into three part: (1) Using questionnaires to get the 99 university staffs’ life and work subjective satisfaction, (2) getting their physical level in their medical check-up index with their permission; after 2 years, (3) adopting the same method to get 68 subjects’ results. By the hierarchical regression method to analysis data, the results indicated: (1) The challenge stressor was positively related to the work satisfaction, however, the hindrance stressor was negatively related to the subjective satisfaction (life and the work), (2) there were no significant relationship between the challenge stressor-hindrance stressor and negative emotion (depression and anxiety), also no significantly relation between the same-time physical level, (3) the change of challenge stressor was significantly related to the change of blood pressure and BMI between two years, (4) gender and position had an influence on the relationship between the challenge stressor and physical level.

Deploying knowledge in healthcare process modelling
Biqing Huang
Tsinghua University, China; Peng Zhu
In the age of rapidly developing economies and aging societies, customized healthcare is becoming a common trend. Preventive, tailored and long-term care has never been more necessary than it is now, thus various healthcare knowledge is critical for constructing an efficient and rapid-responding care process. We analyze and categorize care knowledge as four types: medical knowledge; organizational or regional specific knowledge; health promotion and illness prevention (HPIP) knowledge; and customer-specific knowledge. These four kinds of knowledge can be used and deployed during the care process modelling, following six sequential steps. Texted and unstructured medical knowledge is structured to Clinical Practice Guidelines (CPGs); CPGs become Care Guidelines (CGs) by adding HPIP knowledge according to target population needs; CGs are translated into Computer-Interpretable Care Guidelines (CICGs) by using the Petri Nets model; CICGs are tailored by adding organizational or regional specific knowledge for healthcare localizations and then form Organization-Specific Careflows (OSCs); OSCs become Customer-Centered Care Plans (CCCPs) by adding customer specific knowledge; the Actual Careflows (ACs) are deviated from the CCCP plans since the running instance of the CCCPs might be frequently modified. We developed a health care flow system, in which knowledge is managed and deployed by means of structure, translation, extraction, refinement, and improvement on texts, guidelines, treatments, and so forth.

Health

Influence of gender and self-esteem on psychological wellbeing among diabetes outpatients in Ile-Ife, Nigeria
Femi Ilievare
Obafemi Awolowo University, Ile-Ife, Nigeria; Nifemi Adamolekun; Oluwatosin Ilievare
The study examined the influence of gender and self esteem on the psychological well being in diabetes outpatients in Ile-Ife, Osun State, Nigeria. A descriptive research was adopted for the study. A total number of 100 diabetes outpatients from Obafemi Awolowo University Teaching Hospital Complex, Ile-Ife were drawn as participants through purposive sampling. A questionnaire method was used for the collection of data. Three hypotheses were generated and were subsequently tested using the appropriate statistical tests. Hypotheses formulated were tested at the 0.05 level of significance. The results indicated that there were no significant gender differences on psychological well being among diabetes outpatients (F(1,1440) = 0.05). There were no significant and joint predictions of personal characteristics such as age, educational attainment, marital status and religion on the psychological well being of diabetes outpatients. However there was a significant influence of self-esteem on psychological wellbeing among the diabetes out-patients (r = 2.449, p < 0.05). Based on the outcome of the results obtained, conclusions were drawn and the applied implications for this study are discussed.

Influencing factor on self-esteem of obese adolescents: Perception of obesity rather than obesity itself
Can Jiao
Shenzhen University, China; Minqiang Zhang
Jieting Zhang
Shenzhen University, China; Guobin Liao
Obesity for adolescents has become a global health issue. The most obvious manifestation of the changes about obesity is in appearance, and whether the changes affect their self-esteem is worthy of study. 362 adolescents, including 50% obese and 50% non-obese, are surveyed by Rosenberg Self-Esteem Scale, and the data are analyzed by Mplus. The result includes: (1) Confirmatory Factor Analysis(CFA) showed that the self-esteem scale for obese young people includes seven items, the scale reliability is .734; (2) Multiple Indicators and Multiple Causes(MIMIC) model that self-esteem as a
latent variable, perception of obesity and obesity itself as covariates demonstrates that the model accurately fits the data (Chi-square=47.291, p=0.006; RMSEA=0.48; CFI=0.93; TLI=0.90; SRMR=0.041), and obesity itself has no significant statistical effect on self-esteem (gamma1=0.034, p=0.647), while perception of obesity has a significant positive effect on self-esteem (gamma2=1.97, p=0.003).

Learning styles in patient’s activation of health and mental health care among Latinos. Does gender matter?
Aida Jimenez Carlos Albizu University, Puerto Rico; Dharma Cortes

The purpose of this study was to explore if women and men learn and become activated to ask questions about their mental health care providers and to make decisions about their mental health care using similar processes of learning styles or way of knowing. This study is part of the DECIDE Project, a study that evaluates an intervention that teaches patients a set of skills intended to facilitate active participation in their care. Sixty Latino males and females, age- and site-matched, were recruited for the present study. The answers to two open-ended questions were analyzed by three independent blind coders who coded them as connected or separated way of knowing. Results suggest that women and men express confidence to ask questions and to make decisions through different processes. When gaining confidence to ask questions both females and males relied more on connected manners, but females relied more on separate ways such as formulating questions before the appointments, and learning ways to make questions. Men placed more emphasis on female traits of relatedness with their provider in order to feel confident to ask questions. Women used a connected manner as part of their activation process in making decisions, while men engaged in equal styles. Findings from this study point to the importance of including providers in the training of the DECIDE program in order to further facilitate and promote patients’ activation in their health and mental health care.

Childhood cancer narratives: Transactional patterns of coping
Vinitha Jithoo University of Wittwatersrand, South Africa

The psychological and social factors relating to childhood cancer have been documented in a number of studies conducted mainly in Europe and America and based predominantly on research in Western cultural contexts. A paucity of information exists with regard to developing societies such as those in Africa, generally, and South Africa in particular. Much research into childhood cancer as those in Africa, generally, and South Africa in particular. Much research into childhood cancer has been conducted primarily within the discourse of psychopathology. Within this paradigm children tend to be characterised as victims of psychologically and physically malign processes, while their parents’ adaptation to the illness is characterised as ‘maladjustment’. This study sought to understand the psychological implications of the diagnosis and treatment trajectory of childhood cancer in lower socioeconomic families and to illuminate the processes which mediated successful adaptation to childhood cancer. The study group comprised of 50 children (between the ages of 5 and 16 years) together with one or both of their parents. Data was collected through semi-structured interviews and self-report measures. Participants’ narratives revealed that their perceptions of the illness, communication patterns, psychosocial engagement, educational needs and their experience of grief were grounded in culture, collectivism and spirituality. These findings provide a rationale for a biopsychosocial model of health which is non-prescriptive, culturally sensitive and equally accessible to all strata of society.

Physical and mental ailments in terms of Ayurveda
Shyam Lata Juyal Gurukul Kangri University, India; Shivangi Sharma

Modern medicine is recognising that we must consider the nature of the individual in health and disease. It is not enough to give the same treatment to everyone suffering from the same disease. In the last few years interest in alternative therapy, especially Ayurveda has very much increased, not only in India but also all over the world. Limitations of effective treatment in chronic and psychosomatic disorders and the undue side effects of modern medicines are the major reasons that have caused this changing attitude. Modern medicine treats the ‘symptoms’ or causes revealed by investigations, whereas Ayurvedic Medicine treats the patient as a whole with a psychosomatic approach. Therefore, ‘Ayurveda’, the science that has been neglected for many years, is going to regain its old glory of ancient times. Many scientists and researchers all over the world have started to take interest in understanding this science. International organisations such as the WHO and UNESCO have increased their faith in alternative therapies like Ayurveda. Ayurveda believes that life is a continuous and constant union of Body, Senses, Mind and Soul. According to Ayurveda physical and mental health are interdependent. Ayurvedic theory of health is based on tridosha - vata, pitta and kapha and the balance of tridosha creates health. Through this paper I tried to throw light on the principles of Ayurveda, that a combination of physical, mental and emotional characteristics determines an individual’s constitution.

Adolescent femininity ideology and self-esteem as predictors of sexual risk behaviour in late adolescence
Zuhayr Kafar, Stellenbosch University, South Africa; Sherine Van Wyk; Raghshanda Mohammed

Young South African women are excessively at risk for HIV infection. Extensive research has been conducted on the sexual risk behaviour (SRB) of South African adolescents in response to the HIV pandemic and the subsequent need to understand SRB in order to design focussed interventions. The current study aimed to determine which of six domains of self-esteem (SE) or two domains of adolescent femininity ideology best predicted SRB. We used Du Bois’ self-esteem scale which measures SE in six domains (global, peer, body, family, school and sports) and Tolman and Porche’s Adolescent Femininity Ideology Scale which measures female Inauthenticity of Self in Relationships (ISR) and level of Objectified Relationships with their Bodies (OBR). We administered self-report surveys to young women living in University residences. Only 91 of the 299 participants who answered the questions regarding SRB indicated that they had had sex. Chi-squared analyses indicated a significant relationship between family SE and ISR (p<0.05) and all other domains of SE and ISR (p<0.01). Similarly all domains of SE and OBR were significantly associated (p<0.01). None of the domains of SE were associated with SRB, while ISR and OBR were both associated with SRB (p<0.05). Interventions aimed at reducing SRB in young women have to take cognisance of the effect that their inauthenticity in relationships and objectified relationships with their bodies have on sexual risk behaviour as simply focusing on self-esteem may not lead to significant outcomes for these interventions.

Health performance of individuals within the Campbell paradigm
Florian Kaiser Otto-von-Guericke University, Germany; Katarzyna Byrka

In this paper, we developed a new measure that links individual health attitude with the likelihood of engaging in a wide variety of health-related behaviors. Within what Kaiser, Byrka, and Hartig (2010) call the Campbell paradigm, we equated health attitude with what a person does to retain or promote his or her health. A sample of 391 adults provided us with survey data of different sets of health behaviors, health- and health-behavior-relevant variables, and three personality measures. We found that self-reports of 50 behaviors and self-reports of expressions of appreciation for 20 of these behaviors - from various domains, such as sustenance, hygiene, and physical exercise - form a transversely ordered class of activities. Our findings have theoretical implications as they challenge the conventional view of health attitude as a psychological cause behind individual behavior.

Selected psychological and social influences on health in different European and African countries
Vladimir Kezba National Institute of Public Health, Czech Republic; Miloslav Kodl; Vera Kernova; Iva Solcova

The basic data concerning social influences on health in Czech districts (2000/2005, 3917) are compared with available data from 18 European countries. Czech national statistical data on sick leave, unemployment, income, the Gini coefficient, and their psychological reflection in respective districts of the Czech Republic are compared with the above mentioned European and African data. Income, unemployment and sick leave varies in different districts of the Czech Republic. The poorer Czech districts report a higher morbidity and higher unemployment rate. This Czech finding differs from other European as well as African countries’ findings. European countries with lower level of Gini coefficient (Sweden, Norway, Austria) show a lower average level of unemployment, and a higher average level of income, which is different from some African countries. Some indicators of health (e.g. the number of sick leave cases) are affected by government interventions. The detailed similarities and differences in psychosocial influences on health
within the European and African countries are demonstrated.

Social support and the mediating roles of depression and alcohol use on ART adherence in ART recipients in Gauteng, South Africa
Connie Kekwaletswe, Medical Research Council, South Africa; Hermann Swart; Neo Morojele
The objective of this study was to replicate and expand the model reported by Cha et al. (2008), on the cross-sectional relationship between Social Support, Depression, Self-efficacy Beliefs, and anti-retroviral therapy (ART) Adherence, via the addition of Alcohol Use. Using purposive sampling, we recruited 304 male and female ART recipients from two ART clinics in Tshwane, South Africa; one in a city and the other in a township. The predictor variables were Social Support, Depression, Alcohol Use, and Self-efficacy Beliefs. The outcome variable Adherence to ART was assessed using four measures. Data were analysed using Structural Equation Modeling (SEM). Social Support not only predicted lower Depression and lower Alcohol Use, but was also indirectly associated with greater Adherence via the mediation effects of Depression and Alcohol Use. Furthermore, Depression significantly mediated the relationship between Social Support and Self-efficacy Beliefs. Finally, Self-efficacy Beliefs significantly mediated the relationship between Depression and Adherence and between Alcohol Use and Adherence. This study's findings suggest a complex, and often indirect, positive relationship between social support and ART adherence, and so constitutes a significant replication and expansion of the results reported by Cha et al. (2008). Social support-based interventions could prove useful in ART adherence enhancement interventions, by way of decreasing the untoward effects of alcohol use and depression on ART adherence, while also promoting greater self-efficacy beliefs.

The link between alcohol consumption and art adherence: Perceptions of ART recipients and health care providers in Gauteng, South Africa
Connie Kekwaletswe, Medical Research Council, South Africa; Neo Morojele
This study was conducted to evaluate the perspective of ART recipients and health care providers (HCPs) on the link between alcohol consumption and adherence to ART. We also assessed how HCPs advised their patients about drinking while on ART and the nature of their formal and informal training on alcohol use and ART. We employed qualitative methods: 11 single-gender focus group discussions (FGDs) with male and female ART recipients and 17 in-depth interviews (IDIs) with HCPs across six ART sites. Thematic analysis was conducted. The dominant advice imparted by HCPs was that taking alcohol concurrent with ART lessens the effectiveness of the ART and worsens some ART's side effects. Despite this advice, some patients drank alcohol while on ART but did not inform their HCPs; they even took their ART dose with alcohol rather than water, if at a drinking venue, and reported still achieving optimal ART outcomes.

Another approach was to adjust their alcohol consumption times to avoid drinking concurrent with ART, while a third approach was to consciously skip a dose if drinking. In general, the HCPs felt they lacked sufficient training delineating the relationship between alcohol use and ART. Precise training for HCPs regarding ART, adherence and alcohol use is urgently needed; this in turn will minimise HCPs' likelihood of imparting any inaccurate advice regarding alcohol's impact on ART's effectiveness.

Rural and urban differences in beliefs about breast cancer and help-seeking intentions for the disease among women in India
Neena Kohli, University of Allahabad, India
Breast cancer is the most common malignancy among women in India. Health beliefs are important in help-seeking for potential symptoms of disease, which may be particularly important among women who do not have access to breast screening programmes. The purpose of this study was to examine Indian women's beliefs about breast cancer and help-seeking for the disease and how these beliefs related to their intentions to seek help for a symptom of breast cancer. Furthermore, the study aimed to examine if there were differences in the beliefs of urban- and rural-based women. 685 women completed a questionnaire framed around illness perceptions and the theory of planned behaviour. The questionnaire examined their beliefs about breast cancer and beliefs about help-seeking. One in four women reported that they would delay seeking help for at least one month following the discovery of a symptom of breast cancer. Rural respondents held more negative beliefs about breast cancer, had poorer awareness of symptoms, and were more likely to report an intention to delay seeking help. Rural women were also more likely to report less positive attitudes towards help-seeking and a belief that they would be discouraged from seeking help. Both of these factors emerged as significant predictors of intention to seek help and raised the issue that it may not be individual attitudes but also socio-cultural influences towards seeking help for breast cancer symptoms that may need to be targeted in any intervention aimed at improving early detection and help-seeking for breast cancer symptoms.

Psychological wellness of cancer patients: The role of psychosocial resources
Neena Kohli, University of Allahabad, India
The present study analysed whether availability of psychological and social resources, prior to commencement of radiotherapy is associated with (a) concurrent psychological wellness (PSYW) (b) PSYW at eight weeks of treatment (c) PSYW at a 5-month follow-up and (d) change in PSYW over time. Luminated data was collected from 130 cervical cancer patients. The questionnaire tapped information pertaining to demographics (age, education, marital status, family income, place of residence, number of children), five psychological resources (optimism, perceived controllability, purpose in life, affective state, self-esteem) social resources (emotional and instrumental support) and psychological wellness. Optimism was assessed through the positively worded items of the Scheier and Carver life orientation test. Perceived controllability was measured using the 6-item Multidimensional Health locus of control scale. Purpose in life was measured through an adapted version of Crumbaugh purpose in life test. Affective state was measured through 20 PANAS like adjective checklist and Rosenberg's scale was applied for self-esteem. Social resources were tapped through a self-constructed social support scale. Psychological Wellness was measured through a 24 item self-developed scale. Analyses showed that health beliefs, psychological and social resources showed concurrent associations with Psychological Wellness. In addition belief in God, Fate and Karma, perceived controllability, affective state, purpose in life and social support were associated with PSYW at eight weeks treatment and five month follow-up. There was a significant improvement in Psychological Wellness over time.

Illness perceptions and treatment beliefs of heart attack patients and their role in adherence to treatment
Neena Kohli, University of Allahabad, India
The aim of the study was to examine patients’ beliefs about heart attacks, their beliefs regarding treatment and to assess whether relationships existed between these factors and adherence to treatment. The sample consisted of 80 heart attack patients with a mean age of 46.6 years. All the patients were undergoing treatment at a local hospital in Allahabad, Northern India. Patient beliefs were assessed through the Illness Perceptions Questionnaire (IPQ) and the Beliefs about Medicines Questionnaire. Adherence to treatment was measured through Adherence scale. Illness Perception Questionnaire assesses five components of illness representation: illness identity, cause, timeline, consequences and illness control-cure beliefs. Items were scored on an 11-point scale ranging from ‘never’ to ‘all the time’. The beliefs about medicine questionnaire assesses beliefs about treatment necessity (4 items) and beliefs about the possible harmful effects of treatment (5 items). Items were scored on 5-point scale ranging from ‘strongly disagree’ to ‘strongly agree’. Adherence to treatment (5 items) measured the extent to which patients complied with treatment. Items were scored on a 5-point scale ranging from ‘never’ to ‘always’. Regression analysis indicated that perceptions of illness identity, consequences, and treatment necessity explained a significant amount of variance in adherence to treatment. The results suggest that assessing illness perceptions, especially beliefs regarding identity, illness consequences and necessity of treatment, may play a valuable role in identifying which individuals are least likely to adhere to treatment.

The role of maternal self-efficacy on the effectiveness of nutrition education for Indonesian children
Risatanti Kolopaking, Islamic University of Indonesia, Indonesia; Umi Fahmida; Agus Firmansyah; Jahja Umar
The general objective of the study is to identify the effectiveness of the nutrition education program for children by assessing the effect of maternal self-efficacy in the home food environment on chil-
Previous studies about personality correlates of cancer patients led to inconclusive results since demographic and medical factors were not controlled and the examined variables were not grounded in a coherent theory. This study was done in the framework of the Cognitive Orientation (CO) theory of health behaviour and wellness which enables identifying relevant factors in cancer patients. The goal was to examine whether a coherent set of personality tendencies grounded in the CO theory can be identified in breast cancer patients. The participants were 185 breast cancer patients in different disease stages, 31 to 75 years of age, with disease duration from 3 months to 15 years, and 180 healthy controls matched in demographic characteristics. They were administered a questionnaire of background information, and the CO questionnaire of breast cancer (with high reliability and validity) assessing personality dispositions identified in pretests as relevant for breast cancer. Results showed that the patients and controls differed significantly in most personality dispositions. None of the differentiating psychological variables was related to demographic and medical characteristics. Discriminant analyses showed that the main psychological tendencies of the patients included concern with controlling oneself and others, dependence on evaluations of others, emotional blocking, perfectionism, and conflicts with regard to self-identity and giving to others. The findings support the conclusion that there exists a comprehensive and relevant set of psychological correlates of breast cancer patients that has not been identified previously and could serve as basis for psychological interventions.

Impact of socio-economic status on health

Min moyi Kulkarni IIT Bombay, India

The aim of this empirical study was to investigate the role of socio-economic status, neighborhoods, psychological characteristics and health behaviors on actual health outcomes and perceived health for an urban Indian sample. In part one of the study a cross-sectional design was used with a lower income community sample of 491 adults in two neighborhoods. Neighborhood and perceived stress played a role in distinguishing between risk of chronic conditions as well as perceived health. Positive emotional style was associated with decreased perception of poor health. Results support the importance of combining contextual as well as individual level characteristics in understanding health outcomes. In a follow up study, middle and upper middle income people were interviewed. The results are being analyzed to determine the effect of socio-economic status on health outcomes and perceived health.

Psychology and public health in India

Anant Kumar Xavier Institute of Social Ser, India

Psychology as a discipline has substantive contribution to make in understanding human behaviour and its application to health. Nevertheless, we have neglected to integrate this knowledge into public health practice and policy in India. The challenges for public health are to recognise and incorporate the knowledge, to reconcile competing models of psychology into the prevention of disease, injury and the promotion of positive health and well-being. The paper reviews the significant psychological theories and practices and their contribution to public health and suggests recommendations for addressing these challenges.

Exploring black South African women's barriers and facilitators to cervical screening adherence

Despina Learmonth University of Cape Town, South Africa; Chantelle Chanteel De Abreú

Cervical cancer is the second most common cancer among South African women. Black South African women particularly have the highest cervical cancer risk and mortality rate. This type of cancer is easily treated if detected early. Unfortunately, the majority of South African women do not adhere to recommended regular cervical screening. The purpose of this research was to explore the perceptions, experiences and knowledge relating to cervical cancer and preventative screening amongst Black women residing in two Western Cape urban informal settlements. There is a need to determine the barriers and facilitators specific to black women living in underserved regions of South Africa. This knowledge is vital for community health staff to be able increase screening adherence. The Health Belief Model (HBM) provided a theoretical framework for this study. Four focus groups (n=21), with women between the ages of 21 and 53 years, were conducted using questions derived from the HBM. Thematic analysis was used to analyse the data. The analysis revealed lack of knowledge pertaining to screening as a key barrier to treatment. Other structural barriers identified were: time, age at which free screening is available, and health education. Psychosocial barriers that emerged included fear of the screening procedure and fear of stigmatisation around attending screening. Finally, the presence of physical symptoms, the perception that screening provides symptom relief, the presence of HIV, and the desire to know one's physical health status were identified as facilitators of cervical screening adherence.

The hermeneutic schemes of modulating human psychoneuroimmunology (PNI): Multiple factor analysis model (MFAM)

Sang-Bok Lee Kangnam University, Republic of Korea; Jonathan Lee

The objective of the study is to conceptualize the Multiple Factor Analysis Model (MFAM) by using a meta-cognitive method as the authors review psycho-neuroimmunology (PNI) literature. The authors used key words, PNI and stress, PNI and immunity, immune system and coping, in PsychINFO, PubMed and science journals and read 360 selected journal articles. The authors categorized multiple factors affecting the modulation of PNI. They identified seven major factors: 1) behavioral modulation factor, 2) cognitive factor, 3) emotional factor, 4) bio-neuro-genetic factor, 5) nutritional factor, 6) environmental, ecological, and adaptive factor, and 7) spiritual and transcendental modulation factor. Using the “scientific analogy” method (Gentner, 1982, 1983, 2002), we appreciate the differences-in-similarities among the multiple modulation factors, and aimed to implement the MFAM that differentiates specialized fields or domains as well as dynamically interacts heuristically among the multiple factors. In conclusion, we...
proposed Multiple Factor Analysis Model as a feasible hermeneutic scheme of modulating human psycho-neuroimmunology.

**Common sense illness cognition: Science and practice**

*Howard Leventhal* Rutgers University, United States of America

The Common-Sense Model (CSM) presents a conceptual framework of the cognitive, affective and behavioural mechanisms underlying how individuals manage chronic illnesses in everyday life. CSM describes the implicit, largely automatic and largely conscious, deliberative controls that generate the representations that guide actions to prevent and control illness. In CSM, representations are generated by matching the specific features of deviations from the prototype of the "healthy" self (the normal, asymptomatic and functioning self) with illness prototypes. The model describes how representations created by automatic and executive processes often prove inconsistent with the underlying biology and prescribed treatment protocols for many chronic conditions: The inconsistency arises as automatic processes drive stimuli (symptom and dysfunction) management, whereas executive management is based on the abstract properties of illness representations. Evidence supporting the CSM analysis of the processes underlying the construction of illness and treatment representations suggests new directions for enhancing "self-management" and "team management" of chronic conditions. One such direction involves examining how expert managers discover strategies and construct automatic, habitual behavioural sequences for initiating and adhering to treatment protocols. A second involves identifying the language and communication media for developing representations of illness and action plans for implementing treatment that are shared and guide the behaviour of patients and practitioners.

**Bariatric psychology: A psychopathological minefield of causal factors associated with morbid obesity**

*Hermann Liebenberg* Private Practice, South Africa

Based on a qualitative research study (3 females and 2 males aged 25 - 45 with a BMI > 40), the relationship between prolonged traumatic exposures (e.g. sexual, physical and/or emotional abuse) as a possible primary causal factor related to the development of a Disorder of Extreme Stress not otherwise specified (DSMIV TR), or collectively referred to as "Complex Trauma" in relation to the development of morbid obesity, will be introduced. The interrelationship between morbid obesity, prolonged traumatic exposures and bariatric surgery (gastric bypass surgery) as a "forced behavioural intervention" to patients suffering from morbid obesity, will be explained. All patients in this small group had a history of childhood trauma, consequently displaying symptoms of "Complex Trauma". These aspects, in relation to the benefits of specific psychological assessments and interventions prior to and after bariatric surgery, will be discussed. These combined remedial interventions (psychotherapy and bariatric surgery) to "cure" obesity seem beneficial and sustainable aspects after bariatric surgery for this group. The complexity in terms of true psychopathological comorbid factors (e.g. borderline-, bipolar- and dissociative traits) often associated with Complex Trauma, will be delineated. Based on the researcher's observations and experiences with more than 800 bariatric patients the results of this qualitative study suggests possible generalisations in terms of common themes and workable treatment regimens for bariatric patients. These observations will be discussed and proposed for further quantitative research.

**The effect of immune activation on depressive-like behaviour induced by forced swim stress**

*Wenjuan Lin* Institute of Psychology, China; *Yuqin Pan*; *John Sproule*

To understand the role of immune activation induced by cytokines in behavioral depression, the present study was to investigate the effect of single administrations of lipopolysaccharide, cytokine inducer, on depressive-like behavior induced by forced swim stress in rats. 42 rats were divided into four groups: LPS + swim (LS), LPS + control (LC), saline + swim (AS), saline + control (AC). Rats were injected intraperitoneally with LPS 50ug/kg and saline respectively on the first experiment day. After 2h of injection, rats in two swim groups were conducted forced swim stress for 14 days. On the 2nd day, the 14th day of the stress, and one week and two weeks after stress, depressive-like behaviors in rats were observed in saccharin preference tests, open field tests and elevated-plus maze. The results showed that saccharin preference, locomotor activities in open field, and closed arm entries in elevated-plus maze in the LS group were significantly lower than that in the AS group on the 2nd day of the stress. On the 14th day of stress, both LS and AS group rats had lower saccharin preference and locomotion than AC group rats. The depressive-like behaviors in rats of the LS group lasted for up to two weeks after stress while the depressive-like behaviors in rats of AS group only lasted for one week after stress. The results demonstrate that LPS-induced immune activation strengthens depressive-like behaviors induced by stress.

**Professional situation and well-being of adults living in Switzerland: Modering impact of adapt-abilities**

*Christian Moggiori* University of Lausanne, Switzerland; *Claire Johnston*

Currently, the uncertain labour market has the potential to negatively affect professional and personal development, and thus requires an increased capacity for adaptability. This research aims to explore the relationship between professional situations and wellbeing by considering the direct and moderating effects of individual characteristics, focusing on adapt-abilities (Savickas, 2005). This study is part of an eight-year longitudinal project on professional realities and trajectories, hosted by the Swiss National Center of Competence in Research LIVES. The sample (n=2400) representative of the Swiss population, consists of Swiss and non-Swiss, employed and unemployed adults. Data collection is currently occurring as part of the 1st wave of the larger project. Characteristics of the professional situation, including job strain and factors related to unemployment, are assessed using study-specific developed items. Individual characteristics and resources are measured using the Career Adapt-Abilities Scale (Savickas & Porfeli, in press), NEO Five-Factor Inventory-Revised (Costa & McCrae, 1992), and Belief in a Just World scale (Dalbert, 1999). Wellbeing is assessed using the General Health Questionnaire 12 items (Goldberg & Williams, 1988) and Satisfaction With Life Scale (Diener, 1985). Specifically, a series of hierarchical multiple regression analyses will be conducted to assess the moderator effects of personality, adapt-abilities and just world beliefs in the relation between professional situations and wellbeing. Additional analyses will target specific unemployment factors (e.g. length of unemployment and perceived discrimination during the job search process) and their unique impact on wellbeing. Demographic variables will be controlled.

**Cigarette smoking among lesbian, gay, and bisexual youth in the Philippines: Findings from a national sample**

*Eric Manalastas* University of the Philippines, Philippines

Global research on lesbian, gay, bisexual, and transgender (LGBT) health has shown that sexual minorities have significantly higher smoking prevalence than heterosexuals, using population-based surveys (Tang et al., 2004; Gruskin and Gordon, 2006; Gruskin et al., 2007) and meta-analysis (Ryan et al., 2001; Marshal et al., 2008; Lee, Griffin, & Melvin, 2009). This paper explores the prevalence of tobacco use among Filipino lesbian, gay, and bisexual young adults using data from the national Young Adult Fertility and Sexuality Survey (YAFS3). Young lesbian and bisexual Filipino women had higher rates of experimentation with tobacco, higher prevalence of current smoking, and more cigarettes smoked per day, compared to heterosexual Filipino women. And while sexual orientation did not appear to be associated with disparities in smoking among men across three measures of tobacco use, Filipino gay and bisexual youth had the highest cigarette smoking prevalence of all. The value of a gender x sexual orientation analysis of health risk behaviours such as cigarette smoking, as well as possible implications for tobacco use intervention in the Philippine context, will be discussed.

**A multidimensional theory of health**

*David Marks* Journal of Health Psychology, United Kingdom

No man is an island, entire of itself; every man is a piece of the continent (John Donne). This paper provides a definition and theory of health in the context of society and culture. A multidimensional definition conceptualises the 'continent' of health as a state of well-being with physical, mental, psycho-social, educational, economic, cultural and spiritual aspects, not simply the absence of illness. Each person has a unique makeup of age, sex and hereditary factors. Each person's health is a multidimensional state of balance across the seven domains. A principle of compensation enables any one element that is relatively strong to compensate for lack in another element. Thus balance between the different dimensions is as important as strength in any
particular set of these. The macro-social issues affecting individual well-being are enormously powerful. The world population is increasing to nine billion in 2050. The amount of drinkable water per person will fall by 33%. Half of the global population lacks access to treatment of common diseases and essential drugs. Health gradients are a universal feature of both rich and poor countries. Using a variety of perspectives and approaches, psychology needs to contribute much more towards health improvements in the context of the socio-political struggles of yesterday, today and tomorrow.

Behavioural model of the triggers of headache/migraine: The need for a radical conceptualisation
Paul Martin Griffith University, Australia
We have argued in three recent publications that the standard clinical advice that headache management should involve avoidance of triggers is open to criticism as it has minimal empirical support and problems with it implementation. In addition, the literature on anxiety, stress and chronic pain would suggest that avoidance is generally a maladaptive strategy. We have proposed the ‘Trigger Avoidance Model of Headaches’, which suggests that fear of the experience of headaches drives susceptible individuals to try to avoid headache triggers, and this natural tendency is encouraged by clinicians and advice on the internet. Attempts to avoid triggers will result either in no exposure, or short exposure, to the triggers. This may lead to the capacity of the trigger to precipitate headaches being maintained or increased, through a process of sensitisation, failed habituation/adaptation, or lack of opportunity for learning to cope with the trigger. Hence, whilst attempts to avoid triggers may lead to fewer headaches in the short-term, it may result in more headaches in the long-term. We have argued that counseling avoidance should be replaced with a philosophy of ‘learning not to cope with triggers’. The stress literature demonstrates that no one coping strategy can be selected as the best way of coping with stress for all situations and across time, but approach strategies generally are more adaptive than avoidance strategies. This presentation will critically review literature relevant to our trigger avoidance model and approach to managing triggers, including a series of studies undertaken in our research program.

Cause and effect of embarrassment related to breast cancer screening in Japan
Higuchi Masataka Hiroshima University, Japan; Yoshino Teruya; Masataka Higuchi; Nanako Naka-mura; Hitomi Kuranaga
Breast cancer is one of the most frequent cancers among women, and the number of women diagnosed with it is increasing in Japan. Breast cancer is a disease in which early detection and early treatment are very effective, and although periodical medical checking is very important for early detection, the rate of breast cancer screening is quite low in Japan. One of the major factors that negatively affects participation in breast cancer screening is embarrassment. Although many studies have shown that participation in the screening is strongly inhibited by embarrassment, the causes of the embarrassment have not yet been clarified. This lack of clarification is one of the reasons there is no the effective intervention method to reduce embarrassment. To clarify the causes and effects of embarrassment on the participation in breast cancer screening, we investigated 731 females (ages 30 to 59, mean age = 44.83) via websites. Results of structural equation modelling revealed that embarrassment had inhibited the intention of attending a breast cancer screening by reducing self-efficacy. We also learned that the embarrassment was strongly related to apprehension of the medical staff’s evaluation. These results indicate that, to promote participation in breast cancer screening, we should focus on an intervention method that lowers apprehension related to the evaluation at the time of screening.

Social support as a mediator of postnatal depression among African women
Khonzanani Mbatha University of South Africa, South Africa
Pregnancy is one of the most magical moments any woman can experience, but it may also be a traumatic for some women it is the beginning of a period of stress and depression, especially when social support is limited. This study aimed to explore the role that support from family, partners, friends and professionals such as nurses, play in mediating the psychological effects produced by the transition to motherhood among African women. The study was rooted in an interpretive paradigm and a phenomenological research design was used. The sample was seven African women who attended a post-natal clinic and who were aged from 18 to 25 years. Purposive sampling was used as I was interested in obtaining information-rich cases. Semi-structured interviews were conducted in the mother tongue of the participants. Thematic content analysis was used to extract recurrent themes across participants. The study found that social support from significant others played a mediating role in postnatal depression. Women who are neglected by partners and parents, find it difficult to cope with stress that comes with being pregnant, especially when they are first time mothers. Partners in particular, play a significant role in protecting women from experiencing negative emotions during and after pregnancy. The participants all reported that they had never experienced postnatal depression, but when asked about feelings experienced after giving birth, especially when their parents and partners deserted them, they reported symptoms that were congruent with postnatal depression.

Behavioural changes, anxiety and coping in obese patients with and without psychological intervention
Marina Menorino Universidade de Brasilia, Brazil; Aderson Costa Jr.
To compare behavioural changes in obese patients with and without psychological intervention, eighteen patients, eight of the Experimental Group (EG), participating in a Psychological Preparation Programme for Bariatric Surgery, and 10 of the Control Group (CG) were researched. The control group was obese patients without psychological intervention. The instruments used were: Beck Anxiety Inventory (BAI), Scale Modes of Coping (EMEP), socio-demographic questionnaire and semi-structured interview at the first and last session, for the experimental group, and corresponding dates for the control group. The interviews showed difficulties in the first phase: prejudices, difficulties with clothing, low self-control, damaged self-esteem. In the second phase, significant changes in habits and behaviours of patients were observed in the GE, such as developing more satisfactory coping strategies (with priority focus on the problem and seeking social support), reduction and maintenance of anxiety (n = 6), changes in eating behaviour and weight loss. CG patients, in general, reported no changes during the period, describing the same problems, increase or maintenance (n = 7) of anxiety and reduction of overall scores of coping strategies. The intervention was favourable in terms of changing habits, adherence to nutritional orientations, reducing anxiety and develop coping strategies to adverse situations. The lack of monitoring can increase the likelihood of harm to patients who experience obesity, such as increased anxiety and reduced favourable coping strategies. Thus, understanding this context is essential for care services for obese patients, in Brazil, offering counselling to all patients, not just those who are awaiting surgery.

Motivational correlates of physical activity in Czech and American older adults: Between-group differences
Jiri Mudrak Charles University in Prague, Czech Republic; Steriani Elavsky; Pavel Slepicka
Older adults are the fastest growing segment of the population all over the western world. However, the majority of research as well as recommended practices and discourses related to healthy aging have come primarily from the United States. Other cultures have been considerably less researched. In the present study we examine possible cultural differences related to participation in physical activity in a sample of 426 Czech (n=254) and American (n=172) older adults. An identical battery of questionnaires was administered to both samples in order to measure their self-reported participation in physical activity and its motivational correlates. The results suggest significant differences between the Czech and American sample. In most measures, the Czech respondents stated significantly higher participation in physical activity than the American respondents. Interestingly, respondents in the American sample indicated a significantly higher level of motivation and cognitive strategies (e.g. life-style and barriers self-efficacy, goal-setting, self-monitoring, relapse prevention) as well as perceived social support related to physical activity. Also, between-group differences have been found in prevalent types of physical activity. The American respondents mostly mentioned participation in leisure or sporting activities, whereas the majority of the Czech respondents indicated work or lifestyle related activities as the main source of physical activity. These results suggest that Czech older adults may participate in more habitual forms of physical activity, perceiving it more as a means to certain outcomes rather than as an outcome by itself.

Implicit theories of health predict compliance in chronically-ill children
Claudia Mueller Stanford University, United States of America; Carol Dweck; Robert Wright
Children’s beliefs have been shown to influence their behaviours in a variety of settings. Dweck and associates have demonstrated that when people believe a particular trait is fixed (‘entity theory’) rather than subject to improvement (‘incremental theory’), they respond negatively to situations in which that trait is challenged. We have shown that healthy adolescents have theories about wellness that predict their responses to illness in peers. In this study, we examine how the health beliefs of chronically-ill adolescents predict their adherence behaviors and their coping with disease. 116 adolescents with Type 1 diabetes were given a questionnaire designed to define their theories of health (Health Belief Scale). They were then asked about their attitudes toward illness as well as about their medical compliance. Clear differences were noted in adherence behaviours: entity theorists were significantly less likely to comply with medical regimens than incremental theorists. Health theories were also able to predict medical outcomes. We have been able to demonstrate that children’s notions of health predict their attitudes and behaviours during periods of health and of illness. We believe these findings to have major relevance for the management of chronic disease in adolescents. Future investigations will target feedback messages that might improve coping with disease.

Issues relevant to the mental health of children and adolescents in the Family Health Strategy

Camila Muyloaret Universidade de Sao Paulo, Brazil; Alberto Olavo Reis; Livia Rego; Tatiane Oliveira; Moacyr Neto; Isabella Bastos

In Brazil, the Family Health Strategy (ESF) professionals have to cope with different kinds of problems, including those relating to mental health. Teenage and childhood mental health issues were presented to work teams from the ESF. We applied a questionnaire to 729 professionals from 122 ESF work teams in five cities of São Paulo State (Bauru, Praia Grande, Diadema, Campinas and São Paulo city), regarding the main issues relating to children and adolescents’ mental health, as well as about who typically expresses them. The random sample was cross sectional, in two sequential parts, and was calculated with a sampling error of 3% and confidence interval of 95%. The main issues presented to ESF professionals were “school problems” and “behaviour problems at home or school.” Family was indicated as the group that expresses those problems most frequently, followed by schools, communities, the children and adolescents themselves, and the Child Protection Council. Results point to family and school difficulties in dealing with children and adolescent diversity, school difficulties in working in a networked health system, as well as a trend to blame children and adolescents individually for their suffering. This is further reinforced by some health professionals. This study highlights the need to share responsibilities for mental health problems and accommodate the needs of children and adolescents themselves.

Personality predictors of adjustment to good life in people with stable chronic diseases

Jose Pais-Ribeiro Porto University, Portugal; Rute Meneses; Isabel Silva; Luisa Pedro; Ana Martins;

Estela Vilhenha; Denisa Mendonca; Antonio Martins da Silva; Helena Cardoso

Chronic diseases (CD) are diseases of long duration and slow progression. The most important task for people with CD is adjustment to life. The objective of this research is to identify personality predictors of good adjustment to life in people with stable CD. Participants are 513 individuals aged over 18 years, a diagnosed CD (cancer, type 1, 2 diabetes, epilepsy, multiple sclerosis, myasthenia gravis, morbid obesity), for more than three years, 71% females, mean age 43.02 years. The study is prospective over a period of nine months. Initial variables are demographic and disease variables, more personality measured with a short version of the of the Revised NEO Personality Inventory with five dimensions (Neuroticism, extraversion, openness, conscientiousness, agreeableness). Nine months later the outcome variables measured with four indicators of adjustment, three SF-36 components of quality of life (Keller et al. 1998), namely, general well-being, physical health, mental health, more subjective well-being. Multivariate analysis of co-variance, the five dimensions of personality as independent variables, and the four outcome variables as dependent, controlling for demographic and disease variables, shows that neuroticism is a predictor of negative outcomes for all the four outcome variables (p<0.001), extraversion is a predictor of positive outcomes for all the four outcome variables (p<0.001), and openness is a predictor of general well-being (p<0.006). We can conclude that personality is a good predictor for adjustment to life in people with CD.

Using habit theory and commonsense self-regulation theory to improve medication adherence assessment

L. Alison Phillips Rutgers University, United States of America; Howard Leventhal; Elaine Leventhal Rutgers University, United States of America

Patient non-adherence to medication is pervasive and contributes to poor health and high healthcare costs. Improved adherence measures, based on health-psychological theory, could improve our understanding of the factors involved in non-adherence and the efficacy of interventions to ameliorate it. The most commonly used health-behavior theories to predict adherence do not include repeated, or long-term behavioral factors, and existing patient-reported measures of adherence have problems associated with them that risk their validity. The objective of the current study is to: (1) propose a theoretical framework of long-term health-habit development that utilizes commonsense self-regulation theory; and (2) compare the effectiveness of a patient-adherence measure designed from the framework to that of the current ‘best-practice’ patient-reported measures. The medication routines/habits, experiences, beliefs, and self-reports of adherence of 74 hypertension patients were assessed in person; patients then used an electronic-monitoring pill bottle for one month. Compared to existing measures, patients’ medication habit-strength better predicted the percentage of days on which patients took their medication on time and equally predicted the percentage of prescribed doses they took. Other hypotheses were supported: patients had more favorable treatment-related beliefs and were more certain of their medication effectiveness if they received feedback that their medication worked as expected (they attained ‘commonsense-model coherence’). The results suggest that: (1) researchers and providers can better predict patient adherence by asking patients about their habits than by asking directly how adherent they are; and (2) it is important for patients to experience that their health-beliefs are true, for long-term adherence.

Outcome expectancies and experiences mediate between depression and exercise maintenance after rehabilitation

Sarah Pomp Freie Universitat Berlin, Germany

In 2020 depression will reach second place on the list of global burden diseases. Depression is related to poor physical exercise, reduced adherence to exercise recommendations after rehabilitation and lower benefits of exercise interventions. However, depressive individuals benefit on the physical and psychological level from exercising. Most studies report negative associations between depression and exercise but less evidence exists on processes that explain this relationship. Depression is negatively associated with positive outcome expectancies and positive experiences concerning exercise. Moreover, our expectancies affect the perception and evaluation of the experiences we have. This study examines the relationship between depressive symptoms and exercise by unveiling mediation mechanisms of expectancies and experiences. 187 rehabilitation patients completed an online questionnaire during their rehabilitation and six weeks later. At T1 depressive symptoms and expectancies, and at T2 experiences and behavior, were assessed. A multiple step mediation analysis was conducted. The effect from depressive symptoms through expectancies and experiences on behavior was significant (p<0.01), as well as the effect through experience only (p<0.05). Thus, depressive symptoms lead to less exercise through a sequential path from low levels of positive expectancies to few positive experiences as well as through positive experiences alone. Exercise interventions for depressed individuals should address positive expectancies and thereby foster positive experiences. Moreover, exercise programs should be arranged in a way that depressed individuals have positive experiences with exercise and acknowledge those accordingly. Understanding such processes enables the tailoring of interventions to depressive individuals and thus the appropriate supporting of them.

Exploring general practitioners’ management of patients with depression within the private health care sector in Johannesburg, South Africa

Milica Repensek University of Witwatersrand, South Africa

The majority of persons within South Africa (of whom 16% have claimed to have suffer from common mental disorders such as depression) that use medical treatment do so through primary care (Patel et al., 2007; Williams et al., 2007). However, studies have shown that GPs often overlook, ignore, misdiagnose and even offer inappropriate treatment for mental illness (c.f. Lotrakul & Saipanish, 2009; Qwabe, 2009). Since South Africa is comprised of a multitude of diverse peoples from varying culture backgrounds, cultural diversity needs to be considered within every interaction, especially when gener-
Factors associated with smoking among adolescents (aged 12-15 years) in Medellin, Colombia

Alexandra Restrepo
University of Antoquia, Colombia

To identify factors associated with smoking among adolescents (aged 12-15 years) in Medellin, Colombia, across-sectional study in adolescents aged 12-15 years was performed. The sample was 1998 adolescents. A multi-stage, stratified probabilistic sampling approach and a path analysis was used. The indicators of collective efficacy (social control and social cohesion) were found to be positively correlated with adolescents having good relationships with their parents. Cigarette consumption in female and male adolescents demonstrated the considerable importance of the family as a protective factor, especially the role of the mother within the family. Antisocial behavior (β = 0.088) and stressors at the family and individual levels (β = 0.017) have indirect and potentiating effects on having ever smoked. Having friends that exhibit risk behaviors is positively associated with smoking among adolescents (β = 0.127). Having ever been a victim of violence increases the likelihood of consuming tobacco. A direct and positive relationship was observed between having ever consumed tobacco and having committed aggressive acts (β = 0.140). Likewise, having ever consumed tobacco was directly and positively related to having ever abused alcohol (β = 0.21).

Improving the predictive and explanatory power of health promotion theory: The case for theoretical integration

Jay Richards
University of Newcastle, Australia;
Martin Johnson; Andrew Rutherford; Ursula Wright

Obesity and weight related illnesses create a significant burden on health. Weight related illnesses can be prevented through changes in health behaviour. In Australia health promotion campaigns have targeted obesity and attempted to motivate Australians to adopt behaviours which are consistent with weight loss. Despite these efforts, the rates of overweight and obesity in Australia continue to rise. One reason for this may be that current models are too restrictive, and as such do not explain an adequate proportion of the variance in health behaviour change. Three current models (Extended Parallel Process Model, Stage Model and the Theory of Planned Behaviour) have been utilised to explain health behaviour change, and each has been found to explain approximately 25-40% of the variance in health behaviour change. However, the predictions of each model are very different. The present study aimed to investigate whether predictors from each of these models could be combined and explain a greater proportion of the variance in intentions to change behaviour than any single model alone. 81 participants were exposed to health messages targeting obesity. They then completed measures of perceived message quality, fear, anxiety, perceived susceptibility, severity, self-efficacy, response efficacy, subjective norms, attitudes about behaviour change and intentions. Blocked stepwise multiple linear regression revealed that perceived message quality, self-efficacy, attitudes and anxiety contributed to a model explaining 53.4% of the variance in intentions. Results suggest that integrating models may increase the explanatory power of dominant models of health behaviour change.

Aortic arch surgery using the technique of selective antegrade perfusion at 25 degrees centigrade

Bellkiss Romano
Heart Institute USP, Brazil; Leilane Antoniazzi; Mara Meirelles; Thabata Fonseca; Elaine Hojaij

Cardiac surgery may have neurological complications such as bleeding or brain damage, even with the protective effect of hypothermia. In cardiac surgery, there are questions about mortality and quality of life of patients after surgery, also of brain protection during surgery in order to avoid such compromises. Besides biological and biochemical factors involved in heart surgery, other studies have gained prominence in correlating behaviour, mood and disease, especially with a focus on anxiety and depression. The objective of this study was to examine the progression of depression and anxiety, as well as neurocognitive functions, within one year of aortic surgery. This is an experimental, double-blind study: The experimental group underwent traditional surgery using the technique of selective antegrade perfusion at 25°C; the control group underwent standard surgery. Fifteen patients participated (one year after surgery, until October 2011) and were evaluated at three times: Before surgery, at six months and twelve months after surgery. The Wechsler Intelligence Scale for Adults III, Beck Depression Inventory and Beck Anxiety Inventory were used. The minimum level of anxiety remained prevalent during the study period in both groups. Regarding depression, there was a minimum level of prevalence in the three study phases: Pre-operatively, at six months and one year in both groups. With regard to neurocognitive functions, the control group presented mean IQ’s (performance, verbal and total) that were higher than those in the experimental group at three times during the study. There seems to be no significant difference between the results achieved by both groups. However, these findings are the preliminary results of the study.

The support nucleus of family health and the insertion of psychology in Brazil

Willian Santos UFRB, Brazil; Belinda Mandelbaum

The Family Health Strategy is the main gateway to the public health system in Brazil. To understand the integration of psychology in this context of primary health care, we investigated the activities of selected psychologists who work in the support nucleus for family health. This nucleus, created by the Brazilian government in 2008, was conceived as a space composed of various health professionals (physiotherapist, occupational therapist, nutritionist, psychologist, etc.) in order to broaden the scope of health interventions in primary care. These professionals should support the actions of family health teams (doctors, nurses, dentists and community health workers) with their specific professional skills. The survey was conducted in cities in the interior of Bahia / Brazil, where we conducted semi-structured interviews and focus groups with psychologists and professionals of health teams. We also experienced the everyday activities of a family health unit. In analyzing the discourses and practices investigated, we found confusion among the psychologists about their roles and responsibilities in primary public health, difficulties with co-ordination with the health teams and difficulties on the best techniques and approaches used. Moreover, it was found that psychologists prioritize individual and clinic activities and have great difficulty extending the reach of their practices to a type of psychology that must, to overcome social exclusion, expand its number of consultations and focus on the development of the entire population served.

New possibilities for integration of psychology in primary care health in Brazil

Willian Santos UFRB, Brazil; Aline Rios; Daiany Jesus

The Unified Health System (Sistema Único de Saúde - SUS) is an important milestone as a space for practice and training for Psychology in Brazil. It is more than 20 years since its implementation, and the system is still fragile in terms of integrality and hierarchy services from different complexities of health care. As part of Mental Health, considering the specific practice of psychology, we see the predominance of individual, clinical and a performance that ignores social issues and guidelines of the large area of knowledge called public/collective health. This generates a decontextualized practice of psychology in relation to the requirements of SUS for multidisciplinary actions, preventive and community health promoters. Considering this context, this report aims to provide trainees the inclusion of psychology students at the Federal University of Recâncavo of Bahia/Brazil in the context of primary health in Santo Antonio de Jesus/Bahia. At the beginning of the practice, there was a gradual rapprochement with the health team and the entire community. Gradually it became a practice outlining the activities: Educational activities in the waiting room, home visits, psychological listening and group activities with the staff of the unit. The actions are not limited to the physical space of the health unit, being developed in various community settings. The activities show a practice of health education that makes the psychologist go beyond the traditional clinical work, focusing on preventive, and creating other concepts about health and disease among the population served.

Efficacy of stress management training for hypertension: A randomised controlled trial

Jesus Sanz Complutense University, Spain; Maria Paz Garcia Vera; Ines Mogan; Regina Espinosa; Maria Fortun
Psychological treatments for hypertension have at best received mixed support from empirical studies and expert panels. A controlled trial was conducted to examine the effects of stress management training (SMT) on blood pressure (BP) and psychological measures. Thirty seven patients with essential hypertension were randomly assigned to a treatment group as compared to the control group (respectively, time-group interaction effects were significant with p = .045 and quasi-significant with p = .078 and .070). The mean scores for anxiety measures (BAI and HADS-A) were also significantly decreased in the treatment group as compared to the control group (significant time-group interactions with p = .002 and .001, respectively). No similar significant effects were observed for the remaining BP and psychological measures. The results only partially support the efficacy of STM for reducing BP, but support its efficacy for reducing anxiety, and suggest that STM could be useful for patients with hypertension who report a great deal of anxiety.

Online intervention engagement predicts smoking cessation
Ralf Schwarzer Freie Universitat Berlin, Germany; Lars Satow
While previous studies have focused on individual differences of smokers as predictors of quitting ("Who they are"), the present study focuses on self-regulatory actions ("What they really do"). The purpose is to predict smoking abstinence in internet users who may become involved in numerous social activities within the virtual community. From March 2009 to July 2011, users of a non-commercial web-based smoking cessation coach in Germany made data available for a post-hoc evaluation study (N=13,174), including self-reported abstinence rates for particular time periods (1 day, 2 days, 1 week, 2 weeks, 3 weeks, 4 weeks, 8 weeks, 10 weeks) as well as automatically recorded online activities such as (a) posting a bulletin board entry after the first smoke-free day, (b) offering a donation, and (c) posting messages throughout their course. Such activities reflect intervention engagement that may lead to behavioral maintenance. Surviva analyses for 70 days of self-reported non-smoking documented higher successes for those who made use of one or more of the virtual community activities. Moreover, the effect of making an initial bulletin board entry on 10-week abstinence was mediated by offering a donation and posting messages throughout the course (R²=.125). The indirect effect via donation was .10 (95%CI [.06-.14]), and the indirect effect via message posting was .31 (95%CI [.25-.38]). As intervention engagement is a proximal predictor of success, and as internet use to change behaviour becomes more prevalent, the present study offers some ideas for further research into web-based smoking cessation.

Emotional and behavioural problems in adolescents with mental retardation in Iran
Maryam Sharayati Azad University of Bijanad, Islamic Republic of Iran
The aim of the study was to determine whether psychiatric and behavioral disorders occur more frequently in adolescents with mentally retardation compared to those without mental retardation. 36 adolescents with mental retardation were pairwise matched for age and gender to 36 adolescents without mental retardation. Teachers were interviewed in structured psychiatric interviews and questionnaires measured psychiatric and behavioral problems. Results indicated that aggressive behaviors, fears and phobias and stereotypes were significantly more common in adolescents with mental retardation. Adolescents with mental retardation are prone to psychiatric conditions and behavioral problems.

Internet-delivered psychological intervention for insomnia
Pei-Chun Shih Universidad Autonoma de Madrid, Spain; Carlos Marchena; Alejandra Montoro; Ana Calero
Primary insomnia is a highly prevalent health problem that entails reduced performance during daytime and negative effects on health and quality of life. It is usually treated, if ever, through medication, while psychological help is rarely sought due to the inaccessibility to treatment and specialists. Information and Communication Technology may be one of the means to overcome these limitations and different studies have shown the feasibility of web-based therapy. For this reason, we developed an internet-delivered psychological group intervention for insomnia that includes the main cognitive-behavioural treatment components of face-to-face therapy: Stimulus control, sleep restriction, sleep hygiene, cognitive techniques, relaxation training and relapse prevention. Moreover, one of the most relevant characteristics of this programme is that it utilises two additional tools, apart from instruction-based learning, that help modifying the subjects’ sleep behaviour. First, it includes instrumental learning, as a trained psychologist participates actively along the therapy. Secondly, the psychologist moderates the forum with the aim of drawing attention to those participants that behave in a desirable manner, so that they serve as models for the rest of the group.

The diurnal salivary cortisol pattern of adolescents from families with single, ill and healthy parents
Dominik Sebastian Sieh University of Amsterdam, Netherlands; Anne Visser-Meijer; Anne Marie Meijer
Adolescents of single and/or chronically ill parents (target groups) reportedly have elevated psychological stress. However, their salivary cortisol pattern as part of the physiological stress system has not been compared to controls. The aim of this study is to examine differential outcomes in the diurnal cortisol pattern of the target groups. In total, 100 adolescents of three groups with either single, chronically ill or two healthy parents were compared on cortisol. Three salivary cortisol samples were taken after awakening, one sample at noon and one sample at 20:00, during a non-school day. Group differences and interaction effects between measurement (5 times), group membership and covariates were tested through linear mixed modeling, repeated measures. Covariates were children’s sex and age, socio economic status (SES) and parental depression, as measured with the Beck Depression Inventory. The three groups did not differ significantly concerning the amount of salivary cortisol, even after controlling for the covariates. The target groups had a lower SES than adolescents with two healthy parents. In addition, chronically ill parents were more depressed than single and healthy parents. Male sex and older age of the child, and lower parental depression were associated with increased cortisol values throughout the day. Research on cortisol in children should control for children’s sex and age, and parental depression. Adolescents with single and/or chronically ill parents displayed a healthy pattern of diurnal salivary cortisol.

Parental depression and adolescent functioning in families with a chronically ill parent and single parent families
Dominik Sebastian Sieh University of Amsterdam, Netherlands; Anne Marie Meijer; Anne Visser-Meijer
Adopting a family type perspective, we examined relations between parental depression and adolescent functioning (problem behaviour, stress, grade point average, school problems and school-related self-esteem). Participants were 389 adolescents and their parents from families including a parent with a chronic medical condition, single parent families and intact families with healthy parents (comparison group). Multilevel analyses revealed that adolescents with chronically ill and single parents displayed more internalising problems and worse school grades than controls. Adolescents of single parents comparatively reported more stress and school problems and lower self-esteem related to school. Independently of family type, parental depression was related to child-reports of stress. Being a girl and being older significantly contributed to adolescents’ internalising behaviour and stress. In addition, older adolescents reported more externalising problems and worse school grades. Having a chronically ill parent in an intact family may have less impact on adolescent functioning than having a single parent.

E-health game on overweight and its effects on adolescent girls’ psychosocial responses
CityGirlZ
Marloes Spekman VU University Amsterdam, Netherlands; Eveline Vedder; Elly Konijn; Helyne Riper; Jolanda Veldhuis; Johan Hoorn
In the battle against the world’s overweight epidemic, we developed and tested the e-health game CityGirlZ to promote a healthy lifestyle among adolescent girls. e-Health interventions have become increasingly popular, due to their potential to reach large audiences with relatively low costs. However, to be effective participants should return regularly, whereas many such interventions suffer from high drop-out rates. The present study tests whether an e-health intervention designed as a serious game stimulates adolescent participants to repeated use. Developmental theorizing on adolescents’ use of entertainment media guided the design
of the experimental conditions within the game. Four variations of the game emerged from a 2 (coach size: ‘thin’ vs. ‘slightly heavy’) x 2 (presentation form: ‘game’ vs. ‘game about health’) between-subjects design. An attractive shopping area served as the virtual environment in which the avatar LiZa acted as a personal coach. Participants earned points by making healthy in-game food choices and received incremental rewards each day they returned to play the game. Points could be spent in the game among others, on fashion, groceries, sports, and cinema tickets. Questions were built in and all user data were logged. Currently, we are testing how presentation form and the coach’s body size interact, expecting that the thinner LiZa in the ‘game’ condition induces highest levels of participation. As an exploration, we examine whether the girls’ in-game behavior stretches into real-life, how they respond to and perceive the virtual coach, and how they spend their game rewards. Results will be presented and discussed at the ICP.

Coping-strategies of migraine patients influence their quality of life

Natalya Starikova Perm State Medical Academy, Russian Federation

The characteristics of pain syndromes and quality of life (QoL) of patients may strongly depend on psychological factors including pain coping strategies (CS). 65 migraine patients aged 18-56 were investigated. Migraine-specific QoL questionnaire QVM, generic Goetheborg QoL Inventory (GGQ), Spielberger’s and Beck’s Inventories, MIDAS were used. CS of patients were studied by the means of the Vanderbiilt Questionnaire. Statistical analysis of data was performed using non-parametric possibilities of STATISTICA 6.0. Migraine patients showed poor QoL (Me=57.00, 95% CI 54.79-58.52 points vs Me=67.00, 95%CI 62.60-69.70 in controls; p=0.0006). All indexes of QVM Questionnaire correlated with Goetheborg Questionnaire index (p = 0.011 – 0.00001). The scores of migraine-specific QVM questionnaire correlate with some clinical features of the disease, concentrated in MIDAS score, but the most prominent correlations revealed were those with emotional disturbances and CS of patients. For example, Global index of QVM did not depend on patients’ age, length of the disease, pain intensity, frequency and duration of attacks, but correlated with MIDAS score (p=0.017), non-adaptive CS (p=0.00009), anxiety (p=0.0007) and depression (p=0.002). Functional index of QVM depended on anxiety and depression levels and on non-adaptive CS preference (p=0.002). Psychological index correlated with the levels of anxiety and depression, MIDAS score and passive CS. Social index of QVM depended on the attacks’ duration, anxiety, depression and non-adaptive CS score. Passive CS: anxiety and depression of patients strongly influence and diminish QoL in migraine patients.

Assessment and antecedents of young caring in families

Damodar Suar Indian Institute of Technology, India; Rajalini Sahoo

This study develops an instrument to assess caregiving of young carers and examines the antecedents of caregiving to parents in families. The antecedents include the age, gender, family size, socioeconomic status, awareness, and relationships of caregivers, and diseases of patients. Data were collected from 250 young carers from a hospital in Cuttack and from the slums, shops, garages, and hotels in Cuttack and Bhubaneswar in the state of Odisha (India). Young carers were interviewed to gather personal information and information about their caregiving responsibilities. Their parents were interviewed about the socioeconomic status of the family. Carers were providing informal care to their parents suffering from chronic, mental, and substance abuse illnesses. Results suggest that the constructs of the scale have acceptable reliability and validity. Confirmatory factor analysis of the scores on 20 items of the instrument confirms the four conceptual dimensions including intimate, domestic, administrative, and emotional care. The more intense the caring activity, the more the time spent in that activity. More caregiving is associated with lesser age of carers, girl children, children from smaller families, low socioeconomic status of families, more awareness of carers, adverse relationships, and with chronic illness of parents. Improving the socioeconomic status can decrease the extent of young caregiving because it is the most important predictor of young caregiving.

Menopausal women’s sleep quality related factors in west of Tehran

Simin Taavoni Tehran University of Medical Sciences, Islamic Republic of Iran; Neda Ekbatani; Hamid Haghani

Sleep disturbances, which effect on quality of life is common and clinically important during menopause and old age. To identify related factors of sleep disturbance in menopausal women, in this cross sectional study, 200 volunteer healthy 50-60 menopausal women, who had been visited in health clinics of Tehran University of Medical Sciences in the West of Tehran were interviewed (Year 2010-2011). The tools had two main parts: 1) Personal characteristics, Pittsburgh Sleep Quality Index (PSQI) Average age of the women was 53.6± 3.6, Couples’ age 57.99± 6.6 Number of Children 4.7± 0.3, menopause age was 47.8± 4.0. Regarding to the PSQI frequency of sleep disturbance there was a 70 percent and average of PSQI was 7.8± 4.4. There were significant correlations between Occupational Status, Educational Status, Husband Occupational Status, and Economic status and sleep disturb (p<0.002) There were no correlations between sleep disturbance and samples’ age, partners’ age, number of children, family size, and habits of drinking tea / coffee / cola and samples’ sexual satisfaction. For improving menopausal women sleep disturbance, related personal factors must be considered, and by using suitable guiding, consultation and intervention, improve their sleep quality.

Related factors of postpartum depression in clients who had been visited in clinics of west of Tehran

Simin Taavoni Tehran University of Medical Sciences, Islamic Republic of Iran; Hamid Haghani; Parvin Zarea

Postpartum depression is the most common mood disorder of the postpartum period in women’s lives and it seems multivariate problems are associated with it. The aim of this study was to identify correlation between personal characteristics and scale of Edinburgh postnatal depression. In this cross-sectional study, 597 volunteer postnatal women, who had been visited in 6 primary health clinics west of Tehran during the fourth month after delivery, were involved. (Year 2009-2010) The questionnaire had two main parts: personal characteristics and self-reporting scale of Edinburgh postnatal depression (EPDS). The average age was 27.01± 4.94. There were significant correlations between scores of EPDS and planned pregnancy, the history of Intra Uterine Fetal Death, women’s occupation and that of their spouses, family economic status, women’s educational status and that of their partners, and smoking habits. Regarding to the cutoff point of EPDS, there were significant correlations between two characteristics of unplanned pregnancy and unwanted pregnancy by spouse. Since there were significant associations between postpartum depression and spouse, unplanned and unwanted pregnancy, it is better to have more guiding and counselling for the high risk group during pregnancy and postpartum time. We suggest screening all women during postpartum period by EPDS.

Effect of Ginkgo Biloba on menopausal sexual function in menopausal women: A randomised placebo controlled trial, Tehran, 2011

Simin Taavoni Tehran University of Medical Sciences, Islamic Republic of Iran; Leila Amiri; Naeem Seidfatemie; Hamid Haghani

Sexual dysfunction is prevalent among menopausal women and affects their quality of life. There are various methods for prevention and treatment of this dysfunction, which have been divided into pharmacologic and non-pharmacologic methods. To assess the effect of Ginkgo Biloba Extract (GBE) on sexual function in menopausal women, a triple blind randomised placebo controlled trial was run with 80 healthy volunteers (50-60 year old menopausal women), who had been admitted in three health care centres of Tehran University of Medical Sciences (TUMS), during the summer and autumn of 2010. The instrument of this study had two parts: The first part was personal characteristics, and the second part was Sabbathsberg Sexual Rating Scale (SSRS), which was used for subjective evaluation of sexual function before and after intervention. The participants received GBE 120-240 mg, or placebo, daily for 30 days. Sexual function was significantly improved in the GBE than in the placebo group and included sexual desire (P<0.05), sexual pleasure (P< 0.01), orgasm (P< 0.05), importance of sex (P< 0.01) during last month and importance of sex in comparison to previous years (P= 0.007). The mean score of total sexual function in the GBE group showed significant difference to that of the placebo group (P< 0.05). Findings of this study support the positive effect of Ginkgo Biloba on menopausal women’s sexual function.

Factors affecting alcohol drinking behaviour of Australia youth

Somrat Tayraukham Mahasarakham University, Thailand; Frances Martin
This study aims to develop the structural drinking behaviour in youth. 331 undergraduate students enrolled in the University of Tasmania were obtained by a stratified random sampling technique. An opinion regarding youth drinking behaviour questionnaire was employed. Data were analysed by descriptive statistics and path analysis. The findings revealed that model was consistent with empirical data and validation of good fit, $\chi^2/df=6.54$, $p=.074$, RMSEA=0.016, GFI=0.901, AGFI=0.882, and $R^2$=0.170. Drinking behaviour, attitudes toward alcohol consumption, anxiety, personality, family care, and law were direct effects in statistical significance.

Quality of life, coping strategies, coping effectiveness of women with polycystic ovarian syndrome

Christina Tellis College of Home Science, Nirmala, India; Nirmala Almeida

Globally, the prevalence of Polycystic Ovarian Syndrome (PCOS) is 20-33% and is slowly rising. PCOS carries with it a range of mental health issues. The objective of the current study was to evaluate the QoL of Indian women with PCOS, their coping strategies and coping effectiveness. The sample consisted of 24 women (18-30 years, 9 married, 15 unmarried) with PCOS. Evaluation was accomplished with the help of an interview schedule and three rating scales. Two-thirds of the participants fell in the high/very high QoL category, while one-third, in the moderate QoL category. The high QoL score was obtained on the social, financial and spiritual domains, while the physical and psychological domains yielded an average score. Many reported experiencing physical symptoms, dietary restrictions and an unattractive appearance, but positive changes in their lifestyle and relations with family members. Coping strategies used to a large extent were acceptance (Mean=6.58, SD=1.34), active coping (Mean=6.33, SD=1.16) and positive reframing (Mean=6.12, SD=1.70). Seeking support from loved ones was the most helpful coping strategy and crying, the least helpful. Coping effectiveness was high (Mean=85.33, SD=9.98, theoretical range=25-100). Participants could contain uncomfortable feelings, generate hope, and maintain self-esteem. This study contributes to the body of knowledge in an under-researched area in India.

Cancer screening: A teachable moment for lifestyle change or a health certificate effect?

Carlijn Van Der Aalst Erasmus MC, Netherlands

Worldwide, the burden of cancer is still increasing, which is in a high degree due to an increased adaptation of (cancer related) risk-behaviour. Several cancer screening programmes are effective in reducing cancer mortality, but until now evidence about the impact of these programmes on future lifestyle is scarce. Lung cancer screening is argued to be a teachable moment for smoking cessation, but it might also provide a health certificate effect. The impact of lung cancer screening was investigated amongst smokers of the Dutch-Belgian randomised controlled lung cancer screening (NELSON) trial. Two random samples were selected of 50-75 years old male smokers at high risk for developing lung cancer randomised to the screen (n=641) or control arm (n=643) of the NELSON trial. Smoking behavioural change was investigated at randomisation (T0), 2 years (T1, study 1) and 4 years of follow-up (T2, study 2). At T1, prolonged abstinence was reported in 14.5% of the screen arm smokers and 19.1% of the control arm smokers. After 4 years, these rates were 24.3% (screen arm) and 29.3% (control arm). Multivariate analysis showed that lower baseline nicotine dependence and randomisation to the control arm increased the likelihood of being abstinent from smoking at follow-up. In conclusion, male smokers who received CT screening for lung cancer were less likely to refrain from smoking, possibly due to false feelings of reassurance caused by screening. Research is urgently needed to explore and solve this problem.

"God also forgot about me": The health promoting needs of AIDS orphans in Botswana

Charles Viljoen North West University, Sri Lanka; Constance Keerate

Orphanhood in Botswana is causing grave concern as a result of the growing number of orphans that require care and support. The central research question that guided this research study was: What are the health-promoting needs of orphans in schools in Botswana? A phenomenological research design was used for the study. This research design seemed appropriate to explore and understand the health-promoting needs of orphans in schools in Botswana. The researchers used interviews, focus groups and field observations to obtain the empirical data. The main categories and sub-categories of the health promoting needs of orphans that emerged, were these: The need for psychological and emotional support (loss of love and care, feelings of pain, sadness and hopelessness, self-blame, hatred), the need for physical support (improper shelter, physical abuse and being overworked), the need for educational support (lack of study material, lack of transport and packed meal) and the need for spiritual and mental connectedness (sense of belonging, quest for wholeness). Schools play an insignificant role in providing for the needs of orphans. Recommendations include the development of a health promoting school perspective, life skills education, internal school orphan care programmes, regular talk shows for orphans and other vulnerable children, the empowerment of learners on social relationships, parent and community participation, the involvement of the community and non-governmental organizations, regular internal workshops for the staff in the school, and school collaboration with social workers to empower the caregivers.

Exploring stakeholders’ perceptions of health promotion in schools in Qwa Qwa South Africa

Charles Viljoen North West University, Sri Lanka; Annah Motale; Thomas Chele

Schools have been identified as a key setting for development and health promotion. As such, the settings approach towards health promotion in schools is effective on a number of levels: It encourages multi-stakeholder ownership, allows for connections between people, enables interactions between the various stakeholders and creates opportunities to tackle the different health issues at hand. Health promotion entails enabling the key stakeholders (i.e., teachers, students and parents) to increase over and to improve their health. Instrumental is this endeavour is to understand what the various stakeholders’ perceptions are relating to health promotion. In many school communities the parents are not fully aware of the schools’ practices and policies relative to nutrition, physical activity, smoking etc. Some teachers on the other hand, may view health as a medicalised and physical aspect only without acknowledging other aspects (spiritual, emotional, psychological, etc.) of health. Not all students are aware of the health risks involved in the choices they make. The symposium will draw attention to the possible disconnect between stakeholders’ perceptions of what health promotion entails, and what is really happening in schools. Stated differently, because stakeholders’ perceptions about health promotion in schools can strongly influence the dynamics of a particular school, understanding these perceptions can be instrumental for the successful functioning of a school. The proposed symposium draws on research that was conducted in schools QwaQwa South Africa.

Socio-cultural influences on adolescent smoking in China: The mediating role of smoking-related cognitions

Yan Wang Syracuse University, United States of America; Ambika Krishnakumar

Using online survey data from 658 Chinese adolescents aged 14 to 17 years from Jiangxi, Zhejiang province in mainland China, this study examined the roles of socio-cultural influences, including smoking-related cultural values, parent smoking, extended family members smoking, exposure to media smoking, exposure to environmental smoking, and health-related values, in shaping adolescent smoking behaviours in China. This study also examined the mediating role of smoking-related cognitions, including attitude, subjective norm, and perceived behavioural control, in the link between socio-cultural influences and adolescent smoking behaviours. Results from Structural Equation Mod-
eling indicated that smoking-related cultural values and extended family members smoking had significant direct effects on adolescent smoking behaviours. Smoking-related cultural values, parent smoking, and health-related values also had significant indirect effects on adolescent smoking behaviours through the mediation of smoking-related cognitions. The findings highlight the importance of cultural values and familial influences in shaping adolescent smoking behaviours in Chinese society and suggest that modifying smoking-related cognitions may be an effective way to prevent adolescent smoking.

Peers and siblings effect on alcohol and cigarette use among secondary school male students
Christine Wasanga Kenyatta University, Kenya; Samson Oteyo
Peer effects on adolescents’ alcohol and cigarette use (ACU) have been documented. However, few studies have made a relative contribution to an understanding of selection and socialisation to adolescent ACU. Adolescents may either select friends who also use alcohol and cigarettes, or they use these drugs because of pressure to conform to friends’ behaviours. The study used siblings as a comparison group to peers to establish the extent to which the adolescent ACU was either due to similarity of behaviour or pressure to conform to friends’ behaviours. The ex post facto research design was used. Multistage cluster, Probability Proportionate to Size (PPS) and simple random sampling methods were used to select the participating schools and respondents. A sample of 327 respondents were selected. The results indicated that there was a significant association between students’ ACU with that of older siblings (alcohol: $c^2=32.069$ df=1 p<.05; cigarettes: $c^2=31.783$ df=1 p<.05). The students who perceived that they experienced pressure to conform to the peers’ ACU were 3.130 and 1.755 times more likely to use cigarettes and alcohol respectively. On the other hand, those who selected friends who used cigarettes and alcohol were 2.542 and 1.132 times more likely to use cigarettes and alcohol respectively. Those who perceived that their older siblings used cigarettes and alcohol were 3.064 and 2.18 times more likely to use cigarettes and alcohol respectively. It was recommended that school ACU intervention programs should target both those students who select alcohol and cigarette users as friends and those identified as most susceptible to peers’ influence.

An empirical study on relationship between stress and health of employees
Xiangqian Wei School of Psychology, China; Hongyu Ma
Previous research has shown that stress affected health. The present study focused on exploring the relations between different stresses and physical health, mental health, social health, and overall health, and how different stresses predict the health of employees in the different organizations and the different management levels. Data were collected from 440 subjects of two provinces, Shandong province and Hubei province in China. The results showed a negative relation between the employees’ family stress and overall health ($r=-.368$, p<.01), as well as the work stress and overall health ($r=-.438$, p<.01). No remarkable sexual difference was respectively in the family stress, working stress, physical health, mental health, social health and overall health. Married employees’ family stress was higher than unmarried employees’, but they were actually healthier than unmarried employees. The synergy of work stress and family stress accounted for 26% of the variance in overall health of employee, but that work stress affected the employee health ($AR^2=.17.9%$) was greater than that family stress affected the employee health ($AR^2=15.5%$). There were differential work stresses which affected the health of employees in the different organisations and the different management levels. The present study confirmed that work stress and family stress together were more helpful to predict employee health, and organization role stress was the most important predictor variable to the health of employees.

The unifying psychology application: A psychological study on the causation of the malignant tumor
Zhong Weidong The Unifying Psychology Work-shop, China
Depression is caused by the implied content of the incidents in which a person was injured (including physical pain and emotional hurt). This implied content has the characteristics of being linear, straight, non-logical, not brought about by man’s conscious awareness. In the event of injury, physical pain becomes one of the elements in implied content. Differing implied content can lead to different symptoms. For example, if you give a person the hints ‘go east’ and ‘go west’ at once, he will be disoriented and produce symptoms of anxiety. At the conscious level, we think that physical pain means death, so we instinctively avoid physical pain. But in various hints, there is the hint ‘physical pain means survival’. The existence of these implications is the reason for the brain initiating pain in the body. This affects people’s behaviours. For one thing, it causes people to have the tendency of autopoiesis in external behaviours. For another, it has the tendency to prompt the internal body to grow a useless organisation - the tumor. The tumor’s existence is in order to create the pain because ‘physical pain means survival’. This paper aims to give a preliminary discussion and study on the formation and elimination (therapies) of this kind of hint.

Evaluation of health related quality of life in left behind women in China and compared with norm
Shuqiao Yao Medical Psychological Institute, China
Objective: “Left behind women” refers to those women whose husbands have migrated in search of work in the city (more than half a year) and who have left them behind in their rural homes. At present, there are almost 70,000,000 left behind women in China. The aim of this study was to evaluate the health-related quality of life (HRQOL) in Chinese left behind women. Method: A total of 2077 rural left behind women were randomly sampled using a stratified multiple-stage random sampling method in Changsha. The 36-item Short Form Health Survey (SF-36) was used to assess each individual’s health-related quality of life. The SF-36 scores were compared to norms in Chinese women in the general population. Results: Among the eight SF-36 dimensions, PF (physical functioning), RP (role-physical), BP (bodily pain), GH (general health), VT (vitality) and SF (social functioning) scores showed age-related reduction in the Changsha left behind women population ($p<.01$). The quality of life was relatively better in the younger age groups. Every SF-36 dimension score of the left behind women population was lower than that of Chinese women in the general population. Conclusion: In the left behind women population, the quality of life was reduced with increasing age. Left behind women suffered worse HRQL than general women.

Virtual self-choice enhance resistance towards illusory stress
Kun Yu Peking University, China; Lei Wang Peking University, China; Yu Ku Peking University, China
The current research aimed to examine how resistance towards stress is affected by mere imagined choice (virtual choice) about the work or task. In Study 1 we held a real choice task on computer to identify that participants could bear more stress in task they choose than in task selected by computer. Fifty graduate and undergraduate students were randomly assigned to self-choice condition or computer-choice condition. Results showed that participants in self-choice condition could persist longer in the arithmetic task than computer-choice condition, even though tasks in two conditions were actually all the same. In experiment 2 we introduce virtual choice, that the choice was unreal but just being informed. Three types of job choices were offered to 137 employees, who were then told to imagine they are engaging one of them. Results revealed that subjects in self-choice condition reported higher level of willingness to bear stress than other two conditions. With another sample of 107 employees, we held experiment 3 and replicated findings of experiment 2 without information about alternatives job choices presented. These findings demonstrate that virtual self-choice existing only in mind could enhance people’s resistance towards illusory stress on an imagery task or a job, even though people never do it and even never know about it. Theoretical and practical implications of these findings are discussed.

Relationship between social capital and mental health of the university students
Ali Zadeh Mohammadi Shahid Beheshti University, Islamic Republic of Iran; Mahmood Heidari; Zohreh Ahmadedab; Ghiasar Maleky
In the present study the relationship between social capital and the mental health of male and female students was studied. The 1742 students (920 girls and 820 boys) from 10 government universities completed the Symptom Check List (SCL-25) questionnaire SCL-25 and Social Capital Questionnaire. The results showed that the average support received from the network was higher in girls than boys and the average network size was reported to have more effect in boys than girls. Except having paranoid thoughts in other subscales, girls found a significantly higher mean than boys. Regression analysis showed that for girls communication with
network members received more emotional support and for boys size of network had a significant positive relationship with mental health. Results also indicated that although this was a protective factor for social capital and mental health is the social capital of girls more than boys, girls showed more reduction in mental health. The relationship between social capital and health psychotherapy is influenced by gender. Promotion of mental health will lead to an improvement in social capital among boys more than girls.

The role of empathy, emotional competencies, and affective states in coping with compassion fatigue among health professionals

Moshe Zeidner University of Haifa, Israel

Those who care for or treat traumatised individuals may themselves be subject, over time, to secondary traumatization or “compassion fatigue” (Figley, 1995). This paper examines individual differences in emotional competencies, affective states, and coping strategies in relation to indicators of compassion fatigue among health professionals. Participants were 182 health professionals (89 physicians, 93 mental health workers), who completed the following measures: emotion regulation (MSCEIT branch 4, Mayer, Caruso, & Salovey, 2002), self-reported EI (ESRI, Schutte et al., 1998), empathy (JSPEE-version for health professionals, Hojat et al., 2001), coping strategies (CISS-SCS, Endler & Parker, 1990), affective states (DSSQ, Matthews et al., 2002), and compassion fatigue (PQL, Stamm, 2003). A path analysis showed that both emotion regulation and self-reported EI were positively and significantly related to empathy. Empathy, in turn, worked through negative emotions to impact upon compassion fatigue. Also, EI had a direct effect on problem-focused coping and an indirect effect on compassion fatigue, working through empathy and negative emotions. Problem-focused coping was negatively related to negative affect and compassion fatigue. By contrast, emotion-focused coping was positively related to both negative emotions and compassion fatigue. Both empathy and EI appear to be double-edged swords for clinicians treating traumatised victims.

The effect of self-efficacy on physical and psychological complaints and duration of unemployment 7 years later: A longitudinal perspective

Markus Zenger University Hospital Leipzig, Germany

The purpose of the study was to examine the relationship of self-efficacy and physical as well as psychological complaints to the duration of unemployment during the life course, covering a time span of seven years. This prospective study was launched in 1987 with a representative sample of 1407 pupils aged 14 years in East Germany. After the German re-unification a sample 578 participants had given informed consent for the continuation of the study in conducting annual surveys. In 2002 and in 2009 a total of 348 participants filled in several questionnaires including the General Self-efficacy Scale, the Gielen complaint list (GBB), the Symptom-Checklist-9 (SCL-9) and questions about the experienced unemployment. Initial level of self-efficacy is significantly associated with different physical complaints (Pearson’s correlation coefficients range between -0.18 and -0.26), SCL-9 sum score (r = -0.26) and duration of unemployment (r = -0.25) seven years later. Even after controlling for the baseline levels of these variables, self-efficacy in 2002 explained incremental variance of the dependent variables in 2009. Furthermore, differences between men and women emerged. Self-efficacy was a stronger predictor for heart-related and gastrointestinal complaints in men, whereas it was more strongly related to psychological complaints and duration of unemployment in women. Higher self-efficacy promotes better health and shorter times of unemployment during the life course. Thus, self-efficacy is an important protective factor that contributes to fewer physical and psychological symptoms and should be considered in health promotion programmes.

Session Type: Posters

Effectiveness of cognitive-behavioural intervention on Iranian women with breast cancer

Ali G. Afrozoozi, Iran, Islamic Republic of Iran; Sogand Ghasemzadeh; Ali Afrozoozi

Cognitive behavioural intervention has been used since the 1950s for treating various psychological problems including anger, sadness, stress and anxiety. It is known that psychological aspects aggravate some physical illness such as cancer. Considering the role of distress and negative mood in aggravating breast cancer, the current study was designed to investigate the effectiveness of a cognitive-behavioural intervention on psychological syndromes breast cancer in women. According to previous studies, a combination of medical and cognitive-behavioural therapy is more effective than either modality alone. This combination can be highly effective in improving the quality of life for people who are suffering from breast cancer. The current research was based on a semi-experimental method. 54 sufferers of breast cancer were randomly assigned to experimental and control group (n=27). Experimental group was attended in a 10-session group cognitive behavioural intervention (2.5 hours each session). The cognitive behavioural intervention covers topics such as self awareness, stress and anger management, relaxation, problem solving and cognitive restructuring. At the end of intervention, two groups answered the same questionnaires. Using multivariate analysis of covariance, two groups were compared on post-tests, while pretests were assigned as covariate. The programme was successful, resulting in significant differences in general mental health, stress, anxiety, depression and emotion oriented copings. The current study indicated that cognitive-behavioral based intervention is a useful programme for reducing stress, raising the quality of life, enhancing adaptive copings of patients suffering from breast cancer. These results are congruent with cognitive behavioural model of psychological problems.

The effectiveness of teaching neuro-linguistic programming (NLP) to enhance intimacy

Hamid Arab University of Isfahan, Islamic Republic of Iran; Mohammad Bagher Kajbaf; Mohammad Naghavi

The goal of the present study was to examine the effectiveness of teaching neuro-linguistic programming (NLP) on the level of intimacy between married couples who attend Isfahan’s advisory institution. The research sample included 30 married couples seeking advice from the advisory institution, selected based on the available method and randomly selected, in an experimental and a control group. The experimental group received eight sessions of NLP teaching and the control group received no treatment. The implemented instrument in the study was a survey on married couple’s intimacy that was of high validity and reliability. The data were analysed through the use of SPSS software and co-variance analysis method. The results indicated that teaching NLP increased the intimacy and its dimensions i.e. emotional, supportive, social, communicative and spiritual, and also the overall intimacy (p<.05).

Diabetes and hypertension: Assessing the effects of physical illnesses on the quality of life of elderly people

Dina Cardoso ISPA, Portugal; Isabel Leal; Sofia von Humboldt ISPA, Portugal

Aging with quality has become increasingly relevant in a context in which life expectancy has increased. This research aims at 1) analysing the variation of QoL in older adults with hypertension and diabetes, and 2) examining the variation of physical functioning, role limitations, social functioning, physical pain, mental health and vitality of older adults with diabetes and hypertension. 120 older adults or more

The United Nations World Food Conference in 1974 stated that every man, woman, and child has the right to be free from hunger and malnutrition in order to develop fully and maintain their physical and mental well-being. Likewise the Right and Welfare of the African Child, article 14, emphasises that every child shall have the right to enjoy the best state of physical, mental and spiritual health; strategy includes assurance of provision of adequate nutrition. However, food and agricultural organisation (FAO,2010) reported that there were 925 million undernourished people in the world. By October 2010, the number exceeded one billion (FAO, 2010). Nigeria is among the 20 countries in the world that together account for more than 80% of the world undernourished people with serious hunger state (with an index between 10.0 and 19.9) on the Global Hunger Index (GHI). This research is aimed at finding ways of encouraging the consumption of locally produced food stuffs, due to high in nutritional value. Structured and non-structured questionnaires are developed based on location (rural/urban), education and gender (male/female) in dependent variables, the level of production and consumption. Data is analysed by cross tabulation, using Pearson’s Product Moment Correlation Co-efficient Statistical Measure, from which appropriate recommendations are drawn for policy and immediate use by other researchers and health workers.
than 73 years of age, constituted the convenience sample of this study. The instruments utilised were the Assessment Questionnaire for Health Gains (SF-6D), the Mini-Mental State Examination (MMSE) and demographics. Findings indicated lower QoL scores for elderly people with diabetes (MQoL = 4.7) and hypertension (MQoL = 4.3) when compared with elderly without these diseases (MQoL = 5.2). Findings also indicated variation in the impact of physical illness in the dimensions of QoL. Thus, subjects with diabetes indicated lower scores for social functioning (MPF = 4.5) and mental health (MVIT = 2.8). Subjects with hypertension indicated lower scores for physical functioning (MPF = 4.2) and also mental health (MVIT = 3.06) but, generically, participants with hypertension showed lower scores when compared with participants with diabetes. This study highlighted that hypertension and diabetes affect dimensions of older adults’ QoL, although in different ways, and that hypertension has a higher impact on this population group. It is thus relevant to take into account these results for clinical practice and behavioural strategies for older populations.

The relationship between Chinese private college students’ personality, coping style and mental health
Lizhong Chi Beijing Sport University, China
This paper tried to explore the correlation between the personality, coping style and mental health among private college students. 143 private university students were selected to complete the SCL-90, EPQ, and SCSEQ. The results showed that: (1) No significant gender difference existed, while only-child students significantly differed from students with siblings in terms of hostility (only-child students scored higher than other students). (2) Negative coping correlated significantly with all dimensions of the SCL—90. (3) Psychoticism significantly correlated with hostility; extraversion significantly correlated with obsessive-compulsion, interpersonal sensitivity, depression, paranoid ideation, psychoticism, anxiety and psychotic anxiety; neuroticism significantly correlated with all dimensions of SCL—90. (4) Negative coping, extroversion and neuroticism could significantly predict the total score of SCL-90. (5) Negative coping, extraversion and neuroticism could significantly predict the total score of the SCL-90.

Analysing the association of religion and quality of life in old age
Catarina Costa ISPA, Portugal; Sofia von Humboldt ISPA, Portugal; Victor Claudio
Although aging process research is commonly associated with loss of function and quality of life, most seniors use different strategies to potentiate their integration in society and psychological well-being. This study assessed the incorporation of religion as a relevant intervention in the quality of life of elderly people. The sample comprised 118 participants over 74 years old, from eight different nationalities, with no psychiatric disorders. For the purposes of this study, the Assessment of Gains in Health Scale (SF-6D), one measure of cognitive functioning - the Mini-Mental State Examination (MMSE) and demographics were included. Findings indicated that Taoist older adults showed a higher QoL score for social functioning (MSF = 6.0) while Protestant participants indicated a higher QoL score for role limitations (MRL = 5.8). This study contributed to enlightening the relevance of religion to older adults’ QoL. Recommendations for future research and behavioral approaches on older adults’ QoL and clinical practice are also presented.

Religion and quality of life: A study with an international sample of elderly
Catarina Costa ISPA, Portugal; Victor Claudio; Al-mee Ferreira; Sofia von Humboldt ISPA, Portugal
Previous literature indicates that religion helps within social support and adaptation to aging, mainly in matters like sense of limit and death. This study aims at examining the role of religion in old age and at analysing the impact of different religions in the quality of life (QoL) of elderly people. The sample comprised 118 participants over 74 years old, from eight different nationalities, including Portuguese, German, English and Romanian, with no psychiatric disorders. For the purposes of this study, the Assessment of Gains in Health Scale (SF-6D), one measure of cognitive functioning, the Mini-Mental State Examination (MMSE) and demographics, were included. Results indicated the highest QoL scores in Taoist older adults (MTao = 5.3), Protestant participants (MPro = 4.9) and other religious older adults (MOTH = 4.9) when compared to the population without a religious belief system (MWRE = 4.1). In terms of nationality and QoL, German older adults indicated a higher QoL score (M = 5.3) whilst Romanian older adults indicated the lowest mean value (M = 3.9). There was no correlation between nationality and QoL. This study makes a valuable contribution for the incorporation of religion as a relevant intervention in QoL in old age, emphasising its contribution to healthy aging and behavioural strategies.

Assessment of type 1 diabetes knowledge: What do children and parents know?
Kimberly Driscoll Florida State University, United States of America; Larry Deeb; Elizabeth Gill; Suzanne Johnson
The purpose of this study was to evaluate type 1 diabetes (T1D) knowledge in children with T1D and their caregivers. 108 caregivers (M age=38.06 years, SD=8.19; 83% female) and 76 children (M age= 9.92 years, SD=1.25; range = 7.05-11.96; 53% female) completed the Test of Diabetes Knowledge (TDK). Scores ranged from 0-100% with higher scores reflecting better knowledge. Caregivers demonstrated better T1D knowledge than children (ps<0.001), but there was great variability in scores. Caregivers’ scores were (Mean, SD, range): TDK Total Problems: 91.78%, 10.14, 39-100, TDK General Knowledge: 91.16%, 10.92, 45-100, TDK Problem-Solving: 93.21%, 11.17, 25-100, TDK Insulin: 83.00%, 15.82, 33-100. Children’s scores were TDK Total Problems: 65.89%, 22.2, 0-100, TDK General Knowledge: 65.03, 17.68, 10-100, TDK Problem-Solving: 78.34%, 19.68, 25-100, TDK Insulin: 51.61%, 24.25, ~0-100. Children’s T1D knowledge increased with age (r=-0.39-0.65, ps<0.05-0.001). Psychologists’ assessment training can be of benefit to children with T1D and their caregivers by determining existing disease knowledge levels and rectifying deficits. Although many caregivers have adequate T1D knowledge, a subset requires re-education and would benefit from intervention. Caregivers of school-aged children should maintain primary responsibility for the T1D regimen, as children lack necessary knowledge for good T1D management.

Coping patterns and mental health in nursing and physiotherapy: A comparative study of supervisors and employees
Heike Ehhardt University of Education, Germany; Bernhard Borgetto; Karin Schleider
Due to a dearth of physicians in Germany, an increase of medical responsibilities for nurses and physiotherapists is discussed. To be able to describe the effects of this development, the aim of this study was to investigate current coping styles and the general state of mental health of nurses and physiotherapists in supervisor positions and on staff level. A cross-sectional study was performed with members of the German nurse association (DBBK) and the German physiotherapy association (ZVK). The survey included scales of coping patterns (AVEM-44, Schaarschmidt, Fischer, 2008) and mental health (COPOSQ, Nübling et al. 2005). A total of 140 participants completed the questionnaire: nSuA=60 supervisors with, nSuB=33 supervisors without personnel responsibility and nE=47 employees. Analysis of the sample showed higher values of job satisfaction (p<0.01) as well as cognitive stress (p=0.05) compared to normative sample. Regarding subgroups SuB show significant higher strain at work and more psychosocial stress than SuA. In addition 46% of SuB act with pattern “take-it-easy” which is an indication of poor motivation and protection against inadequate professional challenge (SuA=18%, SuB=26%). The pattern resignation and depression appeared in 21% of SuB and 19% of employees, but only in 5% of SuA. The results indicate an already-existing strain, especially on supervisors without personnel responsibility, and employees. Extra medical responsibilities could be a chance to improve their professional challenge and their motivation. In addition, it is mandatory to develop target group oriented interventions to strengthen motivation and prevent resignation.

The influence of stressful life events on subjective well-being: A test of multiple mediating effects
Cuijing Fan Central China Normal University, China; Hua Wei
The present study tested the multiple mediating effects of self-concealment and social support in the relationship between stressful life events and subjective well-being (SWB), probing the mechanism of effects of stressful life events on SWB. A total of 537 undergraduate students took part in this study. The results confirmed our hypothesis that stressful life events were positively associated with self-concealment, social support and SWB. Self-concealment negatively correlated social support and SWB and there was a positive relationship between social support and SWB. In addition, stressful life events not only exerted a direct impact on SWB, but could also influence the SWB indi-
rectly through self-concealment and social support, indicating that the relationship between stressful life events and SWB was partially mediated by self-concealment and social support. The findings provide an impetus for improvement of life quality of college students. Their SWB can be enhanced by relieving pressure, reducing the tendency to self-concealment and gaining social support.

The relationship between religious beliefs and mental health in female students

Javad Ghanbari Technical University of Zanjan, Islamic Republic of Iran; Akbar Mahdiloo Technical University of Zanjan, Islamic Republic of Iran

This study examined the relationship between religious beliefs and mental health in female students. In this correlation research, 260 female students of the Technical University of Zanjan were chosen as a sample using stratified sampling method. The completed Religious Beliefs questionnaire and Symptom Checklist -90 -Revised (SCL-90-R) questionnaire. Data were analysed using Pearson correlation coefficient in SPSS version 16. Findings showed that there was a positive relationship between religious beliefs and mental health. According to the findings, religious belief is an important factor and has a considerable role in mental health. Religious beliefs are strongly associated with higher levels of mental health.

Impact factors on creativity and its relationship with mental health

Javad Ghanbari Technical University of Zanjan, Islamic Republic of Iran; Akbar Mahdiloo Technical University of Zanjan, Islamic Republic of Iran

This descriptive correlational study identified factors affecting the creativity and its relationship with mental health. 587 people were selected as a statistical sample using multi-stage cluster and stratified sampling method. They filled Abedi Creativity Questionnaire, General Health Questionnaire and personal information questionnaire. Results of correlation analysis, T-test and ANOVA showed that: there was a significant relationship between creativity and mental health, gender, parenting styles, the occupational status of parents, and education level of parents. Also, the creativity was different between students who passed the life skills lesson with those who did not pass. There was a relationship between creativity and mental health of students, so that mental health increases or decreases with increasing and decreasing the rate of creativity. Also, Students who passed life skills lesson had higher scores in creativity. The level of creativity in girls was significantly higher than boys. Students whose parents with the permissive, authoritative and neglectful parenting style, were more creative than who their parents had authoritarian style. Students of parents with high occupational status were more creative, but there was no relationship between creativity and their mother’s jobs. Students whose parents had higher-education levels were more creative than others.

The epidemic of childhood obesity has often been related to the increasing sedentary lifestyle of children, as well as hypercaloric diets. Among the reasons commonly pointed out for sedentarism, those most cited are the abuse of electronic entertainment devices, and excessive television viewing, which do not encourage children to participate in physical activity. The aim of this pilot study is to analyse whether children use, or at least have at their disposal, those entertainment devices or not. 51 Primary school students took part in the study (Mean age: 10.54; SD: 0.61): 62.9% girls and 37.1% boys. Participants completed a developed ad-hoc lifestyle questionnaire; weight, height and truncipal skinfold measures were also obtained. Results show 34.3% of the sample spent at least two hours doing sedentary activities such as watching television or playing video games (17.1% spent over four hours). Besides, 92% of the subjects had the television set on while having their meals. Participants had the following electronic entertainment devices: music players (68.6%), computers (60%), television sets (57%), video games (37.1%) and mobile phones (7%) in their rooms. We conclude that children seem to spend too many hours a day in sedentary activities, and have easy access to electronic devices which encourage them take part in this kind of activity. If these results are confirmed using a larger sample size, we could verify the link between the current childhood lifestyle in developed countries, and obesity.

Burnout Syndrome in practitioners delivering services/ assistance in the area of family violence

Gloria Gurrola Universidad Autonoma del Estado, Mexico; Eloisa Ramirez; Patricia Balcazar; Alejandra Moyaen; Julietta Garay

The present study aims at identifying and describing burnout symptoms in professionals delivering services, and/or assistance to persons who have experienced family violence. The sample consists of 32 professionals (four medical doctors, ten psychologists, ten social workers, and eight lawyers) who work at the Integral Family Development System in the city of Toluca, Mexico. Focus groups and in-depth interviews were used as part of the study’s methodology. The results indicate important physical ailments and effects in the motivation for delivering help, and emotional areas, for professionals. Positive sequelae (such as the learning of healthier interaction schemes at the family level and avoidance of violent behavioural patterns) were also observed. It is concluded that professionals delivering services/assistance in the area of family violence are in need of psychological support and social networks that can act as a protective factor against the wearing down experienced in professional practice.

Bridging the intention-behaviour gap: Life-style modification intervention at the cardiology ward

Stefan Hoefner Innsbruck Medical University, Austria; Marion Platter; Cornelia Hoelzl; Markus Hofer; Alexandra Huber; Daniela Renn

Coronary Heart Disease (CHD) is a life-style related disease. Modifiable risk factors have been identified. The knowledge about modifiable risk factors is increasing, the uptake of a healthy life-style is not. We tested the effects of a brief health-psychology intervention to bridge the intention-behaviour gap and increase the likelihood for the uptake of a healthy life style (physical activity, diet and well-being). Patients with CHD and cardiac risk factors were assigned to an intervention or control group. A brief activating health-psychological intervention was build into an educational group setting. Baseline assessment included perceived self-efficacy, intentional status, physical activity, diet and well-being and was completed during inpatient hospital stay; follow-up data was collected at two and six months. 669 patients participated (physical activity=210; diet=245, well-being=214, age= 64.2±9.4; 64% male). No baseline differences for baseline variables were found. No between group differences for the intention to uptake a healthy life style were found at baseline. Results at two months indicated that those in the IG had more control over their planned behaviour (3±0.7 vs. 2.6±0.8, p=0.05). Patients in the IG report to be 59.5±(52) minutes more physical active per week than the control group (p=0.05). Overall the short-term indicators showed that the brief intervention increased the behaviour control.

Impact of social support, social skills and coping strategies on female teacher’s health

Rubina Kausar University of the Punjab, Pakistan; Yasmin Dr

The present research explored the impact of perceived social support, social skills and coping strategies on the general health of female college and Women University teachers. Lazarus and Folkman’s (1984) Cognitive Model of Coping with stress was used as the theoretical basis for this research project. Non-probability purposive sampling strategy was used. The sample comprised of 212 female college and university teachers. It is hypothesised that perceived social support, social skills and coping strategies would have a positive impact on the general health of female college and Women University teachers. Perceived Social Support Fri /Fa Scales (PSS, Fr/Fa) by Procidano and Heller (1983); Social Skills Inventory (SSI) by Riggio (1986); Coping Orientation to Problem Experience (COPE) by Carver, Scheier and Weintraub (1989) and General Health Questionnaire 30 (GHQ 30) by Goldberg (1978) were individually administered to all the participants in order to assess their perceived social support, social skills, coping strategies and general health. The results suggested that perceived social support, social skills and coping strategies had a significantly positive impact on the general health of female college and university teachers. The findings of this research have implications for promoting our understanding of the impact of social support, social skills and coping strategies on the general health of female college and Women University teachers. Furthermore, growth-enhancing faculty development programmes could be introduced for promoting healthy coping strategies, social skills and social support among female college and Women University teachers in order to enhance their general health in the Pakistani society.

Occupational stress and depression: An issue of balance?

Stefan Koch Rosenneck Center of Behavioral Medicine, Germany
The model of Effort-Reward-Imbalance (ERI, Siegrist 1996) suggests that an imbalance between occupational engagement and experienced reward increases the risk for physical and mental disorders. The aim of this study was to investigate a heterogeneous clinical sample for differential relations between ERI (and its reward components: Job security, esteem, and salary/promotion) and depression. Occupational self-appraisal was predicted to be of health-protective value. The study was based on a cross-sectional sample of 120 participants (60% salary workers, 40% civil servants) in an inpatient psychotherapy, predominantly suffering from affective disorders (76%, ICD-10 F3). Incremental variances of ERI-components and Occupational-Self-Appraisal-Scale (OSAS, Lehr 2010) were analysed by stepwise linear regression models (critera: depression/CES-D). ERI (total model) significantly predicted the extent of depressive symptoms (CES-D, R-Square=11%). An imbalance between effort and job security (EJ) was the strongest predictor (β=0.23). An imbalance of effort and esteem (EII) correlated significantly (r=0.26). OSAS had a protective effect and significantly explained further variance of depression (Delta R-Square = +2.3%). Effort-Reward-Imbalance, especially an imbalance of effort and job security was significantly related to depression. Interestingly, objective job characteristics (such as employment status, years of work experience) had no impact. Instead, a perceived threat to job-security and occupational self-esteem, and deficits of occupational self-appreciation, proved to be decisive for the impact of occupational stress on depression. Initiated early enough, occupational interventions could counteract the mutual amplification of ERI and depression. Further investigations will focus on longitudinal replications and clinical implementations of the ERI-concept in job-related group-interventions.

Measuring mindfulness in mediators and examining how aspects of mediation practice affect mindfulness

Kate Leinberger Texas AM University, South Africa

Mindfulness is an element of consciousness historically associated with well-being. Mindfulness interventions intend to reduce cognitive vulnerability to emotional distress. However, dissent remains among researchers on how to operationally define the construct. Measuring mindfulness in a valid and reliable manner is an essential part of scientific inquiry and facilitates the effort to define the construct. This study examines three self-report instruments, Five Facet Mindfulness Questionnaire (FFMQ), the Toronto Mindfulness Scale (TMS) and the Experiences Questionnaire (EQ). Samples included non-meditators (Texas A&M University students; n=141) and meditators (non-clinical population from Bay Area, California; n=157) with a wide range of meditation experience. Multiple correlations examined the measures at full-scale and sub-scale levels, all yielding significant and positive relations. Regression analyses established that mediation does increase mindfulness. FFMQ Observe, FFMQ NonReact and TMS Decenter increased least. All facets were predicted by mediators except for FFMQ Observe, FFMQ Describe and FFMQ Aware, FFMQ Decenter and TMS Curiosity. Lastly, the study examined how aspects of meditation practice affect mindfulness. Aspects included: number of sittings per week (sit/wk); time spent per meditation sitting (time/med); how long the participant has engaged in formal meditation (how long) and style of meditation (style). “Sit/wk”, “how long” and “style” were predictive of mindfulness, with “how long” being the strongest predictor. Meditation styles mindfulness, Vipassana, Zen and Shambhala were associated with highest mindfulness.

Psychological correlates of risky cannabis use: Alexithymia, frontal lobe dysfunction and impulsivity

Michael Lyvers Bond University, Australia; Fred Thorberg; Reuben Jamieson

A community sample of young adult cannabis users was recruited. Of the 138 participants, 71.7% were defined by their Cannabis Use Disorder Identification Test (CUDIT) scores as low risk cannabis users, whereas 28.3% were risky cannabis users. The CUDIT risk group was significantly associated with the Toronto Alexithymia Scale (TAS-20) defined alexithymia group, p = .004. CUDIT scores were significantly positively correlated with all three TAS-20 alexithymia subscale scores, Barratt Impulsiveness Scale (BIS-11) impulsivity, and all frontal lobe dysfunction subscales of the Frontal Systems Behavior Scale (FrSBe). A two-way (CUDIT risk group X gender) between-subjects multivariate analysis of covariance (MANCOVA) was performed on scores obtained from the TAS-20 subscales, FrSBe subscales, and BIS-11; using age as the covariate. The multivariate effect of the CUDIT group was significant, p < .001. Univariate effects of the CUDIT group were significant for all measures. Heavy cannabis use is known to be associated with residual effects including deficits in frontal lobe functioning that may persist for up to five weeks of abstinence; thus, it is tempting to regard these correlates of risky cannabis use as reflecting residual effects. However, traits such as alexithymia, poor impulse control and executive dysfunction have all been linked to the predisposition to abuse drugs and alcohol. Both directions of causation may apply, for example, those with inherently lower emotion regulation and executive self-control abilities may be more likely to abuse substances, and substance abuse itself may further impair executive functioning and self-regulation.

Motives for abstaining from alcohol questionnaire: Suitability for university students in Limpopo, South Africa

Milkadin Madonsela University of Limpopo, South Africa; Solomon Mashegoane University of Limpopo, South Africa

Alcohol-related beliefs for limiting the use of alcohol have hardly been explored among university students in Limpopo, South Africa. Stritzke and Butt (2001) developed the Motives for Abstaining from Alcohol Questionnaire (MAAQ) to account for cognitive aspects of limiting alcohol use. The properties of this potentially useful measure were explored in an on-going study of university students in Limpopo, South Africa. Analysis limited to abstaining students found that a four factor model fitted the data well, and accounted for 50.686% of the variance explained. Stritzke and Butt’s (2001) factors were largely reproduced, although there were deviations: the indifference and religious constraints factors were merged, and two items of the dispositional risk factors were misplaced. Further analysis showed that gender, domicile and age did not impact the scores on the MAAQ subscales (ps > .05). However, relative to abstaining students, those who reported drinking were less likely to endorse higher scores on the fear of negative consequences (t = -3.704, df =52.615, p = .001; d = .847), religious constraints (t = -2.580, df = 53.696, p = .002, d =.605) and indifference (t = -4.689, df = 303, p = .001; d =.767) subscales of the MAAC. Overall, the results support the use of the measure in research and in the design of alcohol abstention programmes in South Africa.

Spiritual intelligence, happiness, and mental health

Akbar Mahdiloo Zanjan Teacher Training Center, Islamic Republic of Iran; Behrouz Cheraghi; Mostafa Valipour; Behnaz Roudbari Saghahi; Habib Hasani

The following research examined the relationship between Spiritual Intelligence, Happiness and Mental Health. The methodology used is descriptive and correlational with the statistical society of all the female students at Zanjan’s Teacher Training Centers, including 120 randomly selected samples. They completed the Oxford Happiness Inventory, Spiritual Intelligence Questionnaire and General Health Questionnaire. The data gained in Independent T Statistical Tests, Pearson Correlation Coefficient and The Multivariate Regression Analysis was then analysed by SPSS software. Findings of the research showed that there was a significant difference in Spiritual Intelligence between single and married people (p=0/05), however, there was no difference between Happiness and Mental Health. Also, comparing the means in employed people and unemployed ones showed a significant difference in Spiritual Intelligence (p=0/01), Happiness (p=0/01) and Mental Health (p=0/05) in the aforesaid groups. By calculation of the Pearson Correlation Coefficient, the results showed a positive significant correlation between Spiritual Intelligence, Happiness and Mental Health. In addition, The Multivariate Regression Analysis showed that Spiritual Intelligence and Happiness had the ability to predict Mental Health (p=0/001) , and with 99% a certainty that Happiness was the best variable to predict the Mental Health variations in people.

Efficacy of life skills training on adjustment of students

Akbar Mahdiloo Zanjan Teacher Training Center, Islamic Republic of Iran; Habib Hasani; Javaad Ghanbari Zanjan Teacher Training Center, Islamic Republic of Iran

The aim of this study was to investigate the efficacy of short-term life skills training on adjustment of students. The study method was quasi-experimental research method. The type of design was before-after test design of the control group. The statistical society of the study comprised high school students in Zanjan. 60 individuals were randomly selected and were divided into an experimental (n=30; 15 male and 15 female) and a control group (n=30; 15 male and 15 female). The experimental group received a 6-session course in life skills while the
Experiences of teenage mothers with differently-abled children
Tshilizdi Mashamba University of Venda, South Africa; Leslie Mange
Teenage pregnancy has become one of the serious problems in our society. There are a number of factors contributing to teenage pregnancy. One of these factors includes misinformation on sexual health matters. Teen pregnancy may result in pregnancy complications such as high risk of child mortality and morbidity, including mental retardation among other disorders. Teen pregnancy also causes other social problems such as poverty, economic costs, mother and baby’s well-being. The present study aims at investigating the experiences of teenage mothers with differently-abled children. Face to face semi-structured interviews will be conducted with five mothers who reside in Thulamela Municipality of the Vhembe District in Limpopo Province. The focus of the study will be on the following: demographic background; challenges facing them; and their coping strategies. Issues relating to physical, financial and emotional support from the fathers of those children will also be explored. Data will be analysed using thematic content analysis.

Coping, anxiety and habit changing in obese patients before and after a psychological programme
Marinna Mensorio Universidade de Brasilia, Brazil; Aderson Costa Jr.
The objective of the study was to investigate changes in coping strategies and anxiety levels, adopted by obese patients eligible for bariatric surgery, during psychological preparation for the surgery. Over three months, a group of eight obese patients (BMI ≥35), eligible for bariatric surgery, participated in the Monitoring Psychological Preparation Program for Bariatric Surgery, were analysed. Twelve weekly sessions were held in groups, with discussion of specific and previously established topics, and emerging interventions to individual demands. Beck Anxiety Inventory (BAI) and Ways of Coping Scale Problem (EMEP) were applied in the first and last session of the Program. There was prevalence of coping strategies focused on problems and religious practice in the first phase, and, after intervention, predominance of coping strategies focused on problems and seeking social support, as well as decrease (four patients) and maintenance (two patients) in levels of anxiety, at the end of the clinical group. Data obtained enabled planning psychosocial interventions tailored to the needs of this population, facilitating adherence to more effective coping strategies. Psychological intervention also proved relevant in order to assist the anxiety control process, maximising the search for social support for a population that, in general, experience social isolation. The need for continued counselling of patients eligible for bariatric surgery, in search of greater self-control and coping strategies that facilitate the pre and post-surgery, is highlighted. Greater care by health teams towards psychosocial aspects of obese population is suggested.

Eligible patients for bariatric surgery: Modifying behaviours after preoperative psychological intervention
Marinna Mensorio Universidade de Brasilia, Brazil; Aderson Costa Jr.
To evaluate behavioural changes in obese patients, eligible for bariatric surgery, after psychological intervention, eight patients participated in a Therapeutic Group, measured at twelve sequential weekly sessions, by semi-structured interview and Beck Anxiety Inventory (BAI). They answered in two phases: at first and last session of the group; daily food intake record, and clinical monitoring. In the first phase, patients showed negative coping in relation to obese condition, adopting maladaptive strategies; demonstrated high levels of anxiety and reported difficulties in maintaining weight loss behaviours. In the second phase, patients showed lower levels of anxiety in relation to treatment and food control, but not on waiting for the surgery; have developed more effective coping strategies to deal with challenges of treatment and difficulties of the condition still obese, self-control skills, and greater adherence to nutritional orientation. Techniques of self-observation and weight loss were observed. Data suggests that obese patients assisted in the programme, developed more effective coping strategies to deal with treatment and condition while waiting for surgery, reducing anxiety and adhering to healthy behaviours. It has shown the need for systematic action by psychologists, demonstrating the relevance for a multidisciplinary and preventative approach to bariatric surgery. However, the wait for surgery, which does not happen immediately after the end of Therapeutic Group, may have hampered a more significant reduction of anxiety, demonstrating the importance of public health in Brazil to work more effectively. Longitudinal studies are suggested to assess the effectiveness after surgery.

HIV/AIDS preventative strategies among school going adolescent learners
Sikhumbuzo Mfusi Walter Sisulu University, South Africa; Nezivhe Mbebe
Many studies have examined the effectiveness of the preventative strategies of HIV/AIDS among school-going adolescents, using primary and secondary literature as a source of information. Research on the effectiveness of preventative strategies of HIV/AIDS reveals that, while scientists continue to search for a cure, government and communities try to find the most effective ways to educate, and increase awareness, in an attempt to prevent or curb the spread of HIV infection. At the moment, there is no cure for HIV/AIDS, but the spread of the disease can be reduced through awareness messages aimed at adolescents. Sub-Saharan Africa still has the world’s highest number of HIV cases, and most importantly, the statistics for the epidemic are increasing for the target group, because they are more vulnerable to HIV/AIDS transmission than any other age group, due to such lack of sources of support, exploration and the practice of unsafe sex. As they experiment with their sexuality, they contract Sexually Transmitted Infections, and young girls become pregnant which has adverse effects on their academic and social lives or development. This paper discusses strategies and recommendations that can be utilized in coping with HIV/AIDS among adolescents.

Building social support for institutionalised youth in Romania: An exploratory social experimentation project
Adela Militaru Babes-Bolyai University, Romania; Adriana Babon; Diana Taut; Lavinia Damian
Previous research on youth growing up in child protection institutions, reported several negative outcomes for these young people, such as substance abuse, delinquency, and other risk behaviours. In contrast, relevant literature accounts for successful examples of attempts to build supportive relationships between institutionalised youth and adult mentors. In this framework, the objective of our study was to explore the transition process towards an independent life in a group of institutionalised youngsters who were assigned an adult mentor. We conducted 18 qualitative interviews, in order to gain a deeper insight on the perception of social support received by institutionalised youth. We analysed the benefits of maintaining a supportive, year-long mentoring relationship, and other changes in youth’s perception of received support, as expressed by youngsters who had a mentor, contrasting with the experiences of their peers who had no such mentor. Our findings suggest that some interviewees managed to establish a protective emotional bond with their mentor, which led to improvement in their perceived social support. However, other youth who were interviewed seemed not to have benefitted from their mentor’s presence. Possible reasons that were brought forward are the short period of time assigned, the fact that participants could not choose their mentor, or the lack of motivation at the level of youngsters. By gaining a better understanding of conditions that encourage the development of positive relationships of institutionalised youth, research may help inform relevant policies aimed at fostering resilient outcomes in this target group.

The effect of attributional style training on improving general health in a group of retired high school teachers in Isfahan
Shekoufeh Nikneshan Payame Noor University, Islamic Republic of Iran
The purpose of this study was to determine the effectiveness of attributional style training on the general health of retired high school teachers in Isfahan. In this research, the quasi experimental design was used. The statistical population comprised retired high school teachers in Isfahan in 1384 s.c.(2005-6). Initially, the General Health Questionnaire (GHQ-28) was administered to one hundred and fifty retired high school teachers. Thir-
Influence of a passion for academic activities on health

Takuma Nishimura University of Tsukuba, Japan; Shigeo Sakurai

In recent years, Self-determination theory approached a conceptualising passion. Two types of passions were proposed: harmonious passion and obsessive passion. Harmonious passion refers to a motivational tendency to freely engage in activities. Obsessive passion refers to a motivational tendency to coercively engage in it. Many studies that have investigated passions have focused on the favourable activities, such as sports and music among others. These studies have supported the significant role that passion plays in people’s lives. In addition to these, passion is also important for obligatory and necessary activities, such as academic activities of junior high school students. However, such passions have not been the subject of research. Therefore, we examined the influence of passion for academic activities on a person’s health. Japanese students of the seventh, eighth, and ninth grade (N = 1439; 754 boys and 685 girls) participated in a survey with regard to passion for academic activities, and health, such as depression, self-esteem, academic competence, burnout tendency and intrinsic motivation. A multiple regression analysis was conducted to investigate the effect of passion on health. Results indicated that harmonious passion had a positive effect on self-esteem, academic competence and intrinsic motivation as well as a negative effect on depression and burnout tendency. Conversely, obsessive passion had a positive effect on depression and burnout tendency as well as a negative effect on self-esteem. We found that harmonious passion results in better health, whereas obsessive passion is detrimental to wellness.

The interplay of experience, self-efficacy and action control in physical activity promotion

Linda Parschau Freie Universitaet Berlin, Gemany

Many individuals fail to engage in regular physical activity. Previous research suggests that positive experience, self-efficacy and action control are beneficial for the maintenance of being physically active. In line with Social-Cognitive Theory, the present study investigated whether the effects of positive exercise experience (i.e. mastery experience) on subsequent physical activity were mediated by self-efficacy. Furthermore, it was tested whether this mediation is moderated by the individuals’ level of action control. N = 193 adolescents participated in a study on physical activity. At baseline, positive exercise experience was measured as a predictor of physical activity. Two weeks later, self-efficacy and action control were assessed as mediator and moderator, respectively. After another two weeks, physical activity was measured as an outcome. A moderated mediation was specified with baseline physical activity and sex as covariates. Findings revealed that self-efficacy mediated between positive exercise experience and physical activity (β = .15, p < .05) and that this mediation was moderated by the level of action control (χ = .12, p < .05). Within the subgroup of participants with very low levels of action control, positive experience did not translate into physical activity via self-efficacy. Findings imply that postintentional interventions targeting physical activity should not only focus on increasing participants’ perceptions of positive exercise experience and self-efficacy beliefs but also on supporting individuals in developing action control skills to successfully regulate their exercise behaviour.

Service quality measures for substance abuse treatment centres - assessing current practices and improvements

Zainonisa Petersen Medical Research Council, South Africa; John Bartlett; Randy Koch; Bronwyn Myers; Rehana Kader; Ron Manderscheid

Background: Introducing service quality measures (SQM) in treatment services allows programme managers and policy makers to identify opportunities for improved service. This SQM project is aimed at developing a set of reliable and valid measures for service quality in South African treatment centres. The outcome of this initiative is to improve treatment programme implementation by gaining an understanding of the barriers and shortcomings regarding access to treatment and the implementation strategies required to improve services. Methods: This qualitative sub-study was designed to explore the current practices with regards to client data collection and the means of collecting data. Three focus group discussions were conducted with representatives from 11 treatment centres. In total 18 participants, including councilors and clerical staff, contributed to the discussion. A variety of types of treatment centres were included, and included government and private, in and out-patient treatment centres. All interviews were recorded with the permission of respondents. Interviews were transcribed and analysed using content analysis. Results: Respondents from various treatment centres shared and discussed the data collection tools they are currently using, and means to improve and standardise this. All the respondents suggested that data collection procedures need to improve, that standardised data collection tools are necessary for service improvement and that a more modern, electronic approach to data collection needs to be adopted. Conclusion: Although participants felt they are collecting valid data, the overriding opinion was that data collection procedures need to be standardised across treatment centres, as a means of improving service delivery.

Stress, anxiety, depression and body shape concerns: Differences between middle-aged women from different BMI categories

Filipa Pimenta ISPA - Instituto Universitario, Portugal; Joao Maroco; Rita Macedo; Isabel Leal; Raquel Oliveira

Psychological distress has been identified as higher among overweight, obese women, compared with their counterparts with normal body mass index (BMI), independently of lifestyle factors (Zhaot et al., 2009). This study explores the differences between women with three diverse categories of BMI (namely normal/healthy weight, overweight and obesity), regarding several psychological variables: Stress, depression, anxiety and body shape concerns. This cross-sectional study encompasses a community sample of 986 women aged between 42 and 60 years, using the Body Shape Questionnaire (Cooper et al., 1987) and the Depression, Anxiety and Stress Scales (Pais-Ribeiro et al., 2004). Comparative statistics were applied. Several significant differences were found in terms of anxiety, specifically, between normal weight and both overweight (MD=−.102; p=.005) and obese women (MD=−1.35p=0.10). Depression varied only between participants with normal weight and overweight (MD=−.102; p=.026). There were no significant differences between the BMI groups regarding the stress levels. Body shape concerns varied between all groups, particularly between healthy weight and both overweight (MD=−.477; p=0.001) and obese women (MD=−.834; p<0.001) and also between overweight and obese participants (MD=−.357; p<0.001). Middle-aged women with higher BMI present higher levels of anxiety, depression and concerns with their body shape when compared with their counterparts with a healthy weight. This should be accounted for when focusing on this age group in clinical and research settings.

A predictive model of body mass index categories in middle-aged women

Filipa Pimenta ISPA - Instituto Universitario, Portugal; Ines de Matos; Joao Maroco; Raquel Oliveira; Isabel Leal

The aim of this study was to build a causal model to explore the predictors of body mass index (BMI) in normal weight, overweight and obese women, and to examine the influence of socio-demographic, lifestyle, health status, menopause, stress, anxiety, depression, life events and body shape concerns. This cross-sectional study encompasses a community sample of 986 women (aged 42-60 years) validated instruments to assess depression, anxiety, stress, body shape concerns and life events were used. Structural equation modelling was applied to build a causal model. Education was a significant predictor of BMI for normal weight (β=−0.083; p=0.023), overweight (β=−0.085; p=0.023) and obese (β=−0.086;p=0.023) women. Depression also predicted BMI for normal weight (β=0.230;p<0.001), overweight (χ²=236;p<0.001) and obese (χ²=237;p<0.001) participants. Stress predicted body weight only in normal weight subjects (χ²=289;p<0.001). Finally, for normal weight (χ²=247;p<0.001), overweight (χ²=254;p<0.001) and obese (χ²=254;p<0.001) participants, body shape concerns predicted BMI. Depression was a significant and negative predictor of BMI (women with higher levels of depressive symptoms evidenced a lower BMI), stress only predicted BMI in normal weight participants (women with higher scores in stress presented a higher BMI).
Body shape concerns and education were both predictors for all categories of BMI, demonstrating that women with higher education and less frequent concerns with body shape presented a lower BMI. A predictive model of body mass index (BMI) categories in middle-aged women is presented.

Aortic arch surgery using the technique of selective antegrade perfusion at 25 degrees centigrade: Impact on anxiety, depression and cognition

Belliss Romano Heart Institute USP; Brazil; Maria Meirelles; Leilane Antoniazzi; Thabata Fonseca; Elaine Hajolj

Cardiac surgery may have neurological complications such as bleeding or brain damage, even with the protective effect of hypothermia. In cardiac surgery, there are questions about mortality and quality of life of patients after surgery, also on brain protection during surgery in order to avoid such compromises. Currently, besides biological and biochemical factors involved in heart surgery, studies have gained prominence in correlating behaviour, mood and disease, especially with a focus on anxiety and depression. This study examined the progression of depressive and anxiety symptoms, as well as neurocognitive functions, within one year after aortic surgery. This is an experimental, double-blind study: The experimental group underwent surgery using the technique of selective antegrade perfusion at 25°C, the control group went through traditional surgery. Fifteen patients participated (one year after surgery, until October 2011) and were evaluated at three times: Before surgery, at six months and twelve months after surgery. The Wechsler Intelligence Scale for Adults III, Beck Depression Inventory and Beck Anxiety Inventory were administered. The minimum level of anxiety remained prevalent during the study period in both groups. Regarding depression, there was a minimum level of prevalence in the three study phases: Pre-operatively, at six months and one year in both groups. However, these were related to a decrease in stress, but "cause unfolding with self-attribution," "distancing," "making meaning," "positive reappraisal" and "attribution to patient." Before the analysis, the sample was divided into two groups on the basis of the score of "job involvement" because of the theoretical assumption that these relations would be different depending on the degree of the individual’s job involvement. Using hierarchical multiple regression analysis, the relation between each strategy and stress were examined in both groups. In the high job involvement group, “making meaning” and “positive reappraisal” were related to a decrease in stress, but “attribution to patient” was related to an increase in stress. The effects of each strategy were then discussed.

The relation between cognitive emotion regulation and stress in the context of nurse-patient interaction

Sakakibara Ryota University of Tokyo, Japan

The relation between cognitive emotion regulation and stress in the context of nurse-patient interaction was examined. Based on the results of the semi-structured interview, a questionnaire measuring the nurses’ cognitive emotion regulation strategies was developed. Then, the questionnaire was assessed among 265 nurses to examine the relation between cognitive emotion regulation strategies and stress in the context of nurse-patient interaction. A confirmatory factor analysis showed that the six factors model was more suitable than other models. The six factors were named, respectively, “attribution to doctor and hospital,” “cause unfolding with self-involvement,” “distancing,” “making meaning,” “positive reappraisal” and “attribution to patient.”

Religious beliefs through the eyes of older adults: Assessing the impact on sense of coherence in old age

Susana Santos ISPA, Portugal

A strong sense of coherence (SOC) in older adults confers on them a higher propensity to opt for healthy lifestyles and to better mobilize the resources available. Moreover, religious beliefs of older adults have been associated with a better adjustment to everyday life in old age. This investigation aims to: (a) analyze the degree of comprehensibility, management and significance, as main dimensions of SOC, in religious and non-religious older adults and (b) compare the SOC in these two groups.

Newest vital sign: Assessing health literacy among Portuguese adolescents

Oswaldo Santos University of Evora, Portugal; Ana Oliveira; Ana Azevedo; Dagmara Palva; Claudia Carvalho; Nuno Lusa; Isabel do Carmo

Knowledge about health, together with skills to use such knowledge, are determinants of health behavioural self-regulation. In Portugal, there is no nationwide validated instrument for assessing health literacy. The Newest Vital Sign (NVS) assesses health-literacy-related reading and numeracy skills, with low administration and scoring burden. Version in English and Spanish shown to have good psychometric properties (for USA population).

Health

Stress and teaching: A contribution to the inquiry on the coping strategies of teachers

Riccardo Sartori Verona University, Italy; Cristina Rappagliosi
The paper presents the results of a study carried out with 254 primary and secondary school teachers from North, Central and South Italy. In the last decade, school in Italy has been involved in a series of radical changes and, consequently, teachers have been obliged to drastically modify their methods and conceptions of work. This has caused them to continually adapt and re-adapt and thus to become more vulnerable to stress. Nevertheless, some of them seem to be more capable of facing problematic events. This study aims at analysing which coping strategies teachers adopt when they find themselves dealing with difficult situations or stressful events. For this purpose a questionnaire was used. It was composed of 12 items for personal data, 28 items from the Brief Cope (Coping Orientation to Problems Experienced by Carver, Scheier, & Weintraub, 1989), 21 items from the Italian version by Caprara (2001) of the Bandura’s Teacher Self-Efficacy Scale (1977) and 12 items from the Motivation Questionnaire by Galati, Fassio, and Viarengo (2006). Results show that the coping strategies adopted by Italian teachers are influenced by gender (males and females use the same strategies with different frequencies), age and service (young and old use different strategies) and the perception of self-efficacy. Self-efficacy also affects teachers’ motivation to work.

Why are health problems of employees caused by problems in the organisation?
Matthias Schmidt TU Dresden, Germany
Some occupational sectors show particular risks for mental health. Employees in the nursing field are assumed to be at risk. A lot of Germans who work in the health care system need help. The assumption that the risk to develop "burnout" is an individual problem has already been refuted. There are organisational problems related to working conditions. Numerous studies have revealed work-relevant problems among health care personnel in many countries. The workload increases and the problems in health condition of nursing staff are increasingly important. It is argued that integrating these various organisational qualities into a comprehensive model of organisational environments will further research on burnout. The primary themes in burnout research fit into six areas of worklife: workload, control, reward, community, fairness, and values. In this study, with over 500 employees from the care area, the German translation of the questionnaire "areas of worklife" AWS will be validated statistically. In addition, other predictors for the development of burnout were found. A logistic regression was performed to identify factors that show a statistically significant relation with work health. The logistic regression identified the variables in which the constantly high risk were different from the ones who stay healthy. The results of this study provide concrete recommendations for healthy work design. Managers can already make specific changes in work organisation, related to the health of employees.

Comparing personality profile of health individuals with patients suffering from coronary heart disease
Mohammadreza Seirafi Islamic Azad University, Karaj, Islamic Republic of Iran
With due observance to the significance of heart-related diseases, which is the first and prime factor of death toll in the world and Coronary Heart Disease (CHD) is the most common heart disease, the present study has been carried out with the aim of comparing personality profile of healthy women and men with Patients Suffering from CHD. The present study is of a comparative – causal type. For this reason, a number of 120 health men and women, suffering from CHD have been selected randomly. Personality test entitled "MMPI" (Minnesota Multiphase Personality Inventory) was used as research tool. Comparison method of difference of averages was used for analysis of data. The results of the study show that from among scales of MMPI test in the total scales there is a meaningful difference among healthy individuals and those who are suffering from CHD. This difference in psychasthenia (Pt) scale of patients suffering from CHD is more than on other scales. The rate of which is less in Psychopathic Deviate (pd) scale. Although the relation of A personality type has been approved with the outbreak of CHD disease from among mental and psychic factors, findings of the present study show that: 1. There is a meaningful difference between personality profile inserted in MMPI test among healthy individuals and patients suffering from CHD disease. 2. Other mental and psychic factors can play a constructive role in outbreak of CHD disease.

Features of self-concept and coping behaviour in women with ovarian cancer
Natalia Sirota MSUUMD, Russian Federation; Aleksandra Yaltonskaya MSUUMD, Russian Federation; Vladimir Yaltonsky MSUUMD, Russian Federation
The high prevalence of ovarian cancer in women (1.4% according to WHO), with significant psychological impairment as a reaction to severe chronic illness, makes the importance of psychological research among this group of patients. The objectives were to study the self-concept and coping strategies of women with ovarian cancer. The sample comprised 90 patients diagnosed with ovarian cancer at Stage II (Mean age 56 years, SD ± 7.4). All patients had recently received surgical treatment and at the moment of the research they were undergoing chemotherapy. For measuring self-concept and coping strategies, the set of instruments adapted and validated for the Russian population were used: The Twenty Statements Test, Kuhn- McPartland, modification by Rumyantseva; Test "Self-attitude", Stolin et al.; Leary’s Interpersonal Behaviour Test; Life style Index, Plutchik et al., modification Romanova; Coping Inventory for Stressful Situations, Parker et al. Results show that women with ovarian cancer have specific problems in their self-concept, coping with illness and other stressful behaviour. Among this group of patients we determined the low differentiation of actual and ideal "self," and a high frequency use of emotional-oriented coping, escape and distraction with predominance of externality in all domains of locus-control. The most commonly used forms of psychological protections were "regression," "denial" and "projection." The results showed the deep level of psychological impairment among women with ovarian cancer. The determination of specific problems in self-concept and coping behaviour will allow developing target-oriented psychotherapeutic programmes.

Cultural notion of depression in Nepal
Usha Kiran Subba Tribhuvan University, Kathmandu, Nepal
The exploratory study of depression in Nepal is designed to examine the common perceptions of depression, its major causes, cultural attribution of depression, and stigma attached to being depressed and health-seeking behaviour. This study focused on samples of 48 key informants from different geographical regions (mountain, hill, valley and plain). Focused group discussion was used to generate qualitative information. After content analysis of major opinions and attitudes elicited in the FGDS, ten notable themes were identified. They manifested local explanation and expression of depressive episodes, its causes and their own way of health-seeking practices in the community. The results have implications for the delivery of culturally sensitive mental health services in different geographical regions in Nepal. Awareness of culturally appropriate terminology for depression is a useful way of bridging the gap between lay and biomedical models of illness and may help improve levels of recognition and treatment compliance.

Postmenopausal psychological symptoms:
Effect of massage and aromatherapy massage
Simin Tavoni Tehran University of Medical S, Islamic Republic of Iran; Noemeh Seidfatemie; Hamid Haghami; Fatemeh Darsareh
During menopause, women often experience psychological symptoms, which may impair their overall quality of life and could be prevented by complementary therapy. To determine the effect of massage and aromatherapy massage on post-menopausal psychological symptoms, in this randomised clinical trial, 90 healthy volunteer menopausal women, who attended the main referral gynecology hospital of Tehran University of Medical Sciences, were involved in two intervention and control groups (Year 2011). In aromatherapy massage they received 30-min aromatherapy massage sessions with aroma oil, twice a week for four weeks. The massage group, received the same treatment with plain oil, and control group received no intervention. The tools have two main parts: 1) personal characteristics, and 2) psychological symptoms scale, as obtained through psychological sub-scale of Menopause Rating Scale, which was measured before intervention and at the end of interventions. There were significant differences between participants’ pre-application and post-application psychological score in two intervention’s groups (p<0.001), whereas the score in the control group did not differ significantly. Also there was a higher significant effect in aromatherapy massage (p<0.001). Results demonstrated that both aromatherapy massage and massage therapy were effective in reducing psychological symptoms during menopause, but the effect of aromatherapy massage was higher than massage therapy.

Burnout amongst mental health-care providers working at a mental health-care facility
Nicola Themistocleous University of South Africa, South Africa
Burnout is a phenomenon common to many professionals working within the mental health sector, and
Nutrition for good psychological health: What should South African psychologists’ involvement be?

Charles Van Wijk South Africa

This poster puts forward some issues for debate on the role of nutrition in the psychological treatment or management of patients. There is a rapidly emerging body of evidence supporting the positive benefits of good nutrition and also nutritional supplements in the improvement of mental health, brain function, and psychological wellness. Interventions on this level were traditionally seen as part of the biological therapies, and received less attention from psychologists. However, with the advancements in knowledge also came greater acknowledgement of the importance of the bio-psycho-social model in optimising human (mental) health, and a renewed consideration of the role of psychologists. This poster discusses some of the ethical issues involved in the debate around the extent that psychologists should incorporate nutritional advice as part of comprehensive psychological service. This is done with specific focus on the South African context, and includes reference to the scope of practice of local psychologists, the absence of training regarding metabolic processes in professional programs at universities, the wider societal socio-economic situation, and limits to psychological involvement in metabolic processes. Some general guidelines are put forward, framed as conditions for psychological involvement, before the poster concludes with a few examples of specific potential contributions of psychology in either counselling patients directly, or supporting the nutritional interventions of other disciplines.

Exploring the relationship between meaning and health

Hanlie Van Wyk UNISA, South Africa

Research in Logotherapy substantiates the influence of meaning on psychological health and Psycho-neuroimmunology (PNI) corroborates the effects of psychological health on physical health. This research explores the relationship between meaning and physical health hypothesising that purpose affects physical health. The study employed secondary data (N = 1405) using a self-report questionnaire to test the hypothesis. Exploratory factor analysis, ANOVAs and stepwise regression were used to explore three models. Results EFA revealed four factors, purpose, purpose, fear, vitality and aggression. Significant correlations were found between purpose, vitality and work application. Despite the significant relationship between purpose and vitality, the lack of Chi-square is significant, suggesting that additional variables should be introduced into the model. Quantitative results revealed that people reporting high levels of purpose together with low levels of fear and aggression, can be characterised by high vitality and an absence of medical conditions. Future research should focus on evaluating meaning centred interventions on immunity and vitality.

Adjustment to aging and subjective age among Romanian and Portuguese older adults: A comparative multiple correspondence analysis for latent constructs

Sofia Von Humboldt ISP, Portugal; Isabel Leal

The purpose of this study was to analyse the manifestations of adjustment to aging (AtA) and subjective age (SA), identified by older adults and to investigate the latent constructs that can work as major manifestations in AtA and SA, in an older Portuguese and Romanian population. Measurements were completed, using a variety of culturally appropriate methods, including demographics and interviews. Complete data were available for 64 older adults aged between 72-99 years (M=80.1; SD = 5.8). Data were subjected to content analysis. Representation of the associations and latent constructs were analysed by a Multiple Correspondence Analysis (MCA). The most prevalent response of the interviewed participants for AtA was ‘accomplishment, personal fulfillment, and future projects’ (24.1%). ‘With apprehension’ (33.3%) was identified as the most frequent SA response. Finally, a model for each nationality, AtA and SA for Portuguese elderly were explained by a three-factor model: ‘conciliated’, ‘young-at-heart’ and ‘involved’. A three-dimensional model formed by ‘satisfied’, ‘attentive’ and ‘concerned’ was indicated as a best-fit solution for Romanian elderly. AtA and SA are strongly explained by increased likelihood of specific constructs in its definition. AtA was differently related to SA in older adults in both samples.

Neuropsychological and physiological correlates of covert racial discrimination

Monique Wilson Fordham University, United States of America; Rachel Annunziato

The purpose of the present study is to examine the hypothesised role of covert racial discrimination as a source of stress for African Americans (AA) as well as the hypothesised cognitive and physiological correlates of this stress process. The participants will be 40 AA between the ages of 18 and 30. Demographic information including gender, age, race/ethnicity, and relevant medical and psychiatric history will be obtained. Additionally, participants will be asked to provide both parents’ occupations and/or their current occupation in order to determine socio-economic status. Participants’ heart rates, blood pressure, attention, and memory will be assessed pre and post exposure to the experimental paradigm. Within subject comparisons will be made between pre and post measures in the experimental group. Additionally, between subject comparison will be made between the experimental and control groups. Results are not available for discussion at this time.

The influence of glycosylated hemoglobin A1 on neurocognitive functions in type 1 diabetic patients

Rafal Wojciak Poznan University of Medical Sciences, Poland; Alina Pereira

Several studies have shown that psychological functions in type 1 diabetic patients can depend on hypoglycemia and serum concentrations of glycosylated hemoglobin A1 (HbA1C). The aim of this study was to examine the neuro-cognitive function of a cohort of children and youths with type 1 diabetes in comparison to the serum concentrations of HbA1C. The study was carried out the 88 type 1 diabetic patients aged 6-17 years. Subjects were separated into 4 groups according to duration of diabetes (0, 1-3 years, 4-6 years, above 6 years; n = 19, 20, 25, 24 subjects respectively). HbA1C serum concentrations were measured during standard procedures. Neuro-cognitive functions were assessed by analysing all sub-scales of Wechsler Intelligence Scale for Children. Significant differences in serum HbA1C concentrations between sub-groups of diabetic children were found. In the first group of patients (after the first recognition of diabetes) the
highest mean serum level of HbA1C was observed. The lowest serum concentration of HbA1C was in the second group, and in the third and fourth groups HbA1C were increased. These results were associated with general intelligence in the children, as well as with some sub-scales of the test (verbal intelligence, non-verbal, organising images, words, and stacking blocks). The lowest values of neurocognitive functions were found in children with the longest history of diabetes.

**Disease as threat for health and life in adult cystic fibrosis patients**

Vladimir Yaltonsky MSUMD, Russian Federation; Natalia Sirota MSUMD, Russian Federation; Alexandra Yaltaoskaya MSUMD, Russian Federation

The objective of the study was to evaluate illness perception among adult patients with cystic fibrosis. For measuring cognitive parameters of illness perception, the Russian version of the Brief Illness Perception Questionnaire was used. Two groups of patients were identified. The first group perceives cystic fibrosis as a significant threat (N=38) and the other as a moderate threat (N=28). Patients from both groups were receiving in-patient treatment at the time of the study. The severity of cystic fibrosis, subject age, and gender were comparable in all patients. Patients who perceive the illness as a significant threat, reported a higher level in symptom identification and a lower level of personal and treatment control over the illness. They were very concerned by their illness, perceived consequences of the illness as severe, and reported a low understanding of cystic fibrosis. Their emotional response was higher than the other group. Hereditary background was named as the main cause of the illness. Patients with an illness perception as a moderate threat, had a lower level of symptom identification and were less concerned overall. They reported a higher level in personal control over the treatment and a good understanding of the illness. These patients saw the consequences of cystic fibrosis as moderately serious. Their emotional response to the illness was low. All indicated differences between the groups were statistically significant (p<0.05). Illness perception depends upon how threatening they assess cystic fibrosis for health and life. The patient’s perception of illness perception does not always match objective parameters.

**Quality of life among Vietnamese- and Chinese-American breast cancer survivors**

Jenny Yi University of Houston, United States of America; Krystal Luong

This study is to examine the relationship between acculturation, health literacy, and quality of life (QOL) among Asian American women with breast cancer. Study inclusion criteria were as follow: (1) 18 years or older, (2) provided informed consent, and (3) diagnosed with breast cancer at least six months and less than five years prior to study entry. Bilingual researchers conducted individual, face-to-face, semi-structured interviews in Cantonese, Mandarin, English, or Vietnamese with 72 Chinese and 26 Vietnamese women with breast cancer. A majority (75%) of the participants did not participate in breast cancer support groups. The mean age was 57.4 years old. Mean years of residency in the US were 21.8. Of the whole sample, 33% (n=32) reported having the ability to understand, read, speak, and write in English very well. We used the Quality of Life-Breast Cancer Patient Version, to assess quality of life. Based on scoring of 0 (worst outcome) to 10 (best outcome), the overall QOL score was 4.75. Comparison of the four domains indicates greatest needs in the area of physical well-being followed by social well-being, psychological well-being, and spiritual well-being. English proficiency, health literacy, and length of residence in the US were significantly associated with QOL scores. The findings of this study may contribute to the planning and implementation of care that can enhance the quality of life significantly for cancer survivors with limited English proficiency.

**Global health and the role of psychology**

Omomole Amuleru-Marshall St. George’s University, Grenada

Ever since the Declaration at Alma Ata in 1978, the vision of “Health for All”, with Primary Health Care (PHC), positioned as its requisite health care model, has been a hauntingly elusive ideal. Societies, small and large, developing and developed, have made unsuccessful attempts to reform their health systems according to the values, principles and elements of PHC. Within the region of the Americas, the Declaration of Montevideo reaffirmed, in 2005, the commitment to PHC reforms in Latin America and the Caribbean. This presentation will elucidate the principles and elements of PHC and attempt to build a persuasive case that health system reforms based on this model - hence “Health for All” - are unattainable without the significant involvement of psychological science. Since, conventionally, the discipline of psychology has limited its purview to the psychobehavioral phenomenology of individuals, indeed, largely to the aberrant or pathological behaviours of individuals, an argument will be advanced for an integrative and comprehensive application of psychology to public health. The field of public health forces psychology to have collective and systemic targets for research, analysis and intervention. Moreover, it requires psychological intervention to promote health and prevent, rather than merely repair, illness. The thrust of this presentation is that contributions from social, community, organisational, counselling and health psychology, are required in order for the global vision of “Health for All” to be incrementally concretised.

**Psychological science foundations of clinical pain management**

Kenneth Craig University of British Columbia, Canada; Geert Crombez; Amanda Williams; Philip Jackson; Simon Rysyewky

Pain of clinical severity remains a distressingly commonplace human problem, whether one considers acute pain arising from disease or injury, chronic pain related to terminal illness or chronic non-malignant pain. Too often, contemporary pain management and our research-based understanding of pain have proven inadequate. Basic psychological science offers important insights and potential for improved understanding and clinical interventions. An evolutionary model of pain as one of the family of emotions – perhaps the fundamental negative emotion – challenges us to explain what pain means for the person experiencing it in him/herself and for those close by who are aware of the person-in-pain’s experience. To what extent is pain a ‘false alarm’ and to what extent is it always a warning? Not only the person feeling pain acts on its meaning, but so do those around him or her. Different social contexts determine expression and suppression of pain, and the recognition of pain in others. Some of the predictions from the evolutionary model can be tested empirically, others provide alternative explanations for clinical phenomena associated with undertreatment, or for observations in lab and wild animals. Why are all pain patients unique? This presentation suggests that pain is intrinsically psychological, and the result of a complex construction of bodily awareness. Pain is not a primitive sensory message of tissue injury that is ‘interpreted’ at the threshold of consciousness, but, like all perception, a multifaceted emergent property of brain activity. Since each individual constructs his or her pain from a complex and highly individual reality, a constructivist view may explain why pain patients are all unique. Interventions directed at nociceptive pathways can also intervene in the construction of the pain experience itself. Clinical applications of this possibility are outlined. Pain is the result of a dynamic system that codes, transports and processes signals of potential tissue damage. We present an integrative, cognitive-motivational model of pain in which two modes of attentional selection are distinguished: (1) Bottom-up selection corresponds to an unintentional stimulus-driven capture. Important features for bottom-up selection are novelty, intensity, unpredictability, and the threat value of pain. Top-down selection is a goal-directed process that prioritises information relevant for current actions, and inhibits the sensitivity of irrelevant stimuli. After providing experimental and clinical evidence for this model, we discuss the implications for the use of attentional strategies to control pain. The subjective nature of pain renders its perception in others a challenge for clinicians and informal caregivers responsible for its assessment and relief. Adequate perception of others’ pain relies on different behavioural and neurophysiological mechanisms. This talk will discuss recent evidence showing how the perception of pain in other individuals is related to patterns of brain response similar to those found when people are in pain. The extent of this “shared representation” of pain depends on several individual, relational and contextual factors. Current work is being conducted to determine whether this representation, which can integrate different dimensions of pain, is related to the prosocial stance caregivers adopt towards patients, and whether changes in this representation are associated with changes in pain care. Kenneth D. Craig also presents on Perceiving pain in others: A dual processing model.

**Increasing psychology’s role in health research and health care**

Suzanne Bennett Johnson Florida State University, United States of America

Although psychology has traditionally focused on mental health, the role of human behaviour in a larger health context has become increasingly apparent. Over half of the world’s population is living
Health and well-being in human populations are constructed and appropriated in the context of cultural-historical activities important to the identity of segments of the cultural enactors, or participants. The cultural historical activities are often realised in implicit encoded messages that have controlling effects of members’ beliefs about appropriate messages and practices to restore, promote and sustain health. In the context of collectives such as organisations, the controlling beliefs constitute an epistemic environment that primes participants to receive certain messages rather than alternative or competing ones. The paper presents three studies in which applied cultural historical activity theory (CHAT) and concept mapping study prospective health and well-being in faith-based and secular organisations in African settings. CHAT considers organisations and their constituents (members) as active learners in a socio-cultural process, foregrounded by historical learning experiences. Concept mapping is a mixed method deductive-inductive approach to constructing social reality from the viewpoint of cultural participants. Findings suggest that culturally embedded practices provided social capital for health and well-being to church members. However, the same practices had the paradoxical effect to minimise decision-making by church women and child members, which potentially compromised their health and well-being. Church and secular school settings promoted messages and practices for health and well-being that prioritized values congruent with their unique knowledge ideologies. Implicit knowledge values held by church and secular organisations had consequences for the prospective health and well-being of the membership.

Health behaviour change: Theoretical constructs, dynamic mechanisms, and clinical interventions
Ralf Schwarzer Free University Berlin, Germany
Health-compromising behaviours such as physical inactivity and poor dietary habits are difficult to change. Most social-cognitive theories assume that an individual’s intention to change is the best direct predictor of actual change. But people often do not behave in accordance with their intentions. This discrepancy between intention and behaviour is due to several reasons. For example, unforeseen barriers could emerge, or people might give in to temptations. Therefore, intention needs to be supplemented by other, more proximal factors that might compromise or facilitate the transition of intentions into action. Some of these post-intentional factors have been identified, such as perceived self-efficacy and strategic planning. They help to bridge the intention-behaviour gap. The Health Action Process Approach (HAPA) suggests a distinction between (a) preintentional motivation processes that lead to a behavioural intention, and (b) postintentional volition processes that lead to the actual health behaviour. In this presentation, studies are conducted with different samples to examine the role of volitional mediators, in particular perceived self-efficacy, in the initiation and adherence to health behaviours (e.g., physical exercise, breast self-examination, seat belt use, dietary behaviours, condom use, sunscreen use, dental flossing). The general aim is to examine the effects of self-efficacy on health behaviour change based on various behaviours, time spans, and study participants, from different countries.

Cross-cultural evidence-based health/psychotherapy research among North America, United Kingdom, China, Korea and Japan
Convenor: Akira Tsuda
The outcome of trans-theoretical model (TTM)-based stress management and its association with well-being
Yoshiyuki Tanaka Kyoto Tachibana University, Japan
In this presentation: how to provide Trans-theoretical model (TTM)-based stress management for Japanese university students, the effects of the programme, and the role of subjective well-being in the programme will be explained. Over 600 students participated in a programme that was provided through the Internet and a workbook. On first accessing the webpage, they assessed their stress and coping level, and four basic components of TTM: stage of change, decisional balance, self-efficacy, and process of change. Based on the assessment, they read each page in the workbook and practiced by themselves. The book is constructed in such a way that the participant needs to readjust pages fit to his/her stage. The participants moved to the later stage, when their stress level was decreased. Within the participants who had not managed their stress before the intervention, most of them moved to the later stage independently of their subjective well-being. The stage shift within the subjects who had been engaged in stress management was related to their subjective well-being. They continued to practice managing their stress, if they had felt enough subjective well-being. TTM-based stress management is effective to preserve and improve mental health, even if it is not intended for the individual to manage his/her own stress. Moreover, the results showed that practitioners and researchers should study their subjects’ subjective well-being, in order to plan a preventive health practice, especially when his/her mental health is not problematic.

Church and secular epistemic environment effects on health and well-being in African settings
Elias Mpofu University of Sydney-Cumberland, Australia
There could be cathedrals of the spirit as well as stone: An overview of Australian aboriginal and Torres Strait Islander people and psychology
Patricia Dudgeon University of Western Australia, Australia
This presentation will provide an overview of Aboriginal and Torres Strait Islander peoples and the struggle to have indigenous concepts of social and emotional wellbeing recognized and needs met by non-indigenous mental health systems and service providers. This examines the impacts of Australia’s colonial history on indigenous individuals, families and communities. Aboriginal peoples’ resilience and struggle to claim equality and cultural recognition will be highlighted. The history of the discipline and practice of psychology with Australian Aboriginal and Torres Strait Islander people in relation to mental health will be included. Psychology’s key points of engagement with Aboriginal and Torres Strait Islander people will be examined. Whilst acknowledging that psychology has been part of the colonizing process through cultural and institutionalized racism, there is reason for optimism and the potential for empowerment and inclusion of Aboriginal and Torres Strait Islander peoples in the discipline. This brief overview concludes with some important milestones in psychology and Aboriginal and Torres Strait Islander mental health, pointing to positive ways that psychologists can work together to bring about improved social, emotional and spiritual wellbeing for Aboriginal and Torres Strait Islander Australians.

expression of perceived and actual physical pain, psychological distress, and contributors to medical illnesses. In practicality, the biopsychosocial approach is a means to an end in the understanding of how the client’s subjective experience contributes to the clinical diagnosis, observed health consequences, and allows the clinician to develop multifaceted treatment interventions. Currently, a series of cross-cultural studies for stress-related psychological and social factors have been conducted at our laboratory in Japan and collaborative institutes. Emerging data from these cross-cultural studies have indicated that psychological and social factors can be used to predict various health markers commonly affecting the physical conditions reported by patients. In some cases these health markers can be culturally unique and encapsulated within the societies in which the patient resides. Thus, research finding may be assist in the development of effective clinical interventions of highly prescribed cultural and clinical relevance.

Symposium title: Health psychology across cultures: Asian perspectives

Status of health psychology in Malaysia
Kumaraswamy Narasappa (University Malaysia Sarawak, Malaysia)
Counselling is an increasingly important direct service provided by health psychologists in Japan. The basis of health counselling is helping client maintain behaviours that promote health and prevent illness. In a process of counselling, clients need to learn how to achieve personal growth, improve interpersonal relationships, resolve problems, make decisions, and change unhealthy behaviours, from the perspective of health psychology. In this presentation, the theoretical frameworks and the types of health counselling practiced by juvenile guidance counsellors in Japan will be discussed. Also, to optimise support in the network, characteristics of support interventions and some theories and concepts relevant to the design and evaluation of the supportive interventions will be discussed. Health counselling for juveniles involves assisting them to achieve their maximum state of well-being and to prevent juvenile delinquency. In terms of prevention of juvenile delinquency, counselling for primary prevention tries to teach clients information and skills, and to reduce their risk of developing problems. Counselling for secondary prevention tries to prevent the progression of the problem through early detection and prompt intervention. Counselling for tertiary prevention focuses on helping clients understand their situation, and to cope with restoring functioning. In each level, the skills of Micro-counselling and REBT are effective.

Culture-specific social skills for sojourners in cross-cultural interpersonal relations
Tomoko Tanaka (Okayama University, Japan)
Health in transition is an important subject in the current society. Further interpersonal relations are critical for sojourners because they could be both difficult and supportive with regard to cross-cultural adjustment. Social skills deficiency in the new social-cultural context disturbs interpersonal relations, and skillful individuals have an advantage in that they get into comfortable situations. Usually, sojourners usually are not familiar with new cultural skills at the beginning. Psycho-educational intervention of cross-cultural social skills learning could be one of the ways for providing health support in socio-cultural contexts. I will introduce the basic concept, the design of the learning session and its effects on international students in Japan.

Contemporary and combined use of hypnosis and relaxation techniques in pain therapy
A pilot study
Andrea Carta Hsa, Italy; Chiara Pizzagalli; Cesare Basilio
This study is aimed at evaluating the efficacy of treatment combining relaxation techniques and hypnosis therapy in a sample of patients with chronic pain, compared to that of treatment based on relaxation practices in the absence of psychological support. Evaluation will be made before and after the sessions of treatment, which will be different for each of the three sub-samples: one group will undergo combined treatment, another will only be treated with relaxation techniques, the third one will be a control group and will not undergo any type of psychological treatment. Evaluations will give a subjective and objective measure of the pain suffered, and the level of the quality of life as reported by the patient. Moreover, the study will include measurements of the personality traits of the subjects, to verify if the efficacy of the treatment may vary depending on the subjects’ personality differences. Finally, pharmacological compliance will be evaluated before and after treatment, to highlight differences.

Functional psychology: A pilot study in subjects affected by chronic lumbar pain
Valentina Cincotto (Associazione Centro di Psicolog, Italy; Roberta Rosin; Irene Leo; Francesco Caccherelli)
The aim of this research was to investigate the correlation between tonic-postural system, MMPI-3 s profiles and the individual’s basic functioning, in twenty subjects assessed for chronic lumbar pain. The subjects were examined by functional diagnostic psychological interview, diagnostic medical examination (anesthetic visit), and tonic-postural visit. The subjects filled out the MMPI-3, V.A, S and McGill Pain Questionnaire. This study used multivariate analysis of results (SPSS). Correlation indicated that Depression, Social Introposition, and Hypochondria spikes were significantly related to more severe pain and were associated with higher difficulty of movement. Our results suggest that pain rehabilitation programs provide directed intervention on emotions, tonic-postural system and individual’s basic functioning. Functional Psychology represents one of the possible integrated methods of cure.

Psychology in rehabilitative cardiology to tune life style up
Silvana Piazzi Hsa, Italy; Alimee Ferreira
Psychological support in a rehabilitative cardiology ward contributes to the cardiopathic patient’s well-being and to that of his/her family. Moreover it strengthens motivation to adopt the necessary changes in lifestyle. Clinical practice confirms the benefits of combining different forms of psychological support. The psychological interview facilitates the process of clarification with regard to personal objectives, evolution of the new phase of personal life and self perception as cardiopathic patient; it activates personal resources in order to better cope with emotional stress. Group work on relevant issues offers an opportunity for dialogue and confrontation on psychic dynamics, convictions and cultural models which can hinder or facilitate the assumption of healthy lifestyles. Combined psychological support activates in cardiopathic patients compliance with better behaviours, a new pace in personal lifestyle in line with the requests of the heart pathology.

Symposium title: Healthy participation in context: Attributes, performances and systems

Classification system for rehabilitation interventions for health and wellbeing across the life span
Francoise Joseph Illawarra Health, Australia; Elias Mpoju; Richard Madden
Objective. Health interventions for meaningful participation are addressed at many levels or rehabilitation and health care: individual patient, the treatment
team, and institution providing care. This presentation proposes procedures for classifying health interventions for optimal participation by combining variable and case-oriented analysis of target treatments in a subacute hospital treatment setting. Methods. For the prospective optimal participation classification system for rehabilitation interventions, we applied reflective case analysis approach to trial its utility in rehabilitation medicine setting. Case studies were drawn from patients who were admitted to a subacute hospital ward for rehabilitation and requiring at least three rehabilitation interventions. Data were examined for convergence among systems to mark optimization of interventions applying target, action, and means qualities. Results and Conclusion. The prospective classification of rehabilitation interventions system yielded high specificity in the target, action and means for interventions beyond possible using conventional approaches. Combined use of target, action and means led to the optimal selection of rehabilitation interventions likely to result in a person's functional classification. The quality of activity participation offer a multi-dimensional (at body, activity and participation/social levels) created by the interaction of health conditions together with personal and environmental factors, and to compare the experiences of a given patient over the course of his or her treatment.

Symposium overview

Jon Sanford Georgia Institute of Technology, United States of America
Participation is a key indicator of health and well-being across human populations (World Health Organization, 2001). Understanding influences on participation requires a careful consideration of its drivers, the qualities of the types of data that define participation, procedures to construct or classify participation, and the ways participation is enacted in human populations. The symposium proposes to address aspects of participation applying constructs from the World Health Organization’s International Classification of Functioning, Disability and Health (ICF). The specific objectives of the symposium are to: characterize qualities of data for authentic participation by persons in their choice activities; propose a model for environmental influences on participation; operationalize key constructs for rehabilitation interventions for optimal participation; and apply ICF participation concepts to living with chronic illness or disability.

An ICF-based model for assessing environmental barriers and facilitators to activity and participation

Jon Sanford Georgia Institute of Technology, United States of America
Many methods may be used to assess environmental contributions to performance. However, few adequately address the key person, press, and performance factors essential to developing effective environmental interventions for health and wellbeing. Such information is essential to eliminating environmental barriers and identifying environmental interventions as effective rehabilitation strategies across the lifespan. To ensure valid, reliable and inclusive assessment of the environment, this presentation proposes a comprehensive model that builds and expands on the relationship between capacity and contextual factors as they define barriers and facilitators and impact activity and participation. The model I will present draws on the ICF, current literature on environmental assessment, and ecological models of person-environment interaction. The analytical approach is to resolve seeming differences in the interactions among key person x environment constructs to create a prospective model that incorporates and accounts for activity and participation in preferred environments. The proposed model provides a framework for gathering assessment information by accounting for the interactive effects of body function/structure and the full range of environmental demands (i.e., press), including individual factors (e.g. preferences and values), environmental factors include physical factors (e.g., attributes of space and products), social factors (e.g., values), and organizational factors (e.g., policies). External factors (e.g., legal restrictions, availability of interventions) outside

Indicators of health living with HIV and AIDS in Zimbabwean community setting

Tecla Mlimbo University of Zimbabwe, Zimbabwe; Lovemore Gwanzura; Simbarashe Rusakaniko
Objectives: AIDS has become a chronic disease due, in part, to the increased availability of anti-retroviral (ARV) treatments in Zimbabwe. Knowing the extent to which people living with AIDS can meaningfully engage in normative activities of daily living is important to their health and wellbeing. The study sought to determine the activity limitations and participation restrictions (disabilities) experienced by adults living with HIV and AIDS who are on ARVs and the factors associated with health and wellbeing. Methods: A cross-sectional analytical study was done with 59 consented HIV positive adults on antiretroviral drugs attending an opportunistic infection clinic. Mean age was 41 years (+/-9.3), 56% were female, 54% were married and 30.5% were widowed. Mean period on ARVs was 19.5 months, mean CD4 count was 223 (+/- 153). An ICF-based questionnaire was administered on consecutive patients receiving treatments for a typical community clinic. The analyses sought to isolate factors to explain success with instrumental activities of daily living with AIDS. Results and Conclusion: About 36% and 61% either stopped or reduced their usual activities due to the illness respectively. Most affected aspects of instrumental activities of daily living engaged in were: lifting and carrying objects, shopping, housework, remunerative employment and economic self-sufficiency. The quality of activity participation was influenced mostly by physical health, mental and emotional health, and use of assistive devices. Physical wellbeing from use of antiretroviral drugs enabled participation and promoted socio-emotional wellbeing. The effects of ARVs have multiplier benefits to the health and wellbeing of those living with AIDS.

Relationship between the ICF and authentic assessment

Thomas Oakland University of Florida, United States of America
This presentation is intended to examine the relationship between the WHO’s International Classification of Functioning, Disability and Health (ICF) and authentic assessment. The presentation will discuss the ICF model that views disability as multidimensional (at body, activity and participation/social levels) created by the interaction of health conditions together with personal and environmental qualities. Assessment models consistent with the ICF may lead to a better understanding of whether a person has acquired desired activities (e.g. tasks a person is able to perform) and desired participation (e.g. tasks a person does perform and that become integrated into ones life). Activities and participation include the assessment of qualities in nine domains: learning and applying knowledge; general tasks and demands; communication, mobility, self-care, domestic life, interpersonal interactions and relationships; major life areas; and community, social, and civic life. Authentic assessment methods highlight the importance of eight features: acceptability, authenticity, collaboration, evidence, multifactors, sensitivity, universality, and utility. These methods are consistent with those associated with the implementation of the ICF. The combined use of the ICF model and authentic assessment methods offers a framework for assessing and thus describing human functioning dimensions that complement and extend purely diagnostic information. Information about one’s diagnosis or diagnoses coupled with information about functioning offer a multi-dimensional description of an individual’s current clinical picture and environmental factors that may buffer, exacerbate, or otherwise affect that picture. The use of authentic assessment methods within an ICF model allows mental health care practitioners to describe the whole health experience, including environmental factors, and to compare the experiences of patients with different conditions. Their use also allows us to compare the experiences of a given patient over the course of his or her treatment.

Community participation solutions with regard to chronic illness or disability

Elias Mpofu University of Sydney-Cumberland, Australia
This study investigated influences on preferred community participation options with regard to chronic illness and disability. The WHO International Classification of Functioning, Disability and Health (ICF), considers participation important to health and wellbeing. The study involved the participation of 68 individuals with disabilities who sought services from Centres for Living (CILs) in Central Pennsylvania (67% female). 60% of the participants displayed neuromuscular conditions, while 25% had cardiovascular conditions and 15% had other health conditions. Data were collected through means of participants’ responses to an open-ended statement probe to nominate influences on their choice of community living solutions. Data were analysed using concept mapping - a mixed method approach to construct informant-oriented clusters of choices for community living. Results showed that persons with more severe disabilities prioritised service and community access issues as being relatively more important to their participation than did those with less severe disabilities. Involvement with others in the social network was perceived to be important for community participation. Participation in leisure activities was regarded to yield health-related benefits. Disability-friendly policies added to the perceived access to preferred community living options. It was concluded that preferred community participation solutions with chronic illness and disability emphasise social inclusion qualities and that severity of disability influences the salience of infrastructural access issues to community participation.
the control of the individual and task factors (e.g., requirements of the activity, including lifting, pulling, and bending) are addressed with use of this multifaceted model.

**Symposium title: Mental health, neuropsychiatric assessment and integrated health services**  
Convenor: Michela Colombo

**Medical humanities and multiculturality**  
Eleonora Capovilla  
IOV Istituto Oncologico Veneto, Italy; Aimee Ferreira

Illness and death are conditions that put to test all our physical, psychological, functional, social and spiritual being. In the process of oncological pathology and the approach to death, the interplay of emotions, affections, psychosomatic states, life philosophies, spirituality, very little represented in medical or socio-sanitary works, develops in a peculiar way. To know what the oncological pathology is like in the different cultures means modifying and extending our opportunity to communicate and develop an efficient therapeutic relationship with the patient. This work presents a general outline of international psycho-oncological literature about the relationship and communication with patients from foreign countries in the light of the different cultures. Medical Humanitarians can also offer an important contribution to the treatment of oncological pathology in multicultural contexts. Medical Humanitarians are a group of disciplines which analyse the way human sciences (literature, poetry, philosophy, ethics, history and religion), social sciences (anthropology, psychology and sociology) and the arts (literature, music, theatre, cinema and visual arts) can influence education and medical practices. They integrate the scientific knowledge of the body with the knowledge of the patient's life experience, within his own history and personal culture, keeping in mind that health is not only physical welfare but also a psychological and social state. In this area we will refer to our MBSR (Mindfulness Based Stress Reduction) experience, addressed to oncological patients, aiming to improve the patient's capacity to cope with his suffering and to better meet his spiritual needs.

**Critical perspectives on the MDGs**  
Brendon Barnes  
University of the Witwatersrand, South Africa

This symposium brings together five papers that critically engage with the assumptions of the UN millennium development goals (MDGs) and other global development frameworks through the lens of critical psychology. Building on a special edition of the Journal of Health Management published in 2009, the authors offer a range of critiques of the MDGs that are often overlooked in the mainstream. These include papers that highlight how critical psychologists have sought to recover the marginalised voices of those affected by development (Kumar) as well as to deconstruct and re-develop notions of development and change in the first instance (Bradbury & Clark). Papers also highlight the politics of development through, for example, gender mainstreaming (Palmary & Nunez) and alternative economic development models such as public-private partnerships and social entrepreneurship (Moodley as well as Barnes & Milovanovic). Throughout the symposium, presenters deconstruct taken-for-granted concepts such as community, participation, justice and citizenship and, in so doing, offer the space to discuss the possibilities and limitations of critical psychology within the realm of development.

**Symposium title: The state of psychology in Zimbabwe**  
Convenor: Gwatirera Javangwe

**Health psychology in Zimbabwe**  
Tunashe Muromo  
University of Zimbabwe, Zimbabwe, Zimbabwe

Whilst clinical psychology has played an important role in Zimbabwe, the present paper demonstrates how health psychology has been influential in solving some of the health problems bedeviling Zimbabwe. The paper also concludes by focusing on the future of this filed in Zimbabwe and on how a collaborative approach can lead to fruition.

**Symposium title: Critical perspectives on the MDGs**  
Convenor: Brendon Barnes

**Session Type: Symposia**

**Symposium title: Food, water and the politics of need: A Critique of alternative economic development approaches in the context of MDGs**  
Brendon Barnes  
University of the Witwatersrand, South Africa; Minja Milovanovic

The millennium development goals are premised on particular assumptions of (under)development with very little interrogation of what development is or how it should be achieved in the first instance. Drawing on examples from the author's work in the fields of water access and food insecurity in South Africa and India, this presentation focuses on three popular alternative economic development approaches (to pure capitalism or socialism) public/private partnerships, corporate social initiatives and social entrepreneurship, each of which lay claim to a particular kind of development that attempts to balance, to varying degrees, capital and the social. Underlying each of these development approaches, however, are problematic discourses of need, agency, participation and citizenship that ultimately serve to place the source of and solution to the problem at the level of the community. Such discourses not only reinforce psychologist accounts of the problem but, importantly, leave the structural determinants of poor water access and food insecurity in the Global South relatively untouched. The paper concludes with a discussion of the possibilities and limitations of critical psychology in its various guises within the context of (under)development in the Global South.

**Changing goals: Reformulating a research agenda for social change**  
Jill Bradbury  
WITS, South Africa; Jude Clark

This paper engages the framework provided by the millennium development goals to think about the possibilities and constraints for change. The goals are identified on the basis of research that describes the current context of global inequalities along particular dimensions and programmes of intervention are proposed with timelines for the achievement of quantifiable indicators. The research programme is thus articulated in the tasks of documentation and measurement and offers little by way of understanding or explaining what makes change so difficult. If a research agenda aims to contribute to social change, it must entail theorising the relations between structure and agency in terms of dimensions such as gender, national identity and childhood / youth. We suggest that narrative methodologies may offer a productive alternative trajectory for exploring the connections between social and psychological realities and thinking about what makes change possible or impossible.

**Global development and transnational collaboration: What can psychology help re-deem?**  
Manasi Kumar  
University of Nairobi, Kenya

This paper reflects on the politics of global development programmes, such as MDGs, which seek to eulogise a partisan needs-based discourse of socio-economic development. Developing Burman’s (2010, presented at ISTP Nanjing) suggestion that critical psychologists have to deliberate on the nature of transnational coordination around such development projects so that an engagement with development issues and public policies enables recovery of marginalised voices and standpoints. In this process the paper highlights how psychologists have sought to unequivocally intervene and address the larger ramifications of initiatives such as MDGs (Kumar and Burman, 2009). The paper also discusses the exigencies of critical transnational and multidisciplinary research partnerships and how psychology can challenge the biases of policy planners and decision makers by deconstructing the development discourse.

**Critical reflection of handwashing behaviour change interventions in context of development**  
Janice Moodley  
Wits, South Africa

Intense advocacy for handwashing with soap initiated by multinational organisations and initiatives, through the formation of the Public Private Partnership for Handwashing with Soap (PPPHWS), has catalysed the promotion of handwashing behaviour change interventions in developing countries. Aligned with goal 4 of the Millennium Development aimed at reducing infant mortality by two-thirds, the PPPHWS enlisted the consumer marketing expertise of the three largest soap manufacturers - Unilever, Procter and Gamble, and Colgate Palmolive. Despite being situated within the globalisation, economic development, and neoliberal discourses that have very distinct political implications the PPPHWS has been presented as apolitical, with handwashing to prevent infectious diseases advocated as a universally applicable, taken for granted, truth. The appeal of private-public partnerships to save lives appears to be sincere, socially uncontestable and morally justified. However, inherent political conflict resides at the nexus of profit-driven interests of the private sector and the welfare-driven interests of the target communities. While the internet and academic literature are replete with articles putting the advantages for
global handwashing alliances between public and private sectors, there remains a dearth of literature that critically examines the variety of discourses prevalent in the global handwashing movement and the possible political implications thereof. The aim of this paper is therefore to investigate and reveal the underlying discourses manifest in handwashing behaviour change interventions in developing countries and the political implications thereof while contributing to the expansion and contextualisation of the existing body of Critical Health Psychology (CHP) literature to developing countries.

Reflecting on gender mainstreaming as a strategy for accomplishing the MDGs
Ingrid Palmary
University of the Witwatersrand, South Africa; Lorena Nunez
This paper is a reflection on the practice and theory of gender mainstreaming in the context of the Millennium Development Goals (MDGs). In this paper, we ask whether gender mainstreaming represents a strategy that will further the accomplishment of the MDGs, what the central difficulties are in achieving mainstreaming and, indeed, whether and for whom it might be desirable at all. In doing so, we are drawing on the author’s experiences of drafting gender mainstreaming guidelines which, while not to be confused with gender mainstreaming as a practice, have become one of the central mechanisms by which gender equality is thought to occur in development practice. The paper outlines the tensions and sticking points in this process of developing the gender mainstreaming guidelines. These sticking points - where issues could not be resolved or faced particular resistance - are emphasised because, as we will argue, they reflect difficulties and preoccupations of the feminist movement more generally and highlight the ways in which feminist ideas have at times been popularised and re-worked in what, we will argue, are profoundly anti-feminist ways. Although we would hope these tensions in feminist thinking are potentially productive, we would argue that in the context of donor driven research and practice in the African context, they are unlikely to be. As such, this is a paper reflecting on the power of discourse: Discourses on equality, justice and gender that are used and negotiated by different interest groups in different ways and with very different consequences.

Symposium title: Innovative interventions in health psychology
Convenor: Stan Maes
Motivational interviewing and self-regulation to increase physical activity in patients with rheumatoid arthritis
Veronique De Gucht
United States of America
Physical activity benefits patients with rheumatoid arthritis (RA). This study examined the effects of a theory based psychological intervention to increase PA among patients with RA. 78 sedentary patients with RA were randomised to receive a 1-hour patient education session, a motivational interviewing and 2 self-regulation sessions (MI+SR group), or the patient education session alone (control group). Patients filled-in questionnaires assessing PA, autonomous motivation (AM), self-efficacy (SE), self-regulation skills, and pain at baseline, and after 8 and 32 weeks. Results: At 8 weeks, the MI+SR group had significant improvements in days per week with at least 30 minutes of PA, AM and SE compared to the control group, and greater self-regulation skills. These between-group differences in improvements remained significant at 32 weeks. Conclusions: The MI+SR intervention outperformed the control group in terms of sustained increases in PA, and these effects are likely mediated by improvements in AM, SE, and self-regulation skills. This study demonstrates that a minimally intensive, low-cost MI+SR intervention leads to sustained PA at 32 weeks; however, due to pain increases within the MI+SR group, future interventions might pay more attention to pacing and suitability when increasing PA.

Managing behaviour towards diabetes
Elaine Leventhal
Robert Wood Johnson, Medical, United States of America; Elaine Leventhal
Longitudinal studies and RCTs suggest that Self Monitoring Blood Glucose (SMBG) can improve control of blood glucose. However, a few large trials show no benefit of SMBG monitoring. To gain insight into how patients achieve control, we conducted sessions with 8 to 10 diabetics in each of 3 groups (four 2 hour sessions per group) and identified how participants understood and acted (using SMBG) following exposure to a common-sense based behavioural education program. One session focused on how to evaluate the effects of a food eaten at that session, with SMBG taken before and 1.5 hours post-eating; another session examined walking. An average (2 to 3 month levels) glucose levels were evaluated at baseline and 2 months post. Qualitative data illustrate how patients achieved insight in SMBG. An “expert” approach asked patients in excellent control and patients and those whose medication had been reduced, to state how they would advise a patient having difficulty with blood glucose control (specified in scenarios). Patients were asked and/or responded spontaneously as to how they overcame such obstacles. We report on the strategies and tactics extracted from their responses to illustrate how patients achieve control in their home environments.

A randomised controlled trial of a self-regulation program for lifestyle maintenance in post-cardiac rehabilitation patients
Stan Maes
Leiden University, Netherlands
As lifestyle adherence and risk factor management following completion of cardiac rehabilitation (CR) have been shown to be problematic, we developed a brief self-regulation lifestyle program for post-CR patients. Design Randomised-controlled trial. Following completion of CR 210 patients were randomised to receive either a lifestyle maintenance program (n=112) or standard care (n=98). The program was based on self-regulation principles and consisted of a motivational interview, group sessions and home assignments. Risk factors and health behaviours were assessed at baseline (end of CR) 6 and 15 months thereafter. ANCOVAs showed a significant effect of the lifestyle program after 6 months on blood pressure, waist circumference and physical activity (pedometer assessment). At 15-month follow-up these changes were sustained for physical activity, but not for any of the risk factors. This trial indicates that a relatively brief intervention based on self-regulation theory is capable of instigating beneficial changes in lifestyle and risk factors after CR.

Innovative interventions in health psychology
by Stan Maes
Leiden University, Netherlands
In this symposium several innovative interventions, based on self-regulation theory, are presented and discussed. Elaine Leventhal will present a study that gained insight into how diabetic patients achieve control over the monitoring process after exposure to a self-regulation based behavioural education intervention. Marta Marques will report on the effects of a self-regulation programme for patients suffering from ideopathic chronic fatigue. Veronique De Gucht will report on a self-regulation programme to increase physical activity, delivered by physiotherapists and nurses to sedentary rheumatoid arthritis patients. Finally, Stan Maes will report on the effects of a self-regulation programme for post-cardiac rehabilitation patients on risk factors and life-styles. The discussion will try to identify overarching guidelines for future interventions.
A self-regulation based program to promote physical activity in those suffering from chronic fatigue

Marta Marques & Marta Marques

Chronic Fatigue (CF) is characterised by the presence of severe medically unexplained fatigue, affecting patients’ functionality. Physical activity can contribute to the reduction of fatigue. Based on the self-regulation (SR) principles of behaviour change, we developed the "4-STEMS to reduce your fatigue" program. This was a randomised controlled trial (RCT), carried out in Portugal. CF patients were randomly allocated to standard care or the 4-STEMS program. The intervention consists of a motivational interview and brief telephone counselling sessions, in which a physical activity goal is formulated. Patients are assessed at baseline (T1), and three (T2) and 12 months (T3) after. Primary outcomes are fatigue severity and persistence of CFS. Results and Conclusion: 89 CF patients have been enrolled in the study (M=47.39; 97.8% women). No significant differences between both groups were found at baseline. At T1, only 14.6% of the CF patients engaged in regular physical activity. Moreover, higher physical activity levels significantly predicted lower fatigue severity (p<.001) and better physical functioning (p<.05). The results of the RCT (T2) will be presented in the symposium.

Positive and negative health-related consequences of technology (over)use in children and adolescents

Francoise Theurel University of Free State, South Africa; Henriette van den Berg University of Free State, South Africa

This presentation aims to determine the benefits and disadvantages of ICT use among adolescents. Children and adolescents across different cultures, continents and socio-economic backgrounds spend increasingly more time engaging with technology and media. Recent studies on the effects of technology and media (over)use on children and adolescents' health and well-being have highlighted both the beneficial as well as detrimental nature of the interplay between man and digital-machine. A cross-sectional design was used. The sample consisted of 1210 adolescents from the Free State Province, South Africa. Data was gathered using questionnaires assessing the effects of ICT use on the well-being of participants. A regression analysis was performed to determine the relationship between the frequency and nature of ICT use and well-being of participants. Results highlighted that the positive effects is associated with accessible health-information and the fostering of social connectedness, whilst negative consequences relate to effects on increased emotional dysregulation and risk-taking behaviour, decreased physical activity levels, sleep problems and academic difficulties. Empirical-based recommendations to increase the health benefits of technology and media use (and thus reduce harmful practices) for developing children and adolescents are discussed.

Brazilian youth concepts of mental health from a culture perspective

Camila Aquino-Morais Universidade de Brasilia, Brazil

This study intends to present quantitative data of the research "Mental health conceptions and service perceptions on the perspective of the young generation and their families" carried out with a sample of 1163 young Brazilians, with an average age of 15.84 years, from different regions of the country, being 53.2% female and 46.8% male; 42.8% white, 42.3% brown and 12% black; and 697 caregivers of both sex. The survey was conducted with participants from different social and economic levels that use different models of health assistance. The conception of the youth mental health was associated with three main factors: personal well-being, relational well-being and the lack of disease. In order to understand the results related to the cultural aspects, the data was considered from a medical anthropological point of view, using the notion of the macrosystem, derived from the perspective of Bronfenbrenner. Social-economic factors, gender, level of education, finance, religion and access to health services are investigated as a way to understand the influence of cultural aspects on individuals’ quality of life.

Portuguese speaking families living in a multicultural context in Europe: The case of Switzerland

Marta Goncalves Lisbon University Institute, Portugal

International findings confirm that young immigrants often find themselves in a situation of greater vulnerability in terms of mental health problems. Simultaneously, access to health care seems generally more difficult for immigrant families (Alegria, Canino and Pescosolido, 2009). The main objective of this study was therefore to explore possible barriers to access professional assistance in mental health from the perspective of immigrant families. The methodology included both a qualitative study in which semi-structured interviews (n = 170 people from 68 families) and focus groups with health and education professionals (n = 31) were conducted as well as a quantitative survey (n = 887 youths, 417 mothers and 310 fathers). Selected results of the project will be presented, looking at differences and similarities between young caregivers and professionals perspectives. The results indicate the involvement of the patient’s perspective as one of the most valuable sources of information for improving access to mental health care. Overall, the results suggest several trends for intervention projects in order to improve access to mental health care.

Promoting subjective well-being through income: Moderating role of social dominance orientation

Mengying Li Peking University, China

Is higher income effective in eliciting greater subjective well-being (SWB)? Theory and research point to different ways on this controversial issue. In this article, we argue that greater income will be associated with stronger subjective well-being, and this relationship will be moderated by the social dominance orientation (SDO). We tested this hypothesis with a sample of Chinese residents by means of a set of questionnaires assessing the degree of people’s SWB, income and SDO. Results indicated that there was no significant relationship between income and subjective well-being. However, social dominance orientation moderated this relationship: When social dominance orientation is high, people’s income and subjective well-being showed a negative relationship, whereas, when social dominance orientation is low, the relationship of these two variables is positive. The results suggest that income is not necessarily beneficial to people’s subjective well-being. Instead, the impact of income hinges upon people’s degree of social dominance orientation. Implications for the understanding of income and subjective well-being are discussed.

Symposium title: Psychologists’ evolving roles in diverse health care systems

Convenor: Ellen Garrison

Role of psychologists with National Health Service in the United Kingdom

Carole Allan British Psychological Society, United Kingdom

Since its launch in 1948, the National Health Service (NHS) has grown to become the world’s largest publicly funded health service providing free, universal healthcare for 62 million UK citizens. It is funded centrally by national taxation and currently consumes 8% of GDP. Due to the worldwide economic downturn, the NHS faces the tightest financial settlement in its history, and recent legislation has focused on the introduction of competitive tendering for key services. Psychologists including psychologists are opposed to many of these proposals and view them as a threat to the provision of integrated care for vulnerable groups such as older adults, those with long term chronic diseases and those with mental health problems. The British Psychological Society has been at the forefront of supporting psychological research, improving access to evidence based psychological therapies, developing the work of practitioners and engaging with government about workforce planning and the broad healthcare agenda. Psychologists who work in practice are mainly employed within the NHS, with the largest group being clinical psychologists. The model of service delivery has been increasingly as part of multidisciplinary teams located within community or hospital based services delivering to a wide range of client groups. An overview of how the proposed health service changes will affect psychological care and psychologists will be presented as well as the opportunities that have arisen from the focus on evidence based practice.

Health care reform and psychological practice in the United States

Ellen Garrison American Psychological Association, United States of America

Recent and ongoing efforts by the U.S. government to reform the nation’s health care system
have significant implications for the practice of psychology. The goals of health care reform are to extend coverage to 32 million uninsured Americans, while increasing overall quality of care and reducing costs. The new health care reform law preserves the current system of employer-based private insurance and government-run plans but will require nearly every American to obtain health insurance or pay a penalty. The American Psychological Association has been actively engaged in health care reform initiatives in the following key areas: Prevention and wellness, integrated care, access to mental and behavioural health services at parity with medical services, workforce development, elimination of health disparities, and support for psychological research. With health care reform, psychologists will increasingly focus on the needs of the whole patient, including the physical, mental, and behavioural health aspects of chronic conditions. Most psychologists will be providing brief interventions as part of integrated, interdisciplinary teams in primary care settings. Given recent demographic shifts in the U.S. population, psychologists will also be serving growing numbers of older adults and racial/ethnic minorities. These major changes, along with advancements in technology and evidence-based care, will call for new models of psychological practice and professional training.

Psychologists’ evolving roles in diverse health care systems

**Ellen Garrison American Psychological Association, United States of America; Carole Allen; Andromeda Valencia; Lyn Littlefield**

Psychologists’ roles, services, and work settings are evolving with changes in health care systems worldwide. Psychologists are contributing to health care reform by helping to increase access to care, improving the quality of care, and reducing costs. They work in health care systems that differ markedly on such dimensions as sources of funding, degree of integration between and among mental, behavioural, and physical health, and prevention versus treatment orientation. Also, psychologists are faced with significant challenges and opportunities, such as changing demographics, technological advances, and an increasing emphasis on evidence-based practice. This symposium brings together leading psychologists who represent psychological associations in countries with diverse health care systems—the United Kingdom, Australia, Mexico, and the United States—some of which are currently undergoing reform. They will each provide a brief overview of their health care system and any changes in funding of psychological services. They will then respond to several key questions regarding the roles of psychologists, including: Is there a shift underway in the settings in which psychologists generally work? Is the balance among services provided changing? Are psychologists working more collaboratively with other health care professionals that may extend from off-site consultation to co-located, integrated team-based care? The panelists will conclude with reflections on their perceptions of growth areas for psychology within their respective countries and any associated workforce development needs. Dr. Norman Anderson, CEO of the American Psychological Association, will serve as moderator.

**Roles of psychologists in health care reform in Australia**

**Lyn Littlefield APS, Australia**

Australia is currently undergoing significant reform of its health system. The Federal Government is re-organising the primary health care system into regions to be managed by Primary Health Care Organisations. These are being established as companies with governance structures including the spectrum of primary health care providers. Allied health professionals, including psychologists, will have a far greater role in Government funded health services, particularly in multi-disciplinary care, than in the previously medically dominated model. Workforce demands also signal increased scopes of practice. Psychologists have already been included in the Governments’ national Medicare insurance scheme and Australians can now receive rebates for a limited number of psychological services to treat people with mental disorders on referral from medical practitioners. The Australian Psychological Society has played a crucial role in many of these developments which have resulted in significant changes to psychological practice in Australia. An overview of the health system reforms focusing on the impact on psychologists and outcomes for the community will be presented.

**Psychological care in Mexico: From psychologists training to users of psychological services**

**Andromeda Valencia National University of Mexico, Mexico**

In recent years, there has been an increasing demand for psychological services in Mexico. This development is a remarkable result of the use of evidence-based psychological interventions. This study’s aim is to present a brief description of the psychologist’s role in Mexico, as well as an analysis of the main problems that lead people to seek services in a psychological service centre. First, to be described will be the characteristics of the psychological care model used in the Psychological Services Centre of Dr. Guillermo Davila of the School of Psychology of the National University of Mexico (UNAM), located in Mexico City. It is important to highlight the dual role that the centre plays. It is both a place for psychologist training and the most important public centre that attends psychological problems in Mexico. The sample consisted of 1000 people (men and women) who were treated during the second semester of 2011 at the centre. Participants responded to a brief interview, a medical history questionnaire and the Beck Inventories (depression and anxiety). The results showed the main reasons for consultation and its relation to the current economic and social situation of our country. Data also described the skills that are necessary for a psychologist to acquire in formal training. This information allows us to better understand the current situation in Mexico regarding the increasing needs for psychological care and also to identify the competencies and skills to be developed in a psychologist.

Today in most families, religion and family life are deeply integrated. Researches relating to the family processes have shown that spiritual and religious beliefs/behaviours have important roles in the family health performances. Nevertheless, mental health researches specially those interested in family psychology are seeking to understand and explain how religion and spirituality can affect family performances. The aim of this study was to provide an approach regarding the spiritual–religious family therapy and its cultural implications in Iran. Explaining the influence of family performances within Iranian cultural context, the study focused on the foundational components of current concepts for role theory, social and support network, tension and stress and coping perspective and their implications. By virtue of the widely used techniques in spirituality-religion and family therapy, we addressed a number of major principles of the approach in Iranian families within their specific cultural dimensions. The study explored "Forgiveness" and "Positivism" therapy techniques in view of their cultural and marginal meanings. Interesting findings are reported in the study that clarifies how culture can impede or facilitate the process of psychological counselling and psychological diagnosis. We looked at both grand theories within Western paradigm and their psychological prescription and compared their inducing techniques with Iranian local cultures especially the contexts that unfold within family relations. Our study indicated that culture can serve as a significant barrier between the therapists and the clients and can hamper the process of effective dialogical interaction to the effect that both the therapists and the client lose their focus on the problem management.

**Communication skills training programme for physicians in reducing patients’ distress**

**Anita Caruso Hsp, Italy**

To assess the impact on the patients anxiety levels of a training course for oncologists on how to communicate bad news in oncology - to assess the patients perception about communication skills used by the physicians during the communication of bad news. The anxiety levels of two groups of patients (assessed with the ‘Psychological Distress Inventory’ PDI, and the ‘State Trait Anxiety Inventory’ STAI), were compared before and after a medical visit during which bad news was communicated. The first group of patients (Experimental Group-EG) received the communication from a physician, who had previously followed a communication skills training course. The second group (Control Group-CG) of patients received the communication from a non trained physician. The patient’s perception about the physician’s communication skills, was assessed after the medical visit by the Perception of the Interview Questionnaire and the Perceived Physicians Communication Style Scale. The study was conducted on 38 physicians: 19 EG/19 CG and 348 patients of which 168 EG and 180 CG. The decrease in anxiety before and after the medical visit, is significantly higher in the EG patients. (p=0.019). Among the bad news “the ineffectiveness of treatment” is the cause related for
which there has been a significant increase in anxiety in patients (p = .004). It seems that physicians who followed the training course were better perceived by the patients for their relational and communication abilities.

Do stressful life events predict disease progression in breast cancer patients?

Florence Didier European Institute of Oncology, Italy

This is a prospective longitudinal study. Breast cancer patients, aged between 20 to 65, will be assessed in a clinical interview for psychological distress and coping using the Millon Clinical Multiaxial Inventory-III and the Mini Mental Adjustment to Cancer. Adverse life events and any subjective difficulties, emotional stress occurring during life, before and after cancer diagnosis, will be recorded using the Paykel Scale and the Parental Bonding Instrument. Follow-up will be terminated 5 years after breast cancer diagnosis and assessment will be performed twice a year. Disease-free interval time, or date of relapse will be recorded as well as socio-demographic and clinical characteristics of patients, age, marital status, social/professional state, level of education, number of children, type of cancer, treatments (surgery, oncological treatments, menopausal state, affected lymph nodes, tumour size, histological type, and hormonal receptors status, markers). During the follow-up period, time-dependent variables including psycho-social stressors, psychological distress, coping and physical symptoms will be recorded for each month of follow up.

A longitudinal study with LSDM on the risk of cancer

Vito Tummino Sant’Anna Hospital, Italy; Isabella Cardini; Cesare Basilico

It is often said that people who develop cancer have difficulty in expressing negative emotions. Research performed by the Clinical Psychology Service of DSM, Sant Anna Hospital, shows that, according to international studies, people who have a negative approach to life and a negative or poor quality of social interactions, have major probability to develop organic disorder. This is further evidence of the close connection existing between mind and body. The aim of the study was to underline the relationship between psychological defence mechanisms and patient’s health. We adopted the Lifestyle Defence Mechanisms Inventory, which includes two scales: Rationality/Emotional Defence and Need of Harmony, and was developed by Spielberger (1988) and Spielberger and Reheiser (2000). The target group was made up of 314 patients of Italian nationality (from 25 to 65 years of age, men and women). Starting from June 2000 they were submitted to the LSDM Inventory. The Inventory was also administered to a control group of 900 Italian healthy men and women in the same age range. According to the research hypothesis, cancer patients seem to be more accustomed to the use of defence mechanisms (above all denial and repression) which inhibit conscious experiences and the expression of negative emotions.
Research Area: History of Psychology

Session Type: Papers

Towards a history of the indigenisation movement in psychology
Adrian Brock; University College Dublin, Ireland; Corinna Mueller; Raoul Schrott; Hermann Kapelhoff; Raymond Mar; Adele Goldberg

Most internationally-minded psychologists are aware of the existence of the indigenisation movement in psychology. Starting in the 1970s, psychologists in different parts of the world began to argue that the psychology that was being imported into their countries from elsewhere was inappropriate for their needs and that it would have to be adapted to suit the local context. Although the movement is often characterised as one of African, Asian and Latin American psychologists reacting to 'Western psychology', European and Canadian psychologists were involved from the start and it was the dominance of American psychology in their countries to which they were opposed. The movement has now been around for over 40 years and many of its original pioneers (e.g. Rogelio Diaz-Guererro, Virgilio Enríquez, Durganand Sinha) are no longer with us. It is therefore appropriate to attempt a history of a movement whose ideas and practices are often presented in a fragmentary form by people who write only about developments in their own countries. In examining the movement as an international phenomenon, it will be possible to ask questions like: Which countries are at the forefront of the movement and why? What is the status of indigenous psychology compared to more traditional psychology in these countries? Are there any differences in approach between these countries and/or within them? The paper will also examine some conceptual and practical problems that the movement faces and assess its prospects for the future.

The role of "thought leaders" in the advancement of research
Pamela Flattau; IDA Science and Technology Poll, United States of America

It is possible to describe the research landscape in a scientific discipline by analysing not only the patterns of publication of participating scientists, but also in terms of the scientists whose work they cite in the course of designing and communicating their research findings. Analyses of the reference lists of sets of journal publications shed light on the emergence of "thought leaders" in a field. Science policy analysts utilise a number of bibliometric indicators to track changes in the research landscape, including percentage of articles/books cited two or more times; percentage of citations to the top ten authors; and peak year of the age profile in reference lists. The IDA Science and Technology Policy Institute has used this method in a number of its policy analyses. The purpose of the presentation is to outline the bibliometric technique and theoretical underpinnings for purposes and discuss the potential for its use in improving the identification of emerging fields of research in psychological science.

V.M. Bekhterev's contribution to music psychology
Sergey Gilmanton; Yagursky State University, Russian Federation

Russian scientist V.M. Bekhterev is known as a physiologist, a psychiatrist, the author of reflexology and objective psychology, and the founder of the St. Petersburg Psychoneurological Institute. However, his contribution to music psychology is poorly known and his name is not mentioned in the English literature on music psychology (D.J.Hargreaves, A. C.Lehman, A.C.North, A.D.Patel, J.A.Sloboda, et al). Meanwhile, Bekhterev has contributed to practically all directions of music psychology, and deserves a higher estimation of his role in the development of this science. First, he carried out empirical researches of music perception, of influence of music on actions and conditions of the person and on group processes. Long before the research by R.H. Rausher known as 'Mozart's effect', Bekhterev noticed that music could stimulate intellectual activity and efficiency. Second, Bekhterev put forth questions and offered solutions to problems new to his time. These included the social-psychological mechanisms of perception of music where he included both cognitive and emotional processes and personal characteristics; the social-psychological aspects of interaction of the person with music, and considering music as 'combinative stimulus'. Third, he was the pioneer in the development of methods of using music as therapeutic and medical means. Finally, he was a founder of the psychology of music education, having defined its role in the development of a person and principles of its realization. This oral presentation is devoted to the consideration of the contribution of V. M. Bekhterev to music psychology.

Luria's life and contribution to the psychology of the 20th and 21st centuries
Janna Glozman; Moscow State University, Russian Federation

July 2012 is the 30th jubilee of the ICP Congress and the 110th anniversary of Alexander Luria's birth. It is a good moment to cherish the memory of this extraordinary man and scientist. To understand the legacy and contribution to psychology of this worldwide recognised psychologist, even after his death in 1977, I will analyse in my presentation the lines of Luria’s communications and cooperation with other eminent scientists of his time: Luria and Freud, Luria and Pavlov, Luria and Bekhterev, Luria and Vygotsky, Luria and Pribram, Luria and Bruner, Luria and Jakobson, Luria and Sacks, Luria and Cole and more. It permits us to evaluate Luria’s contribution to general psychology, neuropsychology, developmental psychology, neurolinguistics, psychogenetics, special education, theory of rehabilitation and other fields. All these different fields of Luria’s interests have a common base – the inextricable relation between mind, brain and culture. The cultural-historical psychological theory, created by Luria and Vygotsky influenced deeply all branches of psychology. A model of development of neuro-psychology in Lurian and post-Lurian periods will be presented, including the development of methods of neuropsychological assessment, the influence of Luria’s qualitative analysis on modern psychometric batteries and possibilities of combining qualitative and quantitative approaches in the evaluation of assessment data. The longer we live without Luria, the more majestic his personality becomes, and the more evident is the influence of his creative and comprehensive approach on further development of psychology throughout the world.

Extending critical history to U.S. professional psychologist training
Susan Hawes; Antioch University New England, United States of America

Professional psychology training in the U.S. emphasises the "social" in their curricula. However, the courses intended to meet APA's guidelines for Foundation content still employ "presentist" assumptions, indicating a lack of attention to contemporary contextalist and postmodern trends in psychology historiography, as represented in the works of Kurt Danziger, Ian Hacking, Nikolas Rose, & Roger Smith, to name a few. This paper will discuss the relevance of contemporary theories and practices of contemporary histories of the social sciences and present a working outline of a course for doctoral students in professional psychology. Critical input from attendees will be most welcome.

Twenty years of development of Czech psychology since the Velvet Revolution
Daniel Heller; Institute of Psychology, Czech Republic

The author deals with the development of psychology in the Czech Republic during the last twenty
years that have passed since the Velvet Revolution in 1989. He focuses on the psychology as a discipline taught in universities as well as on the development of applied psychology in societal practice, namely the fields of work and organization psychology, health psychology, and school and counseling psychology. He also mentions the research problems and methodological issues. He draws a comprehensive contemporary picture of both theoretical and applied psychology in the Czech Republic.

Review of research trends in psychology in Bangladesh
Sabihah Jahan University of Dhaka, Bangladesh; Farzana Nila; Sarita Mahima; Ummay Jesmine University of Dhaka, Bangladesh; Mahmudur Rahman

The purpose of this study is to reveal and understand trends of research concerning choice of research topic, research question, and research methodology in psychology in Bangladesh. The reason behind such trends was also explored with some recommendations of future requirements for quickly development of the discipline. Historically, psychology was introduced in the geographical location of Bangladesh (the then East Bengal during the period of British Rule), in the Department of Philosophy, University of Dhaka, in 1921. But psychology as a separate discipline started during the Pakistan period in 1956 with the formation of an independent Department of Psychology at the University of Rajshahi (in the northern region of Bangladesh). Psychology gradually got its individual and special identity through a long journey, with varied pace up to this time. We review published research papers (from 1972-2010). From the very beginning, Bangladeshi research followed Western trends. Areas of research were general, social, developmental, clinical, counseling and personality, industrial, organisational, educational, measurement and testing. The selection of topics was based on both personal interests and the perceived necessity for consideration of contemporary social issues. Regarding methodology, the researchers used mainly the quantitative methods. Statistical measures employed were: central tendency; F-test; and T-test. The qualitative research methodologies were greatly ignored. This paper exposes the strengths and weakness of Bangladeshi psychology, in the context of the need for the growth of the discipline of psychology, to be ready to serve its 160 million people.

Famous psychologists: Their unsung contributions to psychology of science
Neelam Kumar CSIR-NIISTADS, India

This paper aims to draw attention to the unsung contributions of a few famous psychologists. These psychologists are extremely well-known and quite famous for their contributions. Ironically, some of their works, especially in the area of the psychology of science, remain largely unknown. Though there are several such psychologists, this paper will discuss some of the stellar examples, such as Karl Popper, James McKeen Cattell, Abraham Maslow, G. Stanley Hall and Donald Campbell. Most of these names are well-known to every psychologist the world over, but their works related to science have not attracted adequate attention. This is strange in view of the long associations between psychology and science. Whether psychology is a science has always been and continues to be debated, not only within the discipline of psychology but also by philosophers of science. Psychologists have made great efforts right from its origin to establish it as a ‘rigorous science’. Psychologists have also studied and talked about scientists as early as 1874. While other disciplines studying science, like philosophy, history and sociology of science developed and became well-established, the psychology of science remains an emerging sub-discipline. Even the contributions of renowned psychologists in the field of psychology of science remain unsung.

The different conceptions of world, society and subject in the work of Raimundo Nina Rodrigues and Silvia Tatiane Maurer Lane
Aluízio Lima Universidade Federal do Ceará, Brazil

The present paper intends to show and discuss the concepts of world, society and subject in the works of Raimundo Nina Rodrigues (1862-1906) and Silvia Tatiane Maurer Lane (1933-2006). The reason for analysing the propositions of these two intellectuals is related to their influence, each in their own time, on understanding the social and political problems in Brazil and to their proposition of a Social Psychology. Rodrigues, influenced by European theories, especially the criminal anthropology, anthropometry, phrenology and sociological positivism, was primarily responsible for the spread of eugenic theories that linked the black race with crime and country’s progress difficulties, which motivated the creation of social medicine and the League of Mental Hygiene in 1923. Lane, mainly influenced by Marxism, in a bold and courageous proposal, in the 70’s and 80’s, was the main proponent responsible for the criticism of unmediated importation and application of theories produced in other countries (especially the colonising countries) in the understanding of Brazilian problems, and the first one to defend intellectual creation and the development of a Brazilian Social Psychology, whose main proposal would holistically study the individual, without strictures, repressed by social determinations and aware of them, but with the capacity (in its universality) to change the entire social landscape, to create new ideas and forms of existence, despite all the effort expended by history and culture, ideas that have culminated in the creation of the Brazilian Association of Social Psychology in 1980.

Theorising ‘relevance’ in psychology
Wahbie Long University of Cape Town, South Africa

Calls for ‘relevance’ in psychology have gathered pace since at least the late 1960s. Beginning with a crisis in American and European social psychology, sentiments about the social irrelevance of psychology found their way subsequently into psychological communities of the disciplinary hinterlands, including India, the Philippines, Malaysia, Turkey, Latin America and Africa. Curiously, however, almost no attempt has been made to theorise the emergence of ‘relevance’ discourse in the discipline. This theoretical approach attempts to do just that by acknowledging, inter alia, developments in the sociology of science, contract theory as a metaphorical recasting of the science-society relationship, the Habermasian theory of cognitive interests, Bourdieusian notions of capital, habitus and field, ideas on disciplinarity, the indeterminacy of psychology’s subject and the discipline’s vexed relationship with social change. The paper concludes that ideas of ‘relevance’, while rooted ostensibly in material concerns, are expressed necessarily in largely rhetorical terms, mirroring stubborn controversies between proponents of realism and relativism.

Heredity and trauma: Reflections from a history of science perspective
Vanessa Lux ZfL Berlin, Germany

Epigenetic research currently investigates the trans-generational transmission of biochemical correlates following traumatic stress. That trauma may be transmitted from one person to another (e.g. compassion fatigue) or even to the next generation (e.g. in Holocaust survivor families) is well known in psychology, and several concepts of psychological or behavioural transmission were developed to explain these phenomena. However, the notion that ‘trauma is hereditary’ produces public excitement as well as discomfort. The reason for this ambivalence can be found in the history of the concept of psychological trauma. Starting in the mid 19th century with a debate on ‘railway spine’, the notion of psychological trauma developed precisely at a time when the notion of heredity was restricted to, first, the germ line and, second, to the genes. The paper reconstructs the history of the concept of psychological trauma from the mid 19th century to 1900 and its separation from the notion of heredity (based on the works of Eichsen, Page, Charcot, Oppenheim, Janet, Breuer, Freud). Paticular attention is paid to intermediate concepts and their unrefereced use as etiological models in epigenetic research today.

Early South African engagement with international psychology
Lionel Nicholas Monash South Africa, South Africa; Mzamo Ntatsi; Maria Damianova

Jan Christiaan Smuts’s contributions to psychology is little known as well as the high esteem in which he was held by Adler, Koffka and Perls. Adler facilitated the translation of Smuts’s first book in German and felt that Smuts’s ideas were of great importance to Individual psychology. Koffka stated that Smuts’s book guided a number of Gestalt psychologists in their work and Perls also acknowledged Smuts’s influence. Jan Christiaan Smuts was the first South African to be rated as an important psychologist internationally. He produced his first psychological manuscript in 1895 analysing Walt Whitman’s personality and in 1926 he proposed a holistic perspective which had a significant impact on Gestalt psychology, gestalt therapy and Individual Psychology. His holistic approach intended to move beyond the purely psychological. He believed that every individual form of life is a unity that operated according to its own inherent laws and forms and shapes the products of life into a harmonious whole which he Smuts named the personality. He cautioned against confusing this term with the transcendental ego or with the ‘self-consciousness’ of psychologists. He considered personality from a biological point of view and he chose to study Walt Whitman because biological phenomena are best studied in the most perfect and fully developed specimens. Joseph
Wolpe, Arnold Lazarus and Stanley Rachman’s contributions are better known and their South African beginnings will be delineated.

Eminence in South African psychology
Lionel Nicholas Monash South Africa, South Africa; Mazmo Ntatsio; Maria Damianova

Studying eminence in psychology has great potential for use in studies in the psychology of science, in historical studies of psychology and in the psychology lecture room. Studies of eminence in psychology have used the following measures; frequency of citation in the professional literature and psychology textbooks, surveys of professional opinion, whether a psychologist’s surname has come to be used as an eponym and receipt of awards or other forms of honorary recognition. No study of eminence in psychology has been conducted in South Africa (SA) and the present study established, using the aforementioned variables, eminence in psychology in South Africa. A rank-ordered list was constructed that reports the first 49 of 50 most eminent psychologists in South Africa. Eminence was measured by scores on two quantitative and two qualitative variables. The quantitative variables were journal citation frequency and South African citation introductory psychology textbook frequency. The qualitative variables were National Psychology Association election as President or a national psychology award. The two variables were combined to produce a composite score that was used to construct a rank ordered list of the most eminent South African psychologists.

Psychology in Ghana: Origin, prospects and challenges
Kwoku Oppong Asante University of KwaZulu-Natal, Ghana

This article presents a brief overview of the origins, training, prospects and challenges of psychology as an academic discipline and profession in Ghana. Psychology, relatively new to Ghana, has a very short history which could be traced to the establishment of the first department of psychology at the University of Ghana, Legon, in 1967. This department had three lecturers. With psychology gradually becoming of one the popular courses to university students, relevant information about how and where to get psychological education and training education are discussed. This paper also highlights the practice of psychology as a profession in Ghana, and the challenges that are encountered in this regard. The absence of a Psychological Act, a weakened and inactive Ghana Psychological Association, overdependence on European and American centric theories and government inability to absorb psychologists, have reduced the discipline to a mere social science. This article concludes with what could be done to make psychology a more relevant academic discipline that would help Ghanaians in their everyday life.

Psychology in Cuba: Past and present
Aymara Reyes Oriente University, Cuba; Asel Viqueuras Moreno; Aymara Reyes Saborit

The development of psychology in Cuba was revealed through the analysis of psychological practices of teaching, investigation and intervention. The objective of this work is characterising psychology in Cuba, taking into account the different stages of development, and defining future tendencies and challenges for the development of psychological science in Cuba. As a result of this work, it was determined that the first stage of development of psychology in Cuba (the end of XVIII Century until 1959) was characterized by the use of North American theories and to a lesser extent, European theories. The second stage (the whole revolutionary period until the present time) has as peculiarity the eminently practical character of psychology: It is linked to the creation of a new society in different performance areas that includes teaching, intervention and investigation; taking as theoretical and methodological bases the socio-historical approach in psychology. The main challenge identified was to continue legitimating the constitution of subjectivity, as a product of human actions and their implication in the analysis of the main problems that affect the country and humanity, contributing science and professionalism to the solution of these problems.

Psychology in Argentina
Maria Richard CIIPME-CONICET, Argentina; Eduardo Keegan; Maria Mikulic; Hugo Kloppenbach; Jose Moreno; Lucia Rossi

In this invited symposium, the present status of psychology in Argentina will be discussed. It will cover a general view about the history of psychology in Argentina and its current state of development, currently in the charge of Dr Hugo Kloppenbach. The influence of psychoanalytic theory in psychological science, psychiatric diagnosis, undergraduate instruction, and graduate training is very significant in Argentina. However, among current educational psychologists and researchers, the cognitive perspective is more widely held than the psychoanalytic perspective. The symposium will also include the characteristics of university teaching, the main theoretical currents, grad and post-grad courses, plans and contents, under Dr Lucia Rossi and Dr Maria Isabel Mikulic. Scientific research in psychology will be led by Dr Maria C Richard and Dr Jose E Moreno, and it includes the development of research, opportunities in the science system, grants, types of research (theoretical and experimental), research centres, among other topics. Finally, Dr Eduardo Keegan will be considering the development of clinical psychology in Argentina including current different clinical schools, and their extension in comparison with other specialties. Since the 1970s, clinical psychology has continued growing into a robust profession and academic field of study. Although the majority of psychologists in Argentina are involved in some kind of therapeutic role (clinical, counselling) or in educational positions, some are employed in industrial and organizational settings, and in other areas such as sports, law, and forensics.

Historicising the relevance debate: South African and American psychology in context
Daniel Sher University of Cape Town, South Africa

The relevance debate in psychology can be described as discourse which calls for the discipline to become more socially valuable and accessible to those who purportedly need it. A literature review suggests that there is a socio-historical dimension to relevance discourse that is frequently overlooked, resulting in a typically ahistorical and axiomatic presentation. It is therefore argued that a historical perspective on the relevance debate is necessary for an informed consideration of its attending issues. This paper compares relevance discourse from South Africa (1974-1994) and the United States of America (1960-1980) by means of a thematic analysis of journal articles published during these periods in the South African Journal of Psychology and American Psychologist respectively. The analysis yielded six key analytic themes: social turmoil; the pure-applied dichotomy in psychology; the role of psychology in socio-political matters; the place of human values in science; equity in psychology; and indigenous psychology. The first five themes are common to both the American and South African debates. Consequently, it is argued that the two debates arose in similar social contexts and that, in particular, the relevance debate is associated with conditions of social turmoil. This historicization of relevance discourse permits a more critical and accurate understanding of the relationship between the debate and contemporary society.

New concept of spirituality in psychological research
Carlos Valiente-Barroso Universidad Complutense Madrid, Spain; Emilio Garcia Garcia

Psychology” and “Spirituality”, which are separate concepts, are intertwined in the course of the history of psychology, inevitably. Thus, from the root meaning of his own word, “science of the soul” to current contributions, through the cataloging of the spiritual, by W. James, as an object of scientific study, has developed a relationship not without dissonance. Interpretation of the spiritual as psychological disturbances that could generate, usually linked to concepts such as bigotry or repression, a bridge emerges harmonisation strength through modern neuroscience research. The aim is to have different data belonging to the corpus of psychological science, that relate psychology with spiritual phenomena, focusing on those that emphasise a harmonious and complementary interpretation. Bibliographic review about different researches, where they associate keywords like “psychology” and “spirituality” in reference publications for the scientific community will be investigated. From the perspective of psychotherapy, researches that put spirituality as a factor in the psychological health of people are growing, and they could support the effectiveness of other treatments, synergistically. From the more neuroscientific perspective we can see studies about temporal lobe epilepsy, Near Death Experiences, ecstasy for psychoactive, neurofunctional changes associated with the practice of meditation, and biological predisposition, among others. Currently, a positive vision of spiritual progress in the psychology is needed, reinforcing a more adequate theoretical understanding and promoting their role in clinical intervention.

Klaus Riegel and the origin of dialectical life-span psychology in Germany
Burkhard Vollmers University of Hamburg, Germany

Klaus Riegel (1925-1977) was as a pioneer of life-span psychology. Klaus Riegel formulated his specific dialectical view on developmental psychology in the sixties as professor in Michigan. He published a lot of contributions in the journal “Human Devel-
opment”. His two most important books (“Psychology Mon Amour” and “Foundations of Dialectical Psychology”) were published after his death. This paper enlightens the origin of his ideas. His dialectical concept can be traced back to his work as a graduate student at the University of Hamburg in the fifties. The title of his PhD thesis was: “Study of Intellectual Abilities of Elderly People.” He received his PhD in 1958. The dissertation is stored in the state archive of Hamburg. The author of this paper did a qualitative content analysis of the text. The conclusion is: The dissertation contains an early version of Riegel’s dialectical concept. The dissertation emphasized the change of cognitive structures in the human lifespan. Riegel used the German translation of David Wechsler’s intelligence test in longitudinal design. He found out that elderly people maintain their numeric level of intelligence though the scores in the subtests of Wechsler’s test change. But linguistic features of intelligence remain stable or even improve in the later phase of human life. The reason is that language is trained continuously throughout the life period. Among the younger ones numeric features dominate within intellectual abilities, but among the elderly ones linguistic features play the decisive role.

Jung’s word association experiments: A giant step forward in our understanding of the psyche

Anthony Wilson Sediri Consulting, South Africa

Freud (1914) said Jung’s Word Association Test (WAT) research under Bleuler at Burghölzli Klinik had “unexpected usefulness”, giving “rapid experimental confirmation of psychoanalytic facts” and was the “first bridge from experimental psychology to psychoanalysis.” The paper outlines the history of empirical research into WAT. Jung’s sophistication of Wundt’s protocol is described. WAT enabled Jung to identify the Complex as “incompatible with the habitual attitude of consciousness”. He said in every conversation “the discussion loses its objective character… since the constellated complexes frustrate the intentions of the speakers.” Jung abandoned experimental psychology after the Word Association Experiments. The author will trace Jung’s thinking on the Unconscious, e.g. in 1928 he said the dream was the most important technical means of opening up an avenue in the unconscious. In 1934, he said the Complex was the true via regia to the unconscious, and “not the dream as Freud thought.” The WAT experiments enabled Jung to trust his intuition. They established his reputation. Jung (1964) admitted that as a young man he was completely disoriented by patients, but the WAT gave him access to their unconscious. For Jung it was the best way of showing how the psyche functions. The Word Association Experiments were important in how Analytical Psychology developed. WAT is relevant today as a didactic tool and its successor lives on in the polygraph.

Letters from Vygotsky: The development of psychology: Socio/historical/cultural
Joao B. Martins Universidade Estadual de Londri, Brazil

The article aims to analyze the letters of Lev Semenovich Vygotsky, written in the period from 1926 to 1934 and published by A. A. Puznyei in 2007, in the Journal of Russian and East European Psychology. For us, this is an opportunity to know more about the reality in which Vygotsky lived, with a panorama of everyday life. The reading of the letters reveals a number of concerns of the author, such as: his struggle with tuberculosis; the consolidation of a new psychology, when discussing theoretical aspects of their research with his counterparts (for example with Luria), as well as aspects about the publication of articles and books; the strengthening of his research group providing referrals for methodological research projects. Moreover, through his letters we can see that Vygotsky’s position in the construction of his theory, incorporates his real life story, the central theoretical principles of his theory, as the inseparability of knowledge and action, and the practice and collaborative nature of the construction of knowledge.

Japanese psychology and research foundations in the US
Hajime Mizoguchi Rissho University, Japan; Tomoko Suzuki Rissho University, Japan

In the present study, I surveyed the relationship between psychology and research grants by research foundations such as the Carnegie Institute (founded in 1902), and the Rockefeller Foundation (founded in 1913) in the U.S. It was found that the Carnegie supported psychological research done by J.M.Cattell, G.S.Hall and E.W.Scripture in the early 20th century. Cattell received a $1,000 research grant from the Carnegie Institute in 1902. Tsuruko Haraguchi (1886-1915), the first Japanese woman who attained a PhD degree in the U.S., studied experimental psychology under Cattell. Hall received $2,000 and Scripture, $1600, research grants from the Carnegie Institute in 1903. Yujiro Motora (1858-1912), the first professor of psychology in Japan, was a pupil of Hall at Johns Hopkins. He attained a PhD degree in 1888. Also, Matataro Matsumoto (1865-1943), the second professor of psychology in Japan, studied experimental psychology under Scripture at Yale. Rockefeller funded the experimental psychology seminar, as a part of seminars in American studies, in the summer of 1952 at Kyoto. Twenty four young Japanese psychologists took part in the seminar. 75% of these participants belonged to national universities. Later almost all the psychologists became professors of psychology. These events have marked an American influence on modern Japanese psychology after World War II. Psychological research was supported, at least in part, by research grants from these philanthropic institutions from the beginning of the early 20th century.

The development of the Binet-Simon intelligence test in Japan
Suzuki Tomoko Yokohama National University, Japan; Hajime Mizoguchi

The development of the Binet-Simon Intelligence Test in Japan was investigated. A literature review, and interviews, identified three important periods in the popularisation of the Binet-Simon intelligence Test in Japan. The first period was the introduction of the test, between 1905 and 1914. In 1908, the psychiatrist Kouichi Miyake translated the Binet-Simon Scale. Between 1908 and 1911, psychologists and educationalists introduced the scale through publications in their specialised journals. The second period between 1915 and 1929 was that of using the scale in practice. The psychiatrist Hiraku Sendaya translated the Binet-Simon Scale, and published the manual and instruments between 1915 and 1916. In 1918, a psychologist, Yoshishide Kubo, standardised the Binet-Simon Scale with 120 children. Both tests were used in schools and child guidance centres. After 1930, there was a period of Japanising and succession. In 1936, a schoolteacher named Harutaro Suzuki standardised the intelligence test among 16,000 children using two items that were originally introduced by Suzuki. A psychologist, Kenichi Tanaka, standardised the Stanford-Binet Test in 1947. The latest version of the Tanaka-Binet Test has original items that have been adapted for Japanese children. In conclusion, The Binet-Simon intelligence Test was first introduced in Japan for specialised use. After the instruments were published, teachers also started to use the tests. Moreover, standardised and revised tests have also been introduced. Today, these tests have original Japanese items and are used in many different fields.

Session Type: Invited Addresses

Social and political history of psychology in Argentina: Main similarities and difference with psychological development in other countries in Latin America
Hugo Klappenbach Universidad Nacional de San Lui, Argentina

Psychology in Argentina also has a long past. The first laboratories and psychological courses were established at the end of the 19th century. Undergraduate programmes in psychology were established in the middle of the 20th century. Therefore, since the 1960’s there has been the history of psychology. There are two main features of the history of psychology in Argentina: first, the clinical biases, and second, the psychoanalytical approach, not only directed at clinical or psychother-
The quality of higher education has suffered as many universities were founded and, particularly, a large number have passed since the beginning of modern psychology in Iran. Psychology in Iran has gone through four stages or phases during this time. The first stage which started with the Revolution in early 1979 which is entitled the establishment phase. During this phase, psychology in Iran expanded considerably and enjoyed appreciable organisational development. The second phase is the ‘retreat’ or ‘crisis’ phase which started with the Revolution in 1979 and continued until the reopening of universities and colleges in the 1982-83 academic years. During this period psychology faced ‘the crisis of legitimacy and existence’. Finally comes the fourth phase which could be called ‘the blossoming’ phase or, more appropriately, the ‘explosion’ phase. This phase commenced in 1983 and continues up to the present time. During this period quite a few higher education institutions were founded and, particularly, a large number of programs in psychology at all levels were initiated, although, the quality of higher education has suffered to some extent. Details of these stages and probable future developments are discussed in the paper.

Profile of community psychology in Ghana: The way forward
Charity Akotia University Of Ghana, Ghana

Community psychology has been in existence since the mid-1960s. However, community psychology was formally introduced in Ghana as a discipline in the early 1990s. Despite this, it still faces many challenges and has lagged behind other sub-disciplines in psychology. By its nature, community psychology would be considered useful if it is able to help deal with the myriad social problems that face people particularly those caused by poverty and lack of education, typically experienced in developing countries. In almost two decades of existence in Ghana, there has not been any comprehensive effort to evaluate the practice of community psychology and training of expertise in Ghana. This presentation aims at exploring the state of community psychology in Ghana by examining the training modalities and its practice. Specifically, the paper will explore the training programmes available, the kinds of practices that exist in this field, the category of individuals involved in community practice and finally the qualifications and level of expertise they have in practicing in this field of psychology. The paper will also explore some shortfalls or gaps in the practice of community psychology. The paper will conclude by emphasizing the importance of the development of training programmes that are appropriate for effective practice towards the wellbeing of different communities in Ghana.

Cultural and neuropsychological assessment: issues discussed from the Tunisian experience
Tarek Bellaj FSHT, Tunisia

In experimental and clinical neuropsychology, tests are useful to render the assessment of cognitive and emotional processes objective, standardised and reliable. However, the use of psychological tests built, almost exclusively, by and for people from Western cultures with populations having African and Oriental cultures provides data that does not guarantee reliable neuropsychological inferences. The translation of items and instructions of a test is governed by codified procedures. Conversely, this can only be a step in the test adaptation process. Very often this step is not sufficient and additional modifications are needed. These changes would be increasingly important as far as the distance between the source culture and the target culture is important with the risk that the extent of changes required may take us away from the original psychological constructs examined. The experience teaches us that even a simple translation or a modification in some test-items may cause artifacts that alter their functional equivalence. In this talk, we present and discuss the Tunisian experience with neuropsychological assessment and the issues raised by the choice between test translation, test adaptation and the construction of new innovative tests. Several studies conducted in Tunisia suggest that the adaptation of neuropsychological tests from one culture to another is unproductive when it is not preceded by thoughtful consideration of the theoretical construction of the test in relation to socio-cultural aspects that shape the functional and structural architecture of cognition.

Theoretical and empirical review of the need for African Psychology
Andrew Mogaji Benue State University, Makurdi, Nigeria, Tarek Bellaj; Charity Akotia; N. Mkhize

This symposium is organized to clarify issues surrounding the need for African Psychology as there is Western Psychology or European Psychology or American Psychology or Asian Psychology. Psychology in Africa connotes the importation of psychology into Africa while African Psychology is a historical concept which is connected to ancient African thought. The emergence and continued presence and practice of African Psychology in America is a testament to its necessity. Even within America, the existence of African Psychology proves that the behaviourisms of Africans in America cannot be defined within the realms of Western Psychology. Theoretical and empirical issues that point to the need for the promotion of African Psychology as a distinct field of study, would be addressed in this symposium.
Psychology in Malaysia came into existence with the opening of the first department of psychology at the University Kebangsaan Malaysia (UKM) in 1979. During the short period of time the area of psychology has grown rapidly with many areas of study. However counseling psychology is the most developed area grown after the establishment of the Malaysian Counseling Association in 1982. It is also known as PERKAMA (Persatuan Kaunseling Malaysia), and it is the national professional association for counseling. Rahman et al (1989) traced the development of psychology in Malaysia up to the point of establishment of the Malaysian Psychological Association. Psychology is a formal discipline, and is increasing its strength and importance with the establishment of new emerging universities and private colleges. It is reported by Kok (2007) in the year of 2006, that there is a shortage of psychiatrists in Malaysia, the country had only 165 psychiatrists and 33 clinical psychologists. Presently, there is also an important need to practice psychological and counseling services in small towns and rural areas, this is not observed very often (See & Ng, 2010). It is suggested that for the development of psychology in Malaysia, laboratory practice should be introduced in all universities, which is observed to follow only few universities in Malaysia. The details will be discussed in the paper.

An overview: History, development, and current status of psychology in Nepal

Usha Subba; Tribhuvan University, Kathmandu, Nepal; Sunil Verma; Aqueel Khan; Usha Kiran

Psychology, it is said, evolved from biology and philosophy, so it was introduced first in Nepal at Tribhuvan University under the department of philosophy in 1947. While almost all powerful countries were involved in World War 2, psychology was nurturing very rapidly and emerged as an important applied discipline. The development of psychology could be traced out as Beginning. Growth and Hope and Uncertainty and Present periods respectively. At present, Tribhuvan University has opened nine departments throughout Nepal. Psychology is taught at the Institute of Education, Medicine and Management as an applied field of study under the management of Tribhuvan University, Pokhara University, Purbanchal University and Kathmandu University. The discipline has not yet flourished as it has in comparison with neighbouring countries. However, it is in process of being addressed within the Nepalese perspective both as a basic and an applied science. However the practice of psychological counselling is the most developed area, having grown since the restoration of democracy in Nepal among both Governmental and Non-Governmental Organisations. Despite major challenges and limited resources, Nepalese psychologists are committed to improve the status of psychology in both the academic and the applied fields to meet international standards. Details will be found in the paper.

Development of psychology in India: A trend analysis

Sunil Verma; Vivekanand College for Women, India; Aqueel Khan; Vivekanand College for Women, India; Usha Kiran Subba

A careful review of the growth of psychology in India reveals that the core issues of study in Indian Psychology was based on the importation and implementation of theories and concepts of Western psychology. The development of the Psychology discipline in India may be categorized in four phases, that is, pre-independence, problem oriented, detachment with Western Psychology and Indianization. Psychology as a discipline in India emerged with the establishment of the Psychology Department at Calcutta University in 1915. And until 2010, more than 100 departments with different objectives were established in the country, which include Central and State Universities, IIM’s and IIT’s. During the course of the development of psychology in India, three associations came to light which helped in the growth of this discipline, that is, Indian Psychological Society (1922), Indian Psychological Association (1924), and Indian Journal of Psychology (1926). After that three other associations National Academy of Psychology (NAOP), Indian Academy of Applied Psychology (IAAP) and Indian Association of Clinical Psychology (IACP) came to light, which facilitated the development of the discipline. However, some factors which still affect the research productivity of Indian academia are: 1) lack of a supportive intellectual climate; 2) poor professional support; and 3) inadequate research funding. Ostensibly, the lack of an academic culture and a non-supportive socio-political environment are barriers to the development of the discipline. The paper discusses in detail the trends of the development of the discipline and how these factors influence the development of psychology in India.

Making an indigenous psychology in the United States, 1926-1966

Carpintero Helio; UDIMA, Spain

The period between 1926-1966 saw the growth of American psychology from academic science to real world application. Events before World War II prepared for the expansion of American psychology after the war and led to the golden age of American psychology. Psychological science and practice grew to encompass many topics and approaches. The expansion of psychology in the United States is placed in its social and political context in order to show how it both reflected American cultural values and shaped those values.

An early view of applied psychology: Piéron’s traite (handbook of applied psychology)

Carpintero Helio; UDIMA, Spain; Heliardor Carpin-tero; Maria Jose Gonzalez; Jose Ignacio Baile

The present paper explores and analyses one of the historical masterpieces on applied psychology, that may serve to represent this conceptual field as it appeared a century ago. Henri Piéron’s “Handbook of Applied Psychology” (in seven volumes) represents a remarkable effort to summarise and organise the field of applied psychology, before the days of the 2nd World War. Piéron, one of the great French psychologists of the 20th century, combined his main interests in
entailed an allegiance between the liberal agenda 19th century and the beginning of the 20th century coexistence and responsibility at the end of the emergence of new forms of government, social progress aiming at analysing the psychological The present paper is part of a wider work-in-

Archives and the internationalising of psych-ology Carpentero Helio UDIMA, Spain Interest in internationalising the history of psy-choology is a relatively recent movement. The International Congress of Psychology offers a unique opportunity to bring together those inter-
ested in developing an international history of psychology. There are a variety of practices and procedures that support an international history of psychology yet there has been little formal effort to identify and synthesise these resources. A good starting point for considering an international his-
tory of psychology is examination of archival sources for research. Archives provide the foundation upon which the historical record is built and maintained. In this session I will describe the efforts of the Center for the History of Psychol-
ogy to establish policies and procedures that seek to ensure that the historical record of psychology is preserved and made available for generations to come. With more than 45 years of experience, the Center for the History of Psychology offers an example of ways in which countries can establish support and maintain the historical record of psychology. Reconsidering psychological applications: Psychology as a cultural technology for the making of liberal citizenship in modern Spain Enrique Lafuente UNED, Spain; Lafuente Enrique; Castro Jorge The present paper is part of a wider work-in-
progress aiming at analysing the psychological bases of the liberal idea of citizenship in Spain, from a historic-genalogical point of view. The emergence of new forms of government, social coexistence and responsibility at the end of the 19th century and the beginning of the 20th century entailed an allegiance between the liberal agenda and the scientific psychology of the period. This "new psychology" merged with other new and already-extant cultural practices, both professional or disciplinal and lay, and gave rise to normative and self-government systems which were determin-
ant in the shaping of a model of subjectivity fitting into the logic of Western liberal democra-
cies. Every project of a nation-state had to face its own social conditions in order to help bring about the liberal utopia. This paper is focused on early twentieth-century political essays published by progressive Spanish psychologists and sociolo-
gists. Its aim is to analyse how psychology was involved as an inescapable practice in the making of Spanish "modern citizens". An attempt is made at establishing how psychology, as a cultural tech-
nology or tool, began shaping areas of practical intervention stemming from socio-cultural and socio-political goals which were specified in the project of a liberal utopia. Strategic fields in this agenda were, among others, education, labour, and the control of social deviance. This paper was supported by funding from the Spanish Ministry of Economy and Competitiveness (Research Proj-
ec PSI2011-28241).

Origins and development of South African psychology Lionel Nicholas Monash South Africa, South Africa From its early inception as a distinct discipline in 1918 SA psychology has impacted significantly on SA society, though not always positively. This paper will delineate SA psychology’s early involvement in underpinning apartheid ideology, the contribu-
tions of two SA prime ministers, J C Smuts and H F Verwoerd and the organisational contestations that led to the thriving enterprise that is SA psychology today.

What is a polycentric history of psychology? Adrian Brock University College Dublin, Ireland The current symposium was inspired by a paper titled, "Towards a polycentric history of psycholo-
gy" which Kurt Danziger gave at the 26th Interna-
tional Congress of Psychology in Montreal in 1996. In this paper, I will introduce the concept of a polycentric history of psychology and explain why it is still of relevance to the field. Danziger maintains that the narrative commonly known as "the" history of psychology is dependent on privileging certain local developments. Thus the origins of modern psychology are frequently traced to the establishment of Wundt’s laboratory in Leipzig in 1879. This is a view that we have inherited from E. G. Boring whose major work was titled, "A History of Experimental Psychology" and was concerned almost exclusively with that field. In reality, we have to look to Galton’s anthropometric laboratory in London, Charcot’s clinic in Paris, the Bureau of Salesmanship Research in Pittsburgh and several other places if we want to trace the roots of modern psychology. A similar situation applies to the more recent history of psychology which has traditionally privileged developments in the United States. These developments form part of the "history of psychology while those in other countries are considered to be of purely local interest. Danziger suggests that we replace this "monocentric" view of the history of psychology with a "polycentric" one where several centres of psychology interact.

The rise of psychological measurement in Brazil Ana Jaco-Vilela UERJ, Brazil Several cultural, political and economic factors in the 1920s contributed to transforming the psycho-
logical laboratories of Brazil into places where psychological measurement tended to predominate. Many of these laboratories were in "Normal Schools", whose main purpose was to train tea-
chers for elementary schools. The Brazilian Mental Hygiene League also promoted the use of psycho-
logical measurement. This paper will examine the ideological ways in which the results from chil-
dren and Afro-Brazilians were interpreted and compare them with the interpretations of similar results that were being made in Europe. The paper will also examine the reasons behind the govern-
ment’s support for this work and how it fitted in with the government’s aims.

French ideas in the beginnings of psychology in Argentina Hugo Klappenbach Universidad Nacional de San Lui, Argentina The presentation analyses the intellectual condi-
tions that made possible the emergence of psy-
chological studies in Argentina around 1900 and

History of Japanese psychology as a local history: Americanisation and psychologisa-
tion Yasuhiro Igarashi None, United States of America Psychology was introduced into Japan from the West in the latter half of the 19th century as one of a number of new forms of knowledge to underpin the modernisation of the country. Japan and the West shared a common social background that characterised conditions of the nation state and in which there were concerns with social management of conduct and mobilisation of each individual’s abilities to take full advantage of their potential to compete and participate in projects of industrialisation and colonisation. Psychologists started to do research in psychophysics, percep-
tion, child development and other fields. Practical psychology such as research of mental testing and industrial efficiency were also started in early 20th century. In 1930s, Gestalt psychology attracted a lot of attention although some introduced Beha-
viourism from North America. Psychologists did research with a variety of methodologies. Howev-
er, Japanese psychology was wholly Americanised in the post-WWII era with the strong influence of USA’s economic and military power. It has been dominated by American mainstream psychology, namely neo-behaviouristic S-O-R type psycholo-
gy. It seems that Japanese psychologists have accepted the status of local history that follows the progress made at the center (Danziger 1996). Since the end of 20th century, psychologisation of the society is going on rapidly. Psychological products to deal with mental problems and people’s personality are so popular in daily life. Today, psychology has become an important actor in the society. Critical history of Japanese psy-
chology is needed to understand its possibilities and constraints.
the Argentine’s reception of French thought. It will be pointed out that although laboratories of Experimental Psychology were established in the country from 1899, these laboratories were quite different from laboratories in Germany. They were used mainly for educational purposes, not with the aim of producing psychological knowledge. In Argentina, the term "Experimental Psychology" was related to the concept of "Experimental Medicine" that was introduced by Claude Bernard in France. Experimental Psychology in Argentina meant Clinical Psychology oriented by the perspective of French psychopathology, especially the works of Janet, Charcot and Grasset.
HIV and AIDs stigma, contact and indirect exposure to persons living with HIV

Toni Abrahams UNISA, South Africa; Mohamed Adam

The appeal of Allport’s Contact Hypothesis lies in the simplicity of its core principle, i.e. contact between different groups may reduce prejudices. Support has been found for the hypothesis in its original form and for those contacts which fail to meet key conditions. HIV and AIDs stigma impedes prevention, treatment and care efforts in South Africa. Further, the health care context is an area where Persons Living with HIV (PLHIV) are regularly confronted with stigma. Accordingly, the study sought to explore and describe HIV and AIDs stigma levels amongst health care workers, exposure, i.e. contact in different forms traditionally defined by the Contact Hypothesis, and the relationship between HIV and AIDs stigma and exposure. A quantitative, survey design was employed with a sample of 202 health care workers in Cape Town. The Capacity Building for HIV/AIDS Stigma Research in South Africa questionnaire, which also provided items to measure contact in its different forms, was used. One way ANOVA, Post Hoc analyses and Pearson correlations were employed in the data analyses. The findings revealed the existence of low to moderate levels of HIV and AIDs stigma and most of the sample were found to have exposure to PLHIV in their personal contexts. A negative relationship between exposure and stigma was also found. The results suggest the need to focus interventions on health care workers with less exposure to PLHIV and provide support for a simpler version of contact which could be utilised to inform stigma reduction initiatives.

Assessment of psychosocial support programmes for orphans/vulnerable children in Uganda

Peter Baguma Makerere University, Uganda

The programme targeting OVC have been running for five years unevaluated. The objectives of the study were: 1. To develop a typology of OVC interventions; 2. To identify and explore the factors that make psychosocial support services accessible and beneficial to OVC, their families and communities; 3. To identify barriers to psychosocial support services to OVC and their households and make recommendations to address the barriers and scale up promising practices. A nationwide, qualitative cross-sectional study with a sample consisted of 27 purposively selected organisations, 75 FGDs were conducted with purposively selected in- or out-of-school children aged 13-17 years (separated by gender); caregivers of OVC; and community members and 41 key informant interviews were held with programme staff. Data was analysed qualitatively. OVC suffered a number of psychosocial problems. A range of psychosocial programmes were targeted at individual, household and community levels. Whether the services were accessible and beneficial were affected by programme, organisation/staff, environmental, and government factors; type of organisation, type of service, being in conflict or non-conflict zones, and location (rural or urban). The programmes had positive outcomes at individual, household and community levels including improved psychosocial wellbeing, but also had unintended negative outcomes of dependence and stigmatisation of beneficiaries. Promising interventions to be scaled up were identified. Barriers to delivery and access to services existed at different levels of intervention and ways of overcoming them were suggested. Recommendations at the national and at programme levels are provided in the text.

HIV risk reduction intervention among medically circumcised young men in South Africa: A randomised controlled trial

Merry Banyini University of Venda, South Africa; Queen Kekana; Leickness Simbayi; Karl Peltzer

Medical male circumcision (MMC) is now considered one of the best available evidence-based biomedical HIV prevention interventions. However, there are some concerns about risks for behavioural disinhibition, or risk compensation, following MMC. The aim of the study was to test a brief one session (180 min) group culturally tailored HIV risk reduction counselling intervention among men undergoing medical circumcision in South Africa in order to limit behavioural disinhibition. A randomised controlled trial design was employed using a sample of 150 men, 75 in the experimental group and 75 in the control group. Comparisons between baseline and 3-month follow-up assessments on several key behavioural outcomes addressed by the intervention were done. The study found that behaviour intentions and risk reductions skills significantly increased and sexual risk behaviour (reduction of the number of sexual partners and the number of unprotected vaginal sexual intercourse occasions) significantly decreased in the experimental compared to the control condition. However, male role norms did not change among the intervention conditions over time, while AIDS-related stigma beliefs significantly reduced in both conditions over time. Study findings show that a relatively brief (one session) and focused HIV risk reduction counselling can have at least short-term effects on reducing sexual risk behaviours in populations at high risk for behavioural disinhibition following medical male circumcision.

Ethical decision-making for psychologists involving mandated HIV disclosure of clients

Joseph Gillis University of Toronto, Canada; Roberta Timothìy; Mercedes García-Umana

In an effort to curb the spread of HIV infection, countries around the world have enacted legislation criminalising the failure to disclose an existing HIV infection to a sexual partner. As psychologists providing professional services to clients with HIV/AIDS, we must consider our ethical and legal responsibilities to our HIV+ clients and their sexual partners in light of duties to maintain client confidentiality and duties to the community at large. This paper will review select legislation worldwide requiring disclosure of HIV+ status and the complexities of medical knowledge and the social determinants of health which are intricately bound up in such legislation and the risk for bias inherent in such prosecutions. Evidence regarding the training and capacity of psychologists to make determinants of HIV risk transmission will be examined within the larger framework of the failure of professional psychology to consider sexual diversity and sexual behaviour as a standard component of a comprehensive mental health assessment. Parallels will be drawn to the famous “due to warn” doctrine derived from the U.S. case of Tarasoff v. Regents of the University of California (Cal. 1976), and a model for ethical decision-making following the guidelines of the UNAIDS Expert Working Group (2005) will be offered. Proposals to improve the training and current practice in professional psychology in relation to sexual diversity, and amplifications of current ethical codes for professional psychologists to facilitate ethical clinical decision-making in cases involving HIV disclosure will be offered.

Trends in condom use and distribution amongst clients and providers from health-care facilities in KwaZulu-Natal

Ross Greener University of KwaZulu-Natal, South Africa; Jenni Smit; Letitia Rambally; Jacqueline Pie-naar; Claudia Ngoloyi; Kedibone Mofele; Cecilia Milford; Zonke Mabude; Melanie Drace; Mags Bekinska

KwaZulu-Natal, South Africa has the highest HIV prevalence globally. Despite efforts to decrease risk behaviour and promote condom use, uptake of condoms remains a challenge. A survey was carried out in 2009 to better understand reproductive health, family planning, and HIV services offered at seven healthcare facilities in eThekweni District, KwaZulu-Natal. As part of this survey, we aimed to assess reported distribution and use of male and female condoms amongst HIV positive and negative clients at these facilities. Questionnaires were administered to 269 clients and 46 providers. A third (32%) of clients disclosed that they were HIV positive, 59% reported they were HIV negative and the remainder did not reveal their status. Results showed a significant difference between clients’ HIV status and reported use of HIV and STI prevention measures (including condom use) (p<0.001). Although almost three-quarters (74%) of providers reported dispensing male condoms to clients in the previous 3 months, only 46% of HIV positive clients reported consistent male condom use compared to 20% of HIV negative clients. Female condoms (FC) were largely unavailable at healthcare facilities at the time of the survey, with 37% of providers reporting never showing clients how to use an FC. Results indicated that consistent condom usage was higher amongst HIV positive than HIV negative clients. This may be attributed to a synergistic interaction of interventions, whereby HIV positive clients receive access to counselling as well as a condom supply. Therefore, interventions to reduce risky sex should draw on such theories of human behaviour.

A grounded theory of decision-making on male circumcision in the context of HIV

Lynlee Howard-Payne University of the Witwatersrand, South Africa; Brett Bowman

The aim of this research was to develop a substantive grounded theory that accounts for the
streams of thoughts and trauma: The untold stories of HIV among discordant couples
Eucharia Igbafe University of Pretoria, South Africa; Clement Musa; Andrew Igbafe

HIV has devastating effects on both couples and families. Presently, there is a growing increase of discordant couples. To date, little attention has been paid to them. The study was undertaken to investigate aspects of HIV-related trauma among discordant couples. The focus of the study was on couples who discovered their status after marriage. Twenty-five discordant couples were purposively selected from Federal Medical Centre, Yenagoa. Data were collected using in-depth interviews and structured questionnaires to capture the daily feelings of the participants for a period of one month. The findings revealed worry, fear, anxiety and depression as core daily experiences. Generally, the study found a strong culture of silence over status-disclosure to family members, when the female partner is positive, and thoughts of divorce were higher among negative males. The study therefore concluded that the impact of HIV among discordant couples seems to be more traumatic than when both couples are positive. HIV discordant couples therefore need urgent special designed programmes. Psychologists should therefore focus on variables such as divorce, raising HIV-negative children, repetitive worries and depression.

Barriers to psychotherapy in the context of HIV primary healthcare clinics in South Africa
Tarryn Kelly South Africa

In South Africa, there is a significant number of people living with HIV/AIDS (PLWHA) who either have or will develop mental health problems. The existence of mental health problems in PLWHA has been shown to have a negative impact on HIV treatment and adherence. The integration of psychological services at primary healthcare clinics will greatly benefit the mental well-being of PLWHA. The aim of this presentation is to highlight potential barriers to providing psychotherapy to HIV positive patients within the context of primary healthcare settings in the Western Cape, South Africa. Data was collected from clinical case material within the primary healthcare clinics and will be analysed using a psychoanalytic theoretical lens. The specific challenges facing mental health service providers in these settings for PLWHA are identified. The presentation will highlight the following therapeutic barriers to effective and ethical provision of psychotherapeutic services: Competing health priorities in under-resourced healthcare systems in low-income countries, the use of surgical masks by therapists and patients for the prevention in TB transmission, physical intrusions into the therapy space due to the multi-functional utility of consulting rooms, language barriers, and the relevance of some psychotherapeutic modalities practiced within these settings. The presentation will furthermore offer some direction to address these barriers so that other psychological service provision to PLWHA may be optimised.

Orphans and vulnerable children: Health policy interventions in India
Anant Kumar Xavier Institute of Social Services, India

The paper reviews and discusses studies and interventions which have addressed the problems and concerns of orphans and vulnerable children (OVC) in India. Most of the research on OVC is based on investigations conducted in African countries. This review focuses on OVC in India in order to facilitate further critical discussion, action and the development of appropriate programmes and policies. The paper is based on review of OVC interventions and programmes internationally and in India. The study shows that HIV/AIDS programmes and interventions are vital to the survival and welfare of OVC but that they have reached only a small fraction of the most vulnerable children in India. OVC in India have also failed to receive the attention they deserve in poverty reduction strategies and other national development instruments. The study suggests a number of measures that government and civil society could take to rectify the problem. These include mobilising resources for supporting community care rather than institutional care, strengthening the care and coping capacities of families and communities, involving children and youth as active participants, building broad collaboration among key stakeholders in all sectors and integrating with other prevention, care and support services. The paper emphasizes the need to learn from the experience and initiatives of other countries in developing appropriate policy and programmes for OVC.

Psycho-social factors impacting on perceived HIV-risk in preparation for an HIV vaccine trial
Antonio Lentoor University of KwaZulu Natal, South Africa; Anna Meyerweitz

The association between perception of HIV-risk and sexual behaviour remains complex and poorly understood, although perception of risk is considered to presuppose behavioural change. The present study emerged as an attempt to gain insight into the relational dynamic, locally, as it is imperative in the development of effective strategies to curb the spread of HIV/AIDS. South Africa remains the epicenter of the pandemic. Failure of preventative efforts has spurred research endeavours to develop an effective HIV-vaccine. In developing an HIV-vaccine trial site, it is important to fully understand the context in which such a vaccine trial will be conducted in terms of psychosocial-economic, behavioural and cultural factors that might impact on the trial success. Semi-structured interviews were conducted with participants recruited from Bojanaquela district using purposive venue-based sampling. Data were analysed using constant comparative method of analysis of developing grounded theory. The findings reveal an association between perceived risk and risk behaviour among males and females. Regardless of their sexual behaviour, the participants from the study continue to adequately assess and personalise their risk. It reveals that HIV/AIDS risk seemed to be influenced by psychosocial issues pertaining to the intra-and interpersonal levels as well as structural/contextual issues that emerged from the broader society. The finding echoes the urgent need to design specific interventions that target psychosocial, economic and contextual factors that continue to put individuals at risk for infection.

What role do communities play in scientific research? Exploring community perspectives on HIV/AIDS and trial participation at a HIV vaccine research centre in South Africa
Anthea Lesch Stellenbosch University, South Africa; Leslie Swartz; Surita Roux

Increasing numbers of HIV prevention trials to develop biomedical technologies such as HIV vaccines are being conducted in settings with high HIV prevalence. Communities play a crucial role in such research. This presentation will examine ideas about HIV/AIDS and the role that communities play in the scientific process in a HIV vaccine research community in South Africa. Without community buy-in and support, efforts to develop an effective HIV vaccine are unlikely to succeed. Researchers face the challenge of balancing the scientific goal of developing a vaccine with the need to build community capacity and leave communities who participate in clinical trials better off as a result of their research participation. Participants in this study were stakeholders involved in community education activities at a HIV vaccine research centre. Data was collected using focus group discussions with community members and key informant interviews with research centre staff members to elicit their perspectives on community participation in HIV vaccine research. Data was analysed using a grounded theory approach. The results of the study highlight community members’ perspectives on HIV/AIDS and HIV vaccine trials. The results of the study also provide insight into the possibilities that community participation in the scientific process offers for empowering communities and building community capacity. Based on the findings of the research, the researcher will use participatory research methods to collaborate with stakeholders to design a community education and awareness-raising model for use at the HIV vaccine research centre.
Aids and death anxiety: A terror management theory perspective on HIV/AIDS and mortality salience
Vicky Malefo University of South Africa, South Africa

In pursuit of many researchers’ quest to explain the disjuncture between HIV/AIDS incidence and prevalence levels, this presentation will illustrate how Terror Management Theory (TMT) may be applied in empirical studies which seek to explore the relationship between HIV/AIDS related death anxiety and a number of dependent variables. It will be prefaced by a brief background of TMT and a discussion of its main tenets followed by a further discussion of how the theory’s hypothesis of mortality salience (MS) has been tested citing a sample of studies identified from a current meta-analysis of relevant research studies. The presentation will further illustrate how TMT may be applied in experimental settings that address issues pertaining to HIV/AIDS and mortality salience. The presentation will posit that reminding people of their HIV related mortality would be expected to prompt self-esteem enhancement behaviours and a tendency to cling to and defend their own cultural worldviews. MS manipulation or priming people with death-related thoughts and ideas as against a control topic will be discussed in further illustration of TMT and MS method applications. The presentation will conclude by arguing that TMT is an appropriate method to apply in experimental settings that seek to explore and explain HIV/AIDS related mortality salience and related behavioural patterns.

Supervision and mentoring of HIV support group facilitators
Glynnis Martin University of Fort Hare, South Africa

The paper focuses on a supervision and mentoring program for first level counsellors of people living with HIV. The program forms part of the Integrated Access to Care and Treatment Program (I-ACT) that is currently being implemented nationally in South Africa. The Department of Health in each province provides the base for the I-ACT program and is supported by a Centre for Disease Control/USAID partner in each province. Facilitators of the I ACT support groups are trained to assist people to live a healthy HIV− lifestyle and bridge the gap between first diagnoses and the onset of Aids. A supervision and mentoring program has been developed and implemented to address the following needs: (a) to ensure effective counselling processes and techniques are applied; (b) to provide ongoing mentoring and support; (c) continued expansion of facilitator’s knowledge base; (d) to address specific counsellor needs related to their personal and professional growth and development. The presentation details the format and content of the supervision program as it is currently implemented across the Eastern Cape Province and highlights some of the findings and progress made over the past 3 years.

Bedtime stories, risk perception and risk communication on sexually transmitted infections like HIV
Fraukje Mevissen Maastricht University, Netherlands; Robert Ruiter; Ree Meertens

People that are unaware of, or do not acknowledge their susceptibility for health threats like sexually transmitted infections (STI), including HIV/AIDS, will be unlikely to take preventive actions. In order to adequately influence these risk perceptions, it is important to know which risk communication methods are effective. In this presentation, studies on the effects of probability-based risk information and scenario-based risk information on perceived risk towards STIs will be presented and discussed. In two randomised controlled trials, the impact of different types of probability information (single incidence, cumulative and different types of scenario information (one vs. multiple scenarios) on susceptibility perceptions to Chlamydia and HIV were tested among Dutch heterosexual young adults (18-25 years old). The outcomes of these studies guided the development of an online tailored risk communication intervention for STI prevention. Perceived risk and risky sexual behavior served as the main outcome variables. Personal risk information, combined with information tailored to motivation and skills, effectively influenced risk judgments and safe sex behavior. Single incidence and cumulative probability information did not influence STI-related risk perceptions. The effectiveness of scenario-based risk information on risk perceptions depended strongly on the imaginability of the scenario information and the characteristics of the participant. The effectiveness of probability-based risk information and scenario-based risk information depends on the format used. When communicating the risks of STIs, using personal risk information or multiple risk scenarios seems to be most effective.

Determinants of HIV/AIDS prevalence in relation to migration in informal settlement areas of Mthatha, Eastern Cape, South Africa
Sikhumbuzo Mfusi Walter Sisulu University, South Africa; Nonpumelo Ntombeni

Over 40 million people worldwide are estimated to be living with HIV/AIDS. The prevalence and spread of the epidemic is largely determined by social, political, structural, and economic factors, to mention a few. Migration has probably become one of the most important determinants of global health and social development. The uprooting, displacement, and resettlements involved in migration can pose complex challenges. Migration has implications for those who move, those who are left behind, and those who host migrants. Its implication for health care systems of communities and the countries involved can also be far-reaching. Migrants bear a heightened risk for HIV infection, given the conditions and structure of the migration process. This paper presents some of the results of a study that was conducted at three squatter camps/informal settlements located in the outskirts of Mthatha. Thirty participants were randomly selected from the three camps. Guided by an interview schedule and observations, a field study was conducted in which participants described, during in-depth interviews, the conditions under which they lived, including economic, sexual, health and other related experiences. Ethical principles including anonymity, confidentiality, and right to withdraw from the study were strictly observed. Findings suggested that i) informal settlements have one of the highest HIV/AIDS prevalence rates, ii) some people resort to transactional sexual relationships to support themselves, and iii) there is a high level of substance abuse which may lead to unprotected sex and therefore susceptibility to contracting HIV. The findings are discussed in relation to migration in informal settlements.

Pre- and post- HIV diagnosis help seeking behaviour by patients receiving antiretroviral treatment
Mamabolo Promise Mohaleni University of Limpopo (Turffloop), South Africa

Studies have indicated that people living with HIV/AIDS resort to Western medicine and alternative health systems to improve general health, prevent opportunistic infections, treat symptoms, reduce side effects from biomedical treatment, pain relief, and stress relief. The aim of this study was to explore pre- and post- HIV diagnosis help seeking behaviour by patients receiving antiretroviral treatment at Witbank Hospital in Mpumalanga Province (South Africa). Specifically, the objective of the study was to investigate the help seeking pathways followed by patients before and after an HIV diagnosis. A qualitative, descriptive phenomenological approach was utilised in the study. Ten participants (male = 5; female = 5, and aged between 25 and 46 years) diagnosed with HIV and who came to the hospital to collect their treatment were interviewed using semi-structured interviews. An interpretive analysis method was used to analyse the data. The results suggest that patients follow a number of pathways when it comes to treatment of their HIV conditions. The paper is concluded by providing suggestions to health care providers on the pathways that are followed by HIV patients before or after consulting with them.

Stress amongst careworkers of institutionalised children
Kesh Mohangi University of Pretoria, South Africa; Cheereen Pretorius University of Pretoria, South Africa

The context of working and living in an institution is accepted as challenging for all concerned. In particular, studies documenting careworker’s stress responses have scarcely been researched. This paper reports on how female caregivers (n=10) of institutionalised children experience stress. In this case study, the BarOn Emotional Quotient Inventory (Bar-On EQi™) was administered to measure emotional awareness. A focus group discussion, individual interviews and an interactive session were utilised to clarify and probe responses on the BarOn EQi™. For this paper, scores on the Stress Tolerance sub-scales and the qualitative data, were examined. Findings show that careworkers (n=4) scored in the effective functioning range and (n=6) scored in the area of enrichment range for Stress Tolerance. Qualitative measures aimed to understand how scores in the effective functioning range of the Stress Tolerance sub-scale could be described as protective factors, thereby enhancing the participant’s resilience. A thematic analysis of qualitative data point out that careworkers found caregiving extremely stressful and unsatisfying. Additionally, they felt unsupported and unappreciated. Coping attempts amongst the participants appeared individualised and unsustainable. Based on these findings, we posit that enhancing the stress tolerance levels as well as stress management abilities of women employed as careworkers could possibly increase their coping efforts and thereby contribute to their overall resilience. As a cautionary
A qualitative study into the fertility intentions of HIV positive women on antiretroviral treatment

Nurhan Moolla
The University of the Witwatersrand, South Africa

The amount of research being done on the impact of antiretroviral treatment (ART) on the fertility intentions of HIV positive women is minimal. This qualitative study has investigated the positive and negative impact that ARTs have had on the fertility intentions of ten HIV positive women attending the Charlotte Maxeke Johannesburg Academic Hospital in South Africa. The findings of this study indicated that HIV positive women have stronger fertility intentions once they are on treatment, compared to when they were not on treatment. This study has also uncovered the way in which the negative impacts of treatment may affect the formation of these fertility intentions. The findings from this study highlight a need for important changes to be made with treatment administration and to start focusing on HIV as a disease that affects the person holistically and not strictly physically. It also highlights the increased need for educating people about HIV so that stigmatization of HIV positive people can be effectively addressed in South African communities.

An analysis of voluntary counseling and testing (VCT) training manuals in the South African public health system

Rakhee Naik
University of the Witwatersrand, South Africa
Rabia Patel

Voluntary counseling and testing (VCT) services, primarily as a diagnostic and prevention strategy, is an early and international response to the large scale challenge of the HIV/AIDS pandemic being faced worldwide. Located within the public health model, it lays the foundation in training people who deliver VCT. Limited research can be found on the adequacy of the content of the VCT training manuals. The primary aim of this study is to qualitatively explore the adequacy and implications of several VCT training manuals utilized within the South African public health context. Moreover, the research aims to explore the topic areas covered and the similarities and differences of the training manuals utilized for analysis. All training manuals have been explored utilizing content analysis providing a rich interpretation of the manuals. Based on the results it is evident that there are vital implications and suggestions which may be employed in further improving the adequacy of the training manuals within the South African public health system. Therefore, the current study has proven valuable in furthering research on improving VCT training manuals.

Meaning in life and the sense of coherence in adults living with HIV

Coenraad Nolte
NNMU, South Africa
Diane Ekino-
in; Ottilia Brown
NNMU, South Africa

Human Immunodeficiency Virus (HIV) infection inevitably leads to an acute stage of the disease referred to as AIDS. Variation in the rate of HIV-disease progression is, amongst others, a function of psychological reactions to an HIV-positive diagnosis and the prevalence of psychosocial stressors. Previous studies have suggested a positive correlation between the sense of coherence and the wellbeing of people living with HIV. The objectives of this study were to explore and describe the search for meaning in life, presence of meaning in life, the sense of coherence and the relationships among these concepts in adults living with HIV. The research sample consisted of 62 participants recruited from an HIV wellness clinic. Search for meaning in life and the presence of meaning in life were measured by utilising the Meaning in Life Questionnaire while The Sense of Coherence Questionnaire was used to measure the sense of coherence in research participants. Key findings include: Levels of the search for meaning in life and the presence of meaning in life were not found to be elevated or suppressed in the sample. The level of sense of coherence of the sample was found to be lower than the level of the sense of coherence obtained in previous studies from mixed populations. A practically significant relationship was found between the levels of presence of meaning in life and the sense of coherence. It is proposed that the presence of meaning in life is a fortifier of the sense of coherence in adults living with HIV.

The use of audio and visual diaries to explore the adherence behaviours of HIV and TB patients: A South African study

Willem Odendaal
Medical Research Council (SA), South Africa
Harry Hausler; Mark Tomlinson; Simon Lewin; Yolisa Mtshizana

Central to improving treatment adherence of people living with HIV/AIDS, with and without TB, is understanding how they experience their illness and treatment. The objective of this study is to reflect on diary-keeping as a method of understanding how experiences of illness and treatment affect the adherence of such patients. Five participants were purposively selected: one person being prepared for antiretroviral treatment (ART); one on ART; and three on ART and TB treatment. Participants received a disposable camera or audio recorder, and recorded their everyday experiences over six months. Visual-participants shared the meaning of their photos in audio-recorded research conversations. The recordings from audio-participants were collected bi-weekly. All data were analysed thematically. The participants described a diversity of illness related psycho-social issues that impacted negatively on their adherence. These included: fear and experiences of ART side effects; struggles to change risk behaviours related to adherence; and their need for emotional support, in particular from the community care workers (CCWs) who support them. The emotionally well patients reported less adherence problems. The diaries facilitated an understanding of the trajectory of treatment experience for those who recently started on ART. The study highlighted the importance of lay counseling skills for CCWs to improve the emotional well-being of HIV and TB patients. Diary-keeping is a powerful approach to understanding how everyday experiences, often inaccessible through other methods, shape the adherence behaviours of these patients.

Living with HIV/AIDS: Psychological symptoms in a Nigerian population

Caroline Ofowewe
University of Benin, Benin City, Nigeria; Catherine Ofowewe

Living with HIV/AIDS, poses severe challenges ranging from the medical, social, economic to the psychological. Research notes the high prevalence of psychiatric and psychological disorders associated with persons living with HIV/AIDS. The present paper evaluates specific psychological symptoms that persons living with HIV/AIDS are exposed to using the Symptom Check List. It is a questionnaire based cross sectional study. The study evaluated the psychological distress experienced by persons living with HIV/AIDS using the Symptom Checklist-90; a psychological instrument capable of assessing 10 symptoms associated with distress. A total of one hundred and fourteen persons living with HIV/AIDS (M= 43, F=71) with an age range of 21-65 years seen in the HIVN Unit of the University of Benin Teaching Hospital, Nigeria were involved in the study. The study was carried out between March and August, 2011. Subjects were consecutively recruited after informed verbal consent was obtained from them. Depression was the most prevalent symptom (15.91) found among the subjects, followed by Somatisation (12.95). The least prevalent symptom was phobic anxiety (3.45). The higher presence of Depression and Somatisation among the symptoms reported emphasises the need for mental health practitioners to explore strategies of ameliorating these symptoms.

Experiences of mental health challenges in women living with HIV/AIDS

Fatima Omar
University of the Witwatersrand, South Africa

HIV/AIDS is a global pandemic that affects millions of people, with its greatest impact being in South Africa (UNAIDS, 2010). Research highlights the increased prevalence of mental disorders amongst this population (Freeman et al. 2007). The main aim of this study was to explore the mental health challenges, including psychological distress and emotional content that have presented in women living with HIV through the course of their illness. It also intended to explore the impact of support structures in managing these challenges. Nine participants, attending a clinic in Johannesburg, were interviewed using a semi-structured interview schedule. Questions centred on diagnosis, disclosure, the appearance of physical symptoms, body image and the caregiving role of the mother. Data from the interviews were analysed using thematic content analysis. Findings suggested that although only one of the participants in the sample had a diagnosable mental health disorder, intense psychological distress was prominent amongst all the participants. Support systems used were often non-professional and were therefore not focused on emotional containment. However, they seem to have assisted in buffering the development of psychological distress towards mental disorders. The findings thus indicated that psychological distress is prominent at particular instances in the illness trajectory and suggests its containment through bolstering current support structures so that mental disorders are recognised, and appropriate referral protocol occurs.
HIV/AIDS

Youth character and behaviour regarding hiv/aids in Kenya
Lucas Othuon Maseno University, Kenya
This study identified specific sexual behaviors and practices of the youth with regard to HIV/AIDS among secondary school students in Rift Valley, Nyanza and Western provinces of Kenya. The provinces were selected because of their high HIV/AIDS prevalence rates. A cross-sectional survey design was used. A self-administered questionnaire was used for data collection. Quantitative data were analyzed using descriptive statistics, while qualitative information was thematically summarized. Of the 3,650 students sampled from a population of 9,000, 3,645 participated in the survey. Boys accounted for 56.2%, while girls represented 43.8%. Their ages ranged between 12 and 22 years, with a mean of 16.4 years. Nearly all the students (98.9%) had heard of HIV and AIDS and were aware of how it is transmitted. Mass media was the most widely reported first source of information. Forty percent of the students had had sexual intercourse before the survey, with more boys (55.7%) than girls (21.6%) reporting ever having sex. The mean age of sexual debut was 13 years for both sexes. The first sexual encounter took place mainly at home. Only 37.2% had used a condom. Peer pressure (43.0%) was reported to be the main reason for having the first sexual encounter. In conclusion, the results indicate high levels of knowledge on HIV and AIDS among youth. However, this knowledge seems not to translate effectively into behavior change. It is recommended that appropriate communication programs be developed with precise messages on HIV and AIDS.

A biopsychosocial exploration of antiretroviral treatment adherence from the patient and health care practitioner perspective
Rabia Patel Rhodes University, South Africa
HIV and AIDS remains a global pandemic, however, the advent of Antiretroviral Treatment (ART) in the late 1980’s has led to major advances in the clinical treatment of the virus. Despite this, adherence to ART remains a significant area of concern. Extensive international research has identified various variables which contribute to non-adherence, yet, African research remains limited. In addition, much of the research is limited to the biomedical perspective. The main aim of this research was to understand the challenges that people who are on ART face from a multiplicity of levels including the psychological and social factors that impinge on adherence levels in PLHIV. A qualitative methodology was used and data was collected from 14 participants using semi-structured interviews. Thematic content analysis was used to generate themes that were then analysed. The main findings suggest that there is a complex web of interaction between what is often understood as personal/individual biomedical challenges and other challenges that are more interpersonal and systemic in nature. As a consequence the response by people to their illness and subsequently to ART is more multifarious than a mere conforming to a set of medical standards and instructions. This is particularly important within the South African context where interpersonal and systemic factors play a very critical role in the patient’s ability to adhere to ART.

Psychographic factors of antiretroviral therapy non-adherence: A critical review of barriers to ART in sub-Saharan Africa
Lebogang Phiri University of South Africa, South Africa; Mohamed Seadat; Ashley Van Niekerk
Antiretroviral therapy (ART) has been provided by the South African Department of Health since 2004 to patients who are diagnosed HIV positive as part of the national ART roll-out. Despite this progress, important questions remain on the best use of ART and how patients should be maintained to achieve maximum benefits from ART. The success of ART for HIV infection is primarily determined by adherence. A literature search was conducted to collect published articles reporting correlates of HIV medication non-adherence among patients receiving ART in sub-Saharan Africa. Based on the review, this paper will describe and discuss the primary factors identified as barriers to ART adherence across the African continent. Despite study diversities in the HIV/AIDS literature base and study limitations, evidence suggests that four types of factors can potentially act as barriers to optimal ART adherence, namely: (1) treatment regimen; (2) social and psychological factors; (3) institutional resources; and (4) personal attributes. The paper offers a critical appraisal of available evidence on ART non-adherence in the African context. It contributes to the conceptualisation and development of context-specific interventions directed at the promotion of ART adherence.

Health systems navigation: A new approach to improving client access within healthcare services
Letitia Rambally MatCH (Wits University), South Africa; Cecilia Milford; Mags Beksińska; Fiona Scorgie; Abigail Harrison; Ross Greener; Kedibone Molefe; Jacqueline Pienaar; Zonke Mabude; Jennifer Smit
Disadvantaged communities are often faced with dual barriers of limited healthcare choices and being least able to access services, resulting in low uptake of many essential healthcare services. Public healthcare systems are most often navigated by members of these communities when they are very ill and consequently treatment is burdensome, for both healthcare providers and clients. These barriers are exacerbated among disadvantaged HIV-positive clients who have complicated treatment regimens, hence often abandoning care. To facilitate access to services, a Health Systems Navigation intervention was developed for clients seeking reproductive healthcare in the South African context, and piloted in a hospital in the eThekwini District of KwaZulu-Natal. Lay people with an understanding of the local communities surrounding pilot facilities and a background in community-based healthcare were recruited and trained as navigators. Through client contact with these navigators, clients were given peer support, potentially inclusive referral assistance and information, in order to improve access to services and enhance their ability to navigate hospital systems. To evaluate the pilot, daily logs were completed by the navigators, interviews were conducted with clients (n=126), pre- and post-intervention focus groups were conducted with healthcare providers (n=6). Preliminary analyses indicate that over three months, 1,853 clients (528 males, 1,295 females) received referral information (n=488), directions (n=765) or were escorted to services (n=875). Overall, the pilot has been positively received by both clients and providers. This intervention could ease some of the burden created by staff shortages and high client loads and could improve adherence to healthcare.

HIV/AIDS and sexual minorities: Community participation and strengths-based practice to address risk propensities
Maheswar Satpathy University of New South Wales, India
Traditionally an erroneous correlation with profligate morality reflected in the form of promiscuity of sexual minorities is identified as antecedent of HIV infection. However, there is a need to analyse lives and life-stories, struggles and the process of negotiation which will bring insights into their sexual subjectivities and vulnerabilities. While sexual minorities are recognised by researchers and Policy makers, because of their risk propensities, they also exhibit enormous strengths in their communities. This paper seeks to understand strengths as well as vulnerabilities of sexual minorities created and reinforced by socio-structural factors and advocate for a community-based participatory approach emphasising on their unique healthcare needs. Socio-structural barrier analysis and need assessment of healthcare conditions of sexual minorities in sub-Saharan Africa was conducted. It was found that there are: i) an incomplete, and often a misrepresented overview of the lives and life stories of ever-diverse sexual minorities; ii) Increased entrapment with a universalised categorisation of ‘LGBTIQ’ and MSM’ neglecting diversity inside sexual minority communities; iii) Lack of proper recognition of Transgender (TG) needs; iii) Large-scale un-prioritised research and lack of emphasis on the Sexual minorities as equal stakeholders in decision-making processes iv) Lack of nuanced understanding of the processes of designing and delivering healthcare services. It is therefore necessary to separate risks propensities and strengths of sexual minorities. This emergent understanding of strengths and vulnerabilities will help in building stronger response in form of evidence-based interventions.

Strategies of signification: Cultural presences and absences of HIV
Corinne Squire University of East London, United Kingdom
This paper will explore how media situates the HIV pandemic within popular imaginations. It will argue that media play an important part in constructing, maintaining and changing everyday cultures around HIV. The paper examines two different strategies that occur across many different media: an interrogative, analytic movement towards explicating and speaking out about the personal, social and political conditions of the pandemic, and a more speculative move expressing the difficulties, sticking points and silences within the pandemic. Generally, the first of these moves is prioritised and viewed as the route towards more treatment access, wider testing and stigma reduction. However, the second move is also often implicitly made by some of the most powerful of those representations. The paper argues that the parallelism of these moves is important in the HIV context and perhaps for other public representations
of personal suffering. It investigates this possibility, through a purposively chosen set of visual and musical representations of HIV, from high and low-resourced epidemic contexts, and from what it designates pre-treatment, treatment possibility and treatment access eras of the pandemic. These case studies include one work of relatively wide audience reach, musical and visual, from the 1990s USA and 2000s southern Africa. The paper will analyse the narrative genres drawn on and reformulated in each case, deploying Kristeva’s understanding of narratives as forms of signification that allow us to acknowledge abjection while continuing to speak and act.

Psychological and social correlates of hiv status disclosure: The significance of stigma
distinction

Sarah Stutterheim Open University Netherlands, Netherlands; Ronald Brands; John Pryor; Arjan Bos Open University Netherlands, Netherlands; Herman Schaalmans.

Objective: To investigate HIV-related stigma, psychological distress, self-esteem, and social support in a sample comprising people who have concealed their HIV status to all but a selected few (limited disclosers, N = 163), people who can conceal but chose to be open (full disclosers; N = 300), and people who had visible symptoms that made concealing difficult (visibly stigmatized, N = 194). Methods: 667 people living with HIV (PLWH) completed a cross-sectional survey measuring disclosure, stigma experiences, psychological distress, self-esteem, social support, and the presence of visible symptoms. One-way analyses of variance least significant differences were conducted, as were mediation analyses in accordance with Baron and Kenny (1986). Results: The visibly stigmatized and full disclosers reported significantly more stigma experiences than limited disclosers, but only the visibly stigmatized reported more psychological distress, lower self-esteem, and less social support than limited disclosers. Differences in psychological distress and self-esteem between the visibly stigmatized and full disclosers were mediated by social support while differences between the visibly stigmatized and limited disclosers were mediated by both social support and stigma. Conclusions: The findings suggest that having a visible stigma is more detrimental than having a concealable stigma and that social support buffers psychological distress in people with HIV. This points to the need to promote social support provision for PLWH, especially those with visible symptoms.

HIV-related stigma in African and Afro-Caribbean communities in the Netherlands

Sarah Stutterheim Open University Netherlands, Netherlands; Marijn de Bruin; Iris Shiripinda; John Pryor; Arjan Bos Open University Netherlands, Netherlands; Herman Schaalmans.

HIV-related stigma in African and Afro-Caribbean diaspora communities in the Netherlands was investigated in face-to-face semi-structured interviews with HIV-positive (42) and HIV-negative (52) community members between January 2005 and May 2008. Interviews were guided by a structured protocol of opened-ended questions with follow-up probes, recorded with a digital voice recorder, transcribed verbatim, and processed with QSR NVivo 2.0. Thematic analyses showed that HIV-related stigma manifests as social distance, physical distance, words, and silence. The consequences of HIV-related stigma for HIV-positive African and Afro-Caribbean people were psychological, social, and health-related. The psychological consequences were emotional pain, sadness, loneliness, anger, frustration, and internalized stigma. The social consequences included decreased social network size, limited social support, and social isolation, and resulted from not only enacted stigma but also self-imposed social withdrawal. Also, poor treatment adherence was a health-related consequence. People living with HIV (PLWH) employed both problem-focused and emotion-focused coping strategies to mitigate the negative consequences of stigma. Problem-focused coping strategies included selective disclosure, disengagement, affiliation with similar others, seeking social support, and, to a lesser extent, activism. Emotion-focused strategies included distraction, positive reappraisal, religious coping, external attributions, disidentification, and acceptance. HIV-related stigma clearly permeates African and Afro-Caribbean communities in the Netherlands, and should be targeted for intervention. Interventions in the community that tackle the manifestations of HIV-related stigma are thus imperative, as are interventions that seek to change the societal and community structures that promote stigmatization.

Beliefs contributing to HIV-related stigma in African and Afro-Caribbean communities in the Netherlands

Sarah Stutterheim Open University Netherlands, Netherlands; Nicole van Kesteren; Marijn de Bruin; Iris Shiripinda; John Pryor; Arjan Bos Open University Netherlands, Netherlands.

Thirty years after the first diagnosis, people living with HIV (PLWH) around the world continue to report stigmatizing experiences. In this study, beliefs contributing to HIV-related stigma in African and Afro-Caribbean diaspora communities and their cultural context were explored through face-to-face semi-structured interviews with HIV-positive (N = 42) and HIV-negative (N = 52) African, Dutch Antillean, and Surinamese diaspora community members in the Netherlands. Interviews were recorded with a digital voice recorder and transcribed verbatim. Data were processed with QSR NVivo 2.0 and analyzed using a general inductive approach. Each transcript was read while listening to the corresponding recording to identify emerging themes and establish categories to which text fragments were assigned. Coding continued until saturation was evident. Findings were subsequently checked with relevant stakeholders in the diaspora communities in the Netherlands. The results show that beliefs that HIV is highly contagious, that HIV is a very severe disease, and that PLWH are personally responsible for acquiring their HIV infection were found to contribute to HIV-related stigma, as did the belief that PLWH are HIV-positive because they engaged in norm-violating behavior such as promiscuity, commercial sex work, and, for Afro-Caribbean diaspora, also homosexuality. These beliefs were found to be exacerbated and perpetuated by cultural taboos on talking about HIV and sexuality. HIV-related stigma reduction interventions should focus on changing these beliefs and breaking cultural taboos on HIV and sexuality in a manner that is participatory and consistent with current theory and empirical findings.

Cognitive remediation therapy improves visual speed of processing and iadls in middle-aged and older adults with HIV

David Vance UAB, United States of America; Pariya Fazeli; Jaspreet Kaur; Peggy Mckee

The purpose of this study was to investigate whether a visual speed of processing training program would improve this cognitive ability in adults with HIV, and translate into improved performance on a measure of everyday functioning. In this study, 46 middle-aged and older adults with HIV (40+ years) were recruited with flyers from a university HIV/AIDS clinic. Their average current CD4 lymphocyte count was 433.75 ml (SD = 220); 6 participants had a CD4+ lymphocyte count below 200 ml which is indicative of AIDS. These participants were randomly assigned to a speed of processing training condition or a no-contact control condition. Those randomised to the training arm received 10 hours of computerised speed visual-cognitive exercises. At baseline and posttest, participants were administered a neurocognitive battery and the Timed Instrumental Activities of Daily Living (TIAIDL) Test. Controlling for baseline performance, ANCOVAs were used to examine treatment effects on these measures between the two groups at posttest. Treatment effects were detected on a measure of visual processing speed, the Useful Field of View (UFOV) test; the speed of processing training group improved on their UFOV performance. Furthermore, transfer of training was observed on the TIAIDL Test; the speed of processing training group improved their speed and accuracy in performing these laboratory IADL tasks. This study demonstrates that speed of processing training may improve cognitive and everyday functioning in this growing population.

Predictors of cognitive and everyday functioning in adults with HIV

David Vance UAB, United States of America; Jaspreet Kaur; Pariya Fazeli

Cognitive deficits are often common in adults with HIV. Such deficits may be more severe as people age with this disease. The purpose of this study was to identify predictors of neuropsychological performance among adults with HIV. Psychosocial (Lubben Social Network Scale, Profile of Mood States, drug use) and neuropsychological measures of processing speed (Complex Reaction Time Test, Useful Field of View, Digit Symbol Substitution), executive function (Clox, Trails B), psychomotor ability (Trails A, Digit Symbol Copy, Finger Tapping Test), and memory (Spatial Span, Digit Span) were administered to 98 HIV-positive adults (mean age = 45.23). Regression analyses were used to examine predictors of neuropsychological performance. Step one examined the contribution of age and education quality (WRAT- 3 Reading), and Step two examined the contribution of health factors to neuropsychological performance. For several measures of neuropsychological performance, older age, poorer educational quality, mood problems, and more drug use predicted poor neuropsychological performance. Among adults with HIV, the best predictors of neuropsychological test performance were age and education quality. Mood problems and drug use added to the prediction of cognitive deficits. Health factors such as years diagnosed with HIV, and the size of one’s social network were not
predictive of performance in any model. Results suggest individuals aging with HIV have some risk of cognitive decline. Implications for practice and research are posited.

Does cognitive functioning predict accurate recall of CD4 and viral load values in adults with HIV without dementia?

**David Vance** UAB, United States of America; **Carrie Ann Gakumo**; **Pariya Fazeli**; **Larry Slater**

Health numeracy has relevancy in that adults with HIV monitor their CD4+ lymphocyte count and viral load. Cognitive complaints are common in HIV; such cognitive problems may interfere with accurate monitoring of such health numeracy information. The purpose of this study was to examine whether cognitive functioning is related to accurate monitoring of these laboratory values. In this study, 88 adults with HIV were asked to report their most current CD4+ lymphocyte count and viral load; this information was compared with their actual and most recent CD4+ lymphocyte count and viral load obtained through electronic medical chart extraction. For 75 participants who had both self-reported and corresponding clinic values for their CD4+ lymphocyte count, there was a high level of agreement (r = .73, p < .001; self-reported value = 523.94 uL; actual value = 463.35 uL). For 32 participants who had both self-reported and corresponding clinic values for plasma viral load, there was a low level of agreement (r = .01 p = .92; self-reported value = 30,418.31 uL; actual value = 27,159.18 uL). In a series of correlation analyses, cognitive functioning on measures of executive functioning, memory, psychomotor ability, and speed of processing was not related to the accuracy of recall for either CD4+ lymphocyte count or viral load. Other reasons associated with accurate recall of such health numeracy may be due to the participants health literacy and locus of control. Implications for other future studies are posited.

Promoting adherence to antiretroviral treatment through motivational interventions: A systematic review

**Bruna Von Muhlen** PUCRS, Brazil; **Marlene Strely**; **Adolfo Pizzinato**; **Helena Scarparo**; **Diego Dewes**

It is very difficult to stop the spread of HIV around the world. It represents a global public health problem. A lot of drugs are being developed and accepted around the world. It represents a global public health problem. It is very difficult, displaying the necessity of qualification in the provided service and new interventions that promote treatment adherence. The HAART (Highly Active Antiretroviral Therapy) adherence needs 95% of pills ingested in order to promote a reduction of the plasmatic viral load of RNA-HIV-1 and acquire a stability of the T-CD4+ lymphocytes. Hence, lower motivation to be bound by the treatment can be related to an increase in severity of symptoms related to the disease, resulting from low levels of treatment adherence. Approaches involving motivational aspects such as Motivational Intervention for people with AIDS, can promote adherence to antiretroviral treatment (HAART) by promoting protective factors in individual health. This work systematically reviewed studies of effectiveness of motivational intervention in adherence to HAART, and searched databases OVID, PubMed, Embase, PsychINFO, through descriptors and pre-defined criteria, intersecting six groups for the syntax, and using only good quality methodological studies (randomized controlled trials, prospective studies), found by the Verhagen (1998) checklist. The analysis of seven studies found suggests that participants have a better adherence when undergoing to Motivational Intervention (MI) - namely, an increase in the taking of pills and the motivation to follow the antiretroviral treatment with medicines.

**Does HIV decrease the level of serum brain-derived neurotrophic factor?**

**Rafal Wojciak** Poznan University of Medical Sciences, Poland; **Grzazyna Barylkiwicz**; **Wlodzimierz Samborski**; **Ewa Mojs**
