MSCs are reviewed for submission. All submissions should be made online, at the International Journal of Psychology’s Manuscript Central site (http://mc.manuscriptcentral.com/pijp). Each manuscript should include a standard document format type such as Word or Rich Text Format. Title page, figures and tables should be integrated into the main document. New users should first create an account. Once an account is logged onto the system submissions should be made via the Author Centre. If any assistance is needed with this, please feel free to e-mail the editorial assistant Duncan Nicholas on review@psychologypress.com.

For more information, please visit the “Instructions for Authors” page of the journal’s website: www.psypress.com/ijp

The International Journal of Psychology is now available online: Please visit our website at psypress.com/ijp for more information (online ISSN: 1448-0486).

Subscription rates

Volume 47, 2012 (6 issues) are as follows:

Europe:

£590.00 (UK); £770.00 (Europe); £796.00 (RoW).

US:

$878.00 (USA); $976.00 (Europe); $972.00 (RoW).

Individuals:

£530.00 (UK); €699.00 (Europe); $878.00 (RoW).

Subscriptions must be purchased with a personal cheque or credit card. The reselling of personal subscriptions is strictly prohibited. Personal subscriptions are sold at a reduced rate only to individuals, who are not in full-time employment, students, researchers or members of non-profit organisations.

Dollar rate applies to all subscribers outside Europe. Euro rates apply to all subscribers in the EU, except the UK and the Republic of Ireland where the pound sterling rate applies. All subscriptions are payable in advance and all rates include postage. Journals are sent by air to the USA, Canada, Mexico, India, Japan and Australasia. Subscriptions entered on an annual basis, i.e., January to December. Payment may be made by cheque, dollar cheque, euro cheque, international money order, National Giro or credit cards (Amex, Visa and Mastercard).

An institutional subscription to the print edition also includes free access to the online edition for any number of concurrent users across the whole of the journal. Subscriptions purchased at the personal (print only) rate are strictly for personal, non-commercial use only. The resolution of personal subscriptions is strictly prohibited. Personal subscriptions must be purchased with a personal cheque or credit card. Proof of personal identity must be requested for fulfilment. For information please visit the journal’s homepage.

International Journal of Psychology (ISSN 0020-7594) is published six times a year (in February, April, June, August, October, and December), by Psychology Press, 4 Park Square, Milton Park, Abingdon, Oxford, OX14 4RN, UK. The 2012 US institutional subscription price is $878.00. For a complete list of suppliers and carriers in the USA, please contact your usual supplier. The US Postal Service rate is $878.00. Periodicals postage paid at Jamaica NY 11434, USA.

US Postmaster: Send address changes to International Journal of Psychology, c/o T&F Customer Services, Informa US LLC, Shippen Place, ZIP Code, Chesterfield, MO 63017-5254; E-mail: subscriptions@tandf.co.uk. Please give six weeks’ notice of changes of address and include both old and new addresses.

Taylor & Francis has a flexible approach to subscriptions enabling us to match individual libraries’ requirements. This journal is available via a traditional institutional subscription (either print with online access or online only at a discount) or as part of the Behavioural Science Collection or SHL Library. For more information, please visit www.tandfonline.com/page/librarians

Copyright: It is a condition of publication that all contributing authors grant the publisher the necessary rights in the copyright to all articles submitted to the journal. The Authors are required to sign an Article Publishing Agreement to ensure that their work is not in conflict with any dissemination and protection against copyright infringement of articles. The “article” is defined as comprising the final, definitive, and final version of Record, and includes (a) the accepted manuscript in its final and revised form, including the title, abstract, and all accompanying tables, illustrations, data, and (b) any supplementary material. Copyright policy is explained in detail at http://journalauthors.tandf.co.uk/prepare/content.html. Authors are themselves responsible for obtaining permission to reproduce copyright material from other sources.

Permissions: Authors are responsible for obtaining permission for the photocopying of isolated articles for non-profit classroom and library reserve use by instructors and educational institutions. This consent does not extend to other kinds of copying, such as copying for general distribution for advertising or for promotional purposes, for creating new collective works, or for resale.

Reprints: Taylor & Francis is a leading publisher of reprints, enabling us to match individual libraries’ requirements. This journal is available via a traditional institutional subscription (either print with online access or online only at a discount) or as part of the Behavioural Science Collection or SHL Library. For more information, please visit http://www.tandfonline.com/page/reprints

The 30th International Congresses of Psychology (ICP 2012) is the first to be held in Africa in the 123-year history of this flagship event in international psychology. ICP 2012 promises to be an unforgettable professional and scientific experience in a unique cultural environment, South Africa’s Mother City, Cape Town.

Under the theme *Psychology Serving Humanity*, ICP 2012 showcases new frontiers of psychological science and practice as a means of improving, developing and enriching human life. ICP 2012 acknowledges that the discipline of psychology is inextricably engaged with the global and local communities in which we live, learn and practice. Hosted by the National Research Foundation and the Psychological Society of South Africa, ICP 2012 includes the widest range of substantive content fields within psychology.

The outstanding scientific programme features distinguished keynote addresses, cutting edge state-of-the-science lectures, controversial debates, and compelling presentations by leaders in the various fields of psychology, as attested to by the abstracts below.

**President: ICP 2012**
Participative appreciative therapy: A positive approach
Manju Agrawal Amity University, India

This paper introduces Participative Appreciative Therapy. It is based on principals of appreciative inquiry combined with the power of visualisation. It has two phases. First is CREAM (catharsis, rapport building, empathy, affirmative topic and motivational environment) and second is DESERT (exploring the dream, seeing the dream implemented, emotional glue, representative actions and behaviour, transformation and discussion). Positive outcomes are visible from the very first session as probing and inquiry are in themselves therapeutic in nature. This paper advocates the importance of positive life orientation in recovery which has a healing touch. Hope, faith, love, will to live, cheerfulness, creativity, playfulness, confidence and great expectations have therapeutic value recognised all over the world and also by medical science. Yet, until now, most of the traditional therapies take a pathology-focused approach: problem – cause - interventions to uproot the cause - find solutions - follow up. In contrast participative appreciative therapy is an alternative approach to counseling and therapy with a life focused approach: catharsis - focus on life giving factors - visioning of what could be - action plan - making personal commitments – take actions - appreciate and celebrate.

Using single block single category implicit association test to measure implicit gender identification
Chuanguo Ai Central China Normal University, China; He Wenhui Central China Normal University, China; Xue Mengjie Central China Normal University, China; Bin Zuo Central China Normal University, China; Guoju Wang Amity University, India

This research used Single Block Single Category Implicit Association Test (SB-SC-IAT) to evaluate undergraduates' gender identification, and try to find out whether it is better than Single Category Implicit Association Test (SC-IAT). SB-SC-IAT integrates two blocks (compatible and incompati- ble) into one block. Fifty-one students were recruited in one university (22 males, 29 females). They were first instructed to accomplish the Bem gender scale in Chinese Revised Version, and then recruited in one university (22 males, 29 females). The two blocks (compatible and incompatible) were presented in a single block single category implicit association test. SC-IAT is better than SB-SC-IAT insofar as it has similar measurement results but fewer blocks.

Validation study of the Parental Concerns’ Scale with a group of parents of children until 2 years old
Susana Algarvio ISPA, IU, Portugal; Joao Maroco ISPA, IU, Portugal; Isabel Leal ISPA, IU, Portugal

The aim of this study was to assess parental concern in young children and to evaluate the Predictive Validity of a scale developed to assess parental concerns. The participants were 54 parents of children between 0 and 2 years old that went to a Day Care Centre in the Lisbon District. Parents completed a Parental Concerns’ Scale that comprised five subscales: Family and school problems; Eating, sleep and physical complaints; Preparation; Fears; and Negative behaviours. Predictive Validity was assessed by comparing differences between this group of parents and a stratified sample of 3842 Portuguese parents of preschool and elementary school children, with MANOVA followed by one-way ANOVA with Post-hoc tests. Parents of young children were more highly concerned with family and school problems, and with eating, sleep and physical complaints, and less concerned with the child’s negative behaviours. The comparative study showed significant differences between the three groups of parents, (F (2, 3866) = 38.314, p< .0005; Wilk’s A .89; partial s2 = .056), for the total score, for family and school problems, and for eating, sleep and physical complaints. There were also marginally significant differences for preparation. Post-hoc tests revealed that parents of younger children were less concerned about all the dimensions than parents of older children. Parental concerns differed among age groups of children. These results supported evidence for the Predictive Validity of the Parental Concerns Scale by distinguishing between different age groups of children.

Factor structure of the MBI-GS survey for college professors in Mexico
Fernando Arias-Galicia Morelos State University, Mexico; Arturo Juarez; Carmen Camacho

Since the 1970s job burnout has deserved attention in the human services, but today it has reached huge proportions at any profession around the world. Like work, human environment changes from a culture. It is vital to have a measurable scale to identify the culture of a group of cultures and professions. Therefore a question arises: Is the factorial structure of the Maslach-Burnout Inventory-General Survey (MBI-GS, 1986) replicated within professors because it is shorter than other versions? The instruments used comprises 16 items classified according to three factors: Exhaustion, professional efficacy and de-personalization. The sample was constituted by 290 Mexican college professors who participated voluntarily in this study. The measurement model was assessed by means of the LISREL package, unfortunately the confirmatory factor analysis did not render adequate indices: Chi-Squared=329.47, df =78, p=.0000, RMSEA=.107; at least one item of each factor showed negative values. So it was necessary to eliminate some items in each factor. The new measurement model indices were significantly improved: Chi-squared=37.71, df=17, p=.00269, RMSEA=.065. The MBI-GS is not the best option to evaluate professors’ burnout, instead it is recommended to evaluate burnout levels by means of the Education Survey version (MBI-ES). Further the Mexican culture implies different faculty job environments from developed countries. The next step is to ascertain another professor sample with the MBI-ES translated into Spanish and adapted to Mexican academic culture.

Development of multidimensional self-concept scale (MSCS) for Filipino college students
Ericson Batican Ateneo de Davao University, Philippines

This study intended to develop a multidimensional self-concept scale (MSCS) for Filipino college students. The model consists of two factors with fifteen dimensions; (a) Independent Self Construal (Physical Attributes, Scholastic Competence, Athletic Competence, Artistic Expression, Autonomy and Independence, Global Self Worth, Financial Capacity, Goal Setting, and Gender and Sex); and (b) the Dependent Self Construal (Family Relation- ship, Morality and Religiosity, Social Competence, Romantic Relationship, Close Friendship, and Af- filiation). A total of 499 students participated in this study. Of 198 items, 19 were automatically removed, 13 were added and 47 were revised based on the content validation ratio (Lawshe, 1975) result from the ratings of 13 experts. The Cronbach’s coefficient is high (.922) while test-retest reliability revealed high correlations in almost all dimensions except Gender and Sex (r =.13 p = .13). Concurrent validity coefficient with the Rosenberg Self-Esteem Scale is significant (r =.55, p < .001), while most of the dimensions yielded significant construct validity coefficients, except Gender and Sex (r =.18, p = .12) and Autonomy and Independence (r =.03, p = .41). Pre-test-posttest change was determined using Wilcoxon Signed Rank Test as another evidence of construct validity. It revealed a significant change of the scores of the participants after the intervention in several dimensions like Physical Attributes (Z=2.16, p = .015), Goal Setting (Z=1.89, p = .029), and Autonomy and Independence (Z=3.18, p < .001). Factor analyses were subsequently employed.

An investigation and analysis of high school student leadership in Central China
Wang Bin School of Physical Education, China; Li Min; Li Gai; Wei Mingding; Li Zhongxian

The study aims to investigate the leadership skills of first-year students in high schools and examine the differences in leadership experience and gender on the five subscales of Student Leadership Practice Inventory. With random sampling, we selected 381 students from over eight high schools in Wuhan – the provincial capital of Hubei – as subjects. They ranged 15–18 years of age and all had leadership experiences prior, with a representation of 55.9% females and 44.1% males. The participants’ scores of leadership practice range from 52–150 with a
mean of 108.8. The most frequently engaged in leadership practice is Enable others to act, followed by Encourage the heart, Model the way and Inspire a shared vision, then Challenge the process. A statistically significant difference is found by length of leadership experience on five leadership practices. The students with more than two years’ leadership experience engage in each leadership practice more than the students with leadership experience under one year and of one to two years do. No statistically significant difference is found between males and females on any leadership practice. The results indicate that the skills to inspire a shared vision and challenge the process should be emphasized more than the other skills when implementing leadership education practices for Chinese high school students. Furthermore, leadership experiences may be good for students’ leadership development and some student leadership developmental programs may be suitable for both boys and girls in high schools.

**Performance of adolescents on two versions of the RAVLT**

Jeanine Blumenau University of the Witwatersrand, South Africa; Yvonne Broom

In South Africa, the multicultural and multilingual nature of society has impacted on the cultural appropriateness of psychological tests. In the assessment of memory and learning, tasks such as the Rey Auditory Verbal Learning Test (RAVLT) are widely used although they may not be standardized for the South African context. This study investigated how South African learners performed on the RAVLT as well as on an adapted version of this test, the South African List Learning Test (SALLT). The impact of language differences on performance was also noted. Subjects were 54 first and second language English speaking secondary school learners. Results indicated that South African learners achieved a higher level of recall on the SALLT than on the Euro-American RAVLT. Findings confirmed the impact of language experience on performance and highlight the necessity for the development and standardization of culturally relevant psychological tests in South Africa.

**A cognitive diagnosis model: Similarity group-level decision model**

Yan Cai; JiangXi Normal University, China; Dongbo Tu; Shuliang Ding

This paper developed a similarity group-level decision model (SGDM) to realize the group-level cognitive diagnosis directly. In this paper, three sections were composed. In the first section, we tried to construct the framework of the new model, and two classification methods were suggested. In the second, we investigated the rationality and feasibility with a Monte Carlo simulation study through three indexes under independent attribute hierarchy. In the last section, we applied the model into the real data analysis, and investigated the consistency with the other assessment. The findings were as follows: (1) The simulation study indicated that the SGDM model was national and feasible. The indexes on the correct matched ratio under the model were relatively great and they decreased while the allowed slip probability increased. (2) When the SGDM model was used in the analysis on English reading problem solving in China, it found that there were three major cognitive skill deficiencies at school-level, which was consistent with the assessments of English education experts. It reflected that the model was feasible in real practice.

**The estimation and comparison of group-level IRT model and individual IRT model**

Yan Cai; JiangXi Normal University, China; Dongbo Tu; Shuliang Ding

Traditionally the assessment of a group was based on the assessment of an individual, but the group-level IRT (GIRT) model could realize the assessment of a group without the individual assessment, which only required the individual in a group to answer one or some items in a test. Thus, it could deal with not only the completed data, but also the missing data. Through the Monte Carlo simulation method, this paper investigated the robustness and estimation precision of 2 parameter GIRT model under small scale group-level assessment. Most importantly, it also made a comparison with the outputs of the 2 parameter IRT model, which provided another profile of the GIRT model. In the study, two aspects (the model assumptions and between variations) were discussed. The findings reflected: (1) The model holds relatively strong robustness. (2) The estimation precision of all parameters was great. The precision of ability and distinct item parameters were first increasing then descending with the value of the between variation varying from small to medium to great. Additionally, the precision of difficulty item parameter was increasing during this varying. Those were similar with the findings under the IRT model. It showed that the GIRT model supplied another feasible group-level assessment method, and it could provide a similar assessment using less data than IRT model.

**Translating the CORE-OM into isiXhosa: A method of psychometric tool translation**

Megan Campbell Rhodes University, South Africa

The Clinical Outcomes in Routine Evaluation-Outcome Measure (CORE-OM), a pan-theoretical, practice-based evidence tool for measuring gross psychological distress and change achieved during psychotherapy, was recently validated on a South African English-speaking student population sample for use in South African university student counselling centres. Following its successful validation, this paper now presents the design used to translate the CORE-OM into an isiXhosa version for use with first language isiXhosa-speaking students in isiXhosa medium South African university student counselling centres. A back-translation design was used comprising a team of 6 bilingual, first-language isiXhosa speaking translators, in combination with a committee approach. The finalised translation was then qualitatively piloted, after which a larger quantitative pilot was conducted in an isiXhosa medium South African university. Data analysis was conducted in Statistics. Confirmatory factor analysis was used to evaluate construct equivalence and internal consistency of the translated isiXhosa version in comparison to the original CORE-OM English version. Test-retest reliability scores were compared to evaluate method bias and reliability within the translated CORE-OM isiXhosa version and differential item functioning (DIF) using logical regression was applied to investigate item bias. Parametric t-tests, effect sizes and confidence levels were used to evaluate differences between population samples as was done within the analysis of the original U.K. referential data and the validation of the CORE-OM on a South African English-speaking student population sample.

**Psychometric properties of the Spanish version of the questionnaire “Stress in Children”**

Alessandra Caquer-Urizar Universidad de Tarapaco, Chile; Alfonso Urzua-Morales

The present study describes the analysis process of the psychometric properties of the Spanish version of the Questionnaire “Stress in Children” (SIC) (Osika, et al., 2007), with the data compiled from a group of 1678 Chilean school children (765 boys and 913 girls) from 8 to 18 years (mean age =11.9 years; SD=2.75). The analysed version of the Questionnaire is integrated by 16 items distributed into two factors: Factor 1, well-being, factor 2, distress, which explain 42.8% of the total variance. The internal consistency indexes (Cronbach’s Alphas) oscillated between .69 and .77, showing appropriate psychometric properties of the Questionnaire Stress in Children in this group of Chilean children.

**The development of Chinese Christians’ social support scale**

Yongsheng Chen; Zhejiang Normal University, Afghanistan; Haiyan Song

The researchers assume that Chinese Christians’ social support includes four dimensions: Organisational support, belief support, affection support, and substance support. The qualitative software analysis of 103 valid participants’ interview information, exploratory factor analysis of 276 valid participants and the confirmatory factor analysis of 269 valid participants have verified the rationality of the hypothesises. Following the four dimensions, the Chinese Christians’ Social Support Scale (CCSSS) has 21 items, of which the organisational support subscale covers 5 items, the belief support subscale covers 5, the affection support subscale covers 6, and substance support subscale covers 5 items. The results of reliability and validity tests shows that CCSSS has good psychometric properties. Of these, the internal consistency coefficient of the full scale is .924 and the internal consistency coefficients of the 4 subscales are respectively .892, .898, .861 and .846. The split-half reliability coefficient of the full scale is .734 and split-half reliability coefficients of the 4 subscales are respectively .856, .873, .835 and .832. Test-retest correlation over a two-week interval is .723. The criterion validity of CCSSS with the Church-based Social Support Measure (Chinese version) is .426. This study concludes that CCSSS is a valid measure for Chinese Christians.

**Development of Chinese urban citizens**

Yongsheng Chen; Zhejiang Normal University, Afghanistan; Lixia Mou

In this study, the operational definition and structure hypothesis is that SOC means community members’ attitude toward the psychological envi-
Environment and mutual influences of community maintenance and development. SOC includes three factors: Collective identity, mutual attachment and the trend of inheritance, and there exists a certain internalality among them. The qualitative software analysis of 72 valid participants’ interview information, exploratory factor analysis of 256 valid participants and the confirmatory factor analysis of 956 valid participants have verified the rationality of the hypothesis. Following the three dimensions, the Chinese urban citizens’ sense of community scale (CUCSOCS) developed has 19 items, of which collective identity subscale covers 6, mutual attachment covers 7 and the trend of inheritance covers 6. Furthermore, the result of reliability and validity test shows that CUCSOCS has good psychometric properties. Of these, the internal consistency coefficient of the full scale is .879, the split-half reliability coefficient of the full scale is .879 and the test-retest correlation over a two-week interval is .749. Besides, the scale also has a good criterion validity, convergent validity and discriminate validity.

The application of survival analysis in psychological research
Chen Chuan South China Normal University, China
Jin-Qiang Zhang

There is not a complete loss of the phenomenon in follow-up data of psychological research subjects. Under the traditional statistical methods in dealing with the loss of such data, it was easy to overlook the phenomenon of the study results. Survival analysis is one of the methods which can track data loss. Compared with OLS and logistic regression, the survival analysis method can handle censored data well, reduce bias, and a good deal of explanatory variables well over time. In the practised data, the application of children Wechsler block design test is also proof of the above conclusion.

Different predictors of test anxiety among adolescents
Sadhan Dasgupta University of Calcutta, India
Sreeparna Dutta

The present study was an exploratory attempt to identify different predictors of Test Anxiety (TA) among adolescents where the students perceived the situation as one in which significant others will pass judgments upon their adequacy in context to a test-like situation. The participants were 131 adolescents (both boys and girls from class 11 and 12), from different Higher Secondary Schools in Kolkata city, India. They were selected from middle class socio-economic families. The participants were selected from all the streams (science, humanities and commerce). Their mean age was M=17.25. A purposive sampling technique was followed and the study was based on a cross-section correlational approach. Stepwise multiple regression analysis identified Reactive Aggression (RA), Emotional Intelligence (EI), Neuroticism (N) and Psychoticism (P) as important predictors of Test Anxiety (TA) among adolescents. The findings may suggest some effective intervention strategies for management of these worrying cognitions in terms of failure outcome expectancies.

Using patterns of career preferences to provide career guidance feedback to individuals
Marie De Beer UNISA, South Africa
Chris Marais
Franco Skrzypczak; David Maree

Background and aim of the study: The Career Preference Computerised Adaptive Test (CPCAT) is a new measure of career-related preferences which provides information on the broad dimensions and sub-dimensions of career related fields, activities and environments. The relative rating between the dimensions and their sub-dimensions is presented as an individual profile of the top 16 of the 34 possible sub-dimensions. Method: Two secondary School samples (n=262 at junior secondary and n=181 at senior secondary level) and a sample of college students (n=75) were used to obtain reliability and construct validity information. Individual case studies were used to explore interpretation of results at individual level. Results: Coefficient alpha reliability values were generally high (above .80 for 27 of 34 sub-dimensions and above .70 for the other 7 sub-dimensions). In terms of construct validity, the patterns of correlations with another interest measure showed convergent and discriminant validity in line with the dimensions measured. Individual case studies examples illustrate how the unique pattern of preferences within and between career fields, career-related activities and environments provide an additional layer of information that can enrich career guidance discussions. Conclusions: This measure and approach for assessing career-related interest provides psychometrically sound information that can contribute to career guidance assessment, feedback and discussions.

The identification of the four cognitive patterns with a unique virtual tool: A pilot study
Marie Dejnos University of Bordeaux Segalen, France; Helene Sureau; Bernard N’Koua; Prashant Arvind Pala

In order to realize a qualitative differential diagnosis, the neuropsychological assessment should answer several clinical objectives such as the identification of distorted and intact cognitive functions. Nowadays the increasing interest given to disability and to everyday life cognitive difficulties, even without objective disorders, encourages development of naturalistic evaluation tools. In other words, we promote the evaluation of cognitive processes as they are in everyday life. In this context, we propose to assess the quality of the evaluation tool based on virtually simulated apartment. This tool provides memory and executive clues in naturalistic context in order to identify many cognitive patterns. A virtual replica of the CVLT simulates a visit in the apartment composed of four rooms. According to the traditional CVLT, different indications are exploited: Learning, free recall, strategic processing, proactive interference, false recognitions, intrusion, and perseverations. The performances of 4 groups of subjects [young (n=15), elderly (n=15), Alzheimers (n=17) and traumatic brain injury (n=7) patients] are compared to those of traditional CVLT. The results show that the virtual-CVLT offers a sensitivity and reliability similar to the traditional version. Moreover, it has a better selectivity, diagnostic value and naturalistic validity compared to the traditional-CVLT. Thus, our study provides an undeniable clinical interest, as it characterizes more precisely different cognitive patterns of elderly (executive pattern), of Alzheimer (memory pattern) and of traumatic brain injury (executive pattern) patients. These first results demonstrate that a neuropsychological evaluation can be more naturalistic without decrease in its psychometric quality.

Organisational culture in a Chilean public university
Guido Demichell Universidad de Valparaiso, Chile
Alvaro Infante

This presentation reports the results of an organisational culture study, aimed at establishing and measuring the masculinity and femininity in 30 institutions, and beliefs about their own organisation. 70 in depth-interviews and 362 questionnaires were complete with a proportional and stratified sample of two populations: Faculty (N=1,120; sample: 212) and Staff (N=789; sample: 150). This research used the Galileo System, an integral quasi-quantitative methodology program that includes software for content analysis as well as tools to construct a specific study questionnaire, to measure and graphically represent attitudes of both populations. Even though the theoretical basic assumption is the shared character of organisational cultures, this study focuses on comparing two very distinctive groups inside the same organisation, in order to discover up to what point each of them report as relevant (or not) the same constitutive cultural features of their organisation, and which are their main attitudes and beliefs regarding the characteristics they distinguish. Regularly, organisational interventions assumes a "general culture" rather than specific ones so, if eventually different groups experience different cultures inside the same institution, this should be relevant for taking into account for future institutional interventions, avoiding the pitfall of treating both groups (if it is the case) as being only one.

Reducing adverse impact experienced with psychometric assessments in the South African context
Kim Dowdswell SHL South Africa, South Africa

Being able to identify and select the top performers who will drive the success of the business is viewed as a strategic priority by many organisations, with the benefits of appointing such well established in the research literature (Aberdeen Group, 2010; Hunter, Schmidt, & Judiesch, 1990). While there is robust validation evidence for several assessment methods, an area that should always be considered in any selection process is adverse impact, which occurs where the use of a test or selection procedure results in a substantially different selection rate between groups (Robertson & Smith, 2001). This is of particular import in South Africa, with reference to the Employment Equity Act (1998). This paper forms part of a broader doctoral study concerning adverse impact and psychometric assessments in South Africa. Using a sample of customer service applicants who completed psychometric assessments (cognitive ability tests and a personality questionnaire) as part of the selection process (N=731), and tracking the applied applicants in terms of their performance (N=83), the
potential for adverse impact resulting from the use of assessments in the selection process will be unpacked. This information will be considered in the light of validation evidence of the assessment battery, demonstrated by correlating appointed candidates' assessment and performance scores. The impact of the broader research project is to provide South African organisations with guidance informed by international research and based on local evidence to address the dilemma of balancing commercial and business needs with social, ethical and legal obligations when using psychometric assessments in their selection procedures.

The use of the South African benchmark test (NBT) as a predictor of academic success

Graham Du Plessis University of Johannesburg, South Africa

Since 1994 the government of South Africa has championed access to opportunities for all citizens. The aspiration of equitable access to education opportunities has increasingly become an area of central theoretical and practical concern. Of particular interest has been the placement of secondary school students into universities. The employ of admission tests in addition to school performance indicators has a long history both in South Africa and internationally. In the South African context the use of these tests is endorsed for two predominant reasons. Firstly, the schooling system is characterised by significant discrepancies that are engendered by both past and present disadvantage. Secondly, the South African population is characterised by considerable heterogeneity in areas such as culture, language and socio-economic background. This study explored whether the NBT had potential utility in explaining the variance in academic performance during the first semester of 944 first year university students enrolled in the Faculty of Humanities at the University of Johannesburg in 2011. A linear regression analysis indicated that both the NBT and secondary school performance explained a significant percentage of the variance in academic performance. A model using both independent variables explained 12% of the variance in academic performance (Adjusted $R^2=.12$, $f(2,994)=65.47$, $p < .01$). The study concluded that the employ of NBT in addition to secondary school performance allowed for a better selection of students than secondary school performance alone; and that selections of this nature are potentially more equitable.

Psychometric characteristics of beta III intelligence scale within contrasted groups and factorial components

Fowzy Ezzat Aly Abd Alazim Dow Suez Canal University, Egypt; Abd El Hamed Regia

The revised Beta III was administered to 164 senior male and female students (age 19–22 years) in the faculty of education, Suez Canal university. The sample was divided into two groups: experimental 23 students, and practical 142 students. By administering Beta III to the experimental group on test-retest interval of two weeks, it was found to have a high reliability of the total test at P.0.01. To verify the validity of Beta III from the practical sample n=142, the researchers used two methods: Contrast groups and factorial components. T-test between means scores between the Egyptian selected practical sample of this study and American male prisoners in the standardised sample of Beta III n=82, (age 20–24 years) contain African American, white, Hispanic and others. The majority of them have a low education level. The results indicated that their were significant relations in favour of the Egyptian sample at p. 0.01 in all the variables of the test. Construct validity factor analysis was conducted, the results indicated that there were two factors: Nonverbal reasoning and processing speed. Picture completion, picture absurdiities, and matrix reasoning influenced significantly the nonverbal reasoning factor. Coding and clerical checking influenced significantly the processing speed factor. Extraction method principal component analysis revealed one component extracted as a general factor in which nonverbal reasoning and processing speed factors loaded significantly on the general factor. The findings indicated that the Beta III scale is relevant to expressive or receptive aspects of intelligence.

Moderators of sex-specific differential prediction in college admission testing

Franziska Fischer University of Konstanz, Germany; Benedikt Hell; Johannes Schulz

Women often perform better than men in college, but they do not outperform men on admission tests. So far there have been many different attempts to explain this underprediction of women's grades. A recurring hypothesis is that female college students show more favorable personality traits such as achievement motivation. Anyhow, no single encompassing personality trait could be identified yet, and usually not more than one personality trait is investigated at once. In the present longitudinal study we compare the influence of the most promising personality traits in order to explain women's superior college achievement. A sample of 596 German freshman students (52% women) in science and management completed a subject-specific college admission test and measures of achievement motivation, conscientiousness, self-efficacy, and test-anxiety. In line with earlier studies, we find a small underprediction of women's first year grade point average. Furthermore, the differential prediction effects are smaller for management students than for science students. For science students, the underprediction of women's college grades can in part be explained by their higher conscientiousness scores. For management students, personality traits fail to eliminate sex differences in the prediction of college grades. Adding high school grades to the prediction model reduces differential prediction, regardless of subject. Therefore, including high school grades in addition to admission test scores is recommended. Highly selective colleges might consider adding a conscientiousness indicator to their admission procedure in order to counter the predictive bias against female candidates.

Detecting answer copying using log-likelihood-ratio and w-index

Yuanyuan Gan Nanjing Normal University, China; Jiayuan Yu

A new method to automatically detect copying on multiple-choice examinations based on Log-Likelihood-Ratio and $\omega$-index is proposed. Two related statistical procedures are combined in the method. The first statistical procedure uses Log-Likelihood-Ratio to identify examinees, called subjects, who have demonstrated inconsistent performance during an examination. For each subject the second statistical procedure uses the $\omega$-index to search for a possible source of the responses. Both stages apply a hypothesis test given a significance level. Monte Carlo methods are applied to approximate empirical distributions and then compute critical values providing a low Type I error rate and a good copying-detection rate. The results from a simulation study in this paper demonstrate the effectiveness of the approach.

International perspectives on test reviewing

Kurt Geisinger University of Nebraska-Lincoln, United States of America; David Burttram

The two authors of this paper were instrumental in the preparation for publication of a special issue of the International Journal of Testing devoted to the various international approaches to the reviewing of psychological measures. This paper would briefly summarise, compare and contrast the various methods utilised by different countries to meet the needs for the public quality control of such measures. The countries and regions involved include the United States, Great Britain, the Netherlands, Germany and...
Spain as well as those procedures used by the European Federation of Psychologists’ Associations (EFPA). Some information is also presented about the Brazilian procedures. The topics to be discussed include the nature of the agency making the review, the selection of reviewers, the number of reviewers used, the criteria used in making the reviews, the specificity of these criteria, how differences of opinions among reviewers are reconciled, roles of the editors of the reviews, how reviews are accessed and by whom. The need for educating reviewers and developing pools of reviewers is referenced. The differing impact of reviews, from simply serving as a publication commenting on the quality of the measure to certification of a measure for use is described. Steps leading to the internationalisation of these procedures will also be discussed. Even with such internationalisation, however, there will be a continuing need for local evaluation of measures and the evidence supporting them.

Test-taking strategies: Fundamental issues to consider in assessment validation processes

Shahram Gaharaki IAU, Iran Khomeinishar Branch, Islamic Republic of Iran; Mohd Sallehuddin Abd Aziz

Validity is the most important attribute of a good test. A test is useful if it is appropriate in terms of the objectives for which the test is utilized. Validity of a test is defined as the interpretation of the correct responses given to its items. In other words, validity of a test has a direct relationship with the way the scores of a test are interpreted. Test performance is affected not only by the test characteristics of test method, but also by test takers’ language ability and test-taking strategies. What the test designer thinks is being tested or will be tested is not always what the test actually will do when test-taking strategies are employed. Therefore, investigating the processes of test-taking at the time of completing a test is vital to interpreting the test and to gain insights into what each item is actually measuring. So, the present article intends to clarify basic concepts and research issues in relation to test-taking strategies. First, various definitions of strategies in general and test-taking strategies in particular are addressed. Then, the issue of consciousness is briefly referred to, and the theoretical foundation of test-taking strategies is explained. The paper also addresses the different type of taxonomies offered for test-taking strategies concerning reading skill. Basic research instruments used for data collection purposes on test-taking strategies, and their application in reading assessment are highlighted. The article gives special attention to test-taking strategies and their implications for test validation.

Assessment use argument: A new approach to test validation

Shahram Gaharaki IAU, Iran Khomeinishar Branch, Islamic Republic of Iran; Allam Woel; Mohd Sallehuddin Abd Aziz

Validity and validation have been the central issues in educational measurement as well as in evaluation and assessment research. Validation examines certain assumptions and influences within a test design, particularly to establish the degree to which all accumulated evidence supports the intended interpretation of test scores for the proposed purpose. An assessment use argument offers a step by step approach, beginning with claims about test score consistency, and ending with the effects of test use on society. The model provides the basis for justifying the intended uses of an assessment. It also offers a conceptual framework consisting of a series of inferences that link the test taker’s performance to a claim about interpretations, and a claim about interpretations, to a claim about decisions, and to claim about intended consequences, along with warrants and backing to support these claims. Moreover, the model enables test users and decision-makers to be accountable to stakeholders for the intended use of the assessment. This article deals with test validation with a particular focus on assessment use argument approach. Specifically, the article reviews the evolution of validity theory and validation frameworks as well as methodologies used to validate tests. Then, we will describe the innovative nature of Bachman’s (2005) and Bachman and Palmer’s (2010) assessment use argument. Concepts such as claims, warrant, backing and rebuttals are explained as a new way to look into test validation. The article gives special discussion to implications of this model over the other approaches in the field.

The evaluation of the effectiveness of interventions into the psychological ambit: A computerised tool and methodological proposal of the dialogics as a science serving humanities

Valeria Gherardini University of Padova, Italy; Denis Poeta; Gian Piero Turchi

The praxis of the evaluation of effectiveness, is a key moment for attesting the transformative impact of interventions in the psychological ambit (and for any kind of intervention referring to scientific criteria), and for monitoring interventions towards the pursuing of their objectives. The present contribution aims at presenting a tool focused on the evaluation of the effectiveness of intervention into the psychological context, regardless of the theoretical model of the intervention. The proposal is based on Dialogueist Science presuppositions, according to which reality is defined as a configuration, and it is discursively generated. On the basis of these presuppositions, a methodology of the evaluation of the effectiveness was designed and, gathering the discursive production at an initial time (T0) and at the end of the intervention (T1), it allows the measurement of occurred modifications. The Computerised System of the Biological Analysis (S.C.A.B.) is a tool that, according to precise presuppositions, measures, through a mathematical model, the difference between the registered value at T0 and the one registered at T1. Consequent-ly, it measures the value of the effectiveness of the intervention. The use of the tool named S.C.A.B. offers guidelines to promote the application of more and more effective interventions, and promotes a culture of the effectiveness for a Psychology which takes the responsibility to deliver effective and quality-driven services to the Humanities.

Research on the revised Fujian version of Minnesota multiphasic personality inventory (mmpi-f)

Jun Gong Jiangxi Children’s Hospital, China; Shuliang Ding

As a result of the enormous cultural difference between China and America, traditional methods of MMPI revision didn’t solve the problem that validity of MMPI decreased obviously in China because American scoring keys don’t suit Chinese scoring keys. The scoring keys in thirteen basic scales (TBSs) of MMPI were recalculated to construct MMPI-FJ in the paper. We selected a Chinese criterion group and a normal control group to screen out native scoring keys of twelve basic scales (except F scale), through an item discrimination index method. F scale was reconstructed with items to which the response rate of Fujian norm was lower than 10%. The comparison of validity between MMPI-FJ and MMPI was made by using Fisher discriminatory analysis and profile comparison. It was found that, (1) TBSs’ scoring keys in MMPI-FJ were 269 items in which 115 items were same as that in MMPI, (2) in multiple discriminant analysis among seven psychiatric groups and the normal group, average discriminant accuracy of the groups was 83.8%, 59.4% through retrospective validation for MMPI-FJ and MMPI respectively, and 78.9%47.3% through cross validation for MMPI-FJ and MMPI respectively, and (3) profile comparison, there were overall higher average T score gaps of TBSs between each psychiatric and norm group in MMPI-FJ than that in MMPI. In the MMPI-FJ profile, the group with highest T score in any clinical scale (except Mf scale) was the corresponding criterion psychiatric group. In the MMPI profile, the group with highest T score in Hy, Pd, Pt, and Sc scales was corresponding to Hypochondriasis, paranoid disorder, bipolar disorder, and paranoid schizophrenia respectively. This paper’s innovation lies in revising MMPI by empirical keying approach; MMPI-FJ is fitter for Chinese than MMPI.

The effect of informative priors on estimating the variability of estimated variance components for MCMC procedure

Li Guangming Guangzhou University, China; Zhang qiang

MCMC procedure is a mobile Monte Carlo method and can be used to estimate variance components which are constrained by sampling. However, these estimates are, like any statistic, subject to sampling variability. They are likely to vary from one sample to another. Therefore, estimating the variability of estimated variance components needs to be further explored in order to ensure the dependability of estimated variance components. The study adopts Monte Carlo data simulation technique to explore the effect of informative priors on estimating the variability of estimated variance components for MCMC procedure based on normal distribution data. This study shows that MCMC with informative priors(MCMC inf) is more precise than MCMC with non-informative priors (MCMC non-inf) for standard error of estimated variance components, but when the item sample is bigger, the trend decreases. This study also shows that MCMC inf is equivalent to MCMC non-inf for confidence interval of estimated variance components, but when item sample is bigger, the trend is still same.

Proactive coping inventory (Spanish): Initial factorial validity, reliability, and cross-lagged relations

Benicio Gutierrez-Dona Universidad Estatal a Distancia, Costa Rica; Ralf Schwarzer
This study was aimed to provide initial evidence for factorial validity, reliability, time invariance and cross-legged relations for the Proactive Coping Inventory (PCI Spanish). German and English versions of the PCI were translated and adapted into Spanish at The Freie Universität Berlin, Germany. Data were collected from a longitudinal sample of Costa Ricans (T1, n=902/T2, n=535). Confirmatory factor analysis (CFA) was used to assess the hypothesised structure of 4 dimensions, 7 factors, and 55 items. SSPPS-CFA yielded a 7-factor model, with eigenvalues greater than 1.00, quite consistent with theoretical assignment of items to scales. Structural equation model implemented (SEM) with LISREL provided consistent evidence for a 4-dimensional structure that clusters 7 scales, and 55 items. Analyses also revealed that the 4-dimensional structure was invariant across time. Correlations were consistent with hypothesised relations between the PCI Spanish and several external scales, namely: The Brief COPE, Personality Trait Scales, Cognitive Appraisal Scales, and The PANAS. Cross-legged panel (SEM-LISREL) revealed significant and positive cross-legged effects between proactive coping and goal oriented coping (reflective, preventive, and strategic planning). It was also found, that early increases in proactive coping were related to later reductions in avoidance coping. Conversely, initial supports in support-oriented coping were linked to later increases in avoidance coping. Theoretical advances will be discussed, and recommendations for further refinements will be given.

Dementia screening with unbiased tasks for high and low education groups
Kit-Tai Hau Chinese University of Hong Kong, Hong Kong; Jianfang Chang; Chi-Shing Tse; Grace Leung; Linda Lam
Particularly in less developed countries, the selection of appropriate tasks in screening potential dementia patients that would not disadvantage those with little or no education is important. For example, reading out and remembering words is inappropriate for illiterates, so are other tasks that are school-curriculum based and are seldom used in daily life. In the present study, we examined the power of various common screening tasks for high and low educational groups and identified those that were biased. We studied the performance of 788 Chinese elderly people (383 normal, 405 with mild cognitive impaired) in a wide range of screening tasks for dementia. The differential screening power of these instruments for high and low education groups was examined and instruments that were biased for people with minimal level of education were identified. While more suitable instruments are to be developed, the present study alerted assessors in the interpretation of results using potentially biased instruments. The findings also provided insights in the development of more sensitive instruments for patients with different backgrounds.

Assessment and evaluation of learning
Roche Herbst Human Capital Solutions Inc., Canada; Maretha Prinsloo
Control measures to survive problems brought on by the global economic crises, were implemented within an international organisation. This resulted in operational and centralised control. The aim of this study was to assess cognitive functioning and learning potential of senior leaders across geographical and cultural boundaries. The population comprised of adults enrolled at post-secondary level, while continuing to work or completing a practicum as required by the academic course. A sample of 2 individual case studies was chosen as representative. In summary, correlations between expected scores on a standard measure of intelligence (WAIS-IV) and scores from a non-traditional intelligence test (CPP and LOI) are considered. Conclusions based on the findings will reveal various recommendations and other helpful interventions to support the individual’s success in a post-secondary academic and/or workplace settings.

Assessing cognitive functioning and learning potential of senior leaders across geographical and cultural boundaries

How to assess communication skills in medical school?
Stefan Hoefner Innsbruck Medical University, Austria; Maria Theresa Barbist; Margit Breuss; Martin Kunnig; Astrid Lampe; Andrea Hofehler; Horst Mitmangrubner; Gilbert Pasch; Gunther Rathner; Ingrid Schneitter; Christian Schubert
Doctor-patient communication is one of the most essential skills medical students need to learn. Teaching as well as formal assessment of communication skills training is a challenge within the medical curriculum. The aim of our project was to adopt and test the Harvard Medical School Communication Skills Form (HMSSCF) and train the lecturers to use it. Face and content validity was assessed, as well as inter-rater reliability (Bland & Altman test) and test-retest reliability. Ten lecturers independently rated five videotaped simulated patient-student interactions. One single interaction was assessed at two times with one week apart. Finally, in a consensus meeting all videos were rated to have a gold standard. The overall relation between the gold standard and the individual assessments was high (r=.81, p<.05), with an average difference of 2 points on the rating scale. However, the Bland & Altman test revealed that 95% of the assessments differed between -10 and +6 points from the gold standard, showing a considerable degree of variation. Test-retest reliability was overall high (rtt = .90, p<.05), and varied again on specific aspects (i.e. providing closure rtt = .32, p=.60 vs. understands patient perspective rtt = 1.0, p<.05) The analysis revealed shortcomings that need to be addressed when assessing communication skills. There is a clear need for a standardized communication assessment form, including a predetermined-passing score and a formal training for teaching staff to assure accurate and consistent assessments.

Young, Black, and participating: Welfare receipt, political socialisation, and efficacy beliefs
Elan Hope University of Michigan, United States of America
Current models of political socialisation emphasise the role of parent voting behaviour, social role models, neighborhood political norms, and involvement in civic activities as predictive factors of political attitudes and civic and political engagement among youth (e.g. Plutzer, 2000, Gimpel; Cho, & Dyck, 2006; Larson, 2004). However, conventional models do not consider the effect of welfare services on youth political socialisation, even though scholars suggest that public policies serve as a source of political information and meaning (Pierson, 1993; Mettler & Soss, 2004). Additionally, studies that highlight the implications of economic hardship on youth political socialisation focus primarily on electoral behaviour, overlooking other dimensions of political and civic engagement that are accessible to adolescents and young adults. Thus, the current study examines the differential impact of welfare receipt on the political socialisation and political and civic behaviour among Black American youth and young adults. Our sample included 625 Black youth with an age range of 15 to 25 years from across the United States. Using structural equation modelling, we found that welfare receipt is related to less parent political socialisation and more political efficacy. Also, the older youth got, the less politically efficacious they were. Finally, youth political efficacy was associated with civic, traditional and non-traditional political participation differentially based on past or present experiences with welfare. These findings highlight...
the complex nature of political socialisation among Black youth and the relevance that experience with welfare services may have on youth political and civic behaviour and beliefs.

The application of generalisability in item response modeling approach
Xiao-Tian Hu South China Normal University, China; Min-Qiang Zhang

Through the distributional assumption of the facets in generalisability theory, Briggs and Wilson (2007) proposed the Generalizability in Item Response Modeling (GIRM) approach incorporating the Rasch model of item response theory (IRT) into the p×i design of generalizability theory (GT). Rather than using the observed scores matrix as the traditional GT approach does, the GIRM approach uses an excepted scores matrix to estimate the variance component within a Markov Chain Monte Carlo (MCMC) simulation. This study presents the GIRM approach in the context of an empirical data set with a p×i measurement design, exploring the effects of the GIRM approach in the achievement test. The data are taken from the multiple choice test items of the educational testing. Using the empirical data with the software WinBUGS, the GIRM approach is shown to produce results comparable to those of the traditional GT analysis, including the estimate of variance component, relative error variance, absolute error variance, generalizability coefficient, and dependability index.

Assessing the psychometric properties of an Afrikaans version of the Adult Adolescent Parenting Inventory-2
Ghouwa Ismail MRC-UNISA SAPPRU, South Africa; Shahnaz Saffa; Ashley van Niekerk; Mohamed Seedat

The ability to identify child maltreatment early is critical to the well-being of both children and their families. Existing child maltreatment instruments have been predominantly developed and validated in Western countries and therefore pose significant limitations in low- to middle-income contexts such as South Africa, frequently rendering themselves inappropriate for use within these contexts. There is thus a need for reliable and valid instruments for the assessment of the potential for child abuse and neglect. The aim of this study was to examine the psychometric properties of an Afrikaans translated version of the Adult Adolescent Parenting Inventory-2 (AAPI-2), Form A. The AAPI-2 is a 40-item survey designed to assess the parenting and child rearing attitudes of adult and adolescent parent and pre-parent populations. It consists of 5 scales. Data collected on a sample of 100 low-income households in Strand in the Western Cape, South Africa were analysed. Each scale was examined using factor analysis in order to determine the uni-dimensionality of the scale. An a priori 5-factor structure reported by the developer was utilised in order to ascertain whether the instrument is measuring the constructs it purports to measure. Each scale was also evaluated based on estimates of the scale’s reliability in order to determine the consistency with which the construct is measured. The presentation will offer recommendations for the utilisation of the AAPI-2 in Afrikaans-speaking individuals in South Africa.

Good emotional intelligence with poor IQ: A study with children who have intellectual disability
Sandeep Jain Avsar, India

This study is intended to examine the emotional intelligence of children with intellectual disability. A total of 60 children were used as the sample. Of these 60, 30 were children with intellectual disability, and the remaining 30 were children of average intelligence. Rating by teachers was used to assess the emotional intelligence of both the groups. Results reveal that children with intellectual disability were rated by their teachers as equal to their counterparts in the control group in terms of their ability to perceive their own emotions and those of others. In addition, their ability to use emotion to facilitate thinking and their ability to understand emotions, emotional language and the signals conveyed by emotions was also rated as equal to the children in the control group. However, children with intellectual disability were found lower in comparison to children of average intelligence in managing emotions to attain a specific goal. Results indicate that in spite of lower IQ, children with ID may have good emotional intelligence.

Estimates of sparse data variance components in the generalizability theory framework
Can Jiao Shenzhen University, China; Min-Qiang Zhang

Missing data are easily found in psychological surveys and experiments. Researchers are always concerned about how to make good use of the observed data, particularly in the examination. Due to time, manpower and material considerations, raters cannot rate all the papers. The rules of rating in college entrance examinations can be briefly summarized as follows: the raters and the papers are randomly assigned; the system randomly assigns a paper to a certain rater. The system recalls the paper randomly assigned; the system randomly assigns a paper to another rater. This shows that the rating in college entrance examinations’ scores is a large sparse data matrix. As the missing data make the estimation of variance components and data mining more difficult, it is necessary to find a simpler method to estimate sparse data variance components. This article provides the estimating formulas of a p×i design of sparse data, which are ones based on the estimating formulas of a p×i design of sparse data provided by Brennan (2001). This article also simulated data which were usually used in examinations, and used the simulated data to test the formulas’ validity. It was found that these formulas could provide a good estimation of variance components. The number of items had the largest effect on the estimation. These formulas could provide good estimation when the number of items was six.

The effect size of psychological interventions on OCD symptoms (Iran 2001–2011)
Mahboobeh Kiani University of Isfahan, Islamic Republic of Iran; Salar Faramarzi; Ahmad Abedi

In recent years, experts in the field of obsessive-compulsive disorder symptoms have been trying to measure the validity and efficiency of psychological interventions on OCD symptoms. In this regard, meta-analysis with the integration of research results, demonstrated the effect size of treatments. This study aims to investigate the impact of psychological interventions in reducing symptoms of obsessive-compulsive patients. For this purpose, accepted researches were selected and meta-analysis was performed on them. The research instrument was a checklist of meta-analysis. It was found that the effect size of psychological interventions on
The structure of the torrance test of creative thinking-figural in Spanish-speaking children: A confirmatory factor-analytic study
Gabriela Krumm CIIPME/CONICET - UAP, Argentina; Viviana Lemos; Vanessa Aran Filippetti
One of the most common and worldwide instruments used to assess creativity is the Torrance Tests of Creative Thinking (TTCT). In spite of the fact that this test has been studied for years, research conducted in relation to its validity is contradictory. Some authors, following the theory proposed by Kirtton, have suggested the existence of two factors: Innovation and Adaptation, which might explain operationalised creativity for the Figural TTCT. The Innovation factor would be composed by the scales of Fluency and Originality and the Adaptation factor would be composed by the scales of Elaboration and Abstractness of Title. The scale of Resistance to Premature Closure of the Figural TTCT would be present in the two factors (Kim, 2006; Kim, Crawford & Bandanus, 2007). Prior parent’s authorisation and informed concept, the Figural TTCT, form B, was administered to 577 children in 10 schools of the cities of Libertador San Martin, Crespo, Diamante and Paraná in the province of Entre Ríos, Argentina. Confirmatory Factor Analysis (CFA) was used to assess three theoretical models: 1. One-factor model, 2. Correlated two-factor model, 3. Uncorrelated two-factor model. The most satisfactory adjustment CFA identified two correlated factors: Innovation and Adaptation. These results are in line with previous studies that suggest a multidimensional structure of the creativity construct assessed by the Figural TTCT.

International psychology: What students need to know
Judy Kuriansky Columbia University Teachers Co, United States of America; Uwe Gielen Columbia University Teachers Co, United States of America
An increasing number of students are interested in pursuing international work, but are not sure about what courses to take and what opportunities they have. This presentation addresses what students need to know about international psychology as a field for study and for a career. The increasing number of resources available will be presented, including courses, websites, newsletters, journals, and schools concentrating on the subject. The presentation will feature a screening of a new DVD documentary about International Psychology: What It Is and How Students Can Get Involved, that informs students about international psychology as a field for study and for a career. The increasing number of resources available will be presented, including courses, websites, newsletters, journals, and schools concentrating on the subject. The presentation will feature a screening of a new DVD documentary about International Psychology: What It Is and How Students Can Get Involved, that informs students about international psychology as a field for study and for a career.

The ‘Big One’ factor of personality and competence: Exploring the validity and meaning of Big 5 and Great 8 totals
Rainer Kurz Saville Consulting, United Kingdom; Peter Saville; Rob MacIver
General factors have recently been found for Competence (Kurz, 2005), Personality (Musk, 2007) and Effectiveness (Kurz, MacIver, & Saville, 2009) variables. MacIver, Kurz, and Saville (2009) validated Great 8 Totals on a mixed occupational group (N ~ 308) for NEO O.C.0 uncorrected and Wave Professional Styles (.32) with external ratings of Global performance (3 item set). This study researched the nature and validity of ‘Big One’ factor composites, on the same sample. The first unrotated principal component (FUPC) was extracted explaining 35% of the variance with all positive factor loadings (albeit marginal for Openness). The results indicate the existence of a positive manifold and a Big One personality factor. ‘Big 5 Total’ scores were created by reversing all Neuroticism scales to become measures of Emotional Stability, and adding up all 5 factors. This content based composite correlated .96 with the FUPC, with r ranging from .73 with Emotional Stability to .36 for Openness while FUPC correlations were .78 and .08 respectively. Both Big One personality variables correlated .17 with the Global score. After parcelling out the Big 5 Total composite, significant correlations remained for Agreeableness (~20) and Extraversion (~17). The results indicate that the Big 5 composite has a moderate level of validity but that further coverage of Need for Power related aspects of Extraversion, and Need for Achievement and Analysis variables - known to correlate negatively with Agreeableness - enhance validity. Content based unit weight composites increase the robustness and meaning of ‘general’ scores and foster clarity in the field.

Reinforcement sensitivity and family factors as moderators of child and adolescent mental health
Valeriy Kuznetsova Institute of Physiology, Russian Federation; Helena Slobodskaya
Recent findings provided support for two higher order dimensions of child temperament, impulsivity and inhibition (Deal et al., 2005), reflecting neuro-psychological systems of Behavioural Approach (BAS) and Behavioural Inhibition (BIS) outlined in Reinforcement Sensitivity Theory. BIS predicts internalising in children, while BAS - externalising (Colder & O’Connor, 2004; Slobodskaya, 2007). An aggregation with family environment may increase the risk of adjustment difficulties in children (Achenbach, Rescorla, 2007). The aim of the study was to explore the possibility of mitigation of risk, by examining the moderating effects of family factors on the association between children’s personality and adjustment. In a community sample of 536 children, Sensitivity to Punishment (SP) and Sensitivity to Reward (SR) were evaluated using the SPSRs scales for children (Colder & O’Connor, 2004), problem behaviours were evaluated using the SDQ (Goodman, 2001) for parents. Family factors were assessed by Life Style Questionnaire. SP was associated with internalising, whereas SR was associated with externalising and internalising. There were a number of significant interactions between SR and family factors in predicting problem behaviours, no interactions with SP were found. For externalising, there were significant moderating effects of urbanisation, neighbourhood safety, family type, parent’s education and family cohesion. For Internalising, there were significant moderating effects of family type, parent’s occupation, family violence and monitoring. For impact on everyday life; there were significant moderating effects of urbanisation, gender, type of family, family aggression, parenting and family cohesion on Impact in everyday life.

Using profiling to support first-year university students
Juan-Claude Lemmens University of Pretoria, South Africa
The Student Academic Readiness Survey© (STARS) is a low-stakes, self-report survey measuring non-cognitive variables for the purposes of student development and psycho-social support. The intention of the survey institutionally, is to address the needs of individual students and to provide early warning of potentially ‘at-risk’ students, so that interventions can be planned for retention and success. The STARS was developed at the University of Pretoria over a number of years and forms part of a first-year retention and success project that was initiated in 2010. The STARS is administered to first-year students during the start of the academic year and ‘at-risk’ students are short listed for a peer mentorship programme. The data of 6062 students from the 2010 and 4252 students from the 2011 student cohort was analysed with a Rasch model to determine the psychometric properties of the survey. The Rasch analysis is a one-parameter item response theory model that enables one to construct unidimensional measures. Analyses of the constructs show that the survey is reliable and valid. Regression analyses also show that three constructs in particular are predictive of academic achievement, namely, self-efficacy, engagement and test-taking skills. These constructs can therefore be used as part of an early warning system to identify students who are at risk for poor academic achievement. Other constructs, such as financial and family support information can be used qualitatively in student support and development initiatives.

Measurement equivalence of Internet-based testing and paper-and-pencil testing: Illustrated with cross-mode repeated measures of five-factor model
Yuhui Li Renmin University of China, China
The merging and flourishing of Internet-based testing brought about advantages and potential, but also

reducing obsessive compulsive symptoms were 1/88 (p ≤ .001).
led to with disadvantages and concerns. From the perspective of psychometrics, the focus is the reliability, validity and measurement equivalence/in-variance (ME/I) between internet-based testing (IBT) and paper-and-pencil testing (PPT). The data was collected from a counterbalance within-subject design during two months. Half of the original sample using computerized assistant sampling technique first completed via IBT and then mailed PPT, while the other half reversed the administering order. The final analysis was based on 169 valid cases with heterogeneous demographic background. The Chinese version of NEO-FFI was used. In the framework of CTT and CFA, ME/I analysis was conducted respectively. In the CTT, differences in means, deviation, kurtosis, and skewness were significant in some indicators and scales. The alpha reliabilities and inter-correlation of five subscales in IBT and PPT were also compared, and found one significant correlation difference. The congruence coefficients were calculated after target rotation and indicated factorial structure equivalence. In the CFA, sequences of nesting constrained models were specified to examine cross-mode ME/I, and found four loadings and three intercepts two factor covariance were significant difference between two modes. The results were most convergent between these two approaches. All the results in general support the Internet version of NEO-FFI in its equivalence to the paper-and-pencil version. In the conclusion, the limitations and issues for future research about cross-mode ME/I were discussed.

The influencing of school conditions and students’ personal factors on their academic performance: A multi-linear model analysis in an large-scale test

Meijuan Li Beijing Academy of Educational, China; Yongmei Zhang; Yi Tian; Yi Hao

This study examines the influence of school conditions and students’ personal factors on their academic performance for fifth-graders and eighth-graders. Through a multilevel analysis, it found that schools’ location significantly influenced fifth-grade students’ academic performance, but did not influence eighth-grade students’ performance. The school sizes also influenced fifth-grade students’ academic performance. More specifically, fifth-graders in large size schools had better academic performance than those in small schools. However, the school size had no impact on eighth-grade students’ academic records. The proportion of non-local students only significantly influenced eighth-grade students’ academic performance. Personal factors such as gender, whether the student was an only-child or not, time for homework, learning styles, learning pressure, and self-education expectations all influenced fifth-grade students’ academic performance significantly. Compared to the fifth-grade students, the eighth-grade students showed similar patterns but were not influenced by how many children were in students’ families.

Examining rater effects in China civil servant candidate writing performance assessment

Yingwu Li Renmin University of China, China; Qian Ye

Although writing tests have a long history in large scale civil servant candidate assessment, they have received extremely limited attention within the recent personnel selection literature in China. This study explores the potential of applying two measurement approaches (Generalisability theory and Item Response Theory) in the analysis of data from writing tests for national civil servant candidates, and apply Generalisability Theory (GTM) methodology to analyse the total variance of the raters and items macroscopically, and build on the many-facet Rasch measurement (MFRM) methodology. The focus was on rater main effects as well as 2- and 3-way interactions between raters and the other facets involved, that is, examinees, rating criteria, and tasks. Another goal was to investigate differential rater functioning related to examinee gender. Results based on GT showed that an acceptable amount of variance component was attributed to candidate ability. Results based on MFRM showed that raters differed in the severity with which they rated candidates and were fairly consistent in their ratings. These findings have implications for controlling and assuring the psychometric quality of the China National Civil Servant Personnel System.

The underlying mechanisms of emotion regulation affecting the decision making process

Yingwu Li Renmin University of China, China

Recently, the constructive influence of emotion on the cognitive processes, especially emotion affecting decision-making, attracts the focus of researchers, and a variety of emotion and decision-making related theories emerged. This paper clarifies the latest theories of emotion and decision-making focused on the underlying mechanisms, experimental paradigms, and predicts developing trends, while provides a new research perspective and experimental method for researchers. The main results and conclusions as follows: Positive emotion and negative emotion have different effects on decision making; individuals do probability decision making with positive emotion, but improbability decision making with negative emotion.

Factorial validity and consistency of brief symptom inventory across occupational groups in China

Chaoping Li Renmin University of China, China

Data from 319 employees was collected to validate the Chinese version of the Brief Symptom Inventory (BSI). EFA analysis replicated the same nine-factor structure after five items were dropped. 824 samples were then obtained from three occupation groups: teachers, policemen and manufacturing enterprise employees. Both separate CFA analyses of different occupations and combined analyses showed that the original nine-factor model clearly better had a fit than other alternative models. Alpha coefficients for all nine subscales were above .70. The results support that BSI provides a suitable measurement to assess psychological symptoms across a diversity of professions in China.

A study on the relations between self-confidence personality and mental health of university students

Che Lijin USST, China

The self-confidence study conducted in China is a new research theme and one of the important psychological research fields. The paper explored the relationship between mental health and self-confidence personality. Findings showed that the dimensions of self-confidence personality and mental health reflected extremely significant correlations. The personality characteristic of self-confidence had a tremendous effect on the formation of a healthy personality. The student’s self-confidence could predict individual mental health obviously if the overall confidence was better. There was a phenomenal difference of various self-confidence groups on healthy personality. The higher scores they got in self-confidence, the better and healthier personality they had. Improving self-confidence is good for raising healthy personality levels. Finally, the results are discussed and accordingly recommendations are put forward.

A study on psychological education mechanism of college students’ entrepreneurship

Che Lijin USST, China

This subject aims to explore and study current university students’ entrepreneurship psychology present situation and education mechanism. Expanding the specific random sampling survey among universities in Shanghai, through literature review, questionnaires, interviews and other research methods combined. In order to reveal the contemporary university students’ entrepreneurship present situation and the existence question, combined with the corresponding regulations and policies with the state, we put forward effective countermeasures and propose specific measures to improve university students’ entrepreneurship level and success rate. Earnestly alleviating the employment pressure on college students, effectively promoting various types of college students’ good start on their own businesses and innovative development of the whole society. This issue has certain theoretical significance and practical value.

Re-test of pay satisfaction questionnaire: CFA and EFA

Bangcheng Liu Shanghai Jiao Tong University, China; Jingqiu Chen; Ningyu Tang

The Pay satisfaction questionnaire (PSQ) developed by Heneman and Schwab (1985) is currently a popular tool to estimate pay satisfaction. Unfortunately, since 20 years ago, there have been arguments about the structure of PSQ. There has been no consistency to the dimensions of PSQ ranged from 2 to 5. Moreover, most of the studies had been from the Western and few from the Chinese context. The study tried to re-test the structure of PSQ in China. A survey of 195 Masters students in human resource management, this study found the three-factor model is a better fit than the original four-factor model although the original four-factor model is supported with the help of confirmatory factor analysis (CFA) and exploratory factor analysis (EFA) technique.

Construction of the South African version of the fear survey schedule for children

Helene Loxton Stellenbosch University, South Africa; Kathe Burkhardt Stellenbosch University, South Africa; Thomas Olleandick

Fears are a normal part of development but excessive fears may interfere with daily functioning and
may reflect serious anxiety problems. The Fear Survey Schedule for Children-Revised (FSSC-R) (Ollendick, 1983), an 80-item self-report instrument, has been widely used to assess the content, number, level and pattern of fear. This instrument however has not been adapted to the South African context. The aim of the present study was to address this by means of a two-phase investigation in order to develop a South African version of the FSSC-R. During phase I semi-structured interviews were conducted with 646 middle childhood students. The qualitative data from the interviews were used to identify and construct additional items, which were added to the existing 80-item FSSC-R. The adapted scale which consisted of 97 items was administered to 646 middle childhood students during phase II. After further psychometric considerations the final version of the South African scale consisted of 74 items and demonstrated good internal consistency (α = 0.97). The factor structure was explored by means of principal factor analysis with varimax rotation. The five factor solution was found to be the best conceptual fit. The five factors are: Fear of death and danger, Fear of the unknown, Fear of small animals and threats to self, Fear of large animals and Situational fears. The adapted scale is referred to as the FSSC-SA. Implications of the study’s results in the South African context will be discussed.

Modification and extension of hierarchical consistency index

Mengmeng Mao College of Education, Nan Chang, China; Shuliang Ding

Cui and Leighton (2009) proposed the hierarchical consistency index (HCI) to detect the fitness of an examinee’s observed response pattern (ORP) to an expected response pattern (ERP) as person fit index. HCI is not defined well in the sense that when an examinee mastered an attribute only and there is an item with the same attribute in the test, HCI could not be computed for the number of comparisons being zero, hence the denominator of HCI being zero. The item ‘j’ is said to be a father-item of item ‘h’ (or ‘h’ is a son-item of ‘j’). This means that all of the attributes in item ‘h’ is a subset of the attributes included in item ‘j’. HCI detects the misfit in the response to the father-item correctly, and to the son-items wrongly, or slipping appears only. And it leaves out of account being wrong about responses to the ‘son’-items and correct about responses to the ‘father’ item(s) (it means guessing). Modification and extension of HCI (named as MHCI) are proposed. The denominator of MHCI can’t be zero and MHCI detects the slipping and guessing simultaneously. The performance detecting misfit of HCI and MHCI has been judged in the simulation research, the results indicate that MHCI is meaningful and intuitive. For example, there are 4 attributes with linear hierarchy structure and 2 ORPs X1 = (0100) and X2 = (0011), HCl(X1) = HCl(X2), and MHCl(X1) = MHCl(X2).

A Rasch approach to construct development of a goal achievement measure

David Maree University of Pretoria, South Africa

The investigation of the construct ‘goal achievement’ is made against the background of a conceptual discussion of goal theory and an empirical investigation of a psychometric goal instrument. Goal theory is briefly discussed in terms of goal setting and goal orientation research. Goal orientation theory makes a distinction between performance and learning goals both of which has an approach or avoidance dimension. The relationship between goal setting and goal orientation is further explored in terms of the role of self-efficacy that figures prominently in the work of Bandura. The resulting taxonomy of goal achievement is then investigated in the analysis of a goal instrument applied to a sample of 1745 persons from diverse backgrounds studying at various institutions. A principle component analysis (PCA) was done on the raw scores, but was followed up with a Rasch dimensionality analysis using PCA of standardised residuals, which gave a better picture of the functioning of items and subsequent components. Further Rasch analysis included item fit analysis and rating scale performance evaluation. The resulting dimensions, namely, pathway, goal setting efficacy, resilience, optimism, agency, absence of state despair, and external locus of control is compared to the conceptual taxonomy discussed above.

A comparison of item exposure methods in computerised adaptive testing

Li Ming-Yong South China Normal University, China; Xiaozhu Jian; Min-Qiang Zhang

This study compared three item exposure control algorithms – the McBride-Martin method (shorted as MM), Restricted method (shorted as RT) and Item Eligibility method (shorted as IE), using the Monte Carlo simulation approach with Maximum Information Item Select Method without controls as compared to base level in computerised adaptive testing. Both advantages and disadvantages of these three algorithms were discussed focusing on RMSE and bias, standard error of examinees’ ability estimated value, test overlap rate, the utilisation rate of item bank, observed maximum exposure rates and proportion of items with exposure over. Results showed that none of these three performs well in terms of all these seven indices at the same time. Therefore, some changes were given to the ability estimation method, the allowed maximum of the exposure rate, item banks and test length respectively, to see the following impacts on the improvement of these three methods under a two parameters logistic model. Conclusions were as follows: (1) Considering all seven indices, the IE method was the most satisfying one but still not perfect, for the IE method doesn’t have a favourable utilisation of item bank. It has an effect on the items with high exposure rate, but has nothing to do with the ones with at low and zero exposure rates. Moreover, a clear trade-off was found in all these methods. In other words, the greater the emphasis given on exposure control, the greater the costs of the measurement accuracy achieved. (2) The changes in this study do perform better to a certain extent. But regretfully it doesn’t put the results better essentially. That is, there is still a trade-off effect in all these algorithms.

Subjective well-being scale: Construction of scales and preliminary tests of reliability and validity

Wen Mo Hunan Normal University, China; Lan Hong; Shitong Li; Yunshi Peng; Shun Peng

Subjective well-being is the presence of positive affect and the absence of negative affect on the
to the overall assessment of the quality of life according to the individual custom criteria. It is an emotional state of the individual’s awareness that their needs are met and their ideals realised. It is a complex, multi-level mental state formed by the interaction of need (including the motivation, desire, interest), cognitive, emotional and other psychological factors. This paper compiled a Subjective well-being Scale (SWBS) for Chinese people, based on the analysis of theory dimensions of subjective well-being and Maslow’s Hierarchy of Needs. The SWBS includes three scales: Survival Subjective well-being Scale, Expand Subjective well-being Scale, and Transcendence Subjective well-being Scale. Both theoretical and empirical approaches were adopted in the present thesis, yielding the following findings: (1) After 2 preliminary studies, the SWBS was administered to 962 individuals. Exploratory factor analysis of the SWBS yielded three 3-factor solutions. (2) Subsequently, an independent sample of 996 individuals completed the SWBS. Confirmatory factor analysis revealed good model fit, and test-retest reliability was very good, with good reliability and validity.

The development of the junior officers core competencies system

Oscar Mthembu South Africa, South Africa

The role of military organisations in serving humanity through peacekeeping, observing and such integrative missions cannot be underestimated. Identification of the most important core competencies and dimensions for the different leadership and management levels and dispensations in the military, would be a step towards the development of tools that could be used in career management and decision-making throughout the employment process of military practitioners. The purpose of this study was to identify valid and reliable dimensions/variables for the development of the Junior Military Officers Core Competency System. The research sample consisted of 111 participants. They were asked to rate the importance of 23 items derived from the current performance appraisal, the organisational values and the individual values of the organisation. The intercorrelation matrix of the 23 items was subjected to a principal factor analysis and rotated by means of the varimax rotation to identify the substructures in the data matrix. The Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy and Bartlett’s test of sphericity confirmed that the properties of the item scores were suitable for factor analysis. The analysis yielded a five factor solution. It was concluded that these five dimensions could serve as the building blocks for most employment decisions regarding junior military officers. This study should contribute to better decision-making in career management and in making organisational entry, personnel development and retaining decisions for junior military officers.

Development and psychometric evaluation of a managerial decision making self-efficacy questionnaire (mdmsq)

Willem Myburgh Psy metric, South Africa; Mark Brownlee; Cheryl Foxcroft

There have been few efforts to conceptualise and measure managerial decision making self-efficacy.
beliefs as a construct. The present research describes the design and development of the Managerial Decision Making Self-Efficacy Questionnaire (MDMSEQ) and provides empirical evidence on the construct coverage, content and construct validity of the MDMSEQ as a multi-dimensional construct. The results of two studies involving 321 experienced managers evidenced a multi-dimensional structure and demonstrated respectable sub-scale internal consistencies for the MDMSEQ. Further validation of these experiences, coupled with analysis of assessment data collected for various projects, assists organisations in identifying ways to optimise their selection of graduates in the future. Taken together, this learning is beneficial from both an organisational and candidate perspective. Through rigorous and scientific-based hurdle approaches, incorporating various screening-out and selecting-in assessment tools, organisations are able to appoint high quality candidates (Burke, 2011; Neilson & Olivier, 2011). By analysing assessment data and different recruitment processes it can be determined which screening and assessment tools add value in selecting the best calibre candidates, and which tools can be omitted or replaced. Experience with managing graduate recruitment projects also allows for a clearer understanding of what forms of communication and what selection processes attract graduates and keep them interested and engaged in the recruitment process. The analysis of results across various graduate recruitment processes allow confirmation that the assessments used in hurdle-processes add value in allowing organisations to screen down applications and select in good-quality candidates. In addition the assessment results provide an organisation with information on their potential future talent pipeline and leaders. Through considering what an organisation requires from a leadership perspective then mapping this to the assessment results of the graduates, clear strengths and development areas can be focused on to assist in de-risking the business and ensuring a healthy talent pipeline.

The use of assessments to enhance the selection of graduates in emerging markets

Ceridwen Neilson SHL South Africa, South Africa

The objective of this presentation is to share experiences in using assessments to select graduates into leading organisations in emerging markets. The consolidation of these experiences, coupled with analysis of assessment data collected for various projects, assists organisations in identifying ways to optimise their selection of graduates in the future. Taken together, this learning is beneficial from both an organisational and candidate perspective. Through rigorous and scientific-based hurdle approaches, incorporating various screening-out and selecting-in assessment tools, organisations are able to appoint high quality candidates (Burke, 2011; Neilson & Olivier, 2011). By analysing assessment data and different recruitment processes it can be determined which screening and assessment tools add value in selecting the best calibre candidates, and which tools can be omitted or replaced. Experience with managing graduate recruitment projects also allows for a clearer understanding of what forms of communication and what selection processes attract graduates and keep them interested and engaged in the recruitment process. The analysis of results across various graduate recruitment processes allow confirmation that the assessments used in hurdle-processes add value in allowing organisations to screen down applications and select in good-quality candidates. In addition the assessment results provide an organisation with information on their potential future talent pipeline and leaders. Through considering what an organisation requires from a leadership perspective then mapping this to the assessment results of the graduates, clear strengths and development areas can be focused on to assist in de-risking the business and ensuring a healthy talent pipeline.

Evaluating the usefulness of psychological assessment of clergy applicants

Aura Nortomaa University of Helsinki, Finland

This paper presents a review of psychological assessment of clergy applicants from the viewpoint of the usefulness of the assessments. A new, three-way model for evaluating the usefulness of the assessments is suggested. Psychological assessment is nowadays used in recruitment in many professions. Churches are increasingly applying tests to screen their clergy applicants. Early on, the assessments were aimed at discarding unfit candidates. Nowadays, the focus is more on selecting those persons who will best succeed in the job. The assessment methods vary greatly from region to region. Research on the assessments has been rather varied. Nation wide samples are difficult to obtain, and only a few follow up studies have been conducted. The usefulness of the psychological assessment of clergy is poorly known. First, studies have not been undertaken to establish whether these assessments are considered useful by the applicants or by the recruiting dioceses. In other words, the subjective experience of usefulness has been overlooked. Secondly, the ability of the assessments to predict future work performance and occupational well-being is not fully understood. At the same time, clergy burnout and other occupational health problems are a growing concern worldwide. Knowing the connections between assessment results and future occupational well-being issues would help with prevention and early intervention. A new, three-way model to evaluate the usefulness of psychological assessment of clergy applicants is presented. The model will be tested on a Finnish sample in the following studies by the author.

International status of test development and use with children and youth

Thomas Oakland University of Florida, United States of America

The development and use of tests may constitute psychology’s most important technical contribution to the behavioural sciences. The level of test development and use differs considerably internationally. The current status of test development and use with respect to children and youth will be reviewed. The following four questions also will be discussed: How did we reach an advanced level of development in some countries and not others? What qualities are needed to attain this development in other countries? What changes are occurring to which tests need to respond? Thus, what changes in test development and use are needed to be on the cutting edge of our profession?

What can we learn from aggregating assessment results? A case study

Danie Oosthuizen SHL South Africa, South Africa

Assessment practitioners sometimes struggle to convince key decision-makers of the added value assessment results can offer in an organisational context. Assessment outcomes are often only used to take short-term decisions: for example, once a candidate has been appointed the results are filed and never used again. However, if assessment results are aggregated to create a project- or organisation-wide view, the information can be used for a number of additional applications (e.g. illustrating business outcomes and ROI through validation studies, trend analyses and comparing the organisation’s own talent to external benchmarks). The purpose of this paper is to reflect on a large-scale assessment project (N=1,367) that was undertaken for an organisation in the financial industry, and to examine how aggregated information may be used to create a better understanding of the bench-strength of a group. The paper will provide a short background to the assessment project, a brief description of the assessments administered and process followed, a group-level view of the assessment results and a summary of the qualitative feedback received on the value-added benefits of reviewing the assessment results in their aggregated form. The paper will also focus on additional utilisation of how such results can be utilised to conduct business outcome studies and benchmark comparisons. Delegates will gain insight on how aggregated assessment results were used in this case, and how they can be used to create additional value and benefits over and above individual assessment outcomes.

An assessment of the psycho-social classroom environment perceptions of students and teachers in mathematics

Ifyeinwa Osegbo Nwofor Oriso College of Education, Nigeria

Two mathematics classroom environment instruments—the mathematics classroom environment scale (MCES) and the individualized mathematics classroom environment questionnaire (IMCEQ)—each having three forms (Osegbo, 2005) were used to establish the perception profiles of students and teachers in mathematics classrooms in Anambra State, Nigeria with a view to improving the present state of secondary school classroom environments in mathematics. To guide the study, three research questions and twelve hypotheses were formulated and tested. The research questions sought to establish whether there are differences in the perception profiles of teachers and students with regard to the MCES and IMCEQ. The hypotheses on the other hand sought to establish whether: (a) The MCES and IMCEQ are capable of differentiating among student in terms of their sexes, location and class level. (b) There are significant differences in the forms of MCES, and IMCEQ with regards to student’s perceptions. (c)
Differences in students’ and teachers’ perceptions of the actual classroom environments. Questionnaires were used to collect data from 1039 students and 45 teachers. A combination of descriptive survey and ex-post facto research designs were used to obtain data from students and teachers in the actual and preferred forms of the instruments. Means standard deviations, multiple analysis of variance and t-test analysis were used to analyse data at a significant level of .05.

**Predictive validity of biodata items generated from personnel files**

Lu Shan Pan; Chinese Academy of Personnel Science, China; Wei Fan

Although biodata has been shown to be one of the best predictors of employee performance and turnover, the problem of it’s being susceptible to faking remains unresolved. Rather than self-report data, relatively little research estimated the predictive validity of biodata by gathering the data from objective life experience. In this paper, 97 items of biographical information was generated from personnel files which form part of the national personnel management system in china. Personnel files were targeted to aspects of five life experiences (personal information, background, education, training and work experiences). 107 personnel files of financial professionals and 103 personnel files of automotive engineers were coded. The degree of item validity was associated with salary growth and promotion rate which were also gathered from the records of personnel files. Results indicated that the factor structure of these items was different from that of non-valid items. The factor structure is a complex structure biographical professional and automotive engineers was also compared. Implications for the construction of biodata forms and the limitations of the study are discussed.

**The improved maximum priority index method for balancing attribute coverage in cognitive diagnostic computerized adaptive testing**

Yirao Pan; Jiangxi Normal University, China; Shuang Ding; Wenyi Wang

Cheng (2007) proposed maximum prior index (MPI) method for content balancing in a traditional CAT and Cheng (2010) extended to the modified maximum global discrimination index (MMGDI) method for cognitive diagnostic computerized adaptive testing (CD-CAT). But priority index in MPI or the attribute-balancing index in MMGDI tends to choose those items with less constraints (e.g. contents or attributes) because the index of the gap from the lower (upper) bound is not greater than one. To overcome these disadvantages, the improved maximum priority index (IMPI) is proposed by redefining the base in the exponential expression of MPI in this study. Considering the combination of balancing attribute coverage with the similarity of any two attribute patterns, the IMPI turns to another item selection method called MGCDI for CD-CAT. MGCDI benefits an item in two aspects: The recovering of attributes and better performance in similar attribute patterns. Compared with MMGDI and MGCDI, results of Monte Carlo simulation indicate that MGCDI is of higher pattern match ratio and marginal match rate than MMGDI and performs as well as MMGDI in balancing attribute coverage. Furthermore, we also attempt to incorporate the IMPI into other item selection strategies for CD-CAT, such as Kullback-Leibler strategy, Shannon entropy strategy and so on. Future research will explore the applications and advantages of using IMPI for test construction using cognitively diagnostic assessment.

**The usefulness of alternative true-false test formats on assessing skill acquisition**

Richard Perlow; University of Lethbridge, Canada; Lori Kopp

One of the ways to assess the usefulness of job-related training programs is to measure trainee learning. One way to assess trainee learning and skill acquisition is through true-false tests, particularly when the use of multiple-choice questions is suboptimal. However, the use of true-false measures is controversial and there is disagreement on the value of measuring learning using that method. One major criticism of true-false measures that critics often mention is that guessing markedly inflates test scores thereby reducing the validity of inferences of those scores. There is some research examining the usefulness of modifying true-false tests as a way to improve the psychometric properties of the scores the test yields. Unfortunately, the research that we found typically involved correlating true-false test scores with other paper-and-pencil measures. In this paper, we describe and evaluate a method used to reduce the effects of guessing on true-false test performance. Specifically, we examine the relation of scores from both traditional and the modified true-false formats to non-paper-and-pencil performance indices that require knowledge application. Participants completed a true-false test assessing job allocation decisions and motivational knowledge before and after performing a complex simulation. Results show that a true-false test incorporating confidence ratings in the scoring algorithm is a useful predictor of complex skill acquisition but it is no more related to performance than the traditional true-false format.

**Standardisation and psychometric investigation of the Emotional Quotient Inventory 2.0 in South Africa**

Martinnette Pienaar; Jopie van Rooyen and Partners, South Africa; Casper van Zyl; Jopie van Rooyen and Partners, South Africa

South Africa has a diverse society when compared to other countries with more homogenous populations. This presents unique challenges when making use of psychometric assessments, and it is thus vital to ensure that imported instruments are appropriate for local use. The revised version of the Emotional Quotient Inventory (EQ-i) was released in 2011. In order to ensure the appropriateness of use of the EQ-i version 2.0 in South Africa, we conducted a standardisation study. The objective of this study was to examine the psychometric functioning of the EQ-i 2.0 in the South African context to standardise the assessment for use in South Africa. The norm sample of approximately 1500 respondents was stratified according to South African census data to ensure a close representation of the working population in South Africa. We conducted ANOVA to determine whether any trends existed across gender, age, and ethnic groups which may require separate norms to be developed. Construct validity was examined by means of exploratory and confirmatory factor analysis. The results were compared to those obtained in North American samples. Item response theory analyses further supported the construct validity of the EQ-i 2.0 scales. IRT techniques were also used to investigate each of the scales for differential item functioning (DIF) which may result in scale level bias if undetected. The data collection process and results of the data analysis will be discussed, along with implications for the continued use of the EQ-i 2.0 in South Africa.

**The future of assessment**

Marethia Prinsloo; Magellan Consulting Pty Ltd, South Africa

The challenges facing psychometric assessment and potential methodological adaptations to addressing these challenges are discussed. Given the dynamic complexity, integrated and contextualised nature of human functioning, in addition to the challenge of dynamic complexity. The "additive approach" characterising current holistic psychometric practice is bound to be replaced by the emergence of integrated assessment techniques. Operational mechanisms and catalysts related to the impact of collective consciousness and contextual factors on individual functioning are discussed. Ethical considerations aimed at benefiting the individual, the organisation and society as a whole as well as the role of the internet to spread the benefits of assessment to a wide audience, are addressed. An emphasis on wisdom, intuition, integrity and related psychometric concepts may be required to accommodate factors linked to the evolution of consciousness. A further challenge is posed by the measurement of the effectiveness of measurement techniques. Traditional psychometric practice relying on ability tests and personality questionnaires is bound to be replaced by integrated, modelling techniques that are electronically delivered.

**The suitability of the Suffolk Reading Scale (2) for South African primary school learners**

Maria Ramaahlo; Vaal University of Technology, South Africa

The field of psychometrics in South Africa faces many challenges. Imported assessments pose various biases to South Africa’s multilingual and multicultural situations, hence the need for test adaptation. The Suffolk Reading Scale (2) (SRS2) is an English proficiency assessment that measures reading comprehension. English, being the language of learning and teaching in most South African schools, makes the SRS2 a significant gain to practitioners and the field of psychometrics. Consequently, this research aimed to narrow the gap in this area of knowledge by evaluating the applicability of the SRS2 as a measure of reading comprehension for South African learners. The study also intended to compare learners speaking English as a first language with...
those who speak it as an additional language on reading comprehension. Primary school learners in Kwa-Zulu Natal were administered the SRS2. Of the 338 participants, 51.9 percent (n=140) of the sample were female, and 48.1 percent (n=130) were male. Sixty-six percent (n=164) of the participants spoke English as an Additional Language (EAL), while thirty-four percent (n=83) spoke English as a first language (EFL). Results indicated a significant difference in performance between EFL and EAL learners, whereby EAL learners performed lower than EFL learners on reading comprehension. The SRS2 proved to have an acceptable internal consistency; however, questions of bias do arise.

Factor-structure of the temperament and character inventory in data of South African and Swedish police trainees

Joerg Richter Center for Child and Adolescent, Norway; Lars Erik Louritz; Deon Melling; Elizabeth du Preez; Nofija Cassimjee; Mehdi Ghazinour; Marethe Vos

The Temperament and Character Inventory (TCI, 9th version) is a 240-item self-report questionnaire developed in the US to measure the four temperaments (novelty seeking – NS, harm avoidance - HA, reward dependence - RD, persistence - PS) and the three character domains (self-directedness, cooperativeness - CO, self-transcendence - ST) based on Cloninger’s psychobiological personality theory. The theory assumes that temperament traits are mainly genetically determined, while character traits are mainly determined by socialisation. However, personality is developed by an enduring interaction between all domains as well as with the environment throughout a lifespan. Cross-cultural equivalence of the TCI’s factor structure could be demonstrated between the US, Swedish and German normative data by procrustes rotation method (Richter, Brändström, & Przybeck, 1999). 1145 black and coloured South African and 103 Swedish police trainees were investigated by the TCI upon entry to training. The individuals of both samples showed, on average, higher scores on SD and lower scores on HA than samples from the general population. Results from comparisons of the factor structure by procrustes rotation method and by CFA’s will be presented. We hypothesise that the factor structure of the TCI is equivalent in the data from both countries, South Africa and Sweden, but mean scores significantly differ on all seven personality domains.

An item and construct bias analysis of two language versions of a verbal analogies scale

Rizwana Roomaney South Africa

The Woodcock Muñoz Language Survey (WMLS) is a test of cognitive academic language proficiency that has been adapted from English into isiXhosa. This study was primarily concerned with the Verbal Analogies (VA) scale of the WMLS and aimed to cross-validate previous research on the two language versions of the scale and improve on methodological issues by employing matched groups. The study employed a monolingual matched-two group design consisting of 150 mainly English speaking and 149 mainly isiXhosa learners in grades 6 and 7. This study had two sub aims. The first was to investigate item bias by identifying DIF items in the VA scale across the isiXhosa and English by conducting a logistic regression and Mantel-Haenszel procedure. Five items were identified by both techniques as DIF. The second sub aim was to evaluate construct equivalence between the isiXhosa and English versions of the VA scale by conducting a factor analysis on the tests after removal of DIF items. Two factors were requested during the factor analysis. The first factor displayed significant loadings across both language versions and was identified as a stable factor. The second factor was stable for the English version but not for the isiXhosa version. Results were confirmed by the Tucker’s phi and scatter plot. It was therefore concluded that factor one is structurally equivalent across the two language versions but that factor two was not structurally equivalent. Therefore the detection and removal of DIF items did not result in structural equivalence being established.

Male gender preference: Is a risk factor for antenatal depression

Maryam Rouhi Islamic Azad University, Islamic Republic of Iran

Depression is one of the major morbidities that affect many women during ante- and postpartum periods. There are many risk factors that many women experienced and thereby became susceptible to depression. One of those items is male preference, especially in Asian women where most families desire a male child. This is a cross-sectional study of 2300 women in three cities (Naghadeh, Mahabad, Sardasht) who attended routine antenatal appointments and during the study period self-completed a questionnaire. The first part investigated socio-demographic, cultural and other possible risk factors, including gender preference. The second part comprised the Edinburgh Postnatal Depression Scale (EPDS). EPDS scores greater than or equal to 13 indicate probable depression. The prevalence of depression was 32.1%. Maternal male gender preference was common and was associated with depression. Family male gender preference, unplanned pregnancy, a history of depression and feeling anxious in pregnancy were associated with an increased likelihood of depression, while support from family and friends, being satisfied with pregnancy and being multiparous were associated with a reduced likelihood of depression. It was concluded that the rate of antenatal depression was very high in women and male preference was a risk factor in this population. On the other hand, antenatal depression was the strongest predictor for parenting stress. Recognizing risk factors play a vital role, especially for different ethnic groups.

Evaluation of the effects of life skills training on male and female students’ stress

Hosein Sadeghi University of Isfahan, Islamic Republic of Iran; Mohammad Reza Abedi; Hosein Sadeghi; Ahmad Sadeghi

The purpose of this study was to determine the effects of life skills training on male and female students’ stress in an Isfahan University. The statistical population of this research includes University of Isfahan students enrolled at the university during 2010–2011. From this population, 108 persons were selected using a stratified random sample method and they were placed in experimental and control groups. In this research, the variety of life skills questionnaire and the stress of student life questionnaire were used to collect data. This is an experimental study with a pretest posttest and control group. Data were analysed using software (SPSS16) and methods of descriptive and inferential statistics. The results show that life skills training can reduce students’ stress. Also, life skills training to students in enhancing their life skills improved all types of skills, with only the creativity skills being rejected. Gender influence in self-awareness skills, empathy, interpersonal relationships and problem solving in general was significant, and in all cases (life skills) girls were more educated.

Tests made in Germany: International use of psychological tests from the German-speaking countries

Naescher Saskia ZPID, Germany; Gabriel Schui; Guenter Krampen

The internationalisation of psychology has led to an increasing anglicisation of psychological publications from German-speaking countries. It is analysed whether this also led to a growing number of psychological tests originally developed in the German language, which are subsequently translated into English. Furthermore, it is examined whether such a tendency increased or decreased the number of tests from German-speaking countries (in comparison to tests of Anglo-American origin) employed in German and Anglo-American research studies. To investigate these aspects, bibliometric data of psychological tests developed in German-speaking countries since the 1950s are presented. The application of tests in German versus Anglo-American empirical research is analysed using data from the German reference database PSYNDEX (containing psychological publications from authors from German-speaking countries) and the American reference database PsycINFO (international coverage with a strong Anglo-American bias). Time series analyses compare the number of German and Anglo-American test developments used in German and Anglo-American publications between 1950 and 2010. Further bibliometric data concerning differences between tests originating from German and Anglo-American countries are analysed according to subject classification. Results suggest a strong influence of the original language on test utilisation and highlight the significance of enhancing the visibility of German test developments in the English-speaking countries.

Development in an academic environment of a web-based test-manager with non-copy-righted psychological tests

Mark Schitette Katholisch-Ghent University, Belgium; John- ny R.J. Fontaine; Marc Covents

The main goal of this project at Ghent University (Belgium) is to develop an on-line test-manager which offers psychology students and our academic staff a tool to facilitate the inclusion of non-copy-righted psychological assessment instruments in their research. Often these instruments are poorly known and underused. Within this initiative both research and practice are included. Practitioners get access to many useful tests, and clients/patients are more likely to be assessed with specifically tailored ones. At the same time researchers can use the responses for
scientific research and for improving the quality of psychological tests. The system has been in operation for a year, and a first evaluation is possible. We have already more than one hundred users and more than one hundred instruments in the system, running completely on open source software. Pro and cons, ethical and technical questions are discussed.

How intelligence facets relate to admission test scores and predict academic success

Johannes Schult, University of Konstanz, Germany; Franziska Fischer; Benedikt Hell

The aim of this study is to explore how intelligence facets that are crucial for academic success are mapped in tests of scholastic aptitude. We assess the differential influence of verbal, numeric, and figural ability separately for economics students and science students. Differential validity regarding gender within each field of study is also investigated. The data from 619 freshman students from two German universities include intelligence test scores (IST2000R) and academic aptitude test scores - both collected during the first weeks of college - as well as subsequent grades from the first year in college. Using structural equation models, we compare the direct influence of each intelligence facet on academic performance with the indirect effects mediated by academic aptitude test scores. Numeric abilities play an important role in the admission test’s predictive power. They also tend to have incremental validity over the aptitude test scores. Verbal abilities are important in science admission tests and science grades, but not in economics, where figural intelligence is a valid predictor for women’s academic success. In general, admission test scores have a larger predictive validity for women than for men. These findings highlight the need for general admission tests that cover all relevant intelligence facets. Omitting a valid intelligence facet is only an option for customised tests and should be preceded by a needs assessment. Direct effects of verbal intelligence on science grades indicate that differential test validity may be due to an incomplete measurement of aptitude.

Working memory and intelligence quotient with academic achievement in female monolingual and bilingual

Abootaleb Seadatee Islamic Republic of Iran; Jonathan Abramowitz; Cynthia Bulk; Donald Baoum; Jennifer Kirby

The purpose of the current study is to investigate the relationship between working memory (WM), intelligence quotient and academic achievement in female monolingual (ML) and bilingual (BL) students. The information processing scale (IP)and Raven’s progressive matrix test (Rpm) were used as tests for the assessment of WM and intelligence quotient respectively. These tests were administered to 366 (183 ML and 183 BL) female high school students in grade three in Persian. In addition, the mean score of all final exams in the present academic year were used as a scale for the assessment of academic achievement. Pearson’s correlation coefficient and t-test methods were then performed to determine which group has better performance in the three variables. Based on the results, although there were a significant relationship between working memory and academic performance in both groups, this relationship in intelligence quotient between ML and BL students was not significant. Great linguistic experiences in the structural, semantic and phonology domains lets BL students outperform ML students in WM tasks and academic achievement, but this is not the case for intelligence.

The exploration of item selection strategy for cognitive diagnostic computerised adaptive testing

Zhiyong Shang Shenzhen Seaskyland Technologie, China; Shuliang Ding; Yan Liu; Wenyi Wang

The purpose of this paper is to construct a new and effective adaptive selection strategy for computerised adaptive testing for cognitive diagnosis based on the DINA model. The new method is designed as follows: First, before the test is administered, the item pool is partitioned to some sub-pools according to the attribute pattern contained in the items, and each subpool parameters (st,gt) are calculated by taking the mean of items parameters in the sub- pool. Secondly, let p(t) be the posterior distribution of knowledge state after h responses are observed, let f(t;ok;t) be a discrimination function (DF) and it is defined below, let g(t=1)=1∑i;p(αi)*p(dok;h+1)*f(αi;ok;h) be the expected DF (EDF). Thirdly, the new method selects the t-th sub-pool if t maximises EDF and selects (h+1)-th item randomly from the sub-pool as the next item. To define DF, consider (st,gt) and any pair of knowledge states (ui, uk). There are 4 possible expected item response (EIR) vectors. If EIRs are not the same, let f(t,ok)=1-(st+gt)/2, otherwise record zero. When compared to selection strategies of random or Kullback-Leibler or Shannon Entropy with EDF, the simulation results show that the EDF is a significant improvement both in the measurement accuracy and the speed of item selection.

Trust behavior in a computerized investment game

Pet-Chun Shih Universidad Autonoma de Madrid, Spain; Alejandra Montoro; Eduardo Estrada; Agustin Martinez

The most common behavioral measure of trust is the Investment Game (Berg et al., 1995), where a sender and a receiver have to decide whether to invest their initial endowment on each other to gain the maximum profit. The aim of this study is to develop and validate a computerized version of the investment game in web setting. Two characteristics of this computerized task contribute to improve the quality and efficiency of research: it allows a higher control over the variables and a complete record of all actions. Three different performance conditions were carried out to (1) explore the psychometric properties of the measure; (2) compare the effect that positive and negative reciprocity has on trust behavior. The sample comprises 112 (82 females, 73.2%), whose age ranged from 17 to 52 years (M = 20.02, SD = 5.506). Internal consistency was good (α = .851) and the instrument showed convergent validity with other trust measures (r = .240, p < .05 with Yamagishi General Trust Scale and r = .331, p < .01 with NEOPI-FFI Agreeableness). A significant difference between positive (M = 5.192, SD = 21.364) and negative (M = 37.437, SD = 17.235) reciprocity conditions was found (F = 15.06, p < .001; partial η2 = .120). Results show that this instrument has good reliability and validity. Moreover, it allows conducting experimental research on trust behavior with a large number of subjects while overcoming time and space restrictions.

The use of the phonic inventories by eight teachers in Japari Remedial Centre: A case study

Sibongile Sibanyoni Witwatersrand University, South Africa

This research is a case study of the use of the Phonics Inventories at Japari Remedial Centre, Johannesburg. Eight teachers at the centre used the error profiles from this instrument to identify each learner’s specific area of difficulty in learning phonics. This study attempted to establish whether this information was useful for planning lessons, and whether this was an effective way of enhancing teaching strategies. The investigation was multimethod. Teacher rating scales and phonic error profiles from the learners’ assessment were used as data for the qualitative aspect of the study. Interview and focus group data were used as qualitative data to identify the teachers’ perspectives concerning the use of the Phonics Inventories in the school, as well as to interpret important trends in the data. These two forms of data were analyzed interpretively. Overall, this study indicated that the phonic error profiles were used by both teachers and reading therapists in the school as a way of focusing on specific areas of reading, spelling and written work in which particular learners were struggling, as well as for planning instruction for groups of learners with similar error profiles. In addition, they provided a useful basis for communication with individual learners and groups of learners concerning their learning needs, as well as between teachers and teachers, teachers and reading therapists, teachers and school HOD’s and administrators, and teachers and parents.

Animal behaviour research in India: Contributions to basic science and conservation biology

Mewa Singh University of Mysore, India

Animal behaviour in India has been studied by zoologists and psychologists. Conservation biology has been researched by hard core conservation biologists and applied by the forest and wildlife managers. In recent years, behavioural ecology has become an independent discipline by itself. Whereas behavioural biologists have paid little attention to the conservation of species, conservation biologists have largely ignored the findings by behavioural biologists. I argue that behavioural ecology bridges the gap between behavioural biology and conservation biology. Animal behaviour research in India, on one hand, has contributed significantly to the basic science of evolution covering areas such as evolution of social systems, behavioural development, dominance systems, parental investment patterns, resource partitioning in sympatric species, social organisation, cognition, etc. On the other hand, a large body of research in animal behaviour in wild habitats as well as in the captive conditions of zoos has a direct application value for conservation and management of species, especially endangered species. Such research includes spatiotemporal distribution, male migration patterns, mate choice, resource utilisation patterns, enclosure designs, etc. In this talk, I will briefly summarise the above topics of research in India.
The development of the revised DINA model and its application
Lihong Song Jinxi Normal University, China; We-nyi Wong; Haigai Dai; Shuliang Ding
This study introduces a revised DINA (R-DINA) model by redefining the ideal response of the DINA model. The new cognitive diagnostic model relaxes the DINA model’s assumption of equal probability of success for all subjects lacking some attributes on an item. It describes the correct answer probability as consistently increasing as the number of task-relevant attributes the examinee masters increases and partitions the latent classes into \( k + 1 \) latent groups, where \( k \) represents the number of required attributes for correct response to item \( j \). A simulation study is conducted to compare the performance of the DINA model, the R-DINA model and the RUM. According to model selection criteria (e.g., AIC, BIC, DIC), classification accuracy of knowledge states and posterior predictive score distribution, the simulation results indicate that: (1) For data generated using the DINA model, the R-DINA model fits best while the results obtained by R-DINA and RUM are comparable, (2) for data generated using the R-DINA model or the RUM, the results by R-DINA and RUM are comparable and better than that of DINA, (3) in some situations, the R-DINA model could be considered an alternative simple model of the RUM. Moreover, the three models are used to analyse Tatsuoka’s fraction subtraction data. The results indicate that, according to model selection criteria and posterior predictive p-value of each item’s chi-square statistic, the R-DINA model and the RUM outperform the DINA model.

Assessment of prenatal psychological risk factors in Peruvian pregnant women by OB-GYNs using the ‘index Mum Screen’ Spanish validation for Latin America
Andria Spyridou University of Konstanz, Cyprus; Martina Ruf; Maggie Schauer; Thomas Elbert
The objective of the study was to validate the KINDEX Mum Screen in Spanish for Latin American language through the assessment of women living in Lima, Peru. The KINDEX Mum Screen is a German validated tool, designed to be administered during pregnancy, for the assessment of some of the main psycho-social developmental risk factors for the child. The KINDEX was translated, and back-translated, to Spanish, and adapted to language specifics in Latin America. A sample of 96 women were screened by gynaecologists and midwives working in a public Hospital serving a poor and crime-ridden area in Lima, Peru. A randomised subsample of 40 women were interviewed by a clinical psychologist with standardised instruments, like the PSS-14, M.I.N.I., PDS, HSCL-25. The results show that gynaecologists, midwives, clinicians and counsellors are able to assess valid information about existing risk factors (including trauma, mental health, acute stress, depression) through a structured 15-minute interview with pregnant women. Abused and women maltreated during childhood, who live in poor and insecure conditions, accumulate several high risk factors that compromise their own and their babies’ health. Adequate treatment is crucial to decrease symptoms related to post traumatic stress disorder, anxiety and depression, and to prevent adverse child developmental outcomes. The important question now is, how to implement the KINDEX Mum Screen tool in the everyday practice of gynaecologists, and midwives, and to develop low-threshold programmes, that are easily accessible, for women in need.

Re-standardising the Griffiths mental development scales: Phase one, its challenges and triumphs
Louise Stroud Nelson Mandela Metropolitan University, South Africa; Cheryl Foxcroft
In 1954, Ruth Griffiths developed the Griffiths Mental Development Scales (GMDS), a developmental assessment measure based on a philosophy of the basic avenues of learning and the observation of children in play. Significantly, modern systemic approaches to developmental assessment remain in line with Griffiths’ (1954) thinking. July 2010 saw the commencement of the re-standardisation of the GMDS. A qualitative, exploratory and descriptive research approach was chosen to underpin Phase One and encompassed various sub-phases. These included a systematic review of recent literature regarding child development and assessment, an Avenues of Learning workshop in which ‘sticky note’ data was collected, the conducting of expert interviews, and the development, the conducting of distribution and analysis of a questionnaire to Griffiths Users and non Users. As the GMDS is widely used and recognised throughout the world, this paper serves to highlight the research challenges and triumphs experienced during Phase One. Themes and trends that emerged from triangulating the data suggested inter alia that developmental theory and knowledge must inform the domains; the screening versus diagnostic nature of the GMDS should be debated; observation and play with reference to the nature of the GMDS must be retained; the age range of the GMDS and the implications for test development was highlighted; and the univer-sity of the link of the GMDS to remediation was expressed. The findings obtained in Phase One will guide the development of the blue print of test specifications to be used in directing Phase Two of the re-standardisation process.

An empirical study on teaching assessment indicators in China
Hechuan Sun Shenyang Normal University, China
It is well-known that the teachers’ quality and the effectiveness of their classroom teaching will affect their student learning and the quality of their learning outcomes. Therefore, the quality and effectiveness of classroom activities, including effective classroom teaching and effective classroom learning, are profoundly important. To assess the behaviours of the teachers and their teaching in classrooms, teaching assessment indicators are needed. However, at the national level, China has no such indicators. In order to find out what kind of teaching assessment indicators are more suitable for building up the national teaching assessment indicator system, we have conducted this study. It focused on searching for the more suitable teaching assessment indicators for China. In the literature review part, it reviewed the related theories. Moreover, it collected the teaching assessment indicators used in different areas at present in mainland China. It compared the similarities and the differences among the collected teaching assessment indicators. Based on that, it designed and conducted an empirical study. School teachers from 14 districts in the east, west, south, north and middle of Liaoning Province were randomly selected for a questionnaire survey. Both qualitative and quantitative approaches were used to analyse the collected data. The findings were presented in the final part of this study.

Application of rough set theory in cognitive diagnosis
Xiaojuan Tang Jinxi Normal University, China; Shuliang Ding
Cognitive diagnosis (CD) aims to diagnose examinees’ knowledge states (KSs), thereby providing them with detailed information. Rough set theory (RST) is a mathematical approach to uncertain data analysis. Through data reduction, it can induce decision rules under the condition of maintaining classification ability. And at the same time, it uses the decision rules for classification of examinees. Though it has been proved that RST is useful for data reduction, decision rule, classification, and so on, references of applying rough sets to CD are rare. In CD, estimating examinees’ KSs, based on examinees’ score matrix, examinees can be classified by the decision rules. The main advantage of the application is that it does not need a cognitive diagnostic model (CDM), i.e., it is a model-free method. It can save a lot of time to estimate unknown parameters in CDM. While, by using RESE (Rough set soft-ware), data reductions, decision rules and examinees classification takes almost no time at all. The results show that the method is satisfactory.

The standardisation of the Wechsler Adult Intelligence scales (4th edition) for use in South Africa
Nicola Taylor Jopie van Rooyen and Partners, South Africa
The Wechsler Adult Intelligence scales (WAIS) have long been the gold standard in the evaluation of intelligence, and have an established presence in South Africa as the same. The development of the Fourth Edition of the WAIS (WAIS-IV) provided an excellent opportunity to adapt and translate the scales for use in South Africa, and provide local, appropriate norms. The WAIS-IV was published in the US in 2008, and standardised for the UK in 2009. In 2010, the process for the adaptation of the WAIS-IV into South African English began, including the preparation of the material for later translation into Afrikaans and Zulu. A panel of South African psychologists and anthropologists examined the existing UK version to determine which scales required adaptation and made recommendations regarding the appropriateness of items for the South African context. Once the changes had been implemented, standardisation data were collected.
Predicting affect and behaviour from irrationality among youth internationally
Mark Terjesen St. John’s University, United States of America

REBT posits that irrational beliefs in the form of absolutes (should, oughts, musts, needs) are the psychological core of children’s and adolescents’ emotional and behavioural problems (Bernard, 2004). The Child and Adolescent Scale of Irrationality (CASI; Bernard & Cronan, 1999) is a self-report measure of irrational beliefs which yields scores on six scales: self-downing, dependence, conformity, low frustration tolerance, and discomfort as well as total irrationality score. This research study explores the relationship between children’s social-emotional functioning, behaviour, and underlying thought processes through the administration of self-report and parental scales measuring student cognitions and beliefs in five different countries. This presentation will describe results of a multi-national, cross-cultural study that examined the relationships between children’s irrational beliefs and their social-emotional functioning. The results of the present study may assist in determining the emotional and behavioural consequences of adolescents’ particular irrational beliefs with the hope that the results could aid practitioners in providing psychological services. The role of cognition and irrational beliefs in emotional and behavioural disorders among children and adolescents as a function of language and culture will be presented.

Accuracy, sensitivity and specificity of psycho-diagnostic tools
Marco Timpano Sportello University of Pisa, Italy; Davide Cammisuli; Sabrina Danti

Recent studies have suggested using tests of episodic memory, learning, ongoing memory, naming, selective attention, planning and sensitivity to interference to diagnose Mild Cognitive Impairment (MCI) and to estimate its probability to convert into dementia. The present study aims at detecting neuropsychological tests that show a greater specificity and sensitivity to the minimal cognitive decline shown by MCI patients. 162 MCI patients (M: F=47:53%; Age: 73.2±7; Education: 5.8±3) were tested by a wide neuropsychological battery, including: Milan Overall Dementia Assessment, ADL and IADL, Digit Span, Corsi Span, Paired Associate Learning, Short Recall, Corsi Learning Suvra-Span, Visual Search Test, Stroop Test, Streak’s Completion Test, Constructive Apraxia Test, Boston Naming Test, Verbal Fluency, Tower of London, Brixton Test, Go-no-Go Frontal Assessment Battery subttest. A. Fisher’s discriminant analysis was used to determine what instruments were able to correctly classify and discriminate between MCI Type I and Type II. Then sensitivity and specificity indices were calculated starting from classification matrix found. A selected set of instruments (Paired Associate Learning, Boston Naming Test and Stroop Test) showed a significant predictive capacity in discriminating between Type I and Type II (p <0.001). 92% and 82% of Type I and Type II, respectively, were correctly classified. The neuropsychological tests presented an acceptable sensitivity (57%) but above all an excellent specificity (97%) and accuracy (84%). We recommend a neuropsychological battery including measures of episodic memory, naming and sensitivity to interference to offer clinicians valuable information on MCI diagnosis and to reduce assessment time.

A multiple-strategies cognitive diagnosis model: the MSCD model
Dongbo Tu Jiangxi Normal University, China; Haiqi Dai; Yan Cai

Almost all of the current cognitive diagnosis models are only adaptive for single-strategy tests or data, and assume all examinees use the same processing strategy. Based on previously published studies, the current study developed a new multiple-strategies cognitive diagnosis model called the MSCD model. Monte Carlo method was used to explore the feasibility of the MSCD model, and to examine the estimation precision as well as the properties of the MSCD model. The following findings were presented: (1) Under the single-strategy test or data, the average attribute match ratio (AAMR), pattern match ratio (PMR) and strategy match ratio (SMR) of the MSCD model were all very high, and were as high as those of the single-strategy cognitive diagnosis model (single-strategy model). (2) Under multiple-strategy test or data, the MSCD model also had high AAMR, PMR and SMR, which was in contrast to the single-strategy model. (3) When the number of strategies reached five, the MSCD model also had very high AAMR, PMR and SMR. These all explained that the newly developed model, the MSCD model, was reasonable and could be accepted for use.

A polytonymous extension of the DINA model
Dongbo Tu Jiangxi Normal University, China; Yan Cai

Most cognitive diagnosis models (CDMs) are only adaptive for dichotomous data. Working from the idea of cumulative category response function in the Graded Response Model (Samejima, 1997), this paper extended the dichotomous HO-DINA model to a polytomous model called the P-HO-DINA model. This paper employed Markov Chain Monte Carlo (MCMC) algorithms to fit the model. Findings suggest that the P-HO-DINA model holds fair robustness, and its attribute match ratios (MMR & PRM) are very high, which indicate P-HO-DINA model is suitable for cognitive diagnosis. Furthermore, the estimation accuracy of parameters, item and s, and the attribute match ratios (MMR & PRM) decrease with an increase in the number of attributes, but the estimate precision of theta and g parameters are to the contrary. Additionally, in real work, if the index PRM is required to be higher than 80%, then it is suggested that the number of cognitive attributes is not greater than seven with the P-HO-DINA model.

Investigating the ethnic equivalence of the 16PF5-SA
Casper Van Zyl Jopie van Rooyen And Partners, South Africa

The 16PF5 has previously been adapted and standardized for use in South Africa. The objective of this study was to examine whether the 16PF5-SA has similar psychometric properties for Black and White respondents in the South African context. Independent sample t-tests were conducted to examine mean score differences and Cohen’s d effect sizes were calculated to determine practical significance. Rasch analysis was used to examine whether the items functioned across the groups. The sample consisted of 207 men and 268 women of which 152 respondents were Black and 122 were White. Rasch analysis identified 38 items in total that demonstrated DIF. The size and direction of the DIF-contrast were considered to determine practical significance. In addition, test characteristic curves were computed for scales with the most DIF items. In none of the scales did DIF translate to bias at the scale level. Thus, the DIF was not practically significant. For Black and White respondents, mean score differences with medium effects were found for the Self-Reliance and Tension scales. A large effect was found for the Reasoning scale. Rasch analysis did not indicate that the assessments functioned differently for White or Black respondents at the scale level. The practically significant mean score differences found between Black and White respondents are therefore likely due to stable differences in the sample group. Consequently, separate norms may be required for these three scales.

Re-evaluating the importance of the criterion on space in assessment centre design
Nadene Venter SHL, South Africa

The assessments Centre Assessments (ACs) offer an organisation concerning the performance and potential of its staff provide powerful information to inform decisions about talent. Taken holistically, such information can enable decisions about the organisation’s talent strategy and determine actions required for various talent management initiatives. However, in order to understand the fit between talent available and talent needed, the organisation must have a clear idea of its requirements. Furthermore, in order for ACs to provide accurate information to key talent decisions, the requirements the ACs are designed to measure must be clearly defined and linked in an objective and rationale manner to the outcomes desired. Hence, lies the importance of job analysis and accurate criterion definition in AC design. Dulewicz (1991) makes the point that job analysis will result in a set of key competencies and "only then should one select or design appropriate tests and exercises which will best measure these key competencies". In a positive reflection of South African AC practices, a recent survey found that nearly all of the organisations participating reported using some form of job analysis before conducting an AC (Krause et al., 2011), with one of the most common techniques being competency modelling. This paper will examine the criterion domain underpinning ACs, review the advantages and limitations of existing job analysis methodologies, and consider new developments in the field. The over-arching purpose is to ensure that AC design and development remains aligned with...
organisational requirements, to continue delivering valuable information for use in talent management practices.

Technology-assisted test construction, delivery and validation

Nadene Venter
SHL, South Africa

This paper will discuss how the Internet drives the need to address efficiencies in assessments to manage the candidate experience and the application of item generation methods to develop secure online tests. The concept of component-driven design to assessment stems from the need for assessment design to incorporate the candidate experience as well as concerns expressed by organisations that the assessment window is managed to avoid candidate fatigue and losing potential talent by the prospect of long assessments. Building on the need for efficient assessments and drawing on IRT models as well as computer generation of test items, the paper will describe how technology allied with effective test definition via computer generation of content provides a powerful new application in developing the large item banks required to manage test security (Burke, 2006 & 2008). It will also describe how these methods can be used to provide for short and valid testing solutions essential for online test security, using the development of online clerical and numerical fluency measures to provide tangible examples of the approach. In summary, the presenter will describe how criterion-focused assessments can be designed with strong construct and criterion validity, and that allow the assessment solution designer to pull together assessment modules to maximise effective assessments of job/role fit, as well as provide a solution that is also efficient for the candidate to navigate and complete.

Assessing predictors of adjustment to aging: A cross-validation study of an adjustment to aging schedule

Soﬁa Von Humboldt
ISPA, Portugal; Isabel Leal

The aim of this study was to develop and validate a schedule to assess the factors that older adults recognized as determinants of their adjustment to aging. The measures used in the study were selected to assess the reliability and validity of one new instrument, the Adjustment to Aging Schedule. Measures were completed using a variety of culturally appropriate methods, including mail-outs, self-administration and interviews. For the purposes of this study, one measure of cognitive functioning - the Mini-Mental State Examination and demographics, were included. Complete data were available for 709 older adults (mean age 82.4, SD = 6.45, range 74-102) from eight different nationalities. Exploratory factor analyses were run for data reduction and for exploring the theoretical structure. Controlling for age, gender and country of origin, we assessed the level of adjustment of elderly people, and its effect on aging. The sampling adequacy was confirmed by the Kaiser-Meyer-Olkin test (KMO=0.775) and the total variance explained by this eight-factor structure is 75.09%. Adjustment to aging appears to be a catalyst to attitudinal markers of maturity and internal development which in turn impact quality of life and aging, across cultures. All estimates were statistically significant (p <.01). This cross-cultural study illuminates links among adjustment and aging in older age, warranting further study across cultures among frailter populations over time. Recommendations for future research on older adults’ adjustment and clinical practice are also presented.

Interational pattern analysis

Charl Vorster
North-West University, South Africa

Traditional approaches to diagnosis within the field of mental health are of limited value to the psychotherapist because the fitting of individuals into predetermined categories strips the individual of his or her unique qualities and potentially useful information for the psychotherapeutic process gets lost in the process. This, however, seemed inevitable in applying the mental health model. In contrast, Interational Pattern Analysis, developed within the theoretical paradigm of the eco-systemic approach, seemingly offers an alternative psycho-diagnostic procedure that retains the uniqueness of the individual and yet provides a systematic and orderly procedure of indication for psychotherapy that has proved to be highly effective in directing the psychotherapeutic process. Interational Pattern Analysis focuses on 17 interpersonal variables imbedded in the interactional patterns within the various interpersonal contexts in which an individual exists. During a one-day workshop delegates will be introduced to the concept of Interational Pattern Analysis and equipped to start utilizing the procedure as an integral part of the psychotherapeutic process. In the workshop the theoretical rationale behind the procedure will be briefly introduced. This will be followed by a series of hands-on interactive practical interpersonal exercises that will aim at equipping delegates with the necessary frame of reference, an enhanced level of perception regarding the relevant interpersonal variables and an introduction to the actual process of producing an Interational Pattern Analysis.

When test equating is necessary in cognitive diagnostic assessment under the DINA model

Wenyi Wang
Jiangxi Normal University, China; Lihong Song; Shuliang Ding

In cognitive diagnostic assessment, the DINA model received much attention. Several factors affecting the quality of the item parameter estimates have been reported, such as Q-matrix misspecifications, sample size, representative samples, etc. (de la Torre & Lee, 2010; de la Torre, Hong, & Deng, 2010; Rupp & Templin, 2008). De la Torre and Lee (2010) discussed invariance of DINA parameters when the model perfectly fits the data and proposed test equating when two sets of item parameter estimates are markedly disparate. But there was no obvious standard of quantity to judge the extent of discrepancy. Considering that many factors could lead bias between item parameters more or less, one should examine the degree of discrepancy between two sets of item parameter estimates to determine whether a test equating is necessary. The aim of this study is to explore the discrepancy threshold of test equating under the DINA model. In order to obtain the threshold, the study mainly investigates the impact of the DINA model parameter bias on classification accuracy of knowledge states. To better understand how classification accuracy is affected by the bias, we conduct a simulation study in which nine levels of anchor item parameter bias are under consideration. The results indicate that the classification accuracy significantly decreases when the bias is above 0.1. In conclusion, we recommend a test equating when the discrepancy between anchor item parameters is above 0.1. Future research will explore the test equating method for the DINA model.

A cross-culture study of the impact of reading engagement and reading strategies on reading literacy

Zhang Wenjing
Beijing Normal University, China; Xin Xin

Reading plays a very important role for the school success and life-long learning for everyone. From the international comparison perspective and based on the data of PISA 2009, this current study investigates the impact of reading engagement and reading strategies on reading literacy of 15-year-old students, while considering the nested structure of the data. Reading engagement is comprised of five variables: time spent reading for enjoyment, reading for enjoyment, diversity of reading materials, diversity of on-line reading activities and reading for school, while reading strategies also include five variables: Memorization strategies, control strategies, elaboration strategies, understanding and remembering metacognition strategies, summarizing metacognition strategies. The study selects three countries from the international PISA 2009 database: Korea, Finland and United States and one PISA 2009 trial study country, Mainland-China and analyses whether the impact patterns are the same or not among the four countries. The findings indicate that the different variables of reading engagement and reading strategies influence reading literacy in differential degrees respectively. The impact patterns are almost consistent in the four countries, especially for the variables reading for enjoyment, reading for school and reading meta-strategies. Last but not least, the study also discusses how to cultivate students’ reading engagement and reading strategies in the context of school education.

The metric invariance of the Wong and Law Emotional Intelligence Scale (WLEIS) across three Chinese university student groups

Gonggyun Yan
Beijing Normal University, China; Donald Saklofske; Tongwei Li

To date, cross-cultural research on emotional intelligence has been scant. The present study aimed to address this shortfall by assessing the measurement equivalence of the Wong & Law Emotional Intelligence Scale (WLEIS) developed in Hong Kong. Two studies were conducted – one in Beijing, China (n=680) with university students, and the other in Calgary, Canada with two groups of Chinese students who were administered the WLEIS in either Chinese (n=151) or English (n=151). The results showed that WLEIS had satisfactory reliability, the four-factor structure was replicated, and metric invariance was supported across the three groups using confirmatory factor analysis (CFA). The present results add to the growing cross-cultural EI research literature, specifically by providing empirical evidence supporting the measurement invariance of the WLEIS across three Chinese student
Development of the health-risk behaviour inventory for Chinese adolescents

Shuqiao Yao Medical Psychological Institute, China; Mengcheng Wang; Muli Hu; Lin Cai; Jinyao Yi Medical Psychological Institute, China; Xiongzhao Zhu

During adolescence health-risk behaviours (HRB) increase the likelihood of negative long-term consequences and predict decreased psychosocial functioning throughout adulthood. However, in China, there is not a comprehensive measure that was developed for examining adolescent risk behaviours using an emic approach. The primary aim was to develop and validate a comprehensive assessment tool, the Health-Risk Behaviour Inventory for Chinese Adolescents (HBICA). Chinese adolescents ages 14–19 years (n = 6633), were recruited from mainland China high schools across 10 cities. In addition, a clinical sample, which included 326 adolescents meeting DSM-IV criteria for Conduct Disorder, was used to evaluate predictive validity of the HBICA. Psychometric properties of the HBICA were analysed. Based upon item analysis and exploratory factor analysis, we retained 53 items, and got 5 factors (Suicide and Self-Injurious Behaviours (SS); Aggression and Violence (AV); Rule Breaking (RB); Substance Use (SU); Unprotected Sex (SS)). The five factors explained 51.75% of the total variance. Cronbach’s alphas were considered strong: ranging from .77 (RB) to .86 (US) for boys and from .74 (SD) to .83 (SS) for girls. The 8-week test–retest reliability was moderate: ranging from .66 (AV) to .76 (SD). Moreover, predictive validity analyses were able to effectively distinguish high-risk behaviours between normal and clinical adolescents (Cohen’s d = 52–1.51). These results provide initial support for the feasibility and validity of the HBICA as an assessment tool for health-risk behaviours in adolescents.

The psychometric properties of the Swedish adolescent drug abuse diagnosis and results from norm-referenced study

Helene Ybrandt Department of Psychology, Sweden

The aim of the studies was to provide a standardisation of the use of the Adolescent Drug Abuse Diagnosis (ADAD) among Swedish adolescents. Data relating to nine life areas (medical status, school history and status, employment, social activities and peer relations, family background and relationships, psychological status and problems, legal involvement, alcohol use, and drug use) was gathered from a randomised population-based sample of 847 adolescents aged 13–18 years and 168 adolescents aged 10–21 years with antisocial problems detained under the Swedish Care of Young Persons Act in special youth homes. The results show that the ADAD instrument produced good interrater reliability; the subscales showed moderate internal consistency and concept validity was satisfactory and comparable with American and Swiss versions. Finally, the ADAD subscales produced meaningful correlations. The Swedish ADAD psychological status and problem area show good concurrent validity for normal adolescents (correlated with the Youth Self Report and Beck’s Depression Inventory), and low to moderate predictive validity correlated with YSR and DICA. The normative study shows that the effects of age, gender, and geographic region were small but significant, with older adolescents, girls, and adolescents in cities scoring higher for problem severity. The conclusion is that the Swedish version of ADAD appears to be a psychometrically good instrument for assessing the severity of adolescent problems and their need for treatment and has the potential to serve as an instrument for assessing individual adolescents’ self-reported problems in Sweden.

Application of multilevel latent class analysis in classification

Jie-Ting Zhang South China Normal University, China; Min-qiang Zhang; Can Jiao

Multilevel latent class analysis provides an accurate classification at both the individual and group level, which is of great importance when conducting cross-culture research or executing different measures to groups of diversity. This study probes into characteristics of the new method in application and the ways to improve the accuracy of model selection, in order to ensure the objectivity of classification. In the first section, application of multilevel latent class cluster analysis is demonstrated through the empirical data of an English comprehension test. In the second section, Monte Carlo simulation is conducted to investigate how sample size affects the judgment of criteria AIC, AIC3, BIC and BIC* in group-level numeration, as well as the conditions of applying these criteria. The result of the simulation is verified by empirical data. Results indicate: (1) Latent class analysis is an effective method of handling categorical data in psychological research and it processes some distinctive advantages, such as weak hypothesis, objectivity, visualization and being ready for further statistics. (2) When the multilevel model is complex, the model selection criteria do not give high or stable accuracy in all sample sizes, and they should be chosen in specified circumstances. When sample size per group is nk<40, AIC3 is preferred, with BIC a second choice, which would be even better when nk reaches 50. When nk<30, BIC* or AIC is recommended, but high accuracy is hardly ensured.

Measurement of Internet addiction: Internet Addiction Test versus Chinese Internet Addiction Scale

Jiahui Zhang Beijing Normal University, China; Tao Xin

Measurement is the most important part of the research of Internet addiction (IA). Analysis based on item response theory is supposed to provide richer information on item level, thus bringing a new perspective of instrument comparison, a valuable complement to traditional analysis. This study aimed to compare the Internet Addiction Test (IAT), which is among the earliest instruments of IA and still currently in use, with the Chinese Internet Addiction Scale (CIAS), popular among Chinese researchers. A total of 467 Internet users participated in the study online. Data were analysed using Muraki’s Generalized Partial Credit Model. Two studies were conducted. The first study focused on the psychometric characteristics of two scales as norm-referenced tests. Results of Study 1 showed both scales had substantial standard errors on two ends of the trait continuum. Item-level analyses provided in-depth information for future instrument development, and items of high discrimination were found to share the characteristic of item description accuracy. The findings demonstrated CIAS may be a better choice than IAT, at least in Chinese culture. Study 2 examined the scales as criterion-reference tests and looked into the effectiveness of cut-off scores and compared classification consistency of two scales. This study also explored the possibility of adaptive testing of IA. The implications for these findings were discussed with a focus on how to improve the measurement of IA. Future IA scales can be improved in several ways in terms of item discrimination and difficulty distribution.

Cognitive diagnosis based on local equating of observed scores

Jiahui Zhang Beijing Normal University, China; Tao Xin

The importance of equating in large-scale test programs is beyond question. Some problems, however, remain unsolved in current research of equating. Traditional equating methods generally ignore the existence of measurement errors, and is thus subject to substantive equating biases. It was in such circumstance that van der Linden proposed local equating: a new equating theory which substitutes a weak hypothesis, objectivity, visualization and being ready for further statistics. (2) When the multilevel model is complex, the model selection criteria do not give high or stable accuracy in all sample sizes, and they should be chosen in specified circumstances. When sample size per group is nk<40, AIC3 is preferred, with BIC a second choice, which would be even better when nk reaches 50. When nk<30, BIC* or AIC is recommended, but high accuracy is hardly ensured.
The revision of adolescent's psychological Sufi questionnaire

Dajun Zhang Center for Mental Health, China; Ling Gong; Jinfang Wang

Psychological Sufi is an intrinsic factor that affects one’s mental health. It is important to accurately measure the level of psychological Sufi among adolescents. On the basis of the structure of the original series of questionnaires from the study by Zhang Da-Jun, et al., this study built Adolescent’s Psychological Sufi Questionnaire (APSQ) framework from three sub-scales - cognition, personality and adaptability - and redefined all of the operational definitions on the basis of literature review, expert interviews and structured interviews. On the initial measurement, 5,500 adolescent subjects were randomly selected, and we removed the items with lower correlational coefficients or discrimination coefficients. On the formal measurement, the data collected from more than 8,000 adolescent subjects were used to evaluate the following aspects of the scales: standard error, homogeneity reliability, re-test reliability, structural validity, content validity, empirical validity of APSQ. We will establish the norm in different genders, grades and professional norms groups from a standard sample consisting of 9,000 adolescent in China. The results showed that APSQ can be used to measure the adolescent’s psychological Sufi with a good reliability and validity.

Latent profile analysis of personality by the Eysenck personality questionnaire: An empirical study of college students in the Chinese mainland

Jie-Ting Zhang South China Normal University, China; Min-qiang Zhang; Can Jiao

Latent profile analysis is a type of latent variable mixture model, which is used to classify individuals of different traits, such as personality, by building a measurement model interpreting the relation among latent class variables and continuous indicators. Furthermore, there are many advantages to using a latent profile analysis to investigate the profile and structure of personality, such as its model-based methodology and flexibility. The present study focuses on the application of latent profile analysis in personality measurement. 1,450 college students in Chinese mainland were measured by the Eysenck Personality Questionnaire. The analysis is demonstrated in three sections as follows. In the first section, different profile models were built and compared, in order to find out the optimal model for personality type and then evaluate the importance of the four dimensions of the EPQ. In the second section, we probed into the relation among the latent personality type and other variables. Some significant predictors would be taken as covariates in the model for further improvement of the latent structure. In the third section, cross validation was conducted, demonstrating the reliability and validity of classification in personality. Finally, different types of personality were discussed based on the final solution of the model.

The prospective effect of social behaviour on mutual friendship: A longitudinal study

Dongmei Zhao School of Public Administration, China; Zongkui Zhou

The present study aimed to investigate the effects of social behavior on children’s mutual friendship longitudinally, and the gender difference on the effects. 285 students from Grade 3 and Grade 4 were collected in June of 2002, 2003 and 2004. Measures included (1) Friendship Nomination, from which we got children’s mutual friends number with boys and with girls respectively, (2) the Revised Class Play, from which we got overt aggression, relational aggression and passive withdrawal scores, Hierarchical Linear Model were used to analyse the longitudinal data. Results indicated that (1) overt aggression significantly negatively affected children’s mutual friends’ number with boys and marginally negatively on their mutual friends’ number with boys at each time. The groups of more mutual friends’ with girls or with boys at T1 could both weaken such negative effect. Compared with girls, if boys showed more overt aggression, they would have difficulty in making mutual friends with girls. (2) relational aggression had significantly positively affected children’s mutual friends’ number with girls at each time, while the influence on the mutual friends’ number with boys was not significant, and (3) passive withdrawal had a significant negative effect on children’s mutual friends number with boys at each time point, the influence on the mutual friends’ number with boys was not significant. Compared to girls, if boys showed more passive withdrawal, they would have difficulty in making mutual friends with boys. While the groups of more mutual friends’ with boys at T1 could weaken such negative effect.

Development of working memory test battery and preliminary application in elderly post-stroke patients in China

Shijie Zhou Central South University, China; Layan Zhang

The aim of this study was to develop a working memory test battery on the basis of working memory model of Baddeley, and test its clinical application in a group of post-stroke patients from mainland China. In the first, we developed a working memory test battery, which comprises four dimensions named as verbal working memory, visuo-spatial working memory, supervision function, and processing speed. The battery was administrated to 200 healthy adults (over 45 years of age), and its reliability was tested. Secondly, the working memory functions of 29 convalescent stroke patients were assessed by the working memory test battery. The results showed that the reliability and validity for most of the subscales were psychometrically acceptable. Compared with the healthy controls, the post-stroke patients group showed significantly reduced performance in the working memory test battery, except backwards digit recall and digit deletion subscales. This study suggested that the post-stroke patients existed all-around declined working memory functions. We consider the working memory test battery to be a promising tool to evaluate the cognitive function for the post-stroke patients.

Revision of Gong’s memory assessment battery for children

Shijie Zhou Central South University, China

The aim of this study is to revise the Gong’s Memory Assessment Battery for children. Necessary modification to the battery was made, and 266 subjects aged from 6 to 12 years old were sampled from 4 schools in Hunan province, Changsha city. Item analysis showed that the difficulty index ranged from .35 to .84, with an average difficulty index of .54, and the discrimination indexes ranged from .27 to .59. The test-retest stability coefficients for the subtest scores ranged from .32 to .81. The split-half coefficients, and Cronbach α coefficients for the subtest scores (except Picture Recall and Delayed Verbal Recall subtests ) were around .80. The revised Gong’s Memory Assessment Battery had reasonable difficulty and discrimination, and psychometrically acceptable internal consistency reliabilities, however, the test-retest stability of some subtests needs further study.

Development and validation of the 17-item uncertainty avoidance inventory (UAI)

Mi Zhou Peking University, China; Lei Wang

Uncertainty avoidance, which refers to the extent to which the members of a culture feel threatened by uncertain or unknown situations, is one of the four dimensions of Hofstede’s cultural values that developed at the society level. However, Hofstede’s measure of uncertainty avoidance is more concerning to sticking to the rules, inconsistent with his original concept of anxiety about uncertain or unknown situations. Moreover, the uncertainty avoidance has great variation on individuals and these individual differences have direct impacts on many outcomes. Therefore, it is necessary and urgent to develop an index that is capable to measure uncertainty avoidance at the individual level. Conceptualising uncertainty avoidance as an individual disposition, the present research developed and validated a 17-item uncertainty avoidance inventory (UAI). Besides, we did a cross-cultural comparison in individual uncertainty avoidance between Chinese and Americans. The results showed the UAI has good reliability, structure, criterion-related validity, convergent and discriminant validity, and predictive validity. The scale has a one-factor structure. High scores in UAI were associated with subjective well-being, optimistic, money ethics, materialistic values and money attitude. Besides, Chinese have higher UAI scores than Americans, indicating that Chinese people are more concerned with uncertain situa-
Cross-cultural adaptation of a diagnostic inventory for screening children
Turana Alvan Alleyeva Baku State University, Azerbaijan
Assessment of the developmental needs of children is considered a major problem in Azerbaijan due to the absence of standardised assessment tools in the country. Although there are several instruments to identify developmental needs of children, none of them are adapted to the Azerbaijani context or validated to be used in Azerbaijan. Considering that the use of standardised assessment tools is an effective method to screen children with developmental delays, this study describes the adaptation of the Diagnostic Inventory for Screening Children (DISC) and the pilot testing with Azerbaijani children. Translation of the DISC into Azerbaijani was conducted according to current guidelines for cross-cultural adaptation of instruments. The tool was piloted with 60 typically developing children with no developmental delay or disability. A convenience sample was used during the study. The translated instrument shows potential as a screening tool for children in Azerbaijan and should be further examined. Research with a larger sample is needed in order to define cut-off scores and verify the instrument’s validity and clinical utility.

Essentialism and mental disorders
Eva Arino-Mateo University La Laguna, Spain; Veronica Betancor-Rodriguez; Armando Rodriguez-Perez
Recent research has shown that people perceive social categories in terms of fixed and underlying realities. Belief in the fixity of features and categories, not only has been a focus of research in the tradition of implicit theories of the person, but has also been discussed in research on psychological essentialism (Gelman, 2003). Essentialism was introduced in Social Psychology by Rothbart and Taylor (1992) to argue that people often mistakenly treat social categories as if they are naturally essence-based, rather than as the artifacts of culture. Treatment of social categories as if they are naturally essential is widely discussed in research on psychological realities. Belief in the essentialist view is considered a major problem in Azerbaijan due to the absence of standardised assessment tools in the country. Although there are several instruments to identify developmental needs of children, none of them are adapted to the Azerbaijani context or validated to be used in Azerbaijan. Considering that the use of standardised assessment tools is an effective method to screen children with developmental delays, this study describes the adaptation of the Diagnostic Inventory for Screening Children (DISC) and the pilot testing with Azerbaijani children. Translation of the DISC into Azerbaijani was conducted according to current guidelines for cross-cultural adaptation of instruments. The tool was piloted with 60 typically developing children with no developmental delay or disability. A convenience sample was used during the study. The translated instrument shows potential as a screening tool for children in Azerbaijan and should be further examined. Research with a larger sample is needed in order to define cut-off scores and verify the instrument’s validity and clinical utility.

Validation of the 12-item center for epidemiological studies depression scale (CES-D12) for use in the NLSCY
Lisa Batten uOttawa IMHR, Canada
The CES-D12 is a self-report measure of depression derived from the 20-item CES-D and adapted for use in the National Longitudinal Study of Children and Youth (NLSCY) to assess parental depression. The original CES-D has established cut-off scores that effectively identify clinical depression in adult populations. To date no studies have been conducted to determine an effective threshold of the CES-D12 as an epidemiological marker for clinically significant depressive symptoms or to assess the suggested cutoff score of 12, currently used. This study will also compare the CES-D12 to the QIDS-SR16, a psychometrically sound self-report scale for depression. Participants with a diagnosis of Major Depressive Disorder were recruited from the mood disorders clinic at the Royal Ottawa Mental Health Care Center. A total of 105 women and 65 men (N=170) completed the questionnaires. The suggested cutoff score of 12 on the CES-D12 yielded a sensitivity of 79.74% and a specificity of 89.65%. The optimal cutoff to 10 yielded a sensitivity of 85.9% and a specificity of 92.67%.

Psychometric assessment of Islamic religiousness in Italy: First and second generation
Nicola Bragazzi University of Genoa, Italy
We have a psychometric scale created by Hisham Abu Raya (PMIR: Psychological Measure of Islamic Religiousness), translated into Italian and in Arabic, for exploring the spiritual attitude of Islamic immigrants in Italy. To the original scale, we added some questions specific to the Italian culture and context, in order to assess the integration of Islamic communities. The sample consisted of 500 Muslim participants from all over Italy. We studied the religiousness score according to demographic parameters, confirming the multidimensional nature of Islam. We present the psychometric parameters of these, translated and validated scales, and we compare Italian Islamic first and second generation with the data present in Hisham Abu Raya, "A psychological measure of Islamic religiousness: Evidence for relevance, reliability and validity".

Burnout syndrome in dental students: Effectiveness of different methods
Juliana Campos UNESP - Univ Estadual Paulista, Brazil; Paula Jordani; Miriane Zucoloto; Fernanda Bonf; Joao Maroco
This study was proposed to estimate the effectiveness of different screening methods of the Burnout Syndrome among dental students. Of the 235 undergraduate students that participated, 78.0% were women and the mean age of was 21.0 (SD = 1.8) years. The Burnout Syndrome assessment was performed using the Oldenburg Inventory-Student survey (OLBI-SS) and the Copenhagen Inventory-Student survey (CBI-SS). The Maslach Burnout Inventory-Student survey (MBI-SS) was used as the gold standard. The psychometric properties of the instruments were measured. The second-order hierarchical model was estimated to calculate the overall scores for OLBI-SS and CBI-SS. The ROC curves were constructed and the areas were estimated (AUROC). The instruments showed an adequate reliability and validity, however three questions had to be deleted from OLBI-SS and one from CBI-SS. There was good discriminating capacity of the Exhaustion dimensions of OLBI-SS, and Personal burnout and Study related burnout of CBI-SS. CBI-SS showed higher discriminating capacity, than OLBI-SS, to identify the Burnout Syndrome (AUROC=0.93; 0.66-0.93). The burnout syndrome had a stronger direct effect on academic achievement, or indirect effects via the dynamic dimensions of personality (proximal variables). The latter play, in the influence mechanism, a mediating role as dependent and independent variables. This supports the findings of other studies indicating that the effective entry characteristics depend on the personal features and affect the students’ behavior and their academic achievement (see Bennacer, 2005; Potvin & Paradis, 2000).

Adolescent worries across time and space
Clara Cantal Universidade de Brasília, Brazil; Isolida Gunther
Adolescence is an important developmental stage that varies across contexts. The majority of articles in English which report findings regarding this stage, are placed in the United States and Europe.

CBI-SS showed higher discriminating capacity, than OLBI-SS, to identify the Burnout Syndrome (AUROC=0.93; 0.66-0.93). The burnout syndrome had a stronger direct effect on academic achievement, or indirect effects via the dynamic dimensions of personality (proximal variables). The latter play, in the influence mechanism, a mediating role as dependent and independent variables. This supports the findings of other studies indicating that the effective entry characteristics depend on the personal features and affect the students’ behavior and their academic achievement (see Bennacer, 2005; Potvin & Paradis, 2000).

Adolescent worries across time and space
Clara Cantal Universidade de Brasília, Brazil; Isolida Gunther
Adolescence is an important developmental stage that varies across contexts. The majority of articles in English which report findings regarding this stage, are placed in the United States and Europe.
Little is known about other contexts and other realities of adolescence, and its characteristics. Considering the different adolescents and Kurt Lewin’s life space theory, this study aimed to verify the factorial structure of Millar and Gallagher’s (1996) the Things I Worry About Scale among Federal District (Brazil) adolescents, compare it to the original Things I Worry About Scale factorial structure (Millar & Gallagher, 1996), and to its North American version (Estes, Tracey, & Millar, 2007), and verify if there are other worries within the lives of adolescents of Federal District that are not included in the instrument. To reach these specific goals, a two-phase study was designed. In the first phase, the translated and semantically adapted scale was applied to 1418 adolescents ranging from 14 to 19 years of age (M=16.56; SD= 1.08). The factorial structure obtained in this study differed from previously encountered structures. In the second phase, focus groups were used to verify other worries within adolescents’ lives not included in the instrument. As Kurt Lewin’s life space theory would predict, worries experienced through adolescence vary across contexts and, therefore, are not globalised. Moreover, the way in which reality aspects, mostly social, enter individuals’ life space, influences adolescents’ worries and, consequently, his or her experience of adolescence.

Temperamental and personality characteristics of sexual disfunction patients: Hospital-based study
Rupesh Chaudhry Dayanand Medical College, Ludhiana, India; Bholeswar Mishra
It is reasonable to assume that personality factors will influence sexual development and establishment of sexual intimacy. Neuroticism was regarded as relevant to sexuality in earlier studies but results are not consistent (Copper, 1968; Eysenck, 1976; Slater, 1945). Costa et al. (1992) found neuroticism to be correlated with lower sexual satisfaction and extrusion with sexual drive. Aim of the study is to see the personality characteristics of the patients presenting with sexual dysfunction and how it associated with the pathology. Personality evaluation of 50 (both married and unmarried) diagnosed patients of sexual dysfunction presenting to psychiatry out-patient department was done using Cattell’s 16 PF questionnaire. Patients with hypertension, diabetes, head injury and co morbid substance abuse were excluded from the study. The 16 PF profile of these patients reflect that they are more prone to decide impulsively rather than using their intellectual ability or reasoning. They have low frustration tolerance and get easily upset and frustrated in smaller things. This type of emotional status leads to premature ejaculation and erectile dysfunction since patient gets distracted to other things. These patients have apprehensive tendencies which in turn lead to depressive cognition which is again a known factor for sexual inadequacy.

Peer victimisation and academic adjustment: The moderating role of teachers
Josafá Da Cunha Federal University of Paraná, Brazil; Lidiane Cardoso
The role that teachers play in the classroom goes beyond the academic one in that they may be faced with the challenges of addressing peer victimisation in and out of the classroom setting. Specifically, peer victimisation describes a student who experiences physical aggression from peers. In previous studies that have examined the role of teachers in dealing with peer victimisation among their students, it remains unclear how teachers influence the association between peer victimisation and academic performance (Konishi, Hyem, Zambo, & Li, 2010). Considering this gap in the literature, the present study expands on previous research by examining how the quality of the student-teacher relationship moderates the association between peer victimisation and academic adjustment among Brazilian adolescents, using a multilevel modelling procedure. Participants were 2135 students from 6th through 9th grades of 72 classes in five public schools located in an urban area of Brazil. Data on the quality of student-teacher relationships were collected from children’s and teachers’ reports. Peer victimisation was assessed through a peer nomination procedure, while academic adjustment data was assessed through the school records and teacher reports on students’ performance. Results show that some aspects of the student-teacher relationship showed a buffering effect in regard to the impact of victimisation on achievement, such as companionship, emotional and instrumental support, while conflict and the use of punishment exacerbated the effects of victimisation. These results highlight how the peer ecology is influenced by the quality of student-teacher interactions.

Animal models of autism and related disorders: Implications for treatment
Petrus Devries South Africa
South Africa
Recently, a flurry of animal models of autism have been developed, based on genetic syndromes associated with the disorder. These models involve measurement of behaviours typically associated with autism, such as social approach and social behaviours, communication (vocalisations), and repetitive actions. Even more recently, based on inferences about the neural pathways affected by the genetic patterns, new medical treatments have been proposed and begun to be tested, first with mouse models, and now even with persons. The paper will show some of these recent findings, and the implications for our understanding of the symptoms of autism and possible mechanisms for treatment.

Study of the psychometric qualities of SCARED_R (Revised version of the Screen for Child Anxiety Related Emotional Disorders) in a Portuguese sample
Filomena Dias UIPES, Portugal; Isabel Leal; Joao Maroco UIPES, Portugal
Our purpose was to evaluate the psychometric properties of the SCARED-R, proposed by Muris, in the Portuguese population. 1238 participants were gathered, through convenience sampling, from normative school children aged between 10-13. To evaluate the fit of the 9-factor original scale, a confirmatory factor analysis was done on the polychoric correlations matrix, with WLSMV estimation implemented in Mplus (v.6, Muthén & Muthén). The original 9-factor structure showed bad fit (X^2/df=15.295756; CFI=0.881; TLI=0.875; RMSEA=0.038). In addition, theoretical considerations led us to divide the factor Separation Anxiety (including school phobia) into two factors: Separation Anxiety (excluding school phobia) and School Phobia. This decision was based on the fact that 3 of the 4 items, concerning school phobia, had weights

Improvement of Berkson’s Minimum Chi-square estimation
Shuangling Ding Jiangxi Normal University, China; Wenyi Wang; Fen Luo; Xiaoling Wang
Baker and Kim (2004) introduced Berkson’s Minimum Chi-square estimation to give the initial value of the item parameters (IVIPs) in the 2-parameter Logistic model (2PLM) in the item response theory (IRT). In Berkson’s scheme there is a hypothesis of the examinees’ abilities being known. Usually this hypothesis is not realistic. An improvement of it has been proposed as below. Based on the empirical logistic regression in which logit transform for the correct-ratio of each item is made, this new scheme built a linear model which employs the iteratively reweighted least squares method in estimation. In more details, firstly, using the initial value of the ability parameters (IVAPs) and employing the Berkson’s scheme, the IVIPs are obtained. Secondly, the item parameters in the error term of the linear model are substituted with IVIPs, and weighted distance of the two vectors of item parameters (IPs) with variance-covariance matrix, then the new IVAPs are obtained through minimising the weighted distance. The above two steps are implemented until the convergent criterion is satisfied. The estimation of IPs is more accurate than that of BILOG3 if the sample size over 2000.

A new polytomous cognitive diagnostic model
Shuangling Ding Jiangxi Normal University, China; Wenyi Wang; Fen Luo; Xiaoling Wang
For the dichotomous cognitive diagnostic models (CDMs), such as Attribute Hierarchy Model (AHM) and Determinant input noise “and” gate model (DNA), the distance between the observed response pattern (ORP) and its corresponding ideal response pattern (IRP) is very important. In fact, these CDMs could be represented as a function of the distance with some weight. It is well-known that the polytomous scoring could provide richer information for cognitive diagnosis and that polytomous CDMs (PCDMs) are few. A new PCDM (named polytomous minimum weighted distance classification method, PMWDCM) with high diagnostic accuracy is proposed. Given the test Q matrix and KSs, PMWDCM calculates IRPs using matrix product according to Tatsuoka (1995, pages 343-344). Then it matches each ORP with all IRPs through computing the sum of the product of the weighted distance between ORP and IRPs. An IRP which minimises the sum is considered as the match of the ORP. To seek the knowledge state (KS) corresponding to the IRP matched ORP, the test blueprint needs to be specially designed. Only when the rank of designed Q matrix equals to the number of the attributes, can one-to-one correspondence between the set of IRPs and the set KSs be obtained.
The principle of the design of the test blueprint Q matrix for cognitive diagnosis

Shuliang Ding; Jiangxi Normal University, China; Wenyi Wang; Fen Luo

In the cognitive diagnosis (CD), Tatsuoka (1995, 2009) gave the definition of equivalent class of knowledge state (KS): if several KSs correspond to the same ideal response pattern (IRP), they are called one equivalent class of KS (ECKS). It is well-known that if an ECKS contains more than one KS, then the accuracy of classification results may be decreased because of the indeterminacy of these KSs. Samejima (1995) discovered that if the test blueprint Q matrix contains identity matrix, then it produces one-to-one correspondence between KSs and IRPs. Obviously, this finding can be applied to independent attributes structure, since identity matrix represents the reachability matrix for independent attribute hierarchical structure (AHS).

Does the samejima’s discovery work for the other AHSs, such as linear, convergent, divergent and unstructured named by Leighton, Grier and Hunka (2004)? The answer is YES. In this proposal we proved that given the non-compensatory cognitive diagnostic model for dichotomous items, if the reachability matrix is a sub-matrix of the cognitive diagnostic test blueprint Q matrix, then the correspondence between KSs and IRPs is one-to-one. The Graph theory is the basic tool for the proof. This principle can guide us to design the test blueprint Q matrix in CD.

Maternal attachment style and ante-postnatal depression

Nerina Fabbro; University of Trieste, Italy; Jennifer Faietti; Antonella Tripani; Laura Rigobello

The prevalence estimates of ante-postnatal depression (PND) vary in literature from 10% to more than 15% considering both pregnant women and new mothers. In literature, several psychosocial risk factors for PND are identified. The hypothesis of this research is that a good quality of a mother’s early experiences with her attachment figures, is a protective factor against the development of PND. Our aim is to quickly identify pregnant women at risk of PND, by detecting the presence of possible risk factors and of mood and anxiety disorders, by analysing the attachment quality of the mother to her own parents, and then by studying the maternal-feetal attachment. The sample is composed of 24 women; the research has been divided into 3 steps: (1) Women at their third trimester of pregnancy answer some questionnaires (Psychosocial risk factors Questionaire; Edinburgh Postnatal Depression Scale - EPDS, Cox, 1996; Parental Bonding Instrument-PBI, Parker, 1979; Prenatal Attachment Instrument-PAI, Muller,1995); (2) On the 2nd day after delivery: the EPDS; (3) Then 3 months after delivery: EPDS. Results expected are: (1) the incidence of PND in this research will be the same compared to the data currently present in literature; (2) the depression indicators detected in the pre-delivery stage are a forewarning of PND; (3) people with secure attachments in their early relationships are less depressed than others who had a more insecure attachment to their parents in childhood.

Assessment of attributional styles and general health of university staff

Ghoreyshi Rad Fakhrossadat; Azerbaijan University of Tarbiya, Islamic Republic of Iran

Attributional (explanatory) style is a core concept of Petson’s terminology in the reformulation of learned helplessness and depression theory, which is interesting to study as a process of attributing and a way of judging people about causes of their social behaviors. Tending toward optimism has been defined as a general expectation for positive consequences in difficult and unclear situations. Optimism is associated with better mental and physical adjustment in confronting stressful situations. This research aimed to study the relation between attributional styles and general health of Azerbaijani University staff. Data were collected from 180 staff using the Attributional Styles Questionnaire (ASQ) of Peterson et al. and Goldberg’s Health Questionnaire (GHQ) and then subjected to F-test, Group Statistics and Independent Samples Tests. The results revealed a significant difference between mean scores of anxiety and depression of staff on the basis of attributional styles. Additionally, there were significant differences between attributional styles and general health. Attributional styles as the cognitive variable could therefore be a good predictor of general health and a guide for practitioners.

An improvement of maximum Fisher information selection item strategy

Luo Fen; Jiangxi Normal University, China; Shuliang Ding; Xiaoping Wang

Item selection strategy (ISS) is a critical component of computerized adaptive testing (CAT). Chang & Ying (1999) proposed a STR and b-STR method to remedy the problem of item overexposure when scoring 0-1 caused by the ISS based on maximum Fisher information (MF). The technology of a-STR and b-STR is static in that the items are stratified on given information at the beginning of test. Polymatous scoring model is a new direction of current test because it could bring in more information on the examinees. How to select the right item to a given examinee in CAT based on polymatous model is a contentious point. In this study, based on the Graded Response Model (GRM) a new ISS named dynamic and comprehensive ISS (DC) is proposed which can dynamically adjust the strata in CAT process by accumulative information. DC, not only is the function of discrimination parameters adjusted by accumulative information, but also, difficult parameters are made full use of in each item that has been done in CAT process by the examinee. It is different from the form of ISSs, which difficult parameters usually adopted dimensionality reduction technology. We hope that DC can be applied to GRM to remedy item underexposure produced by MFI. Monte Carlo simulation results show that estimation precision is basically at the same level when applying MFI and DC to the CAT process separately in the same examinee, but in item exposure rate, DC is superior to MFI.

The assessment of sensation seeking and correlations with other personality factors

Janne Fenger Alans University, Germany; Thomas Eberle

We can hypothesise that people with high and low levels in sensation seeking, self-efficacy, and proactive attitude, have a different outlook towards challenges in daily life, critical life events, the experience of challenging situations, and that they cope with them differently. One part of our study aims to compare basic psychometric properties of the construct of sensation seeking, as well as to identify personality correlates with self-efficacy, and proactive attitude as potential resources for psychological health. Different scales of sensation seeking (SSS-V, Zuckerman, 1994; AISS-D, Arnett, 1994) will be compared with both a psychometric focus and their correlates to the construct of self efficacy (GSE, Jerusalem & Schwarzer, 1999) and proactive attitude (Schmitz & Schwarzer, 1999) in a cross-sectional design on the sample of university students. Research is in progress and only part of the study’s results will be presented at the conference. Theoretical, empirical and practical advancements for psychological health will be achieved by this study. Research is in progress. At the conference, first conclusions will be presented.

The development and validation of the Multidimensional Acculturation Scale

David Goh; City University of New York-QC, United States of America; Maria Caceres

The present study describes the development of the Multidimensional Acculturation Scale (MAS), which differs from more traditional measures of its kind by assessing multiple domains of acculturation and by taking into consideration the most recent research on the concept and measurement of acculturation. The MAS consists of a Receiving Culture Scale and a Heritage Culture Scale, using a parallel format. Each scale contains three subscales measuring Cultural Practices, Cultural Values, and Cultural Identifications. The subjects in the present validation of the MAS were 144 college students in the United States. Statistical analysis of the data indicated the MAS had robust internal consistency (Cronbach’s α ranged from .89 to .90 for major scales and from .50 to .89 for subscales). Content validity was supported by systematic item sampling in content domains identified from comprehensive literature review and by expert judgment. Factor analysis revealed a 3-factor solution that accounted for 45% of the variance on the American (Receiving) Culture Scale and a 3-factor structure that explained 49% of the variance on the Heritage Culture Scale. The underlying factors of the subscales were not orthogonal and showed low to moderate correlations on both the American and Heritage Culture Scales. The authors expect to increase the current sample size to more than 200 in the next two months. The final data set will be re-analysed, and the results discussed in terms of their implications for the refinement of the MAS as well as the measurement of acculturation in general.

The influence of test development on the accuracy of KS-P model

Yu-Na Han; South China Normal University, China; Min-Qiang Zhang

Based on probability theory and knowledge space theory, the KS-P cognitive diagnostic model considers not only the precondition for cognitive relationships between different items but also guessing and mistakes. The KS-P cognitive diagnostic model can not only obtain the level of competence of participants, but can provide the knowledge structure of the subjects. As a result, it is better than the
conventional scored methods which give only a score. This research verified the influence of test development on the accuracy of the KS-P Model, and explored how to develop a test in order to get higher accuracy. The results showed: The accuracy of KS-P cognitive diagnostic model is influenced by the cognitive structure of items, the number of items, the guess parameter of items and the slip parameter of items. (1) If every key point of knowledge has its own corresponding item, the diagnostic accuracy of the test based on the KS-P model will be higher, otherwise lower. (2) If the number of items increases, the accuracy of the KS-P model becomes higher. (3) If the guess parameter of items decreases, the accuracy of KS-P model will be improved. (4) The lower slip parameter of items, the higher the accuracy of the KS-P model will become.

Outpatient analytical individual and group psychotherapy in a nationwide catamnetic study Roland Heinzell Practice, C.G. Jung-Institut Stuttgart, Germany

Unlike many (clinical) outcome studies, this study was designed to measure and evaluate the effects of analytical psychotherapy performed in its most prevalent setting: The ambulatory care in the therapist’s office as individual and group therapy. A one-page questionnaire was sent to almost 1000 former patients of analytical psychotherapy (individual and group) through their therapists using a 20% sample of all members of the two main associations of analytical psychotherapists in Germany. The anonymous return rate was 65%. Subjects were asked for their self- assessed physical, mental, social and overall health status at three points of time: At the beginning and end of their therapy and today. Furthermore they had to report on their utilization of other health care (physician’s visits, hospital days, drug consumption) and on their work-loss days. The responses show that the self-assessed health status of patients had improved significantly by the end of the therapy, and this effect has even slightly increased in the (up to) six years since. The number of hospital days declined on average by two-thirds, the physicians’ visits by one-third and the work-loss days by one-half so that a substantial part of the costs of the therapy was saved in other parts of the health system. Besides a better cost- benefit relation of groups no other significant differences were found between the effects of group and individual therapy.

Development of the Profile of Mood States 2nd edition (POMS 2)

The Profile of Mood States (POMS; McNair, Lorr, & Droppleman, 1992; McNair & Heuchert, 2003), has been widely used – both in a broad range of contexts (research, medical, clinical, sport, space travel, etc.) and in an array of settings (its cross-cultural applications are vast and it has been translated into at least 42 languages – from Afrikaans to isiZulu). However, despite its wide application, its scientific rigor and its clinical usefulness, it became apparent that the instrument needed to be updated, particularly to provide current norms and to replace dated items. The aim of the revision was to confirm the factor structure: an overall score, Total Mood Disturbance, for assessing general distress, and six scales, namely Anger-Hostility, Confusion-Bewilderment, Depression-Dejection, Fatigue-Inertia, Tension-Anxiety, and Vigor-Activity. The development of the Profile of Mood States 2nd Edition (POMS 2™) will be discussed in this paper and our hope is that the POMS 2™ will continue to be used in many countries around the world. We believe that the more than 4000 research reports involving the POMS that have been published, indicate that the POMS 2™ will continue to be at the cutting edge of science and that it will continue to be used in research and applications that improve the quality of human lives. The recent standardization of the POMS 2™ will be discussed and the excellent psychometric properties that were found will be presented under the headings Background, Participants, Measures, Procedure and Results.

Resilience and children development in an environment of vulnerability from Sao Paulo Carla Hisatugo USP Universidade São Paulo, Brazil; Eda Custadio

Resilience is a personal ability to respond to adversity and difficulties involving traumatic events, vulnerability by extreme poverty or lack of minimal resources for normal development of children. Objective was an exploratory study with resilient children, living at Sao Paulo, Brazil. Twenty participants, from 7 through 10 years old, from public schools, living with low income families, 33% female and 67% male, 35% white and 65% brown-skinned. The children demonstrate some important psychological resources, even considering psycho- pathological symptoms and the environment of vulnerability caused by the low-income families.

Verifying the prediction effect of a Guttman-based item-fit index set on the detection of differential item functioning Tsai-Wei Huang National Chiai University, Taiwan, R.O.C.

This study aimed at verifying the prediction effect of a Guttman-based item-fit index set (the BW indices) on the differential item functioning (DIF) detected by the SIBTEST approach. There were 34 achievement test items belonging to three major mathematics contents (arithmetic, algebra, and geometry), and two item formats (pure operation / computation and word problem). There were a total of 1,439 seventh graders from Taiwan (51.01% males and 48.99% females) participating in the test. The BW item-fit indices (difficulty, indistinctness, disturbance, and hint) were calculated from the male and female samples respectively and the differences of individual indices between the two samples were served as the predictors for the DIF measure (BU) estimated by the SIBTEST procedure in a stepwise multiple regression approach. Results showed the three BW indices (indistinctness, difficulty, and hint) significantly contributed 82% amount of explained variances of the DIF measure (BU). The BW-based predictions were further validated by linear discriminant analysis with an overall 76% accurate hit rate (100% for female-favour flag, 100% for male-favour flag, and 63.6% for neutral) and by the nonlinear multinomial logistic regression with an overall 91.2% accurate hit rate (83.3% for female-favour flag, 100% for male-favour flag, and 90.9% for neutral). This implied the BW item-fit indices, especially for the indistinctness index, might effectively interpret the mathematical achievement item DIFs attributed to the different extents of ineffectiveness between genders (too easy to distinguish test-takers whose abilities were much higher than their difficulty levels).

Associations between educational attainment and CAMCOG-R performance in South African older adults

Katharine James University of Cape Town, South Africa; Kevin Thomas; Marc Combrinck

The Cambridge Cognitive Examination-Revised (CAMCOG-R) is a sensitive measure of cognitive impairment in healthy older adults and early-stage dementia. Previous research suggests that CAMCOG-R overall performance is influenced by educational attainment. Few studies have, however, delineated associations between educational attainment and performance on individual CAMCOG subscales. This study aimed to delineate those associations in a sample from a low- and middle-income country (LAMIC), where financial/ resource constraints may have compromised access to education for many older adults. 51 cognitively healthy volunteers over 60 years old (M = 73.51, SD = 8.89) participated. Most had at least a high school education (mean years of education = 13.53, SD = 4.88). Participants were administered the CAMCOG-R under standardized conditions. Regression analyses suggested significant associations between years of completed education and total CAMCOG-R score, as well as scores on four of the eight CAMCOG-R subscales (Orientation, Language, Memory, and Abstract Thinking). Notably, education was not significantly associated with scores on the Leaming subscale, a measure of episodic memory. This is the first study to investigate the influence of education on CAMCOG-R subscales within a LAMIC sample. Some CAMCOG-R subscale scores were more strongly associated with formal educational attainment than others. Importantly, the Leaming subscale, the most useful CAMCOG-R tool for assessing anamnetic MCI and early AD, was not significantly associated with educational attainment; we suggest, therefore, that it may be valid for such clinical use in most settings.

The ability overestimated and underesti- mated under GRM Xiaozhu Jian Jiangshannon University, China; Zhang None

When low-ability examinees make correct responses on difficult items, this is named the guessing phenomena; and when high-ability examinees make wrong responses on the easy items in the test, this is named the sleeping phenomena. For the past researches, the guessing phenomenon indicates overestimation, while the sleeping phenomenon means underestimation. Many researches have proposed some methods to rectify the guessing or sleeping phenomenon. A Paper and Pencil Test is arranged for an average examinee. After the examinee finished the test, an extra item with difficulty parameters arranged from big to small in different test cases was given to the examinee. The author estimated the new estimated ability and calculated
Mechanisms of virtual reality exposure therapy: the effect of the behavioural inhibition and behavioural activation systems

Rong Kai Beijing Forestry University, China

Gray’s (1976) theory distinguishes between two motivational systems that he is involved with as the behavioural activation system (BAS) and the behavioural inhibition system (BIS). Fowles (1980) has indicated that heart rate responses reflect the activity of the BAS, and electrodermal responses reflect the activity of the BIS. Both BAS and BIS are reliably activated during in-vivo exposure to fearful situations. However, because of the constraints imposed by virtual reality (VR), we hypothesized that VR exposure to fearful situations would activate the BIS alone. To examine this hypothesis, a VR free-standing elevator simulation was presented to participants selected for high and low fear of heights in Beijing, China. As predicted, the high-anxious group strongly responded electrodermally (effect size d=1.82), but showed only minimal HR elevations during exposure (d=0.09), and little other cardiovascular or respiratory changes. The low-anxious control group showed little electrodermal and HR reactivity (d=0.19 and 0.09). A comparison with data from a previous study demonstrated that the BIS, but not BAS, is selectively activated during VR exposure, causing discordance between self-reported and commonly used physiological measures of anxiety, such as Foa and Kozak’s (1986) emotional processing theory of fear modification, suggesting different mechanisms underlying VR and in-vivo exposure treatments, which explained the results. Future studies should make direct comparisons between real-life and VR exposure using the same subjects and procedures, and should consider cross-cultural effects.

Assessing point and interval estimation for the indirect effect: Distribution of the product, bootstrap and Markov chain Monte Carlo methods

Olivier Laverdiere Universite de Sherbrooke, Canada; Alexandre J.S.
Dongmei Liang South China Normal University, China; Jie Fang; Min Zhang

Because the distribution of mediating effect is generally not normal, classic approaches to assessing mediation (Baron & Kenny, 1986; Sobel, 1982) have in recent years been supplemented by bootstrap, the distribution of the product methods, and Markov chain Monte Carlo (MCMC) methods. However, little is known about how these methods perform relative to each other. This study extends Mackinnon and colleagues’ (Mackinnon, Lockwood & Williams, 2004; Yuan & Mackinnon, 2009) works by conducting a simulation that examines a host of approaches for assessing mediation. The simulation study has found the following results: (1) Absolute bias of the MCMC with informative prior method was smallest among different methods when the sample size was 25. (2) Relative mean square error and interval width of the MCMC with informative prior method was the smallest of all methods. (3) Power of the MCMC with informative prior method was the greatest among all the methods. We demonstrate that extra power comes at the cost of underestimation of a Type I error. The power of bias-corrected Bootstrap method followed. The simulation results indicated, when informative prior was available, that the MCMC with informative prior method was recommended in mediation analysis. If informative prior was not available, the bias-corrected Bootstrap method could be adopted to analyse mediation.

Comparisons between generalisability theory approach and testlet response theory approach using real data
Dongmei Liang South China Normal University, China; Min-Giang Zhang; Lin Chen

This study applies both Testlet Response Theory (TRT) approach and Generalizability Theory (GT) approach to practical application, exploring the feature of the TRT approach by analyzing real data, to examine the extent to which estimates of variance components based on GT and TRT models are the same using real data. Using the software WinBUGS with the Markov Chain Monte Carlo (MCMC) method, comparisons are made between the two approaches on the estimates of variance components, relative error variances, absolute error variances, generalizability coefficients, and dependable ability coefficients, to inspect the performance of the TRT approach in application. We show that the TRT approach produces results comparable to those from a standard GT analysis.

A practical illustration of the impact of work environment on a team’s emotional and social intelligence
Portia Maphala PWC, South Africa; David Lambiotte

The study explores the perception that the productivity and satisfaction of employees, within corporate organisations, increases noticeably when working remotely and managed differently, as compared to those employees who are restricted to working in an office and managed in a manner characteristic of organisational structures. In order to test this hypothesis, we collected the data through administering the Team Emotional and Social Intelligence Assessment (TESI) on participants within a department at PWC. The identified teams consisted of junior level members all the way up to those at partner level. The main purpose of this research was to specifically look at how emotional intelligence within teams impacts and contributes to the bottom line in all types of work organisations. Based on data from a tool such as the TESI, this could prove to be invaluable for HR practitioners and managers who may need to make the case in their own organisations.

Portuguese version of the mother and baby scales
Joao Maroco ISP-AU, Portugal; Maria Correia; Ana Silva; Sara Sereno; Isabel Leal

The Mother and Baby Scales (MABS) was developed by St James-Roberts and Wolke (1987) to assess the mother’s confidence in the care of the baby. The original version of the instrument is constituted by 64 items distributed by eight subscales: 1 – Instability/Irregularity, 2 – Irritable during feeding, 3 – Alertness/Reactivity, 4 – Alert state during feeding, 5 – Facility, 6 – Lack of confidence in the care of the baby, 7 – Lack of confidence to feed the baby and 8 – global trust. The evaluation of the psychometric properties of the MABS Portuguese version was done on a sample of 430 mothers on the second day of puerperium, from Maternity Dr Alfredo da Costa, aged 15 to 44 years. The 8 factor model showed a poor fit to the variance-covariance matrix of the scale’s items (X2/df=2.638; CFI=.678; GFI=.709; Rmsea=.062). To improve the factorial validity of the MABS, items with factor loadings smaller than 0.4 and modification indices suggesting correlations with different factors were removed. The improved model with 30 of the original items showed a good fit to the 8 factor structure (X2/df=1.779; CFI=.918; GFI=.905; Rmsea=.043). The stability of the reduced 30-item scale was tested on an independent sample of 162 participants in the same conditions. Invariance analysis demonstrated the external validity of the 8 factors/ 30 items structure (Factor weights: DX2(22)=32.605; p=.068; Covariances: DX2(36)=30.362; p=.733).

Factorial structure of Maslach burnout inventory-general survey with Spanish social educators: A preliminary analysis
Rosario J. Marrero University of La Laguna, Spain; Monica Carballero; Jose Luis Rodriguez-Fiestas; Hector Morales

Previous research has analysed burnout in different human service professionals. This study explored the structure of the Spanish version of Maslach Burnout Inventory-General Survey (MBI-GS) with social educators. The questionnaire was completed by 54 child protection employees of Tenerife, Spain, with a mean age of 31.22 years (SD=1.55). Psychometric characteristics of the inventory were analysed using principal axis factoring, which seeks the least number of factors that explained common variance. Varimax rotation was used. The initial results showed four factors with eigenvalues greater than 1, which explained a 67.47% of the variance. A new factorial analysis was conducted to limit the extraction to three factors, as it was proposed by the authors of the scale. The three factors accounted for 62.63% of common variance. Factor 1 was formed by 6 items which related to professional efficacy, explaining a 33.64% of variance. Factor 2 was composed by 5 items about emotional exhaustion, accounting for 18.92% of variance. And Factor 3 was formed by 5 items called cynicism, explaining 10.17% of variance. An excellent internal consistency of scales was shown, being .89 for professional efficacy, .88 for emotional exhaustion and .80 for cynicism. This latter could increase to .88 if item 13 were eliminated. The findings replicated those obtained by the initial study of Maslach, Jackson and Leiter (1996). The Spanish version of the inventory satisfies the psychometric criteria for its use in social education in the future.

Comparing the diagnostic accuracy between the Fusion model and the DINA model
XieMeihua Jiangxi Normal University, China

The Fusion Model and the DINA Model are two important cognitive diagnosing model. The DINA Model is in wide use, while the Fusion Model is rarely studied or used in China. The two models were compared, by the Monte Carlo simulation, combined with practical data. The results of the study showed that the precision of item and person parameters, is greater for the Fusion Model and the DINA Model in Monte Carlo Simulation, while the Fusion Model is more accurate than the DINA Model in the Pattern Match Ratio and mean Marginal Match Ratio with the practical data.

A factor-analytic study for the Bender Gestalt test, 2nd edition: Internal structure and measurement model
Cesar Merino USMP, Peru; Ryann

Bender Gestalt Test has had several modifications. A major change occurred with the second edition (Bender-II: Brannigan & Brunner, 2003), and Hispanic studies are still scarce, especially on its psychometric properties. In this area, factor analysis studies were performed with older versions, and generally the results were inconsistent, sometimes suggesting more than one dimension. The aim of this study is to evaluate the internal structure of the Copy scores of the Bender-II in Spanish-speaking participants. The sample was 207 children between 4 and 7 years old, and 144 between 8 and 15, all from two public schools in Lima (Peru). SEM methodology was used to test hypotheses of dimensionality and the measurement model to the reliability of the scores. The one-dimensional model was examined with free parameters and fixed parameters (error covariance between some items). The measurement model was tested to see the appropriate estimation (parallel, tau equivalent or congeneric) of the reliability of the Bender-II scores. The results show significant evidence of unidimensionality and error covariances between items with designs of points (6, 7, 8, and 10); these covariates improved model fit slightly dimensional. On the other hand, the congeneric model fits the data better, although the differences with the tau equivalent model are small, and this is found in the size of the reliability coefficients. These results suggest additional interpretations to score, and rethink the estimation of the internal consistency using Cronbach’s alpha coefficient.
Temperamental styles in Peruvian children and adolescents: An exploratory and cross-cultural comparative study
Cesar Merino USMJP; Perú; Dora Pflucker; Thomas Oakland

The purpose of this study is to identify temperamental preferences of 1040 Peruvian children, 51% female, ages 9 though 16, and to compare their data cross-culturally with similar data from two other in Latin American countries: Venezuela (n = 441, Leon, Oakland, Wei, & Berrios, 2009), and Costa Rica (n = 432, Oakland & Mata, 2007). The Cuestionario de Estilos Temperamentales (Student Style Questionnaire: SSQ; Oakland, Gutting & Horton, 1996), adapted for use in this study, assesses four bipolar temperament styles: Extraversion–Introversion (E–I), Practical–Imaginative (P–M), Thinking–Feeling (T–F), and Organized–Flexible (O–L). Peruvian children express a strong preference for an extroverted (78%) and organized (72%) styles and moderate preferences for Imaginative (59%) and thinking (60%) styles. Gender differences are found on T–F; boys more commonly prefer thinking styles and girls prefer feeling styles. Age differences are most apparent on O–L styles; younger children express a greater preference for an organized style. Gender and age interactions also were found, especially on T–F for ages 13 and 14. Cross-cultural comparisons indicate T–F distributions is similar across the three Latin American countries (Thinking > Feeling) while differences appear stronger on P–M (more Practical preferences: Venezuela > Peru > Costa Rica) and O–L (more Organized preferences: Venezuela > Costa Rica > Peru); there little differences in Extraversion (more Extraversion preferences: Peru > Costa Rica). Practical issues are discussed.

Exploration of ontological assumptions older people have regarding wellbeing of younger people
Beatrice Mulder North West University, South Africa

By using the concept of ontology, this presentation strives to describe what some members of the older generation regard as social reality of younger people’s wellbeing. Ontology refers to the assumptions on which perceived reality is based. A multiple case study design was used and 13 white, Afrikaans-speaking members of the older generation (ages 60–85 years), from a service centre for the aged in North West Province were purposively selected. Data were collected by applying the Mmogo-method™ (Roos, 2008) and in depth personal interviews. The Mmogo-method™ is a visual projective data gathering instrument which requires people to construct their perceptions by using material such as clay, beads and straws, which are explained and discussed in groups. Visual and textual data were obtained and thematically analysed. Findings revealed that older persons regard their perception of social reality as normative and they tend to evaluate the wellbeing of younger people from this normative stance. Young people have obtained rights due to new political dispensation in South Africa during 1994 and thus older generations perceive young people to be liberal and not adhering to prescribed social norms. The ontological assumptions of older persons about wellbeing of younger people can be harmful for intergenerational relations because the judgments which are based on ontological assumptions of older persons seemingly does not allow for different social realities. It is recommended that older and younger people be exposed to individual interactions, to develop an awareness of each other and an understanding of each other’s wellbeing.

Development of a mental health screening instrument for military personnel
Arthur Neale Military Hospital, South Africa

A cabinet decision, in 1998, determined that all military personnel in the South African National Defence Force, have to be medically fit to deploy on military missions. The implication was that all members of the SANDF have to undergo regular health assessments, that included a psychological or mental health assessment. This posed a challenge for military psychologists to develop an assessing procedure that will be able to assess at least 30000 personnel per year. The solution to this problem was to develop a mental health screening instrument known as the Psychological Risk Inventory (PRI). The PRI was developed and used as a test under development during the past 8 years. It has been subjected to thorough research. One of the important findings was that the psychometric properties of the test are acceptable. A computerised scoring program was developed that could link test results with patient information on a mainframe. More than 250000 military personnel have been tested up to date. Feedback from deployment areas indicates that the screening process is very successful. Less than 5% deployed members are repatriated due to psychological problems. Many lessons have been learnt since the start of the development of the PRI. These lessons are worth sharing with other organisations who want to develop psychometry in the African and other similar contexts.

The Romanian adaptation of the trust in teams measure
Catalina Otoiu Babes Bolyai University, Romania; Adriana Baban; Daniela Andrei; Oana Ferent

The aim of the present is the adaptation and validation of a trust measure on Romanian population. A review of the trust measures that are being used in our country showed that the Romanian version for most instruments lack the adequate psychometric properties that would allow for a proper use of the measure both in research and in practice. Therefore we found it necessary to introduce a new measure, and to follow the adaptation process all the way in order to ensure that the psychometric properties are within appropriate intervals. The Trust in Teams measure, developed by Costa and Anderson (2010), was translated to Romanian, back translation was performed and initial statistical analyses were conducted to verify the reliability and the validity of the scale. Our first results indicated that further adaptation of the initial version was necessary for the theoretical model to better represent our data. For our initial testing of the translated version we used a sample of N=144 (38 teams). A second structural equation modeling analysis was conducted on the adapted version, with a sample of N=390 (65 teams). Confirmatory factor analysis was performed on our adapted version and this time we obtained adequate goodness of fit indices. Our results indicate that this instrument has the properties necessary to capture trust, not as a static concept, but as one of the emergent states of a group. Our results suggest some future research questions regarding trust manifestation and evolution within teams.

The internal and external validities of the Depression Anxiety Stress Scales (DASS-21)
Sajeda Ramassamy AIX-MARSEILLE 1, Mauritius; Pierre Yves Gilles

The objective of this research was to examine the psychometric properties of the French version of the DASS-21 in a Mauritian student population. The DASS-21 consists of three scales: the depression, anxiety, and the stress scale. The DASS-21 scale consists of 7 items. The DASS-21 has been translated into many languages and has been found to possess excellent psychometric properties in adults, and considering its brevity, it is widely used in clinical settings internationally. 1186 adolescent students (385 boys and 801 girls); mean age 14.3 years, responded to a set of four self-report measures: Depression Anxiety Stress Scales (DASS-21); Revised Children’s Manifest Anxiety Scales (RCMAS); Multiscore Depression Inventory for Children (MDI-C); and Coping Inventory for Stressful Situations (CISS). Reliability: Internal consistency of the 3 scales of the DASS-21 was measured using Cronbach’s alpha, α, for the depression, anxiety, and stress scales, α was respectively 0.78, 0.71, and 0.77. Exploratory Factor Analysis: 3 factors were extracted (Eigen values >1) accounting for 43.2%
of the total variance. Oblique rotation yielded three correlated factors that reproduced the DASS-21 scales. The DASS-21 was found to possess satisfactory concurrent validity as moderate positive correlations were obtained with the other measures of depression and anxiety. The DASS-21 has satisfactory structural and concurrent validity. The internal consistency is also satisfactory. Future research will focus on cognitive processes involved in depression and anxiety.

Strengths and difficulties questionnaire: An analysis of its structure in a multiethnic urban adolescent sample

Joerg Richter Center for Child and Adolescent Mental Health, Norway; Espen Roysamb; Brit Oppedal; Aase Sagatun; Sonja Heyerdahl

The SDQ is currently one of the internationally most frequently used screening instruments for child and adolescent mental health purposes. Its structure, cross-cultural equivalence, and applicability in ethnic minority groups is still a matter of discussion. SDQ self-report data of 5,379 ethnic Norwegian and 865 ethnic minority adolescents with a variety of national origins was analysed by means of confirmatory factor analysis. Multi-group comparisons considering equal thresholds combined with more in-depth analyses on factor loadings, residuals composite reliability and average amount of variance explained by indicators of respective constructs, were performed. CFA suggested a good fit of the five-factor model of the SDQ self-report in the subsample of ethnic Norwegian adolescents and an acceptable fit in ethnic minority subsamples without substantial differences between ethnic Norwegian SDQ data and data of Pakistani, or those of ‘other ethnic minority’ adolescents. When assuming equal thresholds between response categories of the items, as well as equal factor loadings, the structure in the data significantly differed between ethnic Norwegian and both ethnic minority samples. Some factor loadings and some correlations between constructs significantly differed between ethnic Norwegian and both ethnic minority samples. To some extent the theoretically proposed five-factor structure of the Norwegian version of the SDQ self-report was supported in 15- to 16-year-old adolescents. When applying this screening method to Norwegian adolescents, our results suggest that the use of the total difficulty score of the SDQ in screening youth should be preferred over the sub-scale scores.

The role of life stressing events and the strategies of coping with the reemergence of PTSD

Mehrdad Sabet Islamic Azad University, Islamic Republic of Iran

The aim of this investigation was to determine the coping strategies for life-stressful events in those injured in the imposed war with post traumatic stress disorder (PTSD) and with people who had been injured in the imposed war without post traumatic stress disorder (PTSD). Statistic society of this investigation was all of the people who had been injured in the imposed war. They lived in Kermanshah in the year of 1389, 60 of this population with random sampling was chosen. 30 of this population have post traumatic stress disorder (PTSD), and the other 30 didn’t have post traumatic stress disorder (PTSD). The method of this investigation was causal comparative. For each groups paykel life events inventory, moods & billings coping responses inventory, and post traumatic stress disorder checklist (PCL) is used. Analyses of data with multi analysis of variance, correlation coefficient, and T test, show that between evaluate dangers, stressfull events in the life and emotion-focused, re-appearing PTSD, old age at the time of investigation and old age at the time of injured, exist positive and meaningful intervening. Or so that’s better to tell: Low age at the time of injury use of problem-focused and high percentage of the injured protect people from PTSD.

Adaptation of parenting practices measure (PPM) in Spanish adolescents

Paula Sanmer University of Valencia, Spain; Ana Llorca; Ana Tur; Vicent Mestre University of Valencia, Spain; Lorena Gimenez

The aim of this paper is to present an adaptation of a multi-dimensional measure of the prosocial practices designed by Carlo, McGinley, Hayes, Batenhorst, and Wilkinson (2007) in Spanish adolescents. Participants in the study were 450 adolescents (boys and girls, with a mean age of 14 years) belonging to public and private schools in the Valencian Community. The subjects completed the Interpersonal Reactivity Index (Davis, 1980; Mestre, Frias, and Sanmer, 2004), the Prosocial Behavior Scale, the Scale of Physical and Verbal Aggression and Emotional Instability Scale (Caprara & Pastorelli, 1993; Del Barrio, Moreno & Lopez, 2001), the Parenting Practices Measure (Carlo, G., McGinley, Hayes, Batenhorst, y Wilkinson, 2007) and the Prosocial Tendencies Questionnaire Revised (Carlo, Hausmann, Christiansen, and Randall, 2003). The questionnaires were filled in a 50-minute session. The results have shown adequate reliability and validity. The discussion is directed towards the need to identify those parenting practices used to promote prosocial behavior not on a global and undifferentiated scale, but specifying different dimensions of this behavior: emotional, altruistic, obedience or conformity, dire, public and anonymous.

Understanding the effects of religious beliefs on older adults sense of coherence

Susana Santos ISPA, Portugal

The rapid worldwide growth of the elderly population has led to an increase of studies addressing the strategies used by older adults to promote healthy aging, as they fact the challenges inherent to this process. This study aims to: (a) analyze if the internal sense of coherence (SOC) of older adults changes with the presence of religious beliefs, and (b) to assess bivariate associations between participant’s sense of coherence and their religious beliefs. 123 older adults, aged above 74 years (M = 82.4, SD = 5.6) were assessed with the Sense of Coherence Scale (SOC) and the Mini-Mental State Examination (MMSE). Sociodemographic data, including the type of belief system or the absence of religious beliefs were also assessed. The findings suggest that religious beliefs have a different effect on SOC. Participants with Judaic religious beliefs showed the highest SOC score (MUD=4.9), (in a likert scale that ranges from 1 to 7), followed by Protestants (MPRO=4.6), whilst the Islamic participants indicated the lowest SOC score (MISL=3.7). This study indicated that religious beliefs appear to have an effect on older adults’ SOC and that this effect can vary according to the religious belief practiced, emphasizing the relevance of religious beliefs for the SOC of older adults and its relevance to healthy aging. Implications of these findings in clinical approaches are also discussed.

Validation study of a model for the assessment of the potential in Italian young professionals

Riccardo Sartori Verona University, Italy; Annalisa Rolandi

This abstract presents the results of a study carried out on the potential profiles of 1068 Italian Young Professionals coming from Assessment Center and Development Center activities. A review carried out on a database of potential profiles made available by GSO, which has acknowledged the potential assessments conducted by 35 medium to large sized companies of 8 different business industries over ten years, showed that the assessment of the potential of Young Professionals was carried out by means of observation grids including 15 to 20 different skills, reaching a total number of 48 skills evaluated in all of the companies under examination. The aim of the study was to achieve an assessment model that includes the smallest possible number of highly predictive potential skills, avoiding dispersions and redundancies in the assessment, and maximizing the opportunities for the companies to make correct managerial choices when using potential data. The research has applied a series of statistical models (correlation, factor analysis and regression) in order to reduce the number of abilities and identify those that predict the overall skill better. The results show that the number of "necessary" skills is below 10. Two assessment models have been obtained, one defined as Narrow (8 necessary skills) and another defined as Broad (14 skills, the necessary ones plus others considered as "secondary" but relevant).

Norming process of Wells’ meta cognitive test on high school students in Iran

Mohammadreza Seirafi Islamic Azad University, Karaj, Islamic Republic of Iran; Mohammad Haka- mi; Mehrdad Sabet

The object of this study is due inspecting the validity, reliability, and finding the norm of the Wells’ Meta cognitive Test. The study is a filed research of an exploratory type. 600 (male and femal) pupils were chosen randomly as samples on the High School Students in the city of Karaj and there was used factor analysis using SPSS software for statistical analysis. Findings of this study indicate that test for high school students has validity. The total reliability coefficient is 0.83 (boys=0.835 & girls=0.825). There is nearly a positive correlation between all its subjects. A general factor has its domination on all questionnaires After being as- sured of the reliability and validity of the test, the general norm tables were prepared, which may be used by the consultants and psychologists in the filed of clinical diagnosis.
Training mental health professionals in evaluating and managing suicide risk in college students
Jose Serra-Taylor University of Puerto Rico, Puerto Rico; Maria Jimenez-Chafey; Carol Irizarry-Robles; Sheila Perez-Lopez

The specific goal of this study is to evaluate the efficacy of training designed to improve the skills of university mental health professionals in evaluating and managing suicidal risk in college students. The training was developed and administered to 39 professionals (counsellors, psychologists, and social workers). Participants were trained on using the Columbia Suicide Severity Rating Scale (Posner, et al., 2009) as an instrument for suicide risk assessment. Four clinical cases were used to perform assessments through role-play. A pre- and post-test was administered consisting of 20 multiple choice questions to assess the participants’ gained knowledge during the training. Also, two other measures were administered: one collecting demographic data along with a 5-point Likert scale exploring their professional practice (17 items); and an evaluation of the training with closed- and open-ended questions (18 items). Results showed a significant difference in the pre- and post-test, t(38) = -9.178, p < .000. The participants evaluated the training as useful for their clinical practice. Results suggest that an evidence-based training that incorporates practical exercises increases the knowledge and improves the skills of mental health professionals in evaluating and managing suicide risk, thus helping to prevent suicide in college students.

The factor analysis and reliability of the Griffith empathy measure in Iranian adolescents
Maryam Sharyati Azad University of Birjand, Islamic Republic of Iran

The construct of “empathy” embodies a number of characteristics necessary for psychological health in adolescents (Dadds et al., 2008). The aim of this study was to investigate the psychometric evaluation of The Griffith Empathy Measure (GEM) (Dadds et al., 2008) in Iranian Adolescents. The Griffith Empathy Measure (GEM) was administered on 300 adolescents in Iran (150 girls and 150 boys). Factor analysis yielded two general factors (a cognitive and an affective factor, accounting for a subset of 22.32 and 15.03% of variance respectively). The reliability coefficient of the Iranian version of GEM, was 0.89. The evaluations provide support for the utility of the measure in capturing an overall dimension of empathy as well as two independent subscales of Affective and Cognitive Empathy for use in Iran.

Assessing community attitudes toward persons with a serious mental illness: A new measure
Mariss Snell Nova Southeastern University, United States of America; William Dorfman

Serious and persistent mental illness affects approximately 1 of every 17 people in the United States. Unfortunately, it seems that persons with long term mental illness are often mistreated and misunderstood in our society. There is a scarcity, however, of scales used to measure such misconceptions at the community level. The proposed study seeks to develop and validate a scale that measures community attitudes and beliefs regarding those with serious and persistent mental illness. The process will begin with the development of an item pool that will be subjected to reliability analysis including statistical measures of homogeneity, and test-retest reliability. Construct validity and concurrent validity studies will follow based on any existing measures in the literature. Various validated scales, such as the Attitudes Toward People with Serious Mental Illness Survey (Black, 2005), which address these factors among professionals, will be referenced and refined to fit the current purpose of assessing these factors among community members. Such a scale is an essential component for much of the suggested research surrounding long term mental illness in that it will provide data on which to base interventions. Knowledge regarding biases and misconceptions that the community holds will aid in developing effective methods to target attitude changes towards persons with a serious mental illness.

New assessment tool measuring global knowledge outcomes for short study abroad experiences
Valeriya Spektor Lehigh University, United States of America; Tina Richardson

Global knowledge can be defined as knowledge relating to self and others, in regards to cultural values, beliefs, and behaviors, which impacts one’s ability to view the world from multiple perspectives and flexibly adjust to diverse interactions. The present study aimed to provide preliminary psychometric evidence for a new assessment tool measuring global knowledge outcomes for short term study abroad experiences with regards to two aspects of knowledge, (1) para-communication and (2) reflection/processing. A total of 108 participants (77 female; 27 male) completed a demographic questionnaire, the Cultural Intelligence Scale (CQS; Ang et al., 2007), and 39 items developed to assess para-communication and reflection/processing. Exploratory factor analysis reduced the global knowledge items into three factors: effective communication, awareness of intercultural challenges, and influence and reflection/processing. The new assessment tool evidenced high internal consistency for each of the three factors, and bivariate correlations with the CQS subscales provided evidence of convergent/divergent validity. Findings indicated that global knowledge is a multidimensional construct that includes behavioural and affective communication skills, affective maturity in order to remain flexible and adapt in intercultural settings, and cognitive processes used to make sense of the cultural interaction. Additionally, the authors discussed implications for study abroad programme developers, providers, and counsellors, as well as directions for future research.

Two generation’s perception of why they need to be involved with each other
Tonette Stavast South Africa

The goal of this presentation is to explore the impact of older people’s responses, on younger people, in an intergenerational relational research project. Qualitative research was used, and data were obtained by using observations of videos and behavioural responses of older people who participated in an intergenerational research project. In addition individual interviews with young people (ages ranging from 21–33), in terms of how they experience the impact of older people (ages ranging from 60–85), were also used. The most important finding is a lack of person centred qualities in the interaction between the younger and older generations can be experienced as a negative impact, for example being experienced as critical and unkind impacted on the members of the younger generation and they tended to withdraw from the interaction. This has serious implications for intergenerational solidarity. It is recommended that both generations become more mindful of their impact on others, and that they develop their person centred qualities such as empathy. Through clearly describing person centred qualities we will know how to cultivate these qualities in all generations to develop and improve the interaction between the various generations.

The effect of religious belief on college students’ mental health
Yaling Su Dongguan Technology University, China

The purpose of the present study was to explore the relationship between religious belief and the mental health of college students. 10957 students were invited to complete the following questionnaires:

Exploration of the impact of interpersonal communication in an intergenerational research project
Sandra Steyn North West University, South Africa

There is a growing emphasis on encouraging intergenerational solidarity. Literature indicated that older people have a tendency to become indifferent about their interpersonal impact. This is often a consequence of either poor intergenerational communication or social insensitivity. The theoretical framework that informed this research is that people continuously develop their relationships with others, through verbal and non-verbal communication in a reciprocal manner. The goal of this presentation is to explore the impact of older people’s responses, on younger people, in an intergenerational relational research project. Qualitative research was used, and data were obtained by using observations of videos and behavioural responses of older people who participated in an intergenerational research project. In addition individual interviews with young people (ages ranging from 21–33), in terms of how they experience the impact of older people (ages ranging from 60–85), were also used. The most important finding is that a lack of person centred qualities in the interaction between the younger and older generations can be experienced as a negative impact, for example being experienced as critical and unkind impacted on the members of the younger generation and they tended to withdraw from the interaction. This has serious implications for intergenerational solidarity. It is recommended that both generations become more mindful of their impact on others, and that they develop their person centred qualities such as empathy. Through clearly describing person centred qualities we will know how to cultivate these qualities in all generations to develop and improve the interaction between the various generations.
University Personality Inventory, Life Event Scale, Coping Strategies Questionnaires and Life Satisfaction Scale (Life Satisfaction Index A and B). Then, 125 religious believers and 125 non-religious believers were randomly selected from the sample, and were asked to further complete the Chinese College Students’ Spirituality Scale and a self-developed scale. The results showed that, when compared with students with religious belief, the mental health and life satisfaction level of non-religious belief students were obviously lower; they also more frequently adopted an infantile coping style and were more sensitive to perceived stress. The research conclusions informed us that we should look at religion from the scientific point of view and pay more attention to the mental health state of college students with religious belief. Most importantly, we need to provide specific mental health education and psychological counselling to college students with religious belief in accordance with their psychological characteristics.

Perception of individual-group relationships as a reflection of perceiver’s abilities of teamwork
Shinkichi Sugimori Tokyo Gakugei University, Japan; Atsushi Furuya; Atsushi Alkawa

Teamwork is counted as an important aspect of key competencies (OECD, 2003). The aim of this study was to build an computer-based assessment tool measuring an individual’s teamwork abilities, implicitly, through projective responses to individual-group relationships displayed by computer graphics (CG). University students (N=165) and workers in various jobs at two companies (N=218) participated in this study. We prepared CG software which presents CGs of a solo fish or person, swimming or walking (1) alone, (2) alone outside of a group, or (3) within a group. To avoid influence by context information, the image of the fish and the person was relatively abstract, i.e. not using real images. We also developed, and used, self-rating teamwork ability scale (Aikawa, Takamoto, Sugimori, & Furuya, 2012) and also other-rated teamwork ability in a company. The teamwork ability scale consists of five factors: communication, back up, team orientation, monitoring, and leadership. The projective responses of participants to each CG were gathered as free descriptions in the first stage, and in the second stage, response categories were prepared for automatic scoring. Statistical examinations revealed many of the responses to CGs have significant relationships with other teamwork measures. It was suggested that the development of CG testing of teamwork abilities is both possible and promising.

Analysing personality scale using nonparametric item response theory model
Wenqiang Tang South China Normal University, China; Xiaojie Wang; Min-Qiang Zhang; Xiao-Zhu Jian

The study analysed Neuroticism scale (N scale) of Eysenck Personality Questionnaire (EPQ) using the Nonparametric Item Response Theory (NIRT) model, and compared it to the Parametric Item Response Theory (PIRT) models. The results showed that the 24 items in N scale all fit the Mokken model and that 4 items didn’t fit the 2PLM, while those 4 items can be accurately measured using the Mokken model. After removing the unfit items based on the NIRT model, the increment of mean item information is much larger than that based on 2PLM model. The analytic procedure and results reveal the feasibility, advantage and applicability of NIRT model in analysing the personality questionnaire.

New development in computerised adaptive testing: Cognitive diagnostic computerised adaptive testing
Wenqang Tang South China Normal University, China; Min-Qiang Zhang; Mu-Hui Huang

With the development of modern computer technology, more and more researchers and practitioners are interested in building CAT based on cognitive diagnostic models (CD-CAT). These models aim to diagnose examinees’ mastery status of a group of discretely defined skills, or attributes, thereby providing them with detailed information regarding their specific strengths and weaknesses. This article aims to provide practitioners and researchers with an introduction to and overview of recent developments in cognitive diagnostic computer adaptive assessments. In this article, the author will discuss the advantages and disadvantages of these methods focusing on six components of CD-CAT methodology, which include psychometric models (CDMs), calibrated item banks, entry level (starting point), item selection rules, scoring method and termination criterion. Development history and research ways of the CD-CAT methodology are summarised, and future research trends are forecast as well. It is hoped that some useful direction will be provided to practitioners wishing to begin working and experimenting with this new methodology.

The use of the millon clinical multiaxial inventory III in the South African context
Casper Van Zy1 Jopie van Rooyen And Partners, South Africa

Psychological instruments require constant research with different cultures, populations and nationalities in order to be applicable to a wide variety of respondents. The purpose of the study was to investigate the reliability, factor structure and gender differences of the Millon™ Clinical Multiaxial Inventory – II (MCM-II™) in the South African context. This study falls within the quantitative research paradigm. Internal consistency reliability, factor analysis, and analysis of variance (ANOVA) were used to compare the psychometric properties of the MCM-III™ with international findings. Second data was used in this study. The sample consisted of 418 men and women from different clinical, cultural and racial backgrounds. Satisfactory internal consistency reliability was found with the South African sample which is comparable to the United States (US) norm group. Congruence between the factor structure of the MCM-III™ and previous studies was found, although unique differences do exist with a third factor. Differences between men and women when compared to the US norms were negligible except for the Compulsive scale where women scored higher than men. The results of this study provided evidence that the MCM-III appears to be appropriate for use within the South African context.

An interbattery factor analysis of the Emotional Quotient Inventory and the Work Personality Index
Casper Van Zy1 Jopie van Rooyen And Partners, South Africa

Stream three or mixed model emotional intelligence (EI) measures have been shown to be correlated with personality in the research literature. The objective of this study was to further examine the nature of this relationship. Previous studies using joint factor analysis to investigate the relationship between personality and mixed model EI have located EI as a separate trait in personality factor space. A common problem with using joint factor analysis for this purpose is the possibility of method artefacts. Thus, joint factor analysis may not reflect the true relationship between two variable sets. In the present study, an interbattery factor analysis was conducted with the scales of the Emotional Quotient Inventory (EQ-I) and the Work Personality Index (WPI). Interbattery factor analysis identifies only common factors between two variable sets. The sample size consisted of 615 working adults who completed the assessments for selection or developmental purposes. After a direct quartimin rotation, an eight factor solution provided the most parsimonious and theoretically meaningful solution. The analysis identified seven common factors between the EQ-i and WPI. Only Teamwork from the WPI loaded on factor eight. In contrast to previous results, EI did not load separately in personality factor space. The common factors between these variable sets indicate that the different constructs measured by EI and personality are related. Some of the relationships identified among the variables were unexpected. This provides additional interpretive information for when the EQ-i and WPI is used in conjunction.

Assessing job applicants’ emotional intelligence in interviews
Ching-Wen Wang National Chung Hsing University, Taiwan, R.O.C.; Chi-Sum Wong

Emotional intelligence (EI) has been shown to be related to important job outcomes. However, existing EI measures may not be applicable in selection contexts because of the possibility of faking, the high costs involved, and the accessibility of scoring keys. In this study, we attempt to demonstrate that EI can be assessed through carefully designed interview questions. Using the position of customer service officer (CSO), we find that both situational interview (SI) and patterned behavior description interview (PBDI) questions are related to job applicant EI and may predict incumbent job performance and turnover intention. Suggestions for practitioners and researchers are discussed.

Present situation, hotspots and Chinese psychological research trend: A CNKI-based analysis
Zhimin Wu Jiangxi Normal University, China; Meirong Chen

CNKI is China National Knowledge Infrastructure or Chinese periodical full-text database. It is the largest Chinese website of information on knowledge. The
following characteristics are found on CNKI psychol- ogy theses after statistically analysing author, journal, psychological topics: (1) The number growth of psych- ological papers in China is consistent with Chinese GDP, 1979-2011. The number of psychological papers increased from 83 in 1979 to 9438 in 2011; (2) In nine kinds of main psychology journals issued, volume is a total of 2979, in the past two years, 2010-2011, accounting for 30.56% of the total of the same period in psychology papers; (3) The research contents and hotspots are to the direction of diversification. In the main psychology journals theses that are related with cognitive and experimental psychology, clinical psychology and mental health, other areas, account for about one-third each; (4) The treatises of "domain experts" are leading the direction and trend of Chinese psychological research; (5) Chinese psychologists should not pay due attention to evolutionary psychol- ogy, cultural psychology, indigenous psychology.

Adaptation of Edinburgh Postnatal Depression and Gotland Male Depression scales in Latvia Diana Zande University of Latvia, Latvia; Sandra Sebė

High rates of depression have been reported in wom- en during the transition to parenthood, and increas- ing attention is focused upon depression which fathers experience during this period. The objective of this study was to evaluate the psychometric prop- erties and convergent validity of two depression scales which have been translated into Latvian: the Edinburgh Postnatal Depression Scale (EPDS, Cox, Holden, & Sagovsky) and Gotland Male Depression Scale (GMDS, Zierau, Bille, Rutz, & Bech). The latter was developed to assess both traditional de- pression symptoms as well as behaviours, which may be more extant for men. For purposes of adapta- tion in Latvia the EPDS was translated from En- glish to Latvian, and the GMDS was translated from Swedish to Latvian. Both questionnaires were com- pleted by a sample of 100 women and their partners at two points in time: during the third trimester of pregnancy, and three months postnatally. Results show good internal reliability ratings for both scales at both points in time (Cronbach's coefficients rang- ing from .80 to .90). Results show similarly strong correlations between EPDS and GMDS both for women and men, although it was initially predicted that this association between scales would be stron- ger for men. There is discussion of the similarities and differences of reported symptoms in relation to gender roles in contemporary society. The EPDS and GMDS Latvian versions appear to be valid and reli- able measures to assess depression symptoms for both men and women pre- and postnatally.

The effect of different conditions on param- eter estimation precision of the MCMC method under the Testlet response theory Jie-Ting Zhang South China Normal University, Chi- na; Wen-na Tian; Min-Qiang Zhang

The number of parameters in Testlet response theory model is more than the IRT model; using a maximum likelihood estimation is inconvenient. Moreover, the MCMC method can be simplified using model pa- rameter estimation. Studies have shown that differ- ent numbers of subjects and items will affect the estimation precision of the MCMC method within the framework of the IRT. It is well worth exploring whether the MCMC method has the same effect in the Testlet response theory model compared to IRT model under different experimental conditions. This paper simulates different experimental conditions (a lower number of subjects and items; a moderate number of subjects and items; changing the number of items under the condition of fixed parameters and the number of subjects; changing the number of subjects under the condition of fixed parameters and the number of items), to explore the precision vari- ation of the MCMC method in the framework of a three-parameter model of Testlet response theory.

The application research of GIRM approach Min-Qiang Zhang South China Normal University, China; Xiao-Tian Hu; Kai-Yin Guo

Through the distributional assumption of the facets in generalisability theory the p×i design of generalisability theory (GT) and the Rasch model of item response theory (IRT) could be incorporated in Generalisability in Item Response Modeling (GIRM). Based on the GIRM model, this study proposes the GIRM approach and presents this approach in the context of simulated and empirical data, exploring the effects of the GIRM approach in the test. Using both simulated and empirical data with the software WinBUGS, the GIRM approach is shown to produce results comparable to those from the traditional GT approach. This includes the estimate of variance component, generalisability coefficient, and dependability index. On the com- parison of reliability in the simulated study, the bias, RMSD and MEANE of two methods are very close. However, on the estimation of SE of variance component the accuracy of the GIRM approach is worse than the traditional GT approach.

Confidence interval for effect size Min-Qiang Zhang South China Normal University, China; Qing-qing Xiong

Confidence intervals for effect sizes cannot be com- puted using formulas. The main classes of effect sizes are: (a) Standardised differences effect sizes, (b) variance-accounted-for effect sizes and (c) cor- rected effect sizes. We compared three methods: The noncentral-based, the percentile (PERC) boot- strap, and the biased-corrected and accelerated (BCA) bootstrap methods for setting a confidence interval (CI) around Cohen's and under different conditions. A set of Monte Carlo simulations was constructed. The biased-corrected and accelerated (BCA) bootstrap is proposed and recommended for general use for above effect sizes, especially in cases when the assumption of normality is violated.

A review of testlet response theory Jie-Ting Zhang South China Normal University, Chi- na; Wen-na Tian; Min-Qiang Zhang

One important assumption made in standard IRT is the assumption of local independence. Violation of this assumption occurs under some conditions such as testlet or item-bundle, in which items share the same stimulation. Lots of examinations contain testlet items or item-bundle. When item response theory models are applied, testlet items can lead to the distortion of parameter estimation. In order to solve this problem, researchers introduced three approaches: (1) Ignore the item dependence, and use the standard IRT model. (2) Consider testlet as a super item, and score it polytomously. (3) Apply the testlet response theory. Method (1) and method (2) have some weak points in parameter estimation. This paper introduces related studies both in appli- cation and theory about testlet response theory, especially methods of parameter estimation, and aims to provide research direction for the future.

Applying MCMC algorithm in estimating var- iance components for generalisability theory Min-Qiang Zhang South China Normal University, China; Guang-Ming Li; Wen-yi Zhang; Kai-Yin Guo

The Markov Chain Monte Carlo (MCMC) method, as a dynamic computer simulation technique, was first applied in psychometrics in 1990s. To an extent, gen- eralisability theory (GT) can be viewed as a combination of classical test theory and analysis of variance proce- dures. It helps to untangle different sources of error so that the efficiency of the measurement can be im- proved. As a result, the estimation of variance compo- nent is the key to GT. This paper summarised some studies about applying MCMC method on the estima- tion of variance component for GT. First, MCMC algorithms can be used in estimating the variability of estimated variance components for GT. The results showed that, compared with other methods (Traditional, Bootstrap and Jackknife methods), it was quite suitable to apply MCMC methods with prior informa- tion in estimating standard errors and confident inter- vals. Second, in GIRM (Generalisability Theory in Item Response Modeling), which connects the sampling model of GT with the scaling model of IRT, the application of MCMC algorithms can separate the interaction of person and item from other residual errors in the p×i design, which has developed and extended the tradi- tional estimating method of variance components for GT. Last but not least, using MCMC methods to deal with missing data can avoid the information loss and improve the effectiveness of the measurement. In view of these studies, applying MCMC algorithms in esti- mating variance components for GT would be the main direction of its basic research.

Reability and validity of cluster-b personal- ity disorders beliefs questionnaire in Chinese university students Shijie Zhou Central South University, China; Qian- qian Zhang

The aim of this study is to examine the reliability and validity of Cluster-B personality beliefs ques- tionnaire. Cluster-B personality beliefs question- naire and Personality Diagnostic Questionnaire-4 + (PDQ-4+) were administered to 600 university students, 57 of which were assessed by Cluster-B personality beliefs questionnaire three weeks later. The results are as follows: (1) The Cronbach's α coefficient for 4 subscales ranged from 0.79 to 0.91, the split-half coefficient from 0.73 to 0.87, and test- retest coefficient from 0.65 to 0.74. (2) Four factors were extracted through exploratory factor analysis, which were consistent with the theoretical concepts. The correlation coefficients between 4 subscales were from 0.42 to 0.62. PDQ-4+ was chosen as a criterion, thus, correlation coefficients between four factors and corresponding personality disorders were between 0.37-0.45. The reliability and validity
of Cluster-B Personality Disorders. Beliefs Questionnaire in Chinese University Students have reached an acceptable level in psychometrics.

Session Type: Invited Addresses

A clinical cognitive approach to thought: Implications in cognitive diagnosis and remediation
Evelyne Clement, University of Rouen, France; Bruno Villette; Pascale Planche; Bruno Vivicorsi

This contribution deals with mentally retarded adults’ problem solving strategies. To assess the strategies and the potentially inter-individual variability, an adapted version of the Twenty Questions Task was given to 30 mentally retarded adults (MRA), 30 mentally nonretarded adults (MNRA) matched on chronological age, and 30 mentally non-retarded children (MNRC) matched on cognitive efficiency. In our version, the items belong to different semantic categories organised in a hierarchical network. This formalisation of the task was conceived in order (1) to identify the strategies that underlie and explain the performances and (2) to take into account the large individual differences commonly reported in the domain. Despite the performances, the MRA of the children did not significantly differ, the individual protocols analysis showed differences in the strategies developed by the two groups. The interpretation of the results as reflecting a conceptual deficit or a chronic cognitive sub-functioning of the MRA as well as their implication in cognitive diagnosis and remediation will be discussed. We question the relevance of the theoretical model proposed by Frith (1989) according to which individuals with autism present a “lack of central coherence” reflecting a deficit in the mobilisation of global processing. Fifteen children with high-functioning autism was compared with 15 normally developing children, matched on age and global level of intelligence and assessed on the WISC-III and the NEPSY. The results show no significant differences between children with high-functioning autism and typical children scores on the items requiring visuospatial processing. However, differences of strategies appeared both between the groups and, in children with autism, according to the task. These results suggest in persons with autism the idea of a priority granted to the local information processing in the absence of a global processing deficit. It is assumed that the evolution of the relations between procedural and conceptual knowledge varies with the individual trajectories. We test this hypothesis by means on a combination of curves of growth, a dynamic modeling and the analysis of the inter-individual variability (van Geert & Steenbeek, 2005). Twenty-eight 5 year old children were assessed eight times during one school year on three tasks: (a) To count collections of tokens ranging from 3 to 25 (the “Counting task” (CT): procedural knowledge), (b) to give a cardinal of tokens ranging from 3 to 25 (the “Give a number task” (GNT): conceptual knowledge), and (c) to count and to give the missing number of tokens ranging from 3 to 25 (the “Arithmetic task” (AT): AT procedural and conceptual knowledge). The results show that significant improvement in performance on the AT are always accompanied by significant improvements on both CT and GNT. Moreover, the children who do not progress on the AT can nevertheless significantly improve their performance either on the CT, or on the GNT, or still on both tasks. We conclude that the relations between procedural and conceptual knowledge are not uniform and vary with the individual trajectories. The aim of this research is to study mathematical preconceptions in problem solving. It was assumed that these preconceptions, i.e. naïve knowledge (Lautrey et al. 2008), constitute a filter to interpret a new conceptual field and guide the strategies developed by the solver. In order to explain children responses, fifty-one 9-10-year-old children were invited to solve 12 problems constructed on the typology of Vergnaud. The data analysis combines a quantitative approach (Implicitive Statistical Analysis) and a qualitative approach (Individual Protocols Analysis). Results will be discussed in the light of the interest of this kind of approach.

Geropsychology for an aging world
Rocar Fernandez-Ballesteros, Autonomous University of Madrid, Spain

Over the last five decades, life expectancy at birth increased, globally, by almost 20 years. On average, the gain in life expectancy at birth was 23.1 years in less developed regions and 9.4 years in the more developed regions. The range in life expectancy within more developed countries varies between 71 years in Latvia to 82 years in Japan (see United Nations). At the same time, fertility rate decreased dramatically from 3.7 children per women in developed countries during the 19th century to 1.4 at the beginning of the 21st century. When psychology developed as a science in the third quarter of the 19th century, societies were young, with higher proportions of people under 16, than of those older than 60. By the second decade of the 21st century, a growing proportion of countries will have aging societies with very a high percentage of elders in comparison with children and adolescents. As a consequence, psychology and psychologists must be concerned with this situation. This contribution will deal with those more important topics of geropsychology from a basic and applied point of view. Geropsychology is defined as the branch of psychology studying the psychological components of the process of aging, the psychological characteristics of age, and of the aged. A summary of the most important psychological issues of aging as well as of successful, normal and pathological will be introduced.

Session Type: Invited Symposia

Symposium title: Cross-cultural evidence-based health/psychotherapy research among North America, United Kingdom, China, Korea and Japan
Convenor: Akira Tsuda

Biopsychosocial approach to stress and health: Recent advances
Akira Tsuda, Kurume University, Japan; Shigeko Tsuda

Bio-Psycho-Social approaches are widely recognised as suitable strategies for the study of complex biologic responses to various stress-related psychological factors from the point of view of indigenous and cross-country differences, which attempt to make the connection between stress and ill-health outcome. Emerging data from our laboratory and cooperative institutions has indicated that these approaches are useful to predict various markers of health, thus may be clinically relevant. This presentation will contain several findings from our laboratory that focus a biopsychosocial approach relevant to health outcomes. Topics will cover a wide range of measures that are currently being employed in psycho-biological research and how they might be used to understand important mechanisms of stress and health from the point of view of Indigenous and Cultural Psychology. We summarise results from our research program into the biological correlates of positive and negative affects with a line of cross-cultural perspective from Health Psychology. There is considerable interest in the relationship between affective states and cortisol output such as cortisol awakening response, but little evidence connecting the cross-cultural consistency of these associations. These topics will not only be of interest to Indigenous and Cultural Health Psychology, but will also be relevant to social psychologists, epidemiologists and public health workers.

Symposium title: Emerging issues impacting test development in four different areas of practice
Convenor: Thomas Oakland

Trends in rehabilitation and health outcomes assessment
Elias Mpofu, University of Sydney-Cumberland, Australia

Patient or consumer rights include their access to and ownership of information used by professionals to make decisions important to treatment or lifestyle planning and care. Consequential questions of what patients or users of health care services seek to achieve from the health care services they transact take center stage. Patients or consumers of health care services have a stake in how data collected with them would help the design of appropriate treatment for lifestyle solutions. This goes beyond test scores to encompass dialogues about assessments for enabling preferred activities in typical environments for the consumers. New directions in rehabilitation and health assessments are suggested when data on typical environments enables for consumers in the context of their actual and aspired lifestyle solutions are prioritised.

Symposium title: Psychological assessment at the crossroads: Methodological advances and psychometric standards
Convenor: Kurt Pawlik

Using ambulatory assessment methodologies to capture daily life experiences
Barbara Lehman, Western Washington University, United States of America; Tamlin Conner

Important psychological questions often focus on the dynamics of individuals as they participate in natu-
Psychometric contributions to the longitudinal assessment of change
Kurt Pawlik University of Hamburg, Germany

There have been many considerations of the importance of reasonable measurement in behavioural science research. But it is also clear that the collection of longitudinal data provides special challenges. Some of the earliest challenges came from classical considerations about the “unreliability of difference scores” (see Cronbach & Furby, 1970; Nesselroade, 1972). Some of these challenges have been overcome by contemporary uses of structural equation models (Joreskog & Sorbom, 1979; Horn & McArdle, 1980). Special representations here include: (1) using multiple variables with factorial invariance over time, (2) using reliable latent variables to represent changes, and (3) using reliable latent variables as primary predictors of changes (see McArdle, & Nesselroade, 1996, 2011). In this presentation, we will use recent longitudinal data on adult cognition to provide a direct comparison of the classical approaches and the contemporary approaches.

Symposium abstract
Kurt Pawlik University of Hamburg, Germany

Beginning with Charles Spearman’s (1904) founding article on the measurement of general intelligence and classical reliability theory, methods of psychological assessment and their psychometric foundation have given rise to what is now a top-leading field of psychological expertise and practice. This symposium will bring together novel approaches in assessment that transcend conventional standards in data acquisition, test design and analysis. So an international panel of experts will introduce designs of psychological assessment beyond conventional questionnaires (presentation 1) or retrospective self-report data (presentation 2), state of the art in the assessment and analysis of intra-individual change (presentation 3), and standards of culture-fairness in cognitive testing (presentation 4).

The technique of objective personality-tests sensu R.B. Cattell nowadays: The Viennese pool of computerised tests
Kurt Pawlik University of Hamburg, Germany

Consideration of the current scene of personality testing reveals that it is primarily personality questionnaires that are being applied, but that so-called Objective Personality-tests sensu R.B. Cattell (or, in more modern terminology: tests for experiment-based assessment of behavior), which have lately been experienced a certain “renaissance” within German speaking countries, are almost not in use. For this reason, a review is given of their typical properties and principle advantages over personality questionnaires. They are primarily lessfakeable. As an illustration, several such tests stemming from a Viennese research group are presented, and their psychometric qualities and shortcomings discussed.

Finally, several applications of these tests already in practice are listed.

Psychometric contributions to the longitudinal assessment of change
Kurt Pawlik University of Hamburg, Germany

There have been many considerations of the importance of reasonable measurement in behavioural science research. But it is also clear that the collection of longitudinal data provides special challenges. Some of the earliest challenges came from classical considerations about the “unreliability of difference scores” (see Cronbach & Furby, 1970; Nesselroade, 1972). Some of these challenges have been overcome by contemporary uses of structural equation models (Joreskog & Sorbom, 1979; Horn & McArdle, 1980). Special representations here include: (1) using multiple variables with factorial invariance over time, (2) using reliable latent variables to represent changes, and (3) using reliable latent variables as primary predictors of changes (see McArdle, & Nesselroade, 1996, 2011). In this presentation, we will use recent longitudinal data on adult cognition to provide a direct comparison of the classical approaches and the contemporary approaches.

Recent developments in cross-cultural cognitive testing
Fons Van De Vijver Tilburg University, Netherlands

The use of intelligence tests to establish similarities and differences in cognitive functioning across cultural groups has a remarkably long tradition. Yet, a century of research has not lead to a clear-cut answer to the issue of similarities and differences. I will describe the scientific highlights in the assessment of intelligence of this century. The conclusion will be that our insight into the nature of intelligence has grown considerably and there is fairly widespread agreement about the structure of intelligence in various cultures. However, we have been less successful in our endeavours to understand cross-cultural differences in scores. I will argue the strong tendency to export western tests to non-western countries and not to adapt tests locally has become counterproductive. I will illustrate how various sources of bias are present in exported tests and how these biases can be avoided. The argument will be illustrated on the basis of a study, conducted in South Africa, in which tests were adapted for use among white (Afrikaans speaking) and black (Tswana speaking) children. It was found that the size of the cross-cultural differences observed strongly depended on the familiarity of the children with the cultural background of the stimuli. It is concluded that the quality of cross-cultural intelligence testing could be enhanced by the use of culturally more appropriate stimulus materials.

Interactional pattern analysis
Charl Vorster North-West University, South Africa

Traditional approaches to diagnosis within the field of mental health are of limited value to the psychotherapist because the fitting of individuals into predetermined categories strips the individual of his or her unique qualities and potentially useful information for the psychotherapeutic process gets lost in the process. This, however, seemed inevitable in applying the mental health model. In contrast, Interactional Pattern Analysis, developed within the theoretical paradigm of the eco-systemic approach, seemingly offers an alternative psycho-diagnostic procedure that retains the uniqueness of the individual and yet provides a schematic and orderly procedure of indication for psychotherapy that has proved to be highly effective in directing the psychotherapeutic process. Interactional Pattern Analysis focuses on 17 interpersonal variables imbedded in the interactional patterns within the various interpersonal contexts in which an individual exists. During a one-day workshop delegates will be introduced to the concept of Interactional Pattern Analysis and equipped to start utilizing the procedure as an integral part of the psychotherapeutic process. In the workshop the theoretical rationale behind the procedure will be briefly introduced. This will be followed by a series of hands-on interactive practical interpersonal exercises that will aim at equipping delegates with the necessary frame of reference, an enhanced level of perception regarding the relevant interpersonal variables and an introduction to the actual process of producing an Interactional Pattern Analysis.
the willingness to voice this victimisation. The failure to voice incidents of workplace aggression may suggest that the aggression is not of concern, and does not allow the organisation to address the issue, ultimately perpetuating the problem. These results are important in that they suggest that there are policies and practices that organisations can engage in that will influence the likelihood of reporting workplace aggression.

**Symposium title: Approaches to teaching ethics in psychology**

**Convenor: Stephen Behnke**

Teaching psychology ethics to students using role-play and group discussions

Yesim Korkut Bahcesehir University, Turkey

One of the aims of undergraduate psychology education is to teach students to be sensitive to ethics. Learning of code(s) of ethics and to understand why our profession needs codes of conduct (Ruiz, 2009) is of the utmost importance. Therefore we should find ways that students “internalize” this. There can be several diverse methods to teaching ethics in psychology. For example, using case vignettes is a widely used teaching method by many lecturers. Some extra learning strategies would help students learn and discuss better. Case studies role-played by the students and discussed in small groups is a very effective method. Using films and media coverage related to ethical issues in group discussions would also be a good way to vitalize the learning process among students. Through these activities they can be quite active. In this specific presentation these techniques and the impressions of undergraduate psychology students about these various techniques will be portrayed.

**Symposium title: Assessment of problem solving: The unsolved issue of construct validity**

**Convenor: Samuel Greiff**

One factor or many? Dimensions of complex problem solving ability

Andreas Fischer Germany

Complex Problem Solving (CPS) is understood as the process of (a) finding a parsimonious representation of a situation that is complex, i.e., which contains a lot of highly interrelated elements; (b) finding solutions based on these representation. Dörner (1986) proposes to use complex computer simulations to measure the operative aspects of intelligence relevant for representing and solving complex problems. In those simulations a problem solver usually has to (a) accomplish a set of multiple goals by (b) manipulating many variables, with each variable potentially having (c) a lot of effects while (d) the structure is partly transparent to the problem solver and (e) the problem’s state may change dynamically, i.e., independent of the problem solvers actions. According to Funke (2001), these features correspond to certain facets of CPS: (a’) Evaluation and priority setting in case of conflicting goals (= evaluation). (b’) The sparing of irrelevant information (= reduction of information). (c’) Successive generation of an adequate internal representation of the system structure (= model building). (d’) Exploration of important information (= information retrieval). (e’) Control of the system with respect to the system’s dynamic (= system control). We want to give a short review of modern CPS testing devices, and we will present empirical data from several studies, supporting the assumption of multiple facets of CPS (e.g., correlations corrected for attenuation mostly between r=0.42 and r=0.72 with α=.75). Implications of these results are be discussed.

**Dimensionality of analytical and dynamic problem solving competence**

Jens Fleischer University of Duisburg-Essen, Germany

The competence to solve both analytical and dynamic problems is of crucial importance in almost all domains of learning and achievement. In analytical problem solving, relevant information is explicitly stated or can be inferred, whereas in dynamic problem solving information needed to solve the problem has to be generated in an explorative interaction with the problem situation. Since the first assessment of problem solving in an international large scale assessment in the Programme for International Student Assessment (PISA) 2003, the concepts of analytical and dynamic problem solving competence have received growing interest. Yet, questions concerning the construct validity of both competencies remain. Most notably, it is still unclear if problem solving competence is 1-dimensional (as was modeled in PISA 2003 and will be in 2012) or if it is a multi-dimensional construct (e.g., representation and solution as separable subdimensions). Two studies on the dimensionality of analytical (N=2452) and dynamic problem solving competence (N=140) by means of item response theory (IRT) and confirmatory factor analysis (CFA) will be reported. Results from IRT analysis and CFA as well as differential relations of the problem solving dimensions with students’ school achievements, school track and gender suggest a three-dimensional competence structure for analytical and dynamic problem solving. Depending on the purpose of the assessment, the multidimensionality of analytical and dynamic problem solving should be accounted for, although the loss of information by modeling both competencies on a 1-dimensional scale might not be severe.

A modern understanding of complex problem solving approach and measurement

Sascha Wuestenberg Germany

Complex Problem Solving (CPS) is seen as a cross-curricular competency, which has recently attracted interest in large-scale-assessments. In fact, for the PISA 2012 cycle, CPS will be assessed using minimally complex computer simulations to gain knowledge on important facets of problem solving, such as (1) the acquisition of knowledge and (2) its subsequent application. Albeit its high ecological validity, empirical research on CPS has been scarce. In this talk, we (1) conceptually introduce MicroDYN, a computer-based test containing multiple items aimed to measure the two aforementioned aspects of CPS. The concept underlying MicroDYN is identical to the PISA 2012 understanding of problem solving and conceptualises CPS as a domain general mental ability, which can be informed by domain specific knowledge and previous experience without relying on it. Further, (2) psychometric properties of MicroDYN are presented, including analyses of measurement invariance regarding different class levels (N=855 Hungarian students in classes 5 to 11). Results showed CPS to be strongly factorially invariant and thus, mean differences between class levels could be interpreted meaningfully. More specifically, latent mean comparisons showed an increase in knowledge acquisition at higher class levels even though this was not consistently the case for knowledge application suggesting that only some aspects of CPS may be sufficiently fostered in school. The assessment of CPS is an important step in measuring cross-curricular competencies of high educational relevance. Results of this study provide important implications on how to use CPS in an assessment context.

**Symposium title: Clinical psychology in the background of culture collision between the East and West**

**Convenor: Weidong Wang**

Establishment, revision of norms of five-pattern personality inventory of TCM psychology

Qiuli Yang China Academy of CMS, China; Chong-cheng Xue
In classical traditional Chinese medical literatures, a lot of statements upon personality and constitution are recorded. In the Yellow Emperor Medical Canon there are two special chapters related to them. One from Yin-Yang theory classifies people as five personality patterns which have different internal components of the body and the other from Five Elements theory as well as the external structures of the body. This classifies people into five body types which have different characters. The former sees the ancient Greek temperaments as well as the works of Pavlov and Esencky except one balanced more, and the latter is like Kretschmer’s study. Based on reference of literatures and the authors’ own clinical experience four examining methods about personality and constitution were established. They are titled as Five-Pattern Personality Inventory. More than 14,000 people from China mainland received four examinations. Both the samples and the examining tools were standardised according to internationally accepted rules. Norms that include national and regional general and sex, national general age, education and occupation etc. are established. For thousands of years in the study of temperament it is said that there is a specific correlation between character and constitution. Our results are not so definite except yin and yang. One’s pattern of constitution and personality are not one or the other, but a combination. This work is the successor and development of TCM and is useful for prevention and treatment of diseases especially for the individual. 

Symposium title: Computer-based assessment and how it affects the construct of problem solving
Convenor: Jens Fleischer

Testing of equivalence between paper-pencil and computer-based tests of analytical problem solving
Florent Buchwald University of Duisburg-Essen, Germany

Analytical problem-solving competence is of crucial importance in almost all domains of learning and achievement. Yet questions concerning the construct validity of the competence still remain. Most notably, it is unclear if analytical problem solving is unidimensional (as modelled in PISA 2003) or if it is a multi-dimensional construct. Furthermore, it is unclear if a computer-based assessment of analytical problem-solving is equivalent to a paper-pencil based assessment (as conducted in PISA 2003). In order to test the dimensionality of the construct, the authors developed several scales assessing different aspects of analytical problem-solving: knowledge of concepts and procedures, conditional knowledge and planning ability. Due to various advantages of computer-based testing (availability, effectiveness, possibility of feedback, log files) the authors plan to administer these scales computer-based. An optimal designed computer-based test has to be equivalent to the original paper-pencil test, which not only concerns the construct validity but also the fairness of the test. In an experimental study the problem-solving scales are presented either as paper-pencil or computer-based test. Equivalence of the test media will be analysed by means of confirmatory factor analysis and by analysing the relations of factor scores with external variables, such as school achievement, reasoning ability, school track, gender and frequency of computer usage. Results from a pilot study indicate similar results in the paper-pencil and the computer-based test for the planning scale.

Technical challenges in computer-based assessment: An IT-perspective
Michael Dorochevsky, ACER, Australia

The development of the “CBA Item Builder” platform has started in 2007 to support the “Electronic Reading Assessment” option of PISA 2009. Since then the system has been continuously extended notably for assessing complex problem solving competencies incorporating dynamic systems (Micro-DYN) and finite state machines (MicroFIN). Our platform has been used in various large and medium scale assessments like PIAAC 2011 and at different universities. The core piece of the CBA Item Builder Platform is a graphical authoring tool which can be handled by test developers without any programming knowledge. We report about the technical challenges we faced during the development and the experiences gained when performing assessments. We investigate how to enable efficient construction of items, in particular for complex problem solving. We address the issue of item translation for international use, including left to right languages with possibly bidirectional tests. We analyse how to automate scoring, in particular for complex problem solving. We examine different approaches to deliver computer-based tests, from a stand alone system up to the internet and "the cloud", from a PC up to a tablet or smartphone and the implications related to performance and security. We also look into the aspects of integration (e.g. in e-learning platforms) and platform independency. Building upon these experiences we deduce general principles and requirements to a system meeting the challenges of computer-based assessment. We close with an outlook on future planned collaborative problem solving items.

Computer simulations over the last decades in problem solving research
Joachim Funke University of Heidelberg, Germany

For more than 100 years, problem solving research has used primarily static material like puzzle problems or insight problems. With the advent of personal computers in the 1980s, researchers interested in thinking and problem solving decided to use computer simulated scenarios as tools for eliciting interactions with dynamic problem situations (labeled “complex problem solving” or “dynamic decision making”). Today, two main approaches are available which allow to analyze problem solving activities of human problem solvers dealing with complex and uncertain events: (1) From a psychometric point of view, formal systems (linear structural equation systems, finite state automata) can be used for a systematic construction of systems with varying complexity. The semantic embedding of these systems can be arbitrarily chosen, which means that domain-specific knowledge is not needed. (2) From a theory-driven point of view, special domain-specific problems can be constructed which put specific requests on the problem solvers’ activities (e.g., balancing goal conflicts; reducing uncertainty). We will present examples from the two approaches and discuss advantages as well as disadvantages of these methodological approaches. Empirical results from different studies underline the specific gains for the development of adequate theoretical explanations. Additionally, we will point to future developments with respect to process analyses that become possible due to extensive data logging. Thus, computer simulations do not simply offer new ways of presenting interactive problem situations but additionally offer new insights into the process of problem solving itself.

Factors that influence the difficulty of problem solving items
Dara Ramalingam ACER, Australia; Ray Phlipot ACER, Australia

Computer-based assessment of problem solving allows problems of both static and interactive natures to be posed. Examples of static problems are scheduling and logic puzzles in which all relevant information is available to the solver at the outset. Problems of an interactive nature, on the other hand, require exploration of the situation to acquire additional knowledge needed to solve the problem. Examples include discovering how to use an unfamiliar mobile telephone or automatic vending machine. This study used data from the 2011 Field Trial of the PISA 2012 computer-based assessment of problem solving which comprised 34 static and 45 interactive items. Fifteen characteristics understood to influence item difficulty were posited. Each item was rated as to the amount of each characteristic it possessed, with weights assigned to the characteristics based on how important a part each was believed to play in problem solving. The items were ranked as to their potential difficulty according to the sum of the weighted ratings. The responses from approximately 39,500 field trial participants from 43 countries were analysed to obtain IRT estimates of item difficulties. Several related analyses involving the predictor characteristics were then conducted. These included a hierarchical cluster analysis of the characteristics, regression analysis with item difficulty as outcome variable, and factor analysis. A tentative conclusion is that the main characteristics predicting item difficulty are “Number of constraints to be satisfied”, “Distance to goal” and “Amount of reasoning required”.

Symposium title: Coping with stress and adversity: New findings and innovative perspectives
Convenor: Yiqun Gan

Is proactive coping a universal construct? Psychometric findings from six cultures
Benicio Gutierrez-Dona Universidad Estatal a Distancia, Costa Rica; Rolf Schwarzer

The Proactive Coping Theory distinguishes four perspectives of coping in terms of time and uncertainty, namely, reactive coping, anticipatory coping, preventive coping, and proactive coping. Specifically, this study was aimed to evaluate the unidimensionality of a brief version of The Proactive Coping Scale within and across six cultures. Psychometric characteristics of the 8-item version scale were examined among a sample of N = 2,701 participants (35% men, 65%
Symposium title: Current models of psychological competencies from around the world
Convenor: Sverre L. Nielsen

Competence-based standards for applied psychologists: The European approach
Dave Bartram
SHL Group Ltd, United Kingdom

Following a short pilot project in 1991, the presenter led the development within the British Psychological Society (BPS) of occupational standards for professional applied psychologists (Bartram, 1996). The approach adopted was to focus on performance requirements (i.e. outputs) and to define these in terms of a hierarchical competency model, with a single key purpose, multiple key roles and units and elements of competence specified with each key role. Four key roles were identified as specifically psychological with two others relating more generally to professional practice. The standards were contextualised to relate to specialisations within psychology (e.g. Clinical, Occupation, Health, Educational etc.), and relevant underpinning knowledge and skills requirements (i.e. inputs) were specified for each unit of competence.

Knowledge and understanding was represented using a four-dimensional model which will be described in the presentation. The UK approach was introduced to the European Leonardo Project group, which ultimately developed the EuroPsy, in May 2000 to encourage the adoption of a European approach that considered both inputs and outputs and not just the former. Together with the earlier work of Robert Roe (Roe, 2002), this provided the starting point for the competency model (see Bartram & Roe, 2005) that was finally developed for the EuroPsy. The presentation will outline the key features of the UK model and how it evolved as the BPS standard since 1995 and review the development of the competency model that now forms part of the EuroPsy specification.

Symposium title: Emerging issues impacting test development in four different areas of practice
Convenor: Thomas Oakland

Emerging issues impacting test development in four different areas of practice
Dave Bartram
SHL Group Ltd, United Kingdom

The growth of organizations operating on a multinational basis and the related development of the global Internet infrastructure have resulted in testing and assessment going ‘online’. We have seen traditional short-listing and recruitment procedures revolutionized by the advent of sophisticated methods to add security levels to unsupervised online assessment enabling the use of high validity instruments for pre-short-listing assessment. Key to this has been the use of item response theory in test construction in place of classical methods and the development of ‘layered’ security models. The increasing bandwidth of the Internet has also seen the growth in sophistication of assessment (e.g. multimedia avatar-based simulations now being used for job previews and situational judgment testing). The Internet has resulted in changes in relationships between test provider, test user, and test taker and has opened up new opportunities for large-volume data-mining.

Emerging issues impacting test development in cultural competence in counselling
Mark Leach
University of Louisville, United States of America

The counselling field has been at the forefront of awareness and knowledge related to cultural competence for over two decades, though developing culturally-competent interventions and assessment strategies has been limited. A brief review of current testing instruments will be offered along with a presentation of the difficulties in measuring and parsing out cultural competence from general counselling competence itself. Some suggestions will be made to reconsider the measurement of cultural competence, and its implications for training counsellors.

Emerging issues impacting test development in four different areas of practice
Thomas Oakland
University of Florida, United States of America

Traditionally, professionals have used tests to describe current behaviours and other qualities, estimate future behaviours, assist guidance and counselling services, establish intervention methods, evaluate progress, screen for special needs, diagnose disabling disorders, help place persons in jobs or programmes, and assist in determining whether persons should be credentialed, admitted/employed, retained, or promoted. Changes in test development and use are occurring in response to methodological, ethical, and other demands. This symposium will present these changes from four perspectives: counselling, industrial/organisational, rehabilitation, and school psychology.

Symposium title: Limits of generalizing in psychological research
Convenor: Kadriye Ercikan

Why criteria for generalisability should include users of knowledge claims in research
Kadriye Ercikan
University of British Columbia, Canada

Generalisation is a critical concept in all research so it is not surprising that researchers and policy makers are concerned with generalisability. However, there is both confusion about and misunderstanding of the concept. This presentation articulates different forms of generalisations across the spectrum of quantitative and qualitative research and discusses limitations of these generalisations and (b) argues for considering population heterogeneity and for including users and users of knowledge claims in considerations of the criteria for general:
isations. Two connected purposes are: (a) To articulate and discuss limitations of different forms of generalisations and (b) to argue for considering population heterogeneity and for including both use and users of generalisation claims as criteria when judging the appropriateness of generalisations. In the first part of the presentation we will present two forms of generalisation that rely on statistical analysis of between-group variation: Analytic and probabilistic generalisation. We then describe a third form of generalisation, essentialist generalisation which moves from the particular to the general in small sample studies. We discuss limitations of each kind of generalisation and propose two additional considerations when evaluating validity evidence for generalisations. In the second part of the presentation, we make a case for taking into account population heterogeneity when evaluating validity of generalisations. Second, we demonstrate a need to consider the use and the users as essential aspects of generalisability of research.

Using referents to improve generalisation in psychological research

Robert Roe Maastricht University, Netherlands

This paper addresses the practice of generalising findings from singular samples (here-and-now) to an overall population (there-and-then). This practice rests on (1) the uniformity-of-nature assumption, which posits that people are similar in their properties and behaviours, and are hence exchangeable; (2) the continuity assumption, which holds that people’s properties and behaviour do not change with history, and can hence be studied at any moment; (3) the ceteris paribus clause, which states that other factors than those examined remain the same. Psychological knowledge obtained by such generalisation is open to two major weaknesses. First, it may give a false or distorted representation of what is true for the overall population. Second, it may lead to ineffective or even harmful applications when the conditions differ from those under which knowledge was obtained. These problems can be averted by (1) using ‘referents’ to specify the conditions of any original study, and incorporating these in all publications and citations; (2) examining the invariance of findings under conditions that are different and/or change over time; (3) labeling ‘referents’ for which invariance has not (yet) been shown as ‘boundary conditions’; and (4) abstain from generalisation beyond these ‘boundary conditions’. The feasibility and potential impact of this approach is illustrated in a critical review of research articles on team diversity, team conflict, and team performance.

Linking generalisability and effectiveness: Evaluation of testing accommodations for English language learners

Guillermo Solano-Flores United States of America; Chao Wang; Khanh Nguyen-Le

This paper links generalisability and effectiveness in testing accommodations (TAs) for English language learners (ELLs) – students who are developing English as a second language. ELL TAs are modifications on the ways tests are administered (e.g., providing glossaries or translations of tests) intended to support ELLs to gain access to the content of items. Because ELL populations are heterogeneous, not all ELLs should be assumed to benefit from TAs in the same ways. Therefore, the generalisability of test scores obtained by ELLs when they are provided with a given TA speaks to its effectiveness. We focus on vignette illustrations (VIs) - images intended to illustrate terms likely to pose linguistic challenges to ELLs. We examined whether ELLs and non-ELLs interpreted VIs in the same ways intended by their creators. Students wrote their interpretations of 16 illustrations shown with and without the text of the science items they were created to accompany. Independent raters scored the descriptions’ alignment with the intended content, elaboration, epistemology, and type of discourse. Generalisability theory – a psychometric theory of measurement error – is allowing examination, among other things, of the magnitude of score variation due to the interaction of student, item, and format (i.e., the extent to which interpretations are shaped by the students’ characteristics, the content of the items, and the content of the illustrations). In addition to comparing scores obtained by ELLs and non-ELLs with and without TAs, we will use generalisability coefficients to report on the effectiveness of VIs as a TA for ELLs.

Symposium title: Lost in translation? Adapting psychometric assessments for language and culture

Convenor: Rob Bailey

A practical overview of adapting psychometric assessments for language and culture

Rob Bailey OPP Ltd, United Kingdom

This presentation will set the scene for a symposium looking at practical considerations for the adaptation of psychometrics for different languages and cultures. It will introduce best practice concepts and approaches, whilst the following symposium presentations will each demonstrate a specific example of test adaptation. The presentations will cover a varied selection of personality and aptitude assessments. Showing skilful test adaptation to another language and country is a key requirement for publishers. Successful adaptation results in assessments that accurately predict behaviours (e.g., job performance) in the new country. Many global test publishers have accumulated substantial evidence of their assessments’ ability to assess accurately in the source country (e.g., US, UK), but evidence of their assessments’ suitability and efficacy in other countries is often sparse and hard to obtain. The session will demonstrate good practice by explaining how global test brands like the 16PF, MBTI, and FIRO-B have been sensitively translated, adapted and validated in different European countries. The session will share experiences in confronting and overcoming unexpected challenges when conducting psychometric research in these countries. The objective of the session and symposium will be to give practical guidance to those wishing to adapt psychometric assessments; but will also give pointers to users of assessments: giving them greater awareness for what to look for in adapted assessments. Our discussant Hennie Kriek, will chair a panel session of questions for the presenters.

From the ground up: Designing and adapting cognitive tests for cross-cultural use

Mark Codman Australia

In the adaptation of tests to new languages and cultures, a distinction is made between translation of instruments that were originally developed in a particular language for use in a specific context, and tests that are designed for international use. The objective of this presentation is to show how cognitive ability tests that, from conception, were designed for cross-cultural use within both English-speaking multicultural groups and non-English speaking background populations can readily be applied and adapted to other cultures and languages. The abilities® suite of cognitive ability tests has its theoretical underpinnings in Gf/Gc theory and incorporates some of the latest developments from experimental psychology (the measurement of self-monitoring ability and bias in decision-making). It includes measures of fluid (Gf) and crystallized (Gc) intelligence, broad general mental ability (Gm) and cognitive speed. An overall measure of general mental ability (gma) is also derived as part of the scoring process. Strategies used in design of fluid intelligence (Gf) tests to minimise cultural bias will be discussed including item selection, graphic material and instructions. Details of investigations into adverse impact and cultural bias amongst English-as-a-first-language and English-as-a-second-language working groups in Australia will be discussed, along with data collected in testing English speaking undergraduates in India and employed graduates in South Africa. The process of making tests of Gf available in languages other than English will be illustrated through experiences in Thailand, including investigations into cultural bias.

International development of Saville Consulting online assessments

Rainer Kurz Saville Consulting, United Kingdom

Founded in 2004 Saville Consulting started with a ‘blank sheet’, 100 years of psychometric assessment experience across the team, and many ideas to enhance assessment in the Internet age. The Saville Consulting Wave® Performance Culture Framework was drafted as a hierarchical model differentiating Behaviour, Ability & Global (BAG) competency components that directly underpin Performance 360 and Job Profiler tools. The corresponding Professional Styles personality questionnaire was developed entirely based on online trials where more than 1000 participants across the world were invited to comment on the clarity and ease of translation of 428 items, and to nominate an external rater. Based on validation evidence the final version was compiled with 108 Motive and 108 Talent questions. In the development of Saville Consulting Aptitude Tests diverse content was created using innovative item formats optimised for on-screen presentation. Reviews by Ethnic Minority and regional representatives ensured that content would ‘travel’ well excluding local peculiarities and even words with US/UK spelling differences. Forward and backward translations were utilised aiming at item level equivalence with subsequent incremental improvements. Across regions with comparable socio-economic status most group differences seem to reflect sample characteristics such
Lessons learnt from the adaptation of a personality assessment in South Africa
Nicola Taylor Jopie van Rooyen and Partners, South Africa; Robert Bailey
The fact that South Africa has 11 official languages creates special challenges for the test developer. The Sixteen Personality Factor Questionnaire (16PF) 5th edition was adapted for use in the South African context with the intention to ensure that items would be equivalent across language versions. During the process, a number of challenges arose that impacted on the adaptation and translation process. This presentation focuses on the nature of these challenges, as well as the actions taken to address them, and presents recommendations to psychologists looking to adapt and translate personality questionnaires in South Africa. The discussion of these issues will take place within the context of the adaptation of the 16PF for South Africa, from the initial trials and validation using student groups (N = 2 536) to the standardisation process followed with working adults (N = 478). Special attention will be paid to the following issues: Choosing items appropriate for multilingual users of an English questionnaire; choosing items to be translated into Afrikaans and Indigenous African languages (using Zulu as an example); collecting representative data for the standardisation of questionnaires; and the applicability of imported personality models in the South African context. The objective of this presentation is to provide psychologists with practical guidelines for the adaptation and translation of personality assessments based on best practice and experience.

Symposium title: New perspectives on the conceptualization and measurement of emotional abilities
Convenor: Sally Olderbak

New perspectives on the conceptualisation and measurement of emotional abilities
Sally Olderbak University of Ulm, Germany; Andrea Hildebrandt
Socio-emotional abilities, while increasingly adopted in consensus models of cognitive abilities, still represent significant conceptual and measurement challenges for basic and applied researchers. This symposium will introduce recent developments that focus on basic and specific processes that are clearly relevant within the structure of more broadly defined emotional abilities. Each speaker investigates such abilities from an experimental, neuro-physiological, and/or psychometric perspective, and integrates these levels throughout with multivariate data and large sample sizes. This symposium begins with a detailed analysis of the status of emotion recognition abilities from faces, specifically the ability to perceive and recognise emotion in faces, and relates these established factors to factors of identity recognition and general cognitive functioning. The second talk focuses on the volitional production of emotional expressions. We discuss scoring procedures of dynamically measured facial expressive behaviour and present a measurement model of facial expressivity. The third talk brings emotion recognition and production together and investigates their relationships at the level of latent variables. In the final presentation, new assessments of emotional understanding and management (which utilise complex socio-emotional situations) are presented, along with variables designed to build a comprehensive nomological network. Such measures are potential criteria that might well be predicted by the basic socio-emotional abilities discussed in the first part of the symposium. Finally, the findings are discussed with an unaffiliated expert, Prof. Dr. Moshe Zeidner. Taken together the presentations included in this symposium help to develop more sophisticated approaches to measuring and working with emotional abilities.

Scoring and measurement model of emotion expression
Sally Olderbak University of Ulm, Germany; Thomas Pinkpank; Andrea Hildebrandt; Oliver Wilhelm; Werner Sommer
Emotion expression is a separate, but related factor, within the broader domain of socio-interpersonal-emotional abilities. Defining and effectively measuring emotion expression in faces has important implications for the applied field, and is important as an additional component in communication. A variety of workgroups have developed computer programmes that automatically assess emotion expression in faces, yet emotion expression as ability is relatively unexplored. We applied a popular emotion expression software programme, FaceReader4, to estimate the intensity of emotion expression in a dataset of 244 participants (18 to 35 years old). Participants were asked to show one of six main emotions – anger, fear, sadness, surprise, disgust, and happiness – through a series of tasks. These tasks included two calibration tasks, in order to establish individual differences in one’s range of facial muscle movement, and various emotion production tasks, where the participants were presented with either: (1) The name of the emotion; (2) a picture of an actor expressing that emotion; (3) a video of an actor expressing that emotion; (4) a picture of an actor expressing an emotion to a specific degree; or (5) a picture of an actor expressing an emotion. The participant was allowed feedback on their imitation. This resulted in data that is nested, multivariate, intensive longitudinal, and correlated. We will discuss data handling methods, and scoring procedures. Then, we will discuss our final measurement model of emotion expression, that was based on these scoring procedures.

Symposium title: Marriage and cohabitation separation adjustment
Convenor: Kim Halford

Motivational interviewing: Enhancing family mediation
Megan Morris Australia; Kim Halford; April O’Mara
Goodpost separation adjustment involves separated partners maintaining a co-operative parenting arrangement, yet this arrangement must be negotiated during the often heated climate of adjustment from a couple to separated individuals. Separated parents have to manage their own feelings about the break-up, and transcend conflicts with their ex-spouse, if they are to establish and sustain a productive co-parenting relationship. Family mediation is mandated under Australian Family Law (2006) as the preferred method to be used by separated parents to resolve conflict in regard to parenting responsibilities. However, there is no rigorous empirical research evaluating the efficacy of mediation in producing sustainable co-parenting arrangements, or the effect of mediation on child or adult adjustment. It is known that existing mediation processes often fail to produce mutually acceptable arrangements for separated parents, which often results in costly litigation and ongoing inter-parental conflict. Motivational Interviewing (MI) is an empirically-supported approach, and seems able to engage parents constructively in the mediation process. The current paper reports on preliminary results of a randomised controlled trials evaluating the effectiveness of MI in enhancing family mediation outcomes.

On the relationship of emotion expression and emotion recognition
Sally Olderbak University of Ulm, Germany; Werner Sommer; Andrea Hildebrandt
The previous presentations define and describe separate factors within the larger of socio-interpersonal-emotional ability domain, and where available, demonstrate how these abilities differ from general human cognitive abilities. In this presentation, we will show how these separate factors, specifically...
emotion expression, emotion recognition, and emotion perception, relate to one another. The factors presented in the previous talks will be related within a structural equation model, to demonstrate in what ways they tie in together. Then, we will discuss the implications of this final model, and what that means in terms of the larger of socio-interpersonal-emotional ability domain.

Assessing emotional understanding and management using situational judgment test paradigm: New conclusions

Sally Olderbäck University of Ulm, Germany; Gerald Matthews; Carolyn MacCann

There is growing evidence for the importance of emotional intelligence in applied contexts, including school, work, social relationships, and mental health. There remains, however, concern within the scientific community around validity evidence for many existing assessments. In this presentation, we will discuss a programme of research designed to develop new measures of emotional understanding and management using the situational judgment test paradigm, given in both self- and other-rating formats, and as text or multimedia. Across nearly a dozen studies, we show the measures (particularly of emotion management) have acceptable reliability, and appear to predict a range of valued outcomes (including academic performance, well-being, and coping with stress). These relationships remain after controlling for personality and cognitive ability. Nevertheless, there are measurement challenges and the presentation will conclude with some of the more sober lessons learned.

Psychosocial interventions for OVC in South Africa

Peter Baguma Makerere University, Uganda; Kassese Hara; Leickness Simabyl

OVC suffers many and severe psychosocial problems. The study identified these psychosocial problems. It assessed the psychosocial interventions being instituted by civil society and government organisations. Their benefits and barriers were identified as possibilities of scaling those good ones. Recommendations at the national and programme levels are given in the text.

Postgraduate studies in psychology and public mental health at Stellenbosch University

Ashraf Kagge Stellenbosch University, South Africa; Desmond Painter Stellenbosch University, South Africa

The presentation will showcase two masters degree programmes at Stellenbosch University that aim to build and sustain social science research capacity in Southern Africa and more broadly on the African continent and the global South. In the context of an ageing cohort of social scientists in South Africa, underdeveloped and under-funded social science research capacity in Africa, and the need for social science research to respond to growing challenges in the global South, such as economic disparity, climate change, and the burden of disease, including mental health, the symposium will present Stellenbosch University’s Master of Arts degree programme in Psychology by research and a Master of Philosophy in Public Mental Health. Both programmes provide training in state-of-the-art social science research methodology, including qualitative and quantitative approaches to inquiry and require a full research thesis as a core degree component. The MA in Psychology may be located in a range of sub-disciplines, including social, developmental, community, family, and health psychology. The M. Phil in Public Mental Health, jointly administered with the Department of Psychiatry at the University of Cape Town, focuses on research in the areas of public mental health, mental health policy, services, legislation and human rights. Both programmes offer students the opportunity to work with a mentor and conduct an in-depth research study in an area of interest to them.

Investigation into reasons for stoppages at a leading mine in South Africa

Alex Pires Jopie van Rooyen and Partners, South Africa

Mining operations are often stopped due to unsafe work environments. This most notably occurs when mine inspectors deem work environments, or work practices, unsafe. Mine inspectors then issue a Section 54 which halts mine operations. These Section 54s also impart reasons for these stoppages. In order to determine the most prevalent reasons for mine stoppages 178 Section 54s from a leading mine in South Africa were analysed using a textual analysis. This was performed so that overarching themes could be extracted in order to determine the most frequent reasons for mine stoppages. This analysis was used to extract recurring words which were clustered into sub-themes. These sub-themes were further clustered into 4 overarching themes. The overarching themes were then subjected to a frequency analysis in order to determine which of these themes were most prevalent. Results indicated that the theme Human Management Functions was the most frequent reason for mine stoppages. The theme Equipment and Maintenance was the second most prevalent, followed by Environmental Conditions and finally Accidents. These results indicate that most reasons for mine stoppages are related to operational, supervisory, training, development, knowledge, quality control, and adherence aspects followed by the organisation on a management or workforce level. A positive trend between the frequency of Human Management Functions theme and the Accidents theme was also found. Misconceptions related to mine stoppages will thus be debated based on these findings.

Influence of individual differences and organisational factors on employee attitudes to workplace safety

Leon Steyn Eskom Holdings SOC Ltd, South Africa

Research suggests that 95% of all workplace incidents (including driver accidents) can be at-
Dynamic assessment: A framework for testing potential?
Alan Cliff  University of Cape Town, South Africa

The principal focus of this paper is on the conceptual design and sample item development of a test artefact which attempts to incorporate principles of Dynamic Assessment Theory as the basis for the artefact. The paper draws on notions of providing qualitatively different levels of feedback and mediating learning through raising learners’ levels of awareness in the test-taking situation to what they are learning. The article further explores the incorporation of these (and other) principles of Dynamic Assessment in the context of what is essentially a test-taking environment that cannot involve teacher/assessor intervention – as is usually a requirement for the implementation of Dynamic Assessment. Challenges for the design of a test artefact that includes feedback as an instructional component of the test are presented and discussed. Sample items on the test – a test based on the construct of Academic Literacy – are also presented and analysed in terms of how they create the conditions for providing feedback that can be used by test-takers in subsequent test-tasks. Concluding comments attempt to address questions of whether such a test can be regarded as ‘dynamic’ and the extent to which it enables test-takers to complete test-tasks that they might otherwise have been unable to do had they not received feedback and mediation.

Assessing scientific reasoning using cognitive diagnosis models: A project between Costa Rica and Cape Town
Guauer Rojas  Universidad Autonoma de Madrid, Spain

The scientific reasoning test (SRT) was developed in Cape Town University, South Africa, because of the necessity to select educative disadvantaged students. This test takes place on the assumption that the conventional assessment won’t take into consideration the academic potential of the students. The SRT main purpose is to assess the ability to engage with the logical thinking typically required by the students in higher education. SRT evaluates the student’s capability to identify the appropriate evidence to support an assertion or an argument; criticize suppositions and thoughts that underlie the argument; understand the nature of tentative and decisive reasoning; be able to perceive the relationships between events; and understand the meaning of “chance”. The purpose of this study is to provide an alternative assessment of scientific reasoning using cognitive diagnosis modeling (CDM). A cognitive diagnosis model, namely the generalized deterministic input noisy and gate (G-DINA; de la Torre, 2011) model is applied to SRT for classification purposes. CDM is incorporated into the diagnostic assessment process as a way to provide feedback for individual examinee’s mastery levels of the attributes of interest. CDM application requires a Q matrix, which contains attribute assignment of SRT items. Data were collected from 293 students in Costa Rica. Results suggest that attribute profiles show a large difference among examinees. Furthermore, mean score differences between item master and item nonmasters are large for the majority of the items.

A comparison of 4 tests for use among applicants to the University of Costa Rica and the University of Cape Town
Maria Villarreal  Universidad de Costa Rica, Costa Rica

In order to combine efforts for improving the selection of students, the University of Costa Rica (UCR) and the University of Cape Town (UCT) are developing a joint research to implement 4 tests: The Academic Literacy Test of Academic Potential (ALTAP) and Scientific Reasoning Test (SRT) of UCT, and Quantitative Ability Test (QAT) and Figural Reasoning Test (FRT) of UCR. This study compares UCR and UCT tests regarding item and person parameters. Four tests were compared based on classical test theory, Rasch model approach and factor analysis. Preliminary results pertaining to the four tests applied in 6 secondary schools from Costa Rica show high reliability indexes. Particularly, ALTAP, QAT, FRT and SRT had Cronbach’s alpha values of .82, .50, .77 and .81, respectively. The person and item reliabilities were .76 or higher. A conducted factor analysis for each test provides information for measuring each construct. Furthermore, evidences supporting the construct validity of the test scores were found. Remaining results and conditions under which the four tests can effectively be applied will be presented and discussed at the meeting in Cape Town.
Measurement of academic literacy using a South African test applied in Costa Rica
Maria Villarreal Universidad de Costa Rica, Costa Rica

Tests are made for measuring people’s skills and abilities; however, the vast majority of tests focus on reporting a single score, used by teachers and practitioners to make students’ selection or classification. Therefore, it is important to provide more information on the performance in tests to benefit both, the students and the institutions. Hence, detailed information on the level of performance on the construct of interest (i.e., academic literacy) is required. Using diagnostic information will allow item test makers to have more clarity in order to develop tests in regards to the construct measured. Therefore, in order to collect valid evidence, cognitive diagnosis models (CDMs) approach seeks the attributes measured in items, in relationship to the specific skills measured in a test. The data were collected from 297 students in Costa Rica. These data were responses to 50 items involving 10 attributes of The Academic Literacy text of Academic Potential (AL TAP). AL TAP aims to assess academic literacy defined by 6 domains of students’ abilities to (1) make meaning from texts that they are more likely to encounter in their studies; (2) understand words and discourse signals in their contexts; (3) identify and track an academic argument; (4) understand and evaluate the basis of an argument; (5) extrapolate and draw inferences and conclusions from what is stated or given; and (6) differentiate main from supporting ideas in the overall organization of a text. Results show that CDMs provide particular information concerning levels of student’s mastery.

These include strategic planning regarding membership – addressing the needs of student, early, mid and seasoned career members, governance structure, enhancing financial resources and human capital, increasing capacity to be responsive to community needs, identity and philosophical challenges, and overcoming the proclivity toward individual internalisation of the Western academy.

Fundamental task and challenge of black psychology
Cheryl Grills Loyola Marymount University, United States of America

In recognising that the mental health and well-being of African people world-wide is directly dependent on our ability to assist in the re-conceptualisation and reconstruction of African (black) people’s reality independently of Eurocentric thought and Western hegemonic, white supremacist conceptualisations, this presentation will suggest that black psychology is the critical discipline missing from the discourse on Africa’s renaissance and development and recommend that the discipline of black psychology serve as a key praxis in the restoration of the African mind, identity and consciousness. It will further outline the fundamental task and challenge of black psychologists to defend and promote the interest and image of Africa and Africa’s children by understanding the past, present and future of our human story through the Africanisation of the epistemological, terminological, aesthetic and hermeneutical groundings of the scientific, artistic and investigative discourse.

The challenges facing the Association of Black Psychologists
Cheryl Grills Loyola Marymount University, United States of America

This presentation will address the challenges faced by the Association with respect to elements considered vital to the Association’s life and growth.

The future of the MBTI assessment: A new scoring approach based on latent class analysis
Michael Morris OPP, Inc., United States of America

The MBTI assessment has been through several revisions since its introduction in 1942, and in the near future a new form will be released for use internationally. This paper briefly describes the history of MBTI scoring approaches, including the current item response theory (IRT) based approach, and details the scoring approach underlying the new form, latent class analysis (LCA). The LCA approach has two primary advantages over previous scoring approaches. First, LCA is based on the assumption that people are members of categorical latent (unobservable) classes. Past approaches were based on computing a continuous score and dichotomizing the result to get the MBTI preference categories, while the LCA approach is built on the assumption that the categories exist and that item responses are caused by one’s membership to the MBTI preference categories. In the present context, this assumption means that the statistical theory of LCA aligns with MBTI theory, in that people are either Extraverted or Introverted, Sensing or Intuiting, Thinking or Feeling, and Judging or Perceiving. Second, the LCA approach allows for computation of a posterior membership probability for each preference assignment, giving assessment takers a more intuitive idea of how accurately the new MBTI assessment predicted their preferences. In contrast, the current approach reports “preference clarity indexes”, which are difficult for end users to understand. Other advantages of the LCA approach and details of the new scoring approach, including adjustments for different countries and languages, are discussed.

The distribution of psychological type in South Africa
Nicola Taylor Jopie van Rooyen and Partners, South Africa

The Myers-Briggs Type Indicator instrument was first distributed in South Africa in 1993, and has a long history of use and research in the country. In 1997, the first study documenting the distribution of
psychological type in South Africa was published. Over the last decade, many changes to the political landscape, working environment, and general way of life in South Africa have occurred. This study provides a follow-up to the initial study to examine whether any changes can be found in the distribution of psychological type in South Africa. The sample consisted of 10,705 South Africans who completed the MBTI assessment between 2004 and 2010. The ages ranged between 14 and 74 years. From the total sample, 2,967 respondents indicated their group ethnicity. In this study we examine similarities and differences in type distribution across population groups in South Africa, and compare the South African type distribution to those found in previous studies to examine changes over time. Patterns within specific job categories are also explored. The implications of these differences in type preference will be discussed.

Revising the Myers-Briggs type indicator: A global collaboration
Richard Thompson CPP, Inc., United States of America
Recently, a revision of the Myers-Briggs Type Indicator (MBTI) assessment was undertaken by the publisher. Unlike many personality assessments that are initially psychometrically developed and commercialised in one country, then translated and adapted into other languages and cultures, this revision started with a global approach. Specifically, the publisher of the MBTI, along with distributors in Europe, Australia, and Canada, along with the copyright holders of the intellectual property created a committee to oversee the revision. This session will discuss the development of the research project, and discuss how the various parties collaborated to develop a large scale revision that is global in nature. This revision involved translation of a research form of the MBTI, originally compiled in Europe from a pool of items developed in the United States. Following the International Testing Commission translation and adaptation guidelines, the research assessment was adapted into 20 languages. Data were collected in 22 countries using these languages, using a multi-wave approach to collect the data. Data were then analysed using classical test theory, Item Response Theory, and Latent Class Analysis to arrive at a final Step I MBTI Instrument that can be used globally. This approach to developing an assessment provides a template for test publishers who wish to have a more global and inclusive development process.

The equivalence of the Myers-Briggs type indicator form M across language versions in South Africa
Casper Van Zyl Jopie van Rooyen And Partners, South Africa
The Myers-Briggs Type Indicator (MBTI) instrument has been used successfully in South Africa (SA) for many years. Although SA has a diverse population when compared to the more homogenous population of the USA, local research has found that the questionnaire is appropriate for use in this context. In an attempt to satisfy the ever increasing demand, the MBTI questionnaire has been translated into Afrikaans. It often occurs during translation that no adequate terms exist in the translated language that convey the exact same meaning in the original language or that the most appropriate terms may represent an older and out-dated use of the language. For this reason it is important to investigate whether such effects have a significant impact on the psychometric functioning of the translated version. In this study, we present the process and difficulties experienced in creating an Afrikaans translation of the MBTI instrument in South Africa. Data from 505 Afrikaans-speaking South Africans were obtained. We examined the psychometric equivalence between the Afrikaans translation and English versions of the MBTI Form M. This involved analyses from both an item response theory and classical test theory perspective. The results obtained in this study and implications for the continued used of the Afrikaans translation of the MBTI instrument in South Africa will be discussed.
Predicting training performance of air traffic controller trainees: Challenges and latest findings
Kristin Conzelmann DLR German Aerospace Center, Germany; Doris Keye; Dietrich Grasshoff; Alexander Heintz; Hinnerk Eissfeldt

The job of an air traffic controller (ATCO) is highly specific and demanding. The assessment of potential suitable candidates requires a customised and efficient selection procedure. The German Aerospace Center (DLR) conducts a multi-stage selection procedure for ATCO applicants of Air Navigation Service Provider (DFS) which is highly selective and difficult to pass. Successful applicants complete an initial training at the Academy and a unit training phase in life traffic. The final training success rate of more than 80% at DFS is rather high compared to other countries. Validity studies are scarcely reported in the international scientific literature, since specific challenges (i.e., effort, sufficient sample size, appropriate methodology, continuous changes of the process) have to be handled. The validation study at hand encompasses the complete data of 476 ATCO trainees of the DFS from the selection of candidates to the completion of their training and the corresponding reference data of 13,716 applicants. Univariate and multivariate data analysis involves the prediction of training success, training performance, and trainees’ personal evaluation of the selection and training process. The findings demonstrate that selection measures were adequate to predict criteria from initial training (i.e., theoretical exams). Basic ability measures and a semi-structured interview predicted success in training best. Performance in early training courses was positively related to successive stages and to overall training success. The findings and challenges that have been encountered in this validation study are discussed, and recommendations for future validation studies in the field of ATCO are provided.

Study on pilots’ cognitive situation
Wei Liu Beijing University of Posts and Telecommunications, China

The aim of this paper is to study the problem of evaluating pilots’ cognitive situation. The model of fuzzy comprehensive evaluation on pilots’ cognitive situation was built from the concepts and methods of environmental quality evaluation in environment science. After theoretical consideration and analysis of experimental results, the status of pilots’ cognitive situation were opened out primarily. The result shows that the fuzzy comprehensive evaluation method on pilots’ cognitive situation can provide real, complete and reliable cognitive information of situation for pilots’ training and safety.

Emotional intelligence and management of episodes with disruptive passengers by airline cabin crew
María Jose Pinar-Chelso Universidad Autonoma Barcelona, Spain; Jordi Fernandez-Castro

The aim was to prove that emotional intelligence is a necessary ability for cabin crews to be able to suitably handle unruly passengers. According to the emotional intelligence cascading model, 28 crew members were selected. 14 had obtained high scores and 14 had obtained low scores in the MSCEIT emotion management scale. They were recorded during a role play conducted with an actor playing the part of a highly troublesome airline passenger who had violated a safety regulation. Their abilities to identify emotions from faces, voices and postures were measured, as well as the emotional work strategy they employed. Six judges – five customers and one expert – evaluated the videos using a rating scale with 30 items, which included communication, quality of service, persuasion, passenger’s aggressiveness control and an overall score. The MSCEIT emotional facilitation scale (χ²=44 p<.01) and the strategy of concealing emotions (χ²=.74 p<.01) predicted perceived stress (R²=.55). For customer-judges, the ability to identify emotions from postures predicted scores in non-verbal communication (ICC=.60), voice (ICC=.40) and credibility (ICC=.44). High-scoring participants in the MSCEIT strategic area received better overall scores (t(20)=2.12, p<.05) by the expert, and were more skillful at containing the potential aggression of the difficult passenger (t(20)=2.08, p<.05) for customers (ICC=.50). This experiment shows that cabin crew’s emotional intelligence is necessary for containing potentially aggressive passengers.

Risk management in military aviation: Personality traits and cognitive factors
Marie-Pierre Fornette IRBA, France; Jean-Yves Jolans; Marie Bourgy; Jacques Fradin; M-Heloise Bardel; Jean-Claude Ardouin

Research on risk-taking must integrate psychometric and neuropsychological approaches (Llewellyn, 2008). This study investigated the relationships between personality traits (e.g., narcissism, assertiveness, sensation seeking), cognitive factors (e.g., problem-solving ability, cognitive flexibility), risk-taking propensity, and actual risk-taking behaviour during an operational simulated flight. 21 fighter pilots performed a flight in a full-scale simulator. Complex and risky situations (various aircraft failures and deteriorating weather) were simulated. Personality traits, cognitive factors and risk-taking propensity were measured using questionnaires (revised NEO Personality Inventory, Narcissistic Personality Inventory) and computer-based or paper-and-pencil tests; problem solving, task switching, and Balloon Analogue Risk Task (BART). In-flight risk management was assessed based on recorded flight parameters and pilots’ behaviour during the flight, using indicators designed with the help of expert pilots. Correlations between these different variables were explored. Among personality and cognitive variables, only the problem-solving abil-
Advancing Aeromedical Standards for Pilots of Unmanned Aircraft Systems

Lesego Bogatsu

A presentation by the SA-CAA regarding recently proposed aeromedical standards for pilots of unmanned aircraft systems (UAS). The presentation emphasizes the importance of establishing clear medical certification guidelines for UAS pilots to ensure safety and compliance with international standards. It highlights the need for ongoing research and development in this emerging field.

Determining the workload of ability tasks in a job selection process.

Daniela Gundert

German Aerospace Center, Germany; Viktor Oubaid; Susanne Oechsle; Frank Zinn

The presentation discusses methodologies for assessing the cognitive demands and workload of ability tasks in the selection process for pilots. It focuses on the development of computer-based tasks to measure cognitive resources and workload, particularly in the context of unmanned aircraft systems (UAS).

Co-operative arrangement for the prevention of spread of communicable diseases through air travel (CAPSCA)

Lehlohonolo Majake-Mogoba

South Africa

The presentation introduces the Co-operative Arrangement for the Prevention of Spread of Communicable Diseases through Air Travel (CAPSCA), a framework designed to enhance international cooperation in monitoring and controlling the spread of diseases through air travel. It highlights the role of aviation authorities in implementing effective strategies to prevent the global spread of communicable diseases.

Aeromedical standards for recreational pilots, cabin crew and air traffic controllers

Michele Du Preez

University of Pretoria, South Africa

The presentation covers the development of aeromedical standards for recreational pilots, cabin crew, and air traffic controllers, focusing on the importance of comprehensive medical assessment to ensure safety and efficiency in aviation.

Vertiginous conditions of the ear and the aviator

Louis Hofmeyer

South Africa

The presentation addresses the impact of vertiginous conditions on aviation safety, discussing the importance of early detection and management of such conditions to prevent accidents and protect pilots.

Allergic rhinitis and the aviator

Louis Hofmeyer

South Africa

The presentation explores the implications of allergic rhinitis on aviation safety, emphasizing the need for comprehensive medical evaluation and management to prevent health risks associated with this condition.

New standards and protocols currently in force

Lesego Bogatsu

South Africa

A presentation by the SA-CAA regarding recently proposed aeromedical protocols, highlighting their importance in ensuring the safety and health of pilots.

Aeromedical standards for UAV Pilots

Bjorn Buchner

South Africa

The presentation covers the development of aeromedical standards for pilots of unmanned aircraft systems (UAS), emphasizing the need for comprehensive medical evaluation to ensure the safety and health of UAS pilots.

Overview of computerised aeromedical submission systems in use worldwide

Philip Buys

South Africa

The presentation provides an overview of computerized aeromedical submission systems in use worldwide, discussing their adoption and effectiveness in managing medical certification processes for pilots.
Aviation safety implications of high body mass
Samantha Mokoena Institute for Aviation Medicine, South Africa
Obesity has become a worldwide epidemic and is seen as a major risk factor for a variety of chronic diseases. There is a lot of speculation regarding the best tool to use as a measure of obesity and overweight that will be able to identify the individuals most at risk for cardiovascular disease. Amongst aircrew the prevalence of obesity and overweight is rising and this presents a concern to the aero medical community with regards to aviation safety. The increase in obesity leads to an increase in co-morbid conditions and potentially an increased risk in flight safety due to sudden medical incapacitation. In this presentation a review of the literature will be done on the best tool to use as a measure of obesity and it will also assess if there is any impact on aviation safety and aircraft accidents due to the increase in obesity amongst aircrew. Based on the findings of the literature review recommendations will be made to the SACAA.

The use of Champix in aviation?
Braam Nieuwoudt South Africa
Considering the negative effects of smoking, particularly on the respiratory system, it is easy to see why smoking cessation is considered a very good thing for a pilot. The first drug which was used to aid smoking cessation was Zyban, which falls into the category of anti-depressants, and was therefore prohibited for use by aircrew. Although Champix (varenicline) seems clinically to be better tolerated than Zyban, it is still a centrally acting drug. Varenicline crosses the blood-brain barrier, and works by interaction (as a partial agonist) with the central nicotine acetylcholine receptors. It therefore fits the definition of a psychoactive drug (a drug which acts primarily upon the central nervous system where it alters brain function, resulting in changes in perception, mood, consciousness, cognition, and behaviour). The obvious conclusion would therefore be that Champix is also prohibited in aviators. The presenter, however, asks the question whether this is necessarily the case, and explores this topic in more detail.

Fatigue/Alternative regimes
Braam Nieuwoudt South Africa
Various fatigue countermeasures and operational management interventions are described to counteract the negative impact that fatigue has on aviation operations. These tend to be based on relatively standard approaches to the management of sleep and fatigue. The author takes a closer look at some lesser known alternative regimens that can be used in the management of fatigue.

Dermatology protocols in aviation medicine
Mahendra Pramchand South Africa
An FAA study indicates that pilots have a 1.6 times increased risk for dermatological malignancies or pre-malignant conditions in comparison with people of similar race, age and sex in other occupations. The implementation of simple measures and the acquisition of inexpensive equipment by AMEs/DAMES can reduce morbidity and mortality in aircrew. A protocol including prophylactic screening of pilots for dermatological malignancies or pre-malignant conditions by means of dermatoscopy is proposed. This should promote the early detection of suspicious lesions followed by immediate excision and or referral to a surgeon with a view to biopsy and complete excision.

Incapacitation in apparently healthy individuals
Gert Saayman South Africa
Sudden death and incapacitation amongst pilots (as well as passengers) is of great importance in the aviation medical environment. A practical overview of the scope, nature and pathology of conditions which lead to sudden death, especially in persons/patients who may appear to have been previously/otherwise healthy. In addition, medico-legal perspectives and procedures regarding the investigation in such cases will be highlighted.

Forensic pathology/toxicology/accident investigation
Gert Saayman South Africa
A practical overview of forensic toxicological aspects, with specific reference to currently prevalent illicit drugs as well as prescription medication commonly abused and the problems associated with laboratory analysis, medico-legal aspects, sampling procedures, medico-legal management of specimens. Especially relevant would be the medico-legal aspects of sampling, not only after an aircraft accident, but also sampling of aircrew suspected of using substances which may affect aviation safety, and follow-up sampling of aircrew after rehabilitation.

Fatigue risk management of flight and cabin crew
Jarnail Singh South Africa
Fatigue is an important factor in flying safety, and one which often does not deserve enough attention in the operational aviation environment. International guest speaker Dr Jarnail Singh, who is the Chairman of the Civil Aviation Medical Board of the Civil Aviation Authority of Singapore, will present his approach to the important aspect of managing Fatigue in the aviation environment.

DAME Oversight in South Africa
Zumpa Sishaba South Africa
The South African Civil Aviation Authority (SACAA) is mandated to ensure civil aviation safety according to the guidelines of the International Civil Aviation Organisation (ICAO). Part of this mandate is carried out by designating suitably qualified Designated Aviation Medical Examiners (DAMES) in order to perform aviation medical examinations on air crew and Air Traffic Controllers. Although ICAO prescribes the basic curriculum for AME training, the methods used for the quality control of aviation medical examinations are not prescribed. Whereas the training of DAMES by the Institute for Aviation Medicine has been brought into line with ICAO requirements, much still needs to be done regarding the quality control of aviation medical examinations by the SACAA. This presentation makes proposals for the oversight of DAMES in South Africa.

The respiratory system protocol
Gwen Tonyane University of Pretoria, South Africa
Due to the dangerous nature of hypoxia in aircrew it is necessary to have a clear and concise protocol when dealing with disorders of the respiratory system. Compared to the protocols of countries such as Australia, Canada and Europe the ICAO recommendations, although extensive, do not always delve into sufficient detail, are in some respects inadequate and are not ideally tailored to the South African situation. The proposed protocol aims to provide clear and succinct guidelines to be followed for each specific disorder of the respiratory system.

Substance abuse in aviation: A psycho-social perspective
Susan van Niekerk South Africa
Until 20 years ago, substance abuse was almost unheard of in South African aeromedical certification, but unfortunately, is becoming more problematic. While fairly clear guidelines exist regarding aeromedical certification following substance abuse, a view of the problem which is much wider than just the question “can this person fly or not?” is required to holistically manage such patients.

Session Type: Symposia
Symposium Title: Changes and stability under a simulation of extended space flight
Convener: Iva Stuchlikova
Emotion regulation during isolation
Iva Polackova Solcova United States of America; Iva Solcova
When a small group of people is isolated for a long period of time it is important to keep the emotional level of social relations “healthy” in order to maintain a cooperative and productive atmosphere. Even people with an optimal affective disposition may demonstrate changes when meeting stressful challenges of living “cut off” from the world. Under such circumstances adequate expressions of positive as well as negative emotions may be important. In our study we investigated changes and stabilities in emotion regulation during a simulated flight to Mars. Our findings indicate that positive outweighs the negative affectivity. Although “marsonauts” sometimes experienced strong emotions with negative valence (sadness, anger, etc.) their emotion regulation strategy was usually “expression” or “deamplification” of emotions. Our findings also showed that the last third was the most difficult part of isolation. The results shall improve our understanding of emotion regulation tendencies during isolation and confinement.

Changes in visual perception during long-term isolation
Radovan Sikl Institute of Psychology, Czech Republic; Michal Simecek; Michaela Porubanova
The experience of long-term isolation may affect, among others, the subject’s visual perception. To be more specific, being exposed to the same objects and faces for a long time period may lead to the
increased rigidity of perception and a decreased
sensitivity to details. Also, being confined in the
interior obscuring open-space views may negatively
affect the sensitivity to perspective information. In
order to evaluate these hypotheses, the six crew
members of the Mars-500 project were tested in a
series of computer-based psychophysical experi-
ments for ten times in the course of their isolation.
Contrary to the expectations, the changes in crew
members’ perceptual performance were insigni-
cificant as compared to the control group. Still, the
accuracy of the generalisation of these findings is
limited due to several intervening factors.

Project MARS 500 as an opportunity to study
changes vs. stability
Iva Stuchlikova University of South Bohemia, Czech
Republic
The symposium will present data gathered during
the MARS 500 project. During the isolation period
elements of the Mars mission (travelling to Mars,
orbiting the planet, landing and returning to Earth)
were simulated. The project has been conducted by
Rusian Institute of Biomedical Problems (IBMP)
and European Space Agency (ESA) with the partic-
ipation of the six crew members (three Russian, two
European and one Chinese). The symposium will
present data regarding the changes and/or stability
of specific cognitive, emotional and motivational
processes during the 520 days of isolation. The
psychological functions associated with adaptation
to isolation will be discussed from different perspec-
tives of emotional well-being and regulation, moti-
vational processes and cognitive processing of visu-
al stimuli. Specifically, the present symposium will
present following topics: Changes in most salient
personal goals and their interaction with the central
goal of the group mission (USB), emotion regula-
tion during isolation (CAS), changes in visual per-
ception during long-term isolation (CAS), changes
in subjective evaluations of psychological state dur-
ing simulated flight to Mars (IBMP), and attitudes
toward the individual past, present and future during
the long-term isolation (MSU). The symposium will
shed light on some aspects of the dynamics of
adaptation to long lasting isolation of a small group
during a space flight.

Changes in personal goals during simulated
flight to Mars
Iva Stuchlikova University of South Bohemia, Czech
Republic; Michal Sery; Yvona Mazehoova
When a small group works on a specific task in a
isolated environment, the steady motivation to con-
tribute to the group mission is essential. However,
the dynamics of individual motivation under such
conditions is quite unclear. Although the commit-
ment to the mission goals could be seen as stable and
predominant, each crew member’s individual goals
are developing and changing (Suedfeld, Legkaia,
Brcic, 2010). The interaction between/with these
individual and central goals may vary, and thus the
overall strength and adaptivity of motivation (Klin-
ger, Cox, 2004) may fluctuate as well. According to
the Self-Determination Theory, the conditions sup-
porting the satisfaction of basic needs of autonomy,
competence, and relatedness foster high quality
forms of motivation and engagement for activities,
including enhanced performance, persistence, and
creativity (Deci, Ryan, 2002). The aim of the pres-
ent study was to investigate changes in crew mem-
bers’ personal goals and examine their subjectively
perceived satisfaction of basic psychological needs
of autonomy, competence, and relatedness. The
most salient personal goals were recorded every 3
months during the 17 months of isolation and ana-
lyzed in relation to the implicit motivational tenden-
cies, subjective feeling of purpose in life and self-
determination theory postulated basic needs satis-
faction. The results show different patterns of per-
sonal goals. These patterns vary from very stable
one to others which reflect the decrease of control
over the personal issues outside of the mission. The
results may improve our understanding of motiva-
tional states during long lasting isolation.
Building capacity for mental health treatment in the developing world: Developing and assessing the success of cognitive behavioral group treatment of anxiety disorders in a group of Tanzanian men
Rehman Abdurrahman University of Manitoba, Canada
Psychology plays a very limited role in most of the developing world; many countries’ health systems are run without any mental health policy. According to the World Health Organization, developing countries have significantly fewer resources to treat mental health problems. Pharmacological treatment is the primary mode of treatment, but is difficult to access and costly. Since CBT is proven to be very effective treatment for the most common mental health problems (i.e., anxiety and depression), and is more cost effective than pharmacological treatment, a model to develop CBT in developing countries may prove useful. An alliance of psychologists from the University of Manitoba and the Muhimbili National Hospital (in Dar es Salaam, Tanzania) conducted a group CBT program for anxiety disorders. The group consisted of 7 male outpatients from the university hospital who were diagnosed with an anxiety disorder and were open to exploring non-pharmacological treatment as the primary means of treatment. The group was run by a local psychologist, clinical psychology student, and remotely supervised by a psychologist who specializes in CBT of anxiety disorders, at the University of Manitoba, in Canada. This workshop presents the development of this project, the course of treatment, evaluation by the researchers and by participants, and challenges along the way. This method of training and treatment may serve as a possible model for future training of health care workers in developing countries for the treatment of common mental health problems, and therefore build capacity for overall availability of mental health treatment.

Prevention programmes on mental health: A systematic review
Samia Abreu Universidade de Brasilia, Brazil; Sheila Murta
Mental health disorders are a public health problem worldwide, with high costs to countries and suffering for patients and families. Preventive programmes have been seen as effective in promoting quality of life and reduced spending. The aim of this study is to identify prevention programmes in mental health, evaluate the interventions’ characteristics and describe their results. We performed a systematic review of the international literature about these programmes, published between May 2005 and May 2011. Although 51 articles have been found, only 12 of them had experimental designs. The evaluated programmes have been effective in their preventive goals, using resources of easy execution and low cost. There are few experimental studies, based on the guidelines of Evidence-Based Psychology, with no homogeneous geographical distribution and published recently, in 2009, 2010 and 2011. This shows a promising branch, which should be nurtured. The results offer implications for psychologists studies and practice, as well as for reconsidering their role in public health, social welfare and education policies.

The role of problem solving, locus of control in the relationship between obsessive beliefs and OCD
Nil Adali Okan University, Turkey; Ismail Gulum Okan University, Turkey
Studies which are conducted on obsessive compulsive disorder mostly underline cognitive processes, control feelings and automatic-obsessive beliefs. The purpose of this study is to examine the effects of obsessive beliefs on OCD symptoms and the possible mediating role of problem solving behaviours, locus of control, and depression symptoms in the relationship between obsessive beliefs and OCD symptoms. For this purpose, 176 participants were recruited from a non-clinical population (123 females and 53 male). It was a convenient sample with an age of 25.81 (S.D=5.36). All participants were asked to fill out online forms via the Internet: A demographic information form, Problem Solving Inventory, Maudsley Obsessive Compulsive Inventory, Obsessive Beliefs Questionnaire, Beck Depression Inventory and Locus of Control Scale. Data have been analyzed via SPSS software so as to constitute answers for the research. We have tested the mediating role of problem solving behaviours, locus of control, and depression symptoms on the relationship between obsessive beliefs and OCD. The data was analysed with stepwise regression analysis. The results of the study revealed that there are significant relationships among obsessive beliefs and OCD symptoms, interpersonal problem solving behaviours, locus of control and depression symptoms. Moreover, problem solving behaviours, depression symptoms and locus of control levels partially mediated the relationship between obsessive beliefs and OCD symptoms. The findings of the study were discussed in the light of the related literature.

Effectiveness of cognitive behavior therapy with incarcerated women
Saajda Agha King Saud Bin Abdul Aziz University, Pakistan
The present study investigated the efficacy of cognitive behavior therapy on incarcerated women in a Pakistani women’s jail. It was hypothesized that cognitive behavior therapy would help female inmates manage their anger and self-harm behaviors, with a subsequent improvement in their self-esteem and adaptive coping mechanisms. It was a one group pre-test post-test study conducted on 17 convicted female inmates. The women were divided into two groups, each group receiving ten sessions of cognitive behavior therapy for anger management. A third group was then formed of the self-harming incarcerated women who received six further sessions of cognitive behavior therapy to deal with their maladaptive coping mechanism. The participants’ self-esteem, level of state anger, frequency of deliberate self-harm and coping strategies were assessed both prior to and following the sessions. Post therapy evaluations did not yield statistically significant results but there was an overall improvement in the mean scores of all the variables studied. The inmates and the prison administration reported positive changes in the behavior of the participant women. Both the participants and the jail officers requested ongoing therapeutic sessions. These tentative findings, though not generalizable due to the small sample size, strongly indicate that the application of cognitive-behavioral therapy can be successful in producing positive outcomes in jail settings.

Stigma and discrimination faced by asymptomatic schizophrenics
Japeet Aahuwalia Kasturba Hospital, Manipal, India; Krishna Kadam; Usha Ram
Stigma and discrimination faced by individuals diagnosed with a psychiatric disorder who are currently asymptomatic has been minimally researched. The aim of the present study was to explore the experiences of stigma and discrimination by people suffering from schizophrenia (now asymptomatic) in rural and urban environments. A cross-sectional design, with a convenience sample of 132 patients aged 15-60 years, diagnosed with schizophrenia (any sub-type) according to the International Classification of Disease – 10, asymptomatic for at least 6 months, with less than 6 years duration of illness, attending outpatient services of psychiatric units of two hospitals in Pune, India, during the period January 2009 to August 2009, were selected for the study. The Stigma and Discrimination Questionnaire (Murthy, 2005) was administered in English/Marathi. The data obtained were analysed using descriptive statistics and Chi-square testing. The findings indicated no significant difference between rural and urban residents who had suffered from schizophrenia in facing shame, ridicule and discrimination. Urban residents were found more likely to hide their illness as compared to rural residents. Rural and urban respondents significantly differed in terms of worry about avoiding neighbours’ physical abuse, giving another diagnosis as a strategy to fight stigma, avoidance of disclosure of the illness, being turned down for a job due to mental illness even though qualified, as well as the nature of stigma in social and marital areas. The findings highlight persisting maltreatment for psychiatrically diagnosed individuals and its variation in urban and rural populations.

The effectiveness of cognitive behavioural spirituality therapy on anxiety in students
Seyedhabibollah Ahmad Isfahan University, Islamic Republic of Iran; Mohammadbagher Kajbaf
The purpose of this study was to investigate the effectiveness of cognitive behavioural spirituality therapy on the rate of anxiety in students. In an experimental study, 18 students who were clients of a counseling center in Isfahan University were randomly selected and assigned to one experimental (N = 9) and one control (N = 9) group. Eight weekly sessions of cognitive behavioural spirituality therapy were administrated to the experimental group. The Beck Anxiety Inventory was used as the pre-test and post-test for both two groups. Result: Ancova showed a significant difference between the two groups in anxiety scores in the post-test.
stage (p <0.005). Conclusion: Cognitive behavioral spirituality therapy is effective in the reduction of anxiety in students.

Comparison of the attachment styles of mothers of children with oppositional defiant disorders and mothers of normal children
Mohnaz Aliaikbari Dhekdari Payame Noor University, Islamic Republic of Iran; Asad Sadeqkhani; Aliasghar Jooybari
The current research has been conducted to compare the attachment styles of mothers of children with oppositional defiant disorders and mothers of normal children. This research is a post-incidence comparative one in which 60 mothers of children with oppositional defiant disorders and mothers of normal children were chosen by random categorizing sampling in Ilam city. The child behaviour list (reporting from the parents and the teacher) was used as a selector tool, and a questionnaire of attachment styles of the adults was used to survey the mothers’ attachment styles. The results of this research showed that there is a significant difference in the attachment styles of mothers of children who suffer from oppositional defiant disorders and the mothers of the normal children in the three styles of insecure (avoiding), insecure (ambivalent) and secure attachment at the level of p<0.05. Undoubtedly, the mother and her secure feelings about others have an important role in the behavioural and social evolution of the child, because a secure mother who is mentally healthy has a sense of belonging, friendship and confidence towards others and, more generally, the world. In relationship with others, she feels happiness, calmness and a lack of opposition towards the other.

The effect of Pivotal Response Treatment training to mothers of autistic children on family functioning
Mahnaz Aliaikbari Dhekdari Payame Noor University, Islamic Republic of Iran; Narges Chimeh; Ahmad Alipor; Tayebeh Mohtashami
This study was designed to evaluate the effect of Pivotal Response Treatment (PRT) training to the mothers of autistic children on family functioning. The statistical population of this study included all mothers of autistic children in Tehran. Twenty mothers were selected in the sample by means of non-convenience sampling and randomly assigned to two control and experimental groups. The research used a pretest- post-test design with control group and follow-up. The experimental group were trained in PRT for three months. The Parents Self-efficacy Questionnaire, Parental Stress Scale, Family Functioning and Family Satisfaction Scale were used in this study to measure family functioning. The results showed that training in PRT was significant in reducing maternal stress, increasing self-efficacy and family functioning (p<0.05). No significant effect was seen on the family satisfaction scale. Since the PRT training was effective in reducing stress and increasing self-efficacy and family functioning, it is recommended that this treatment method be taught to mothers, along with conventional methods in the field of autism, because it could be effective in improving family functioning.

Attachment, defense mechanisms and emotion usage in children in institutions during middle childhood
Zaytoon Amad Wits University, South Africa; Megan Robinson
Although the importance of attachment in the normal development of a child has repeatedly been shown (Bowby, 1961; 1979) there is a limited amount of research into its relationships with the usage of defense mechanisms and emotions. This research, therefore, investigated the relationships between attachment type, defense mechanisms and emotions during middle childhood (8-12 years) in 64 children from 4 children’s homes and 1 hospital in the Gauteng area. The children completed the Deferential Emotions Scale IV (DES-IV), the Attachment Story Completion Test (ASCT) and the Attachment Security Scale (ASS). The legal guardians of the children completed the Comprehensive Assessment of Defense Scale (CADS). Significant correlations were found to exist between the usage of defense mechanisms and emotions. The results obtained from the analyses therefore suggest a complex interplay of relationships between attachment, defense mechanisms and emotion during middle childhood for the children in these institutions. For example, the research found that certain defense mechanisms and emotions were found to be correlated in a complex and interrelated system of interactions. Similarly, although no significant associations were found between attachment, defense mechanisms and emotions, the frequency distributions provided detailed information suggesting that attachment does influence the defenses used and emotion during middle childhood. These findings suggest that further research needs to be conducted in this area to further this knowledge base and to inform the caregivers and staff at such institutions.

Brain-based therapy
John Arden Kaiser Permanente Medical Center, United States of America
This seminar will examine the role of attachment in development of affect regulation and hemisphere asymmetry. Apply a brain-based approach to treating depression, anxiety, OCD, PTSD, mood and attention deficit disorders. Understand which elements of traditional psychotherapy are relevant and which are counter-therapeutic. Discover how the synthesis of neuroscience, evidence-based treatment and attachment theory fosters optimum therapeutic outcomes. Understand the role of memory and attention in the therapeutic process. Understand how diet effects and can improve your brain. Applying the Latest Developments in Neuropsychology to Everyday Practice. Recent advances in the neurosciences have increased our knowledge of how and why people change. Brain-based therapy synthesizes neuroscience, evidence-based treatment, and attachment theory into a hybrid therapeutic approach. This model helps identify which elements of theoretical psychology are relevant and which may be counter-therapeutic. Brain-based therapy envisions the therapeutic process as a method to change the brain in order to change mood and behavior, using evidence of brain function and activity and moving beyond the theoretical school paradigm. This seminar will examine the use of brain-based psychotherapy to enhance outcomes with a variety of client populations. Participants will identify the role that brain function plays in mood, memory and behavior. You will evaluate the latest research indicating certain aspects of traditional theoretical psychology that may be counter-therapeutic. Using a synthesized model of neuroscience, attachment theory and evidence-based treatment, you will learn how to more effectively treat clients with depression and anxiety disorders as well as PTSD and OCD. Participants will develop a new way of looking at the therapeutic process to move beyond the traditional theoretical school approach. You will learn how to use this information in the therapy session to educate your clients and make the goals of treatment understandable. Course Content Brain-Based Therapy: Brain-based therapy approaches to treating anxiety, depression, trauma and attention deficit disorders. Translate knowledge of the brain into client education and motivation strategies.

Assessment of self-esteem, locus of control and management of low self-esteem among psychoactive substance abusers in federal neuropsychiatric hospital, Yaba, Lagos, Nigeria
Oyevemi Ayeni University of Lagos, Nigeria; Esther Ayeni
This study was designed to assess level of self-esteem and locus of control as well as to manage low self-esteem among psychoactive substance abusers as carried out in two stages. In the assessment stage, the Index of Self Esteem (ISE) and Novicki-Strickland Low Self Esteem Scale (N-SLCS) were administered to 50 substance abuse patients aged between 18 and 53 years. Participants were randomly selected from a population of inpatients in the drug unit of the Federal Neuropsychiatric Hospital, Yaba. In the management stage, 20 participants manifesting low self-esteem were constituted into treated and untreated (control) groups. The treated group had 10 sessions of Group Cognitive-Behavioural Therapy (CBT) over 5 weeks before post-treatment assessment of the two groups. Analysis of the data with Pearson’s product moment correlation and t-test showed that substance abuse patients had lower self-esteem than non-abusers and the locus of control of non-abusers was more internal than those of the abusers. Also, a significant positive correlation coefficient was found between ISE and N-SLCS. Furthermore, the group that had the CBT treatment had significantly lower ISE scores than the control group. The results were discussed in terms of the efficacy of the group CBT in managing low self-esteem among substance abuse patients. The use of CBT for substance abusers by clinical psychologists and other practitioners was recommended.

Burnout as correlate of psychopathology
Esther Ayeni University of Lagos, Nigeria
The main objective of this study was to investigate the relationship between burnout and psychopathology among lecturers in a tertiary institution. It also aimed at examining both gender and age differences in the manifestation of burnout and psychopathology. Three hypotheses were formulated and tested to realize the objectives: (1) There will be a significant positive correlation between the scores of the participants in MBI and PSC. (2) There will be a signifi-
The therapeutic change process
Psychotherapists

Three major instruments (MBI and PSC) were used to collect data. Participants’ age ranged from 25 to 68 years. Three major findings resulted from the study. First, a significant correlation was found between the scores of MBI and psychopathology. Second, a significant positive difference was found between male and female participants in the manifestation of burnout and psychopathology. Third, different age groups manifested burnout differently. Some of the recommendations made include: (1) Public enlightenment on causes of burnout should be taken seriously by both government agencies and NGOs. (2) Organizations should put in place activities for employees’ relaxation and incentives for belongingness.

Psychotherapists’ views on themselves and the therapeutic change process

Pallavi Banerjee Bethune College, Kolkata, India; Jayanti Basu

The study aimed at exploring psychotherapists general understanding of the therapeutic change process in individual psychotherapy and their understanding of themselves as psychotherapists. Method: The participants of the study were twenty psychotherapists from four professional backgrounds – Psychoanalyst, Clinical Psychologist, Psychiatrist, and Trained Psychotherapist (psychotherapists not belonging to the above three categories). They responded to semi-structured interviews focussing on their clinically acquired overview of the change process and filled the Indian version of the Development of Psychotherapists Common Core Questionnaire (DPCCQ). Content Analysis was used for analysing the data obtained from the semi-structured interviews. Chi square test, Kruskal Wallis H Test and Mann Whitney U Test were used to compute the significance of differences in the response of the four categories of psychotherapists. Results: The results indicate reasonable uniformity in the psychotherapists’ views on themselves and the therapeutic change process. Implications: The findings underscore the need to research the core psychotherapy processes, across therapist communities.

Therapeutic Accompaniment as a resource in the mental health care field to treat psychoses

Natasha Bazhumi Universidade de Sao Paulo, Brazil

This paper focuses on Therapeutic Accompaniment (TA) as a practice introduced in the mental health care field during the psychiatric reform in Brazil during the 1960s. TA aims to develop social reintegration strategies to enable patients suffering from severe mental illness to reintegrate with society, while respecting their individual peculiarities. The purpose of this paper is to verify which theoretical, ethical and epistemological foundations are in the psychological science field as TA does not exclusively practice in these areas. In order to do this, the paper is based on articles highlighting this topic which have been published by psychologists in Brazil since 1990. Results have shown that the basis for this clinical practice largely stems from Winnicottian and Lacanian psychoanalysis. It is concluded that TA may be theoretically well sustained, based on principles that guide psychoanalytical practice with psychoses, as a practice that sustains withdrawals and lessens the severity and allows individuals to experience social bonds.

Anxiety in children and adolescents: The roles of attachment and emotional dysregulation

Patrick Bender University of Copenhagen, Denmark; Francisco Pons; Mikael Soemhovd; Barbara Hoff

Within the last decades, research on child and adolescent anxiety has shown evidence of strong links to both attachment and emotional dysregulation. However, the way in which these three factors interact, is still a matter of debate. The present study investigated the interrelations between anxiety, attachment, and emotional dysregulation by the means of structural equation modelling (SEM) in a sample of 944 typically developing children and adolescents (510 girls and 434 boys) in the age of 9–16 years. Anxiety was assessed using the Screen for Child Anxiety Related Emotional Disorders-Revised (SCARED-R). Emotional dysregulation was measured by the Difficulties in Emotion Regulation Scale (DERS). Attachment was assessed using the Security Scale. The SEM indicated that attachment predicts anxiety in children and adolescents. However, when emotional dysregulation was entered into the model as a mediator between attachment and anxiety, the previous, direct effect became insignificant, replaced by a significant mediation effect of attachment on anxiety via emotional dysregulation. Findings are discussed with respect to theoretical implications and future research.

A study of delinquency in relation with aggression, personality and early deviance

Shaina Bhatia Ambedkar University, Delhi, India

The present investigation was designed to study aggression, personality and early deviant behaviour in juvenile delinquents. In all, 60 respondents - including 30 males and 30 females - were taken from an observation home in Ajmer, Rajasthan. Delinquents in the study were apprehended for various crimes and were awaiting trials. They were administered the Buss and Perry (1992) Aggression Questionnaire, Eysenck’s (1959) Maudsley Personality Inventory and an Early Deviance Behaviour Checklist. The results indicated high levels of anger and hostility in both male and female delinquents. Males scored higher on physical aggression and anger while females scored high on verbal aggression. The total aggression in both the sex groups was much higher than the norms for normal adolescents. Both male and female respondents scored very high on neuroticism (compared to norms for normal adolescents) and low on extraversion. On the Early Behaviour Deviance Checklist, both males and females scored very high - males showing significantly greater deviance than females. Dimensions of physical aggression, anger and hostility were correlated with neuroticism and deviance for both sex groups. In addition, neuroticism and deviance were related with verbal aggression for females. The results were discussed in light of major theoretical formulations of psychology.

The experiences of siblings of individuals with autism

Sunette Bishop University of Stellenbosch, South Africa; Charmaine Louw

Autism Spectrum Disorder (ASD) affects every aspect of a child’s interaction with his/her world and therefore should also have a detrimental effect on the siblings of individuals with Autism as it undermines social responsiveness, ability to communicate, and feelings for other people (Mash & Wolfe, 2005). However, little research has been done on the experiences of the siblings of individuals with ASD. Results regarding adjustment of the siblings of a child with a disorder are contradictory. Some studies presume that the presence of a sibling with a disability has negative effects on the adjustment of children, some show positive effects and other studies show no difference. Many studies are quantitative studies which measures and compares aspects like strengths and weaknesses, development, adjustment of siblings, family problems and psychosocial adaptability. This study will aim to explore what the experiences of the siblings of individuals with ASD are without preconceived ideas and without having to prove a hypothesis. The study shall take the form of a qualitative interpretive design. Data will be collected through semi-structured individual interviews with siblings, and questionnaires completed by parents. The research is still in progress.
Challenges in professional selection to a clinical masters programme in South Africa: Experienced hurdles
Linda Blokland University of Pretoria, South Africa; Maria Marchetti-Mercer
A professional masters programme in clinical psychology is a popular choice for post-graduate psychology students wanting to make a career in the discipline. The training itself typically demands intense academic and personal training of the students, as well as placing a drain on resources from the departments in which these training programmes are housed. Of all the applicants who enter the selection process with high expectations, only about 4% are accepted at the largest university department. In the absence of research on the topic, this paper examines what literature is available in the area of selection to these programmes, and also discusses the risks faced by university departments while engaging in the process. South African training institutions face certain specific challenges in addition to the need to be fair, ethical and sensitive. The paper draws on some experiences of a clinical programme in a South African university.

Self-regulation, psychopathology and gender in a group of university students
Karel Botha North-West University, South Africa; Wilma Breytenbach; Anke Cloete
Self-regulation is a psychological skill that helps individuals to flexibly plan, execute and monitor their own behaviour. Although it is clear that poor self-regulation is associated with psychopathology, the role gender plays is not well understood. The aim of this study was therefore to determine the relationship between self-regulation, psychopathology and gender. Participants were graduate university students (N=384) from different gender and ethnic groups. Self-regulation was measured with the Shortened Self-Regulation Questionnaire (SSRQ) of Carey, Neal, and Collins (2004). In this study, the factor structure proposed by Potgieter and Botha (2009), based on a factor analysis of the SSRQ in the South-African context, was used. Psychopathology was measured with the General Health Questionnaire (GHQ) of Goldberg and Hillier (1979), as well as with a self-compiled Alcohol and Eating Risk Questionnaire (AERQ). Data were captured and analysed using SAS. A negative association was found between self-regulation and psychopathology, but results were significantly stronger for male students. Self-regulation was found to be more important to males regarding alcohol use and to females regarding eating behaviour. Gender differences in the relationship between self-regulation and psychopathology are probably due to differences in the tendency to rely on self or others, as well as to differences in socio-cultural and control mechanisms regarding alcohol and eating behaviour.

Family psychology and therapy: Scientific advances in understanding and treating couples and families
James Bray Baylor College of Medicine, United States of America
Scientific study has advanced our understanding of couples and families and this research has facilitated the development of evidence-based interventions. This paper will review recent advances in couple and family process research. Application of these findings to evidence-based practice will be discussed. In addition, this talk will review the status of current evidence-based couple and family therapies and discuss future areas for research in couple and family psychology and therapy. The learning objectives of this talk are to: Understand current family process research and its application to couple and family therapy; understand current evidence-based couple and family therapies.

Inducing rumination and differentiating between mood and ruminative process
Jay Brinker The Australian National University, Australia
A vast amount of research has examined rumination and its relation to depressed mood and other psychological variables. Much of this research is based on Nolen-Hoeksema et al. (1999) correspondence, measure and experimental induction of rumination. The contribution of this seminal work has been invaluable, but is limited in its ability to differentiate the unique influence of rumination vs. mood. This project compared typical mood inductions, traditional rumination/distraction inductions, and novel rumination inductions on their influence on mood and cognitive performance measures. Typical mood inductions involved participants reading a series of 24 mood-valanced statements while listening to corresponding music (positive, negative and neutral). The traditional rumination and distraction conditions were those designed by Nolen-Hoeksema and colleagues. Finally, the novel rumination inductions consisted of participants reading 3 repeating mood-valanced statements while listening to a corresponding music (positive, negative and neutral). The effects of the inductions on mood were as expected with the 2 negative inductions and the rumination induction producing similar increases in negative mood, the positive rumination inductions producing increases in positive mood, and the neutral inductions producing no change in mood. Interestingly, when comparing only the two neutral conditions (sequential or repeating phrases), the novel rumination condition showed significantly more errors of attention on the cognitive performance measure, suggesting that without any change in mood, the repetitive nature of the task is affecting cognitive processes. Implications for research methodologies will be discussed.

ADHD in adults, sensation-seeking, and type-A behaviour: All the same?
Alban Burke University of Johannesburg, South Africa
Although the DSM-5 will accommodate ADHD in adulthood to a greater extent than in the past, there is still little consensus about the clinical picture. In this paper I will argue that one of the reasons is that this disorder is viewed one-dimensionally from a DSM perspective. Drawing on empirical research I will argue that the constructs (as mentioned in the title) are intertwined and that we need to look wider, including (but not limited to) “normal” personality traits that can be misconstrued as pathology. People with Type-A behaviour are often described, inter alia, as aggressive, hostile, or impatient, and that they experience interpersonal problems. These characteristics have also been described in adults with ADHD. Sensation-seeking can superficially be described as a tendency to pursue sensory pleasure and excitement. High sensation seekers typically pursue novel, complex, and intense sensations, and they tend to become easily bored without high levels of stimulation. Once again, these are typical characteristics of adults with ADHD. The ultimate aim of the study is to investigate whether these three constructs share neuropsychological substrates; however, in this paper only correlations between these three constructs will be reported. This is based on survey that was done on approximately 400 young adults. The measurement of the constructs were done by means of the Jenkins Activity Scale, Arnett Sensation Seeking Scale and the Zuckerman Sensation Seeking Scale. Preliminary findings indicate a significant relationship between ADHD, Type-A behaviour and Sensation Seeking.

Parental acceptance-rejection, locus of control, and social support in Turkish adolescents
Canan Buyukasik Colak Middle East Technical University, Turkey; Tulin Gencoz
The aim was to examine the factors associated with the psychological maladjustment of Turkish adolescents. Participants were 375 high school students (age range 14-18, M= 16.07, SD= 9.3). For this aim, several measures namely, Parental Acceptance-Rejection Questionnaire/Control: Child Version, Social Support Appraisals Scale for Children, Nowicki-Strickland Locus of Control Scale for Children, and Personality Assessment Questionnaire: Child version were administered to the students. Hierarchical regression analyses revealed that having more than one sibling and being male were associated with psychological maladjustment. Additionally, after controlling for the effects of demographic variables, perceived social support from family, from teacher, and from friends was negatively associated with psychological maladjustment. Moreover, after controlling for demographic variables and social support, external locus of control was found to be positively associated with psychological maladjustment. Lastly, maternal hostility/aggression was found to be positively associated with psychological maladjustment. The results were discussed in the light of the literature.

Effects of treatment focused on trauma in victims of intimate partner violence
Eduin Caceres-Ortiz Universidad Catolica de Colombia, Colombia; Francisco Labrador
The purpose was to evaluate the adherence to and effects of a group treatment focused on the trauma of women victims of intimate partner violence (IPV). The participants were 47 women, 82.5% with complex trauma and 17.5% with only IPV. The instruments used were: attendance and assignment records, scales of satisfaction with the treatment and change perceived, and follow-up interviews. Participation in the treatment was 85.1%, with a 14.9% abandonment rate. Of the 40 women who completed therapy, 95% attended the eight sessions and 5% attended six. The easiest assignments and techniques used during and after treatment were breathing, problem solving and stop
thinking. The least used and of greatest difficulty were cognitive restructuring and carrying out of pleasing activities. The perception of change and satisfaction with the treatment was high, as was the adherence of the therapists. Follow-ups show that 75.8% of women use the techniques learned in couple conflicts and other situations. The conclusion is reached that the treatment was effective, with good indices of adherence of participants and therapists. It is recommended to review the exercises of the cognitive component.

Holding addiction and relapse in mind: The psychotherapy of addictive behaviour

Alexander Carter UCT, South Africa

A broad body of theory and clinical knowledge has developed over the last 25 years that has led to new developments in understanding the theory of mind, self and affect regulation. Mentalizing has been a conceptual cornerstone in these developments and is understood as the psychological process people develop in order to hold mind(s) in mind. Mentalizing as a theory has roots in attachment, developmental neurobiology and contemporary psychoanalytic thinking. In clinical practice mentalizing holds powerful explanatory potential and evidenced value in psychotherapeutic practice. Sub stance Dependence Disorder is currently largely understood as a brain disease and recidivism as inevitability a consequence of the disease’s process. This suggests psychotherapeutic interventions have a somewhat limited role to play in the treatment of SDD. This paper presents themes from the preliminary analysis of transcripts of interviews with ten counseling dyads (counselor and patient) in a residential addictions treatment context. The paper will aim to show, from the point of view of critical psychology and mentalizing, how ‘collapse’ in mentalizing occur in the counseling relationship in the addiction treatment context. It is posited that these ‘collapses’ in mentalizing play a significant role in the efficacy of addictions counselling. The paper further aims to explore mentalizing in the context of addictions counseling regarding what influence adopting this frame of reference may have on understanding recidivism and Substance Dependence Disorder (SDD). This paper argues for the validity and therapeutic value of mentalizing as a concept, therapeutic process and intervention in the domain of addictions psychotherapy.

Endophenotypic strategies for schizophrenia research for psychologists: A link between genetics and clinical manifestations

Raymond Chan Institute of Psychology, China

The identification of genes with large effects that contribute to susceptibilities to neuropsychiatric disorders such as schizophrenia has not been very successful. Increasingly powerful molecular genetic approaches exist (New Nature S. Purcell et al. 2009), not unlike the state of affairs for type-2 diabetes (Zeggini et al., 2008). One possible limitation of these studies is that carriers of vulnerable genotypes may be classified as ‘normal’ unless they exhibit a full symptom manifestation of them as a diagnosis. Psychiatric diagnoses are likely to be heterogeneous as not all people with the same diagnosis carry the same susceptibility genes. A new encouraging direction is the identification of endophenotypes, characteristics upstream of symptoms and downstream of genetic polymorphisms, which may be more closely linked to gene expression. A substantial number of studies, especially of at-risk offspring, have suggested that neurocognitive dysfunctions are among the most promising of the candidate endophenotypes. Neurological indicators in schizophrenia have been recognized as among the ‘target features’ through which genetic and non-genetic processes lead to neuro-integrative defects that later manifest in neurocognitive systems. As such, aberrant neurological indicators have been suggested as potential endophenotypes in schizophrenia. In this presentation, we will review the substantial evidence for the utility of quantifiable neurological soft signs as potential endophenotypes for schizophrenia spectrum disorders. Recommendations for additional research to further elucidate the potential use of neurological soft signs for schizophrenia research are made.

Event-based prospective memory deficits in depression: Evidence from eye movements

Siyi Chan Beijing Normal University, China; Renlai Zhou

To date, only a few studies addressed PM (prospective memory) and its correlates in depression. Previous results are in line with the cognitive-initiative account of depression-related cognitive deficits. The purpose of the present study was firstly, to test the prediction that clinically depressed patients have deficits compared to non-depressed control participants on the PM task commanding attention resources, and secondly, to explore further which processes may result in failures in PM of depressed patients by combining behavioural measures and eye-tracking methodology. Participants with depression (n=19) and healthy participants (n=19) were asked to perform a visual image searching task which embedded the PM task, and complete a self-report about intention retrieval after the experiment. The performances of patients with depression in event-based PM were worse than controls, especially in the condition of target plus cue trials; both patients with depression and controls showed a larger number of fixations and longer first and average fixation durations for PM conditions than ongoing conditions; patients with depression showed a larger amount of fixations and longer first and average fixation duration than controls in both ongoing and PM conditions; most patients reported they saw the prospective cue but made wrong responses. Results revealed that patients with depression may have deficits in event-based PM relative to controls, resulting from a lack of effective strategic monitoring processes or deficits in the process of inhibiting distractors, because of a reduction of overall cognitive capacity.

Case study: Substance use disorder, seizure disorder and organic mood disorder

Nandita Chaube Aligarh Muslim University, India; Roomana Siddiqui; Sanjay Pattanayak

The objective of the study was to illustrate the importance of psychotherapy, assessments and strong therapeutic alliances in an adult male with substance use disorder with the occurrence of severe and organic mood disorder. Mr. R.D. came with the complaints of irresponsible behavior, stubbornness, irritability, extravaganza, increased consumption of Alprazole and increased frequency of seizures. No history of alcohol dependence or consumption, inconvenience of urine or stools, fever, conversion, dissociative signs or psychiatric illness except the present one were found, but a history of brain hemorrhage, clouding of consciousness and loss of consciousness was found. There was no history of any psychiatric illness or any significant medical illness in the family. On MMSE the patient showed cooperation with the examiner. The rate and quantum of the speech was increased in comparison to the normal. Thoughts were preoccupied with feelings of guilt and the patient was sensitive about his children. No delusions were present. No perceptual disturbances could be found. Subjectively, the mood was reported sad and objectively the mood was observed anxious. Sixth grade insight was present. The patient also showed a disturbed profile on a Sentence Completion test and 16 PF. In conclusion, the patient showed a marked improvement over a number of interventional sessions focusing on catharsis, relaxation and rational emotive behavior therapy (REBT).

Technological adjuncts to increase adherence to therapy: The role of mobile phones

Bonnie Clough Griffith University, Australia; Leanne Casey

Homework is an important part of many therapy styles, providing continuity between sessions and allowing clients to apply therapeutic techniques in real world settings (Freeman & Rosenfield, 2002). Homework adherence has been related to treatment outcome in a linear fashion, with greater adherence being associated with better outcomes (Scheel, Hanson, & Razhavskiy, 2004). However, many psychologists still experience difficulties with patient adherence to homework. Although compliance with clinical medications has been estimated at approximately 50%, adherence with behavioural regimes is often even lower (Haynes, McDonald, & Garg, 2002). A therapeutic Smartphone Application was developed which contains electronic, interactive versions of homework tasks. This application allows patients to complete homework via the mobile phone, whenever and wherever they choose. Homework can be carried with the patient at all times, is easily accessible and usable, and can be accessed by therapists between therapy sessions. A Randomised Controlled Trial is currently being conducted, involving 120 outpatients diagnosed with an anxiety disorder. Treatment involves an eight week therapy programme utilising the Unified Protocol for Transdiagnostic Treatment of Emotional Disorders (Barlow et al., 2010). Participants in the experimental group are provided with loan Smartphones and access to the therapeutic application. Measures of adherence are collected during the course of therapy by self-report ratings and therapist observation. Measures of outcome are taken at baseline, end of treatment, and six month follow up. Preliminary results of the application are discussed in terms of impact on homework adherence, treatment outcome, maintenance of treatment gains, and patient satisfaction.
Gruesome twosome: A literature review on the male coerced female sexual offenders
Charmaine Collins-McKinell UNISA, South Africa; Elmaire Visser
Mathews, Mathews, and Speltz (1991) have developed a typology of female sexual offenders. In this paper the focus will be on male coerced female sexual offenders and their relationship. The media often sensationalises female sexual offenders; this creates an inaccurate perception of this phenomenon. When there is a co-perpetrator this picture becomes complex and perplexing. The media often considers the phenomenon in a linear manner, further distorting the picture by classifying her as the ‘victim’ or the ‘perpetrator’, thereby only considering part of the phenomenon. The aim of this paper is to consider literature on this phenomenon focusing on the family systems perspective. This perspective focuses on the system as a whole and seeks to explore the patterns of interrelationships that maintain problem behaviour. Problem behaviour may be seen as dysfunctional to the community but at the systems level it is functional (Becvar & Becvar, 2009). Hetherton’s (1999) study illustrates that sexual offences committed by females are hidden to ideali(se women and because of her care giving responsibilities. Another explanation for the phenomenon could be that her actions were as a result of domestic violence. Current literature provides some insight; but it only takes into account certain aspects of this phenomenon. There is a need to explore the relationship and the dynamics of the relationships between the female and her co-perpetrator and the factors that maintain this relationship.

Father involvement and children’s psychological adjustment
Victoria Del Barrio UNED, Spain; Miguel Carrasco
This study explores the relationship between children’s perceptions of their fathers’ involvement in children’s psychological adjustment, controlling for the effects of perceived maternal and paternal acceptance as well as fathers’ power and prestige as perceived by children. The sample was composed of 313 Spanish children (47% boys), ages 9 through 18 years (M = 12.05; SD = 2.08). Correlational and multiple regression analyses showed that children’s perceptions of maternal and paternal acceptance significantly mediated the way children experienced their fathers’ involvement. More specifically, perceived father involvement no longer made a significant contribution to children’s psychological adjustment when the influence of perceived maternal and paternal acceptance were controlled. Moreover, results varied by the level of children’s perceptions of their parents’ (fathers’ versus mothers’) power-prestige. That is, the perceived acceptance of high power-prestige fathers made a stronger contribution to children’s psychological adjustment than did the perceived acceptance of lower power-prestige fathers. Additionally, in families where fathers were perceived to have higher power and prestige than mothers, perceived paternal acceptance made the greatest contribution to children’s psychological adjustment. On the other hand, in families where mothers were perceived to have higher power and prestige than fathers, perceived maternal acceptance made the greatest contribution to children’s psychological adjustment.

Dialectical behaviour therapy (DBT) for adolescents with emotional and behavioural problems
Giofa Del Fabbro University of the Witwatersrand, South Africa
Dialectical Behaviour Therapy (DBT) is a system of therapy that combines standard cognitive-behavioural techniques for emotional regulation and reality testing with concepts of distress tolerance, acceptance and mindful awareness (Linehan, et al., 1991). This paper details the process of implementing a DBT programme for an adolescent patient population manifesting these behavioural and emotional difficulties, as well as signs of emerging personality pathology. This paper will discuss the adaptation of DBT skills from an initial unsuccessful weekly programme implementation to a one-day workshop which has proved a more successful format. In addition, such a programme has been paired with a parallel parent workshop that equips parents with skills for managing such behaviour utilising the principles of DBT. The development and adaptation of the traditional DBT programme to this format is detailed and evaluated, together with its strengths and weaknesses, and future avenues for its development and continued implementation are explored.

Measuring object relations in therapy sessions with the object relations rating scales (OQRS)
Louis Diger Universite Laval, Canada; Juergen Gallinat; Dominick Gamache; Olivier Laverdiere
Object relations theories assume that object relations are internalized as mental representations of self-object interactions laden with cognitive, affective and experiential information about the self, the other, and their interaction. These representations are used to organize interactions with others, including psychotherapists. The aim of this study was to examine how object relations activated in therapy sessions can be reliably measured with the Object Relations Rating Scales (Diger, 2001). 40 patients in the early phase of psychotherapy participated in the study. Results on interrater reliability and convergent validity (using Blatt’s scales of object and self-representations as well as Diger et al. (2001) personality organization scales (PODF)) reveal sound psychometric properties.

Evidence-based psychotherapy: Implications for the globalization of mental health services
Keith Dobson University of Calgary, Canada
The governments of many countries attend to the scientific body of evidence when they consider which health services they should include in their regulated and publicly funded health services. Within the field of psychotherapy, there have been great strides in the development and recognition of an evidence base that can be defended in the public arena, although challenges also remain. The current presentation reviews some recent developments in Western societies, and argues that psychology is now in an extremely strong position to advocate its inclusion in public health systems that focus on mental health problems. At the same time, these developments may or may not be appropriate for other cultures and health care systems. Opportunities for the globalization of mental health services, as well as challenges are discussed. It is argued that existing international organizations, such as the World Health Organization, need to be involved in the further development, evaluation and dissemination of evidence-based psychotherapy.

Healing the dragon: Heroin dependence recovery; treatment and policy recommendations
Monika Dos Santos FPDA, South Africa
The consequences of heroin dependence can be extremely difficult to escape from, resulting in unpleasant and potentially terrifying experiences. Contrary to popular belief, the reality is that many people do eventually recover. Despite the vast sums of money devoted to intervention for heroin dependents in South Africa and worldwide, the processes by which recovery occurs remain fairly unclear. Moreover, relatively little is known about the contribution of interventions and processes in facilitating such recovery. An initial descriptive study of the experiences and suggestions of 40 long-term voluntary abstinent heroin dependents was undertaken. Ongoing academic and research studies have informed policy recommendation. The findings revealed that behavior modification and the promotion of recovery occurred mostly through psychosocial/pharmacological intervention, producing a range of positive effects that facilitated natural recovery processes. Other contributors in promoting behaviour modification, and reducing HIV/AIDS risky behaviour, were identified and discussed as well. A number of challenges to successful intervention were also identified. In conclusion, clear support was obtained for the maturing-out hypothesis of heroin dependence. Although many interventions and procedures have begun to be integrated routinely into clinical practice within the South African context, pragmatic and evidence-based public health policies and interventions designed to reduce the harmful consequences associated with heroin use and HIV/AIDS need to be implemented within the South African context.

Layers of responsibility: Managing conflicting treatment, training and research interests
Marna Dreckmeier-Meiring University of Pretoria, South Africa
The Health Professions Council of South Africa states in its introduction to the Ethical Code of Conduct that healthcare professionals shall first ‘do no harm’. This principle seems sound and simple, especially to those who intend to do good; however, as soon as professionals engage in their work as clinicians, trainers or researchers, good intentions often fall short when it comes to managing the interests of various role players. This is especially true in multiple participant contexts such as family therapy. If you add a one-way mirror and reflecting team as well as an academic context (focused on professional training of clinical psychologists and on research) to the family therapy context, the coordinator of such a project has their work cut out for them. This paper explores ethical concerns encountered in the initial phases of a family therapy training and treatment project at the department of psychology at the University of Pretoria.
Mirror neuron theory and socio-emotional processing in Anorexia Nervosa: Implications for intervention

Elizabeth Du Preez Auckland University of Technology, New Zealand

This paper offers a brief review of the literature on mirror neuron theory, socio-emotional processing and its implications for the development and maintenance of interpersonal difficulties in Anorexia Nervosa. Current research supports the presence of difficulties in social interaction prior to the onset of Anorexia Nervosa. Implications of these constructs for the therapeutic relationship and intervention strategies will also be discussed.

Flexing the frame: The impact of employing multiple ports of entry in psychoanalytic parent-infant/child psychotherapy

Nicola Dugmore University of the Witwatersrand, South Africa

Daniel Stern coined the term “ports of entry” to describe the basic elements of the parent-infant system that may be the immediate object of the therapist’s technical clinical focus. Within the parent-infant psychotherapy literature this concept is widely accepted. An extended definition is employed in this interrogation of the impact of using different ports of entry on the process of parent-infant/child psychotherapy, and particularly on the psychoanalytic frame. Multiple ports of entry introduce complexity to the therapeutic process given the presence of triadic versus dyadic relationships, systemic versus individual diagnostics, competing therapeutic alliances and oscillating transferences. The maintenance of a psychoanalytic frame is challenged by issues that include shifts in the identification of ‘patient’, the use of developmental guidance, non-exclusivity of the therapeutic relationship, non-traditional sites of intervention and variations in therapy duration. Illustrative clinical material will be used to explore these complexities and challenges. Multiple ports of entry allow for an inclusion of multiple theories, approaches and relationships. These multiplicities are reflected in the developmental period that constitutes early childhood and early parenthood. An argument for greater flexibility of the psychoanalytic frame is presented. This is an important conclusion in the development of parent-infant/child psychotherapies suited for application across South African public, private and community settings, particularly given the numerous and various pressures such settings impose on psychoanalytic practice.

An investigation into pain and stress-induced analgesia during self-harm

Katie Dykes Salamanca Psychology, Australia; Janet Haines

The aim of the study was to investigate the relationship between pain and stress-induced analgesia by comparing responses of individuals who reported pain (n=10) and did not report any pain sensations (n=10) during self-harm. A cold pressor test was administered under a stress and no-stress condition as a measure of tolerance and threshold to pain. In addition, participants attended a laboratory session where they were presented with three personalized guided imagery scripts (self-harm, emotionally neutral and accidental injury) while psychophysiological measurements of heart rate and respiratory rate were taken. Visual analogue scales were used to measure individuals’ subjective responses to the guided imagery scripts. Cold pressor results indicated a significant effect for condition for the measure of tolerance, with individuals recording a higher pain tolerance during the stressful condition compared with the non-stress condition. Imagery results indicated a significant script by stage by group interaction for the VAS measure of pain. Results indicated that both groups experienced a higher tolerance to pain during a stressful condition than a non-stress condition. It is speculated that individuals engaging in self-harm experience increased levels of anxiety and a decreased ability to utilize adaptive coping skills. This distress increases the likelihood of experiencing a dissociative episode during times of high stress. Furthermore, it is proposed that individuals who experience stress-induced analgesia during self-harm have an increased propensity to experience dissociation resulting in a stronger dissociative experience and, therefore, lower levels of pain during the act.

NARRATIVE EXPOSURE THERAPY

Thomas Elbert University of Konstanz, Germany; Maggie Schauer

In narrative exposure therapy (NET), the patient, with the assistance of the therapist, constructs a chronological narrative of his life story with a focus on the traumatic experiences. Empathic understanding, active listening, congruency and unconditional positive regard are the key components of the therapist’s behavior. The autobiography is structured according to their chronological order with the help of the therapist. The aim of this procedure is to transform the generally fragmented reports of the traumatic experiences into a coherent narrative. For traumatic stress experiences the therapist asks in detail for emotions, cognitions, sensory information (visual, auditory, tactile, olfactory and gustatory) and physiological reactions, probes for respective observations and records this information. The patient is encouraged to relive these emotions while narrating without losing the connection to the ‘here and now’: using permanent reminders that the feelings and physiological responses result from memories, the therapist links the experiences to episodic facts, i.e., time and place. The exposure to the traumatic experience is not terminated until the related fear reaction presented and reported by the patient shows a significant diminution. In this way, the narrative is driven forward in a supportive but rather directly guiding style by the therapist, in order to counter avoidance and to recover the full implicit information of the traumatic experience. If requested by the client, a written report may be used for rights and human rights advocacy.

Physiological measurement of the process of perspective shift in the imagery of anger

Ekin Eremoy Dogus University, Turkey; Abdulkadir Özer; Emel Kromer

The effect of using a field vs. observer perspective on emotional experience when imagining an event has mostly relied on the subjective and retrospective self-reports of the participants. The present study aims to measure and justify the effects of the process of perspective shift on the experience of anger by using physiological responses. One hundred participants were asked to imagine themselves in a situation in which they have experienced high levels of anger. Once the original perspective they used during the imagery process was established, they were asked to shift to the other perspective and then back to the original one. Gender differences were found only in surface electromyography responses. Gender collapsed results indicated that heart rate decreased significantly when those starting with an observer perspective shifted to a field perspective. However, for females, heart rate responses were not influenced by perspective shift. Similar trends were observed in electromyography responses. This result may indicate that in anger as an emotion, holding an observer perspective has an increasing effect on level of emotional experience. The findings provide physiological evidence that perspective shift affects emotional experience. However, the effects of perspective shift in imagery of anger were quite different than the effects observed in test anxiety.

A comparison of depression and anxiety of Iranian women using hard weight loss diets

Maryam Esmaeili University of Isfahan, Islamic Republic of Iran; Saeideh Mahdavii; Shahrzad Sharlati; Zohreh Latfi; Safura Hoseini; Bahareh Mohhebi

Despite the existence of a large volume of literature and research on depression and anxiety of the general population, very few studies have focused on depression and anxiety of Iranian women using Hard Weight Loss diets (totally omitting bread, rice, carbohydrates, sugar and fat). The aim of this research was to compare the depression and anxiety levels of Iranian women on this diet as opposed to no dietary regime. Subjects were selected randomly from nutrition centers: 180 women aged 20-35, 90 single and 90 married, in Isfahan City. They were assigned to two groups: experimental (Hard Weight Loss diet) and control group (non diet). We performed a SCL90R questionnaire (validity in iranian version=0.92) for the experimental and control group individually. The results of ANOVA showed that there was a significant difference between the experimental group and control group in depression and anxiety (p $\leq$ 0.002). We believe that can use this finding only for Iranian women and suggest that this research be done for different kind of diets used by women elsewhere.

The use of therapist's self in psychotherapy

Dianne Everitt UNISA, South Africa; Boshadi Seme-nya UNISA, South Africa

Traditional psychotherapy models emphasise the acquisition of various techniques for becoming a therapist, maintaining that neutrality is required for
effectiveness. The therapist is required to wear the mask of "expert," and to remove the self from the therapeutic encounter. A shift toward a postmodem and social constructionist paradigm places the self of the therapist as central to the process of therapy. Social constructionism argues for the adoption of a ‘not-knowing’ position, meaning that the therapist is not the expert, but is open to co-constructing a unique story with the client. According to these paradigms, the self of the therapist cannot be removed from therapy, as the therapist and client are seen to co-construct meanings and reality through language. What is important then, within the context of training and in continued practice of therapy, is the self-knowledg and self-reflexivity of the therapist. Cheon and Murphy (2008) argue that the development of self and self-reflexivity might be as important in the training of therapists as the acquisition of techniques. I argue that the use of self in therapy may be a greater catalyst for change than any technique. The therapist must learn to utilise the self in a way that is an effective catalyst for change. This paper explores how the development of the self of the therapist takes place, and how the therapist can make use of the self to effect change within the context of therapy.

Exploring the cognitive origins of excessive reassurance seeking in depression
Lyndsay Evraire University of Western Ontario, Canada; David Dozois In 1976, Coyne proposed an interpersonal theory of depression that emphasised the importance of examining the social context of individuals with depression. Central to this theory is the interpersonal behaviour of excessive reassurance seeking (ERS), defined as the relatively stable tendency to excessively and persistently seek assurances from others, regardless of whether such assurance has already been provided. In the beginning, others willingly provide the requested support. However, when the individual seeking reassurance questions the authenticity of this support, close others may become frustrated. The subsequent deterioration of relationships leads to symptoms of depression and creates an environment of social isolation. A paucity of research has elucidated the mechanism(s) by which individuals come to engage in ERS. In the present study, three hundred and three undergraduates completed measures assessing early core-beliefs, ERS, and depression. Anxious attachment, avoidant attachment, and an abandonment/instability schema added to the prediction of ERS. Although ERS did not mediate the relationship between early core-beliefs and depression longitudinally, it did moderate the prospective relationship between avoidant attachment and depression and an abandonment/instability schema and depression. Furthermore, individuals who received an interpersonal partner or friend prime reported significantly higher levels of ERS than did individuals presented with the academic prime. These results are consistent with the idea that individuals seek reassurance as a result of early core-beliefs reflecting insecurity in relationships. The findings also suggest that it may not be ERS behaviour per se, but rather characteristics of the individual in combination with ERS that are associated with depression.

Stigma schizophrenia and art: A discourse analysis
Kirsten Farquharson Rhodes University, Grahamstown, South Africa; Trudy Meehan Rhodes University, Grahamstown, South Africa
This paper situates itself in the study of stigma in mental illness. In particular, we aim to explore the potential for art making and exhibiting in reducing stigma for those with a diagnosis of schizophrenia. The paper explores one aspect (the exhibition stage) of an ‘art as therapy’ project. The exhibiting of one’s art work aims to counter limiting ‘patient’ identities by allowing those labeled as psychiatric patients to extend their self identity to an alternative identity of the ‘artist’. However, this idea only stands strong if the art work created is not discriminated against as ‘naïve art’ and is accepted or at least considered for acceptance as legitimate non-professional artwork. This research explores the ways in which art created by in-patients with a diagnosis of schizophrenia is received by the general art viewing public. Using the Grahamstown Arts Festival in Grahamstown, South Africa. The study uses a discourse analytic framework to analyse the interviews of members of the public who attend the art exhibition of patient art work. We examine the ways in which the public construct the art works and how they position the makers of this art across a continuum, from patient to artist. The results of this paper have implications for rehabilitation practices for people with a diagnosis of schizophrenia particularly with regard to opportunities to ‘perform’ alternative identities in public spaces.

Enhancing relationships and relationship interventions through prayer: Fact or fiction?
Francis Fincham Florida State University, United States of America; Frank Fincham
Approximately 4.54 to 5.92 billion people profess some religious faith. Yet social scientists have tended to keep “their distance from religion and spirituality” (Hill & Pargament, 2003, p. 65) and this is especially true regarding the role of religious and spiritual resources in the prevention of couples and family problems. The present paper addresses this omission by examining how prayer may influence intimate relationships. Colloquial, petitioner prayer is used to illustrate how specific religious and spiritual practices may be helpful in the prevention of marital distress and in strengthening marital relationships. It presents data from a randomised clinical trial with African American couples (n=393) in which prayer was added to an empirically-supported preventive intervention, the Prevention and Relationship Enhancement Programme (PREP). Although both PREP and prayer enriched PREP were equally efficacious following the intervention, prayer enriched PREP showed significantly greater maintenance of gains at a 12 month follow-up. In addition to discussing the theoretical and practical implications of these findings, this paper describes a programme of basic research. Using data from both laboratory and daily diary studies, this programme of research examines the impact of prayer on variables that may protect relationships (e.g., forgiveness, gratitude) as well as variables that are known to be risk factors for relationships (e.g., infidelity, alcohol consumption). The presentation concludes by placing the research described in the context of an emerging empirical literature on the impact of prayer much of which, it will be argued, is both scientifically and theologically misguided.

Individual therapy in rural community settings?
Lindsay Fredman South Africa
It is well documented that psychological services do not reach the marginalised and vulnerable communities in South Africa. Provision of services has focused on providing primary mental health care, and it is perceived that individual psychotherapy does not meet the criteria for an efficient and cost-effective treatment modality. This paper examines the provision of mental health care in the form of individual psychotherapy being provided by an experienced psychotherapist as opposed to using lay counselors or other modalities such as group psychotherapy. The provision of individual psychotherapy from a resource constrained world model to recipients in an under resourced peri-urban or rural third world environment is described. Using the work done with child and youth care workers from Isi-bindi projects initiated by the National Association of Child Care Workers (NACCW), this paper will examine the challenges and successes of individual psychotherapy provision in these settings.

Symptomatic heterogeneity in depression: A longitudinal study of depressive symptoms in medical residents
Ekio Fried Freie Universitaet Berlin, Germany; Srijan Sen; Randolph Nesse
Major depression has many causes and contains heterogeneous symptoms that vary dramatically among individuals. Prior research suggests that symptoms vary systematically depending on the cause. This study addresses how baseline and state predictors of depression influence mood symptoms in a longitudinal study. We assessed 760 medical residents at five time-points spanning one year. We measured baseline predictors, including neuroticism, early family environment (EFE), gender, family history (FHD) and history of depression (HD), and state variables, including ten adverse life events (ALE) and workload. We studied the influence of these variables on nine depression symptoms as measured by the Personal Health Questionnaire Depression Scale (PHQ-9). We used mixed models to determine whether different symptoms were predicted by different covariates. We then ran growth mixture models to explore latent classes within each symptom. Residents exhibited a dramatic increase in depressive symptoms over time. In the mixed models analyses, some variables significantly predicted depressive symptoms in general (neuroticism, workload, EFE, HD, specific ALE), while others predicted only single or few symptoms (FHD, specific ALE, gender). Growth mixture modeling analyses found latent classes in seven symp- toms, which were predicted by different sets of covariates. We provide evidence that baseline and state variables have dramatically different effects on depressive symptoms and latent classes within symptoms in a longitudinal study. Altogether, our findings document the heterogeneity of depression symptoms and that symptom patterns can be predicted by baseline and state variables and their interactions.
The clinical application of psychotherapeutic drumming as a complimentary addiction therapy
Kim Gabriel Lenteguer Psychiatric Hospital, South Africa; Garth Newman

Substance abuse among South Africa youth and the associated risk/vulnerability to psychotic disorders is of growing concern in South Africa. These youth present with quite a unique set of therapeutic needs focusing on treatment of both psychosis and substance abuse/addiction. Psychotherapeutic drumming has been an integral part of the therapeutic programme at the Lenteguer Adolescent Psychotic Recovery Unit. It was found to be a useful vehicle for engaging often overtly psychotic and manic patients in a fairly interactive, non-threatening way. Benefits included anxiety reduction, sensorimotor coordination and integration and an increase in bodily awareness, concentration and social relatedness. Moreover, the use of drumming also addresses multiple needs of substance addicted patients: Physiologically by inducing the relaxation response, psychologically by reinforcing self-awareness, insight and psychological integration, and socially, by providing group connectedness and interpersonal support. Drumming is of particular significance in the South African context as it draws on traditional polyrhythmic beats that have its origins in African culture, providing a rich source of resonant creative expression, with observable and reported therapeutic benefits. This paper will reflect on both facilitators’ and participants’ subjective experience of the shared psychotherapeutic drumming experience.

Long-term levels of anxiety and depression in victims of terrorism attacks in Spain
Maria Paz Garcia-Vera Complutense University, Spain; Clara Gesteira; Natalia Moreno; Alejandro Zapardiel; Sara Gutierrez; Beatriz Cobos

This study is aimed to examine long-term levels of anxiety and depression in victims of terrorist attacks and to compare them to those in the general population. The Association of Victims of Terrorism (AVT) of Spain assisted in obtaining a sample made up of more than 300 adults who live in Spain and who had suffered a terrorist attack or who are direct relatives (parents, spouses, and children) of someone who had died or had been injured in a terrorist attack. Using the Beck Anxiety Inventory for Primary Care (a short version of the Beck Anxiety Inventory or BAI) and a short form of the Beck Depression Inventory-II (BDI-II), we assessed by phone members of that association who agreed to voluntarily participate in the study. We examine the relation of scores on the BAI-PC and the short form of the BDI-II with the degree of exposure to the terrorist attacks, the presence of physical sequelae, and the time elapsed since the attacks occurred. We also compare victims’ scores with those obtained by adults selected from the Spanish general population (a sample of 470 Spanish adults who completed the BDI-II and a sample of 249 Spanish adults who completed the BDI-II and the BAI). Results are discussed in terms of the long-term psychopathological repercussions of terrorist attacks and the need of providing psychological attention at the short, medium, and long term to direct and indirect victims.

A woman’s prison: Gender, trauma and psychic space
Diane Garland United States of America

Women’s prisons have often gone unrecognized as unique in the penal system. While male prisons have a reputation for callous machismo and indifference, a close inspection of female prisons yields a very different picture. Nearly all women in prison have been found to suffer the effects of trauma, most of them from early life experiences, and consequently exhibit a number of characteristics that, due to gender and circumstance, differ markedly from those of male inmates. A resulting atmosphere of chaos within one such women’s prison in the US has defied attempts to establish coherence and constraint as boundaries are relaxed and psychic space collapses. The introduction of a third psychic element mediating toxic relationships has been used with some facility in men’s prisons but, in a prison housing and staffed only with women, regulations to developmentally early behaviours are commonplace and intrusive. The establishment of a tranquil mental space for creative intellect within which to pursue psychological healing is continually burdened with difficulty. Wanting a reliable and certain, but benign, structure that is gender specific, the imprisoned woman may have a more promising future if her own rhythm is found, understood and complemented with, beneath the psychological wounds. This paper is based on the author’s work managing large programs in men’s and women’s prisons, as well as relevant readings in trauma, development and gender.

Adult patients’ perceptions and expectations of clinical psychologists
Catherine Geils UKZN, South Africa

The perceptions and expectations of clinical psychologists and psychological services by members of the South African public have received little attention. In this study, ‘perceptions and expectations’ include beliefs about, attitudes towards, and knowledge and understanding of clinical psychologists and the services they offer. Beliefs and expectations significantly impact on utilisation patterns and treatment outcomes. There are suggestions from the literature that state psychological services are undervalued, and both the literature and the authors experience suggest a high drop-out rate of referred patients after only one or two consultations. This study included all patients over 18 years who were referred for the first time to clinical psychologists at district hospital and community clinic settings. Participants were given a questionnaire to complete after signing informed consent. The questionnaire sought to examine patient’s beliefs about the reasons for referral as compared to the referring agent, knowledge about the job of a psychologist and how they came to know this. In addition, their knowledge about or expectations of the intervention methods used by clinical psychologists, how long this would take, and their perceptions of stigma attached to consulting a psychologist were also assessed. It is hoped that the results of this study will inform how to educate the public on the role of a psychologist and assist with greater concordance between the public’s expectations and service provision, thus reducing drop out of patients referred and encouraging greater utilisation of and benefit from psychological services by the public.

The effects of grateful intervention on female adolescents: Test of broaden-and-build theory
Amir Gharamani University of Isfahan, Islamic Republic of Iran

The main purpose of this study was to explore the effects of grateful intervention on hope in Iranian female adolescents, based on the broaden-and-build theory (Fredrickson, 2004). A total of 80 female adolescents (40 experiment subject and 40 control subjects) participated in the grateful intervention program and respond to the adult hope scale (Snyder, 1991). Results showed that the effect of gratitude intervention on female adolescents’ hope was significant. Based on this result, the efficiency of the broaden-and-build theory was confirmed in the Iranian culture.

Depressive symptoms in association with socio-demographic factors, family functioning and classroom environment in a Malaysian secondary school population
Siti Raudzah Ghazali University Malaysia Sarawak, Malaysia; Aziah Ahzar

The increasing prevalence of depression among adolescents has sparked concern among many healthcare providers. The objectives of this study were to determine the prevalence of depressive symptoms among secondary school students and their associated factors including socio-demographic, perceived general family functioning, and perceived school environment. A cross sectional survey was employed: 386 students were recruited, aged between 13 to 16 years. A random sampling was performed to choose four secondary schools: two schools were from the rural area and another two were from the urban area of the district. The rate of depressive symptoms among secondary school students in this area was quite high (34%). Two socio-demographic characteristics were significantly associated with depression; ethnicity and location. Chinese adolescents were more depressed compared to other populations. Students staying in rural areas were less depressed compared to students staying in urban areas. Perceived school environment was also significantly associated with depressive symptoms. Students who were depressed were significantly more likely to perceive that their school environment was less conducive to a positive outlook. Gender, family functioning, type of schooling, parental arrangement, number of siblings, birth order, family history of depression, staying with extended family members and area of residence had no significant association with depressive symptoms. Findings in this study highlight that socio-demographic characteristics and school environment should be given consideration in health promotion and intervention programmes. Thus, health care professionals should recognise that depression among adolescents may become one of the top public health issues in the near future.

Personal ethics as a guide to therapeutic practice
Michael Guilfoyle Rhodes University, South Africa

Can a client’s personal ethics function as a platform for the construction of a therapeutic agenda and goals? The narrative practice of ‘re-authoring’ sometimes involves the privileging of clients’ eth-
The efficacy of cognitive behaviour group therapy based on religious attitudes on quality of couples marital relationship

Najmeh Hamid, Shahid Chamran University, Islamic Republic of Iran

The purpose of this research was to study the efficacy of cognitive-behavioural group therapy based on religious attitudes and quality of couples’ marital relationships. The research method was exemplified with pre-post-test, follow up, and control group. The sample consisted of 40 couples with marital problems referred to psychotherapy and counselling clinics in Ahwaz. They were matched by age, educational status, duration of marriage and other criteria considered in this research, then randomly divided into two groups as experimental and control group. We used 12 sessions of cognitive behavioural therapy based on religious attitudes for experimental group, the control group didn’t receive any intervention. The instrument was marital relationship inventory. The results revealed that there was a significant difference between two groups in quality of marital relationship, and style of communication (P<0.001). The rate of marital relationship and styles of communication in experimental group were significantly higher in comparison with pre-test and control group. Also, these results were significantly persistent in follow up period.

Music preference, impulsivity and suicide ideation in Zanjan adolescents

Habib Hasani, Shahid Beheshti Teacher Training College, Islamic Republic of Iran; Akbar Mehdiloo, Shahid Beheshti Teacher Training College, Islamic Republic of Iran; Behrouz Cheraghhi

The issue of youth suicide is one of the most important issues facing human societies that, despite the different fields of science, as well as many related factors is unknown. Understanding the music preferences of individuals is a window into their world, may be useful in the evaluation of individuals internal reality that reflects the values, attitudes and emotions they experience. Thus, this study aimed to investigate the role of music in impulsivity and suicidal ideation in male high school students in Zanjan. Study subjects were 162 male high school students, selected randomly, and responded to the Barrat impulsivity scale (BIS), Beck scale for suicidal ideation (BSSI) and Music preference questionnaire. The results showed that there is a significant relationship between suicide ideation and music preference. Students who tended to metal music have higher score in suicide ideation scale than other groups. There is a significant relationship between suicide ideation and impulsivity. There is no significant relationship between music preference and impulsivity. There is a significant relationship between suicide ideation and academic achievement. Tendency to suicidal thoughts in the students with lower scores was more than the other groups. No significant relationship between academic orientation and impulsivity and suicidal thoughts were found. Although the relationship between impulsivity and music preference was not significant, impulsivity can be used as an intermediate variable, to explain the relationship between music preference and tendency to suicidal thoughts.

Self-help for anxiety disorders. A meta-analysis and meta-regression of effects and potential moderators.

Thomas Haug, Helse Bergen, Norway; Odd Havik; Lars-Garån Øst; Tine Nordgreen

Self-help treatments have the potential to increase the availability and affordability of evidence-based treatments for anxiety disorders. Although promising, previous research results are heterogeneous, indicating a need to identify factors that moderate treatment outcome. The present article reviews the literature on self-help treatment for anxiety disorders among adults, with a total sample of 56 articles with 82 comparisons. When self-help treatment was compared to wait-list or placebo, a meta-analysis indicated a moderate to large effect size (g=0.78). When self-help treatment was compared to face-to-face treatment, results indicated a small effect that favored the latter (g=0.20). When self-help was compared to wait-list or placebo, subgroup analyses indicated that self-help treatment format, primary anxiety diagnosis, and procedures for recruitment of subjects, were related to treatment outcome in bivariate analyses, but only recruitment procedures remained significant in a multiple meta-regression analysis. When self-help was compared to face-to-face treatment, a multiple meta-regression indicated that the type of comparison group, treatment format and gender were significantly related to outcome. We conclude that self-help is effective in the treatment of anxiety disorders, and should be offered as part of stepped care treatment models in community services. Implications of the results and future directions are discussed.

Quitting or cutting back? Predictors and stability of individualised treatment for pathological gambling

David Hodgins, University of Calgary, Canada; Jonathan Stea

As legalised gambling expands world-wide, many jurisdictions are struggling with providing effective treatment options for individuals diagnosed with gambling disorders (pathological gambling). However, even when treatment is available, the large majority of sufferers do not seek treatment. Offering flexible therapeutic goal choice (e.g., abstinence versus moderation) has been thought to be one way to increase treatment seeking and decrease treatment drop out. Nevertheless, there is a dearth of research that examines the predictors and stability of goal selection, as well as its influence on treatment seeking, attrition, and outcomes. This study presents findings related to the predictors and stability of goal selection in a randomised controlled trial of brief motivational treatment for problem gambling (Hodgins, Currie, et-Guebaly, 2001; Hodgins, Currie, et-Guebaly, Peden, 2004). The results demonstrate that particular predictors (male, employment, greater problem gambling severity, history of treatment) are related to initially choosing an abstinence goal. Additionally, the results demonstrate that goal selection is fluid over 24-months, with more participants choosing abstinence than moderation; more participants switching from abstinence to moderation than vice versa; and 15% of participants switching their goal more than once. The results are discussed with respect to implications for goal setting in clinical work and with respect to the small research literature on goal selection in gambling disorders.

The value of art in the context of mental health: In-patient’s experience of the art group as therapy

Minna Holzhueschen, Rhodes University, South Africa

This paper explores mental health patients’ experiences of an art group. In particular, we aim to examine the personal experience of psychiatric in-patients with a diagnosis of schizophrenia, who participated in an art-making and exhibiting project, with a particular focus on the impact of the art-making process on the construction of self. Schizophrenia is regarded as an ‘I am’ illness, as it becomes the ‘master identity’ through re-defining and overtaking the identity of the individual. This research explores whether self-expression facilitated through art enhances a more alternate and richer sense of identity through integrating different aspects of the self. The study uses an in-depth qualitative design. An interpretive phenomenological approach was taken to examine six psychiatric in-patients’ individual experience of the art group. The participants are residents in a rehabilitation hospital in the Eastern Cape, South Africa, who have been involved in the art group for a period of three months or more. Transcripts from semi-structures will be analysed. The results of the research are pending.

Efficacy of TIP treatment for primary insomnia: A randomised controlled trial

Lan Hong, Guang‘anmen Hospital, CACMS, China; Qian Diao; Weidong Wang; Xueyu Lu

To evaluate the short-term efficacy of the sleep regulation technique of Thought Imprint Psychotherapy in lower resistant state (TIP) for the treatment of primary insomnia, we adapted a randomised, single-blind study. 30 hospitalised outpatients with primary insomnia were included according to DSM-IV criteria. Outpatients from a sleep medical clinic of Guang‘anmen Hospital were randomised in a 2:1 ratio to a TIP or Zopiclone (ZPL) group. In the TIP Group, patients received sleep regulation technique of TIP twice per week. The ZPL group received ZPL 3.25mg or 7.5mg; the
The effectiveness of schema therapy on self esteem and anxiety patients with chronic social phobia
Atiefeh Hosseini University of Isfahan, Islamic Republic of Iran; Mohammad Reza Abedi; Hamid Taher Neshat Dust; Ahmad Abedi
This study investigated the effectiveness of Schema Therapy on self esteem and anxiety patients with Chronic Social Phobia. The present study has a single-subject method with multiple baselines across participants. In this study, four participants that were selected by purposeful sampling were studied through sixteen individual sessions of schema therapy. Afterwards, they were given follow up tests after 2 successive weeks of treatment. Research instruments were early maladaptive Schema scale and social phobia, anxiety and self esteem inventories. The results of the data chart analysis were based on descriptive statistics and visual analysis. The obtained results revealed that the intervention has been effective on all four individuals. Findings of this study showed that this intervention (schema therapy Approach) can effectively increase self esteem and results in the decrease of anxiety in these kind of participants.

Trauma, why me? A hypnotherapeutic investigation into the unconscious dynamics of trauma
Debbie Howes South Africa; Bahramali Ghanbari-Hashemabad; Ali Mashhadi
The author is a clinical psychologist in a private practice in Johannesburg. The author incorporates the principles of hypnotherapy into a therapeutic model of the unconscious mind. The technique includes a projective story telling and drawing technique. The logic of the unconscious mind is that of a child. Each person when in a trance will tell a different story. The way in which they tell the story will illustrate and outline the repetitive unconscious belief systems and emotional patterns. Missing conscious information occurs from that perspective. Direct correlations and parallels are investigated relative to the way in which an individual tells the story and the concurrent trauma experienced. The balance of mother-father-child is therapeutically reprocessed and the individual is re-parented. The degree to which the unconscious mind has confusion between truth and illusion is illustrated. The technique serves to instill constructive coping skills and answers many questions posed by individuals relative to trauma. By desensitizing and reprocessing the story, a new reality emerges which mirrors these inner changes. The possibilities for empowerment and prevention of trauma from recurring are investigated. Case studies are discussed. The author has written a book entitled ‘Little Red Riding Hood Revised. A hypnotherapeutic interpretation, analysis and application’, runs regular training workshops, and has appeared as a guest on SABC TV2 House Call.

Anger management, a hypnotherapeutic investigation into the unconscious dynamics
Debbie Howes South Africa
The author proposes a hypnotherapeutic technique which serves to illustrate the process of transmuting anger in an individual from the destructive, irrational and volatile form of expression, to the more constructive and rational manner where results are elegantly achieved. Conscious information that an individual has relative to how to express anger is lost when the individual resorts to the irrational, explosive ways that spontaneously emerge when least expected. An individual often experiences a loss of control where they may act in inappropriate ways that correspondingly result in feelings of guilt, humiliation and self hate. A projective story telling and drawing technique is discussed which serves to illustrate and explain this process from the logic of the unconscious mind. The unconscious mind has the logic of a child. When we become angry, we resort to becoming the child. The technique illustrates how to bridge the child aspect of an individual to the conscious, adult male aspect in a split second. The unconscious mind is addressed via the story telling process while the client is in a mild trance via Ego–state and Eriksonian hypnotherapeutic principles. Each person will tell a different story which will indicate the relevant missing information. Anger that is implosive is a precursor for depression, suicide and self-mutilation. The inter-changeable relationship between guilt and anger is also illustrated relative to the management of anger. Case examples are cited.

Exploring psychological sense of community in narcotics anonymous
Hillary Howrey Nova Southeastern University, United States of America; John Lewis; Christian DeLucia; Amy Heinowitz
Substance use disorders account for approximately 5% of the world’s diseases. Narcotics Anonymous (NA), an international 12-step organisation hosting 58 000 meetings weekly across 131 countries, represents a popular treatment option. Although research suggests 12-step organisations are effective in lowering substance use, less is known about mechanisms of action. Social support is one mechanism that has garnered empirical support. The present study will extend prior work by focusing on the PSOC measure. Given prior theory and measurement work, we will likely use a mix of exploratory and confirmatory methods. Next, we will examine whether PSOC dimensions are associated with measures of well-being, over and above social support. Implications of these data for US cultural values will be explored.

Role of supervision as a protective factor among mental health workers in Turkey
Ferhat Jak Icoz Istanbul Bilgi University, Turkey
Due to its very nature, psychotherapy involves empathic engagement, exposure to disturbing memories and various re-enactments that might affect a mental health worker’s psychological well-being. In the training phase of new psychotherapists, supervision has become an integral part of many training programmes. Some psychotherapists choose to take supervision sessions after their training as well as gaining collegial professional support. However, results about supervision’s role as a protective factor in current literature are mixed. This study aims to take a closer look at supervision’s effect on mental health workers’ psychological well-being in terms of vicarious traumatization and burnout of workers who work in Turkey. It is hypothesised that supervision would decrease levels of both vicarious traumatization and burnout among mental health workers. In addition to this main aim, the present study investigates supervision behaviours of mental health workers in Turkey across gender, age, work setting, geographical region, experience, educational level, occupation, trauma work, populations worked with and personal trauma history. Results indicate that mental health workers who take supervision sessions score significantly lower in vicarious traumatisation. Similarly, mental health workers who take supervision sessions have a lower degree of burnout. In conclusion, this study provides support for supervision, as taking supervision appears to be a protective factor against burnout and vicarious traumatisation. However, results also indicate that taking supervision is not solely at the discretion of mental health workers. Socio-economical factors dictate largely the possibility of taking supervision.

Postpartum depression: The role of self-esteem, social support and age
Chinwe Ifeacho University of Nigeria Nsukka, Nigeria; Solomon Mumah; Agatha Ogwo
The study examined the role of self-esteem, social support and age on postpartum depression. 200 puerperal mothers presenting in 5 hospitals for postpartum check-ups participated in the study. In this single cross-sectional survey, the mothers were individually administered the Index of Self-esteem, Edinburgh postnatal depression scale and
the Social provision scale. A three-way ANOVA with unequal sample sizes was used for data analysis. Results indicated that 58% of these respondents exhibited postpartum depression (a score of 9 and above in the Edinburgh postpartum depression scale). Of these, 20 mothers were selected from Anambra State University Teaching hospital, 19 from Ikechukwu hospital and maternity, 17 from Regina Caeli hospital, 14 mothers from Christ the King hospital and maternity, and 46 from Nnamdi Azikiwe Teaching hospital, Ukpo complex. On self-esteem, mothers with low self-esteem experienced more postpartum depression than mothers with high self-esteem (F=14.097; p<.05). Additionally, there were no significant differences in postpartum depression between younger and older mothers. These findings underscore the importance of assessing postpartum depression on mothers may be devastating. Thus integration into that long-term effects of postpartum depression on postpartum women for depression. Evidence suggests that relationship between Depression (BDI-II; Beck, Steer, & Brown, 1996), Dissociation (DES; Bernstein & Putnam, 1986), Absorption (TAS; Tellegen & Atkinson, 1974) (a personality trait), and SP among Egyptians. Results suggest that lifetime frequency of SP is significantly higher among Egyptians than Danish individuals (P = .001). Moreover, lifetime frequency of SP was associated with higher Depression symptoms (r = .55, P < .017 among Egyptians; on the other hand, a lifetime frequency of SP was not associated with higher levels of Dissociation and Absorption. To further investigate whether lifetime frequency of SP is associated with PTSD, a follow-up study will be conducted. Our findings will thus provide insight into whether the relationship between SP and psychopathology generalise to other cultures, and how psychopathology may predispose to having episodes of SP.

Religiousity and spiritual interpretations of sleep paralysis

Bamo Jalal The University of Copenhagen, Denmark; Devon Hinton; Baland Jalal The University of Copenhagen, Denmark

While the phenomenology of sleep paralysis (SP) displays great similarities across cultures, interpretations of SP vary greatly. Recent research (Jalal, et al., under review) suggests that a high number of Egyptians (48%) having experienced SP believe it to be caused by the Jinn, spiritual beings with roots in Islamic tradition. To date very little research has examined the relationship between cultural interpretations of SP and psychopathology. In the current study we addressed whether the belief that SP is precipitated by spiritual forces is associated with increased fear of the experience, prolonged paralysis during SP, and symptoms of psychopathology among Egyptian adults. The Sleep Paralysis Questionnaire (e.g., Yeung, Xu, & Chang, 2005) was administered to individuals (N = 123) from Egypt. Participants were also asked to complete the BDI-II (Beck, Steer, & Brown, 1996) and the DES (Bernstein & Putnam, 1986). We found that higher levels of religiosity and believing that SP was caused by spiritual forces were associated with prolonged paralysis during SP (ps < .01). Likewise, individuals who believed SP to be caused by spiritual forces were more fearful of the experience (p < .05). While believing that SP was caused by the supernatural was not associated with higher dissociation symptoms, believing that the Jinn had caused SP was associated with higher depression symptoms (p < .05). A follow-up study will examine the relationship between spiritual interpretations of SP and PTSD. These data suggest that particular interpretations of SP may moderate the relationship between SP and specific symptoms of psychopathology.

Prevalence rates of isolated sleep paralysis in Egypt and Denmark

Baland Jalal The American University in Cairo, Egypt; Danielle Beck-Ellsworth; Devon Hinton

The prevalence rates of isolated sleep paralysis (ISP) vary across cultures, with some studies reporting prevalence as low as 6% (e.g., Ohaeri, Awdalla, Makanjuola, & Ohaeri, 2004) and others as high as 40% (e.g., Wing Chiu, Leung, & Ng, 1999). Moreover, there is data to suggest that ISP may be more prevalent among certain ethnic groups (e.g., Paradis & Friedman, 2005). To our knowledge no studies have compared prevalence rates of ISP in Egypt and Denmark. In the current study we compared the mean lifetime frequency rates of ISP of 137 individuals from Egypt and 61 individuals from Denmark. The Sleep Paralysis Questionnaire (e.g., Yeung, Xu, & Chang, 2005) developed by coauthor, Devon Hinton, was orally administered to participants. We found that participants from Egypt had a significantly higher mean lifetime frequency of ISP compared to participants from Denmark (p < .01). Moreover, follow-up analyses revealed that in the Danish sample, non-ethnic Danish individuals (N = 21) had a significantly higher mean lifetime frequency of ISP relative to ethnic Danish individuals (N = 36) (p < .05). Furthermore, Egyptian individuals with low SES (N = 91) had a significantly higher mean lifetime frequency of ISP relative to high SES Egyptians (N = 48) (p < .05). Our data is consistent with previous literature that has found rates of ISP to be higher in populations with heightened social stressors and in ethnic minority groups.

Predictors of sleep paralysis hallucinations with a supernatural theme

Bamo Jalal The University of Copenhagen, Denmark; Devon Hinton; Baland Jalal; Joseph Simons-Rudolph

During rapid eye movement (REM) sleep an individual may experience sleep paralysis (SP) which is a brief period of bodily paralysis where the person is unable to move or speak (Hobson, 1995). Symptoms of SP include hallucinatory experiences, either hypnagogic (upon falling asleep) or hypnopompic (upon awakening). It has been found that members of certain cultural groups report hallucinations with a supernatural theme (e.g., seeing spirits and ghosts, and even space aliens (McNally & Clancy, 2005)). In this study we explored whether the likelihood that an individual would experience SP hallucinations with a supernatural theme could be predicted in a combined sample of Danish and Egyptian individuals. The Sleep Paralysis Questionnaire (e.g., Yeung, Xu & Chang, 2005) was orally administered to 195 participants from Denmark and Egypt. Out of these 195 participants, 58 (30%) reported either hypnagogic or hypnopompic hallucinations. Logistic regression analyses found lower levels of education and SES, and higher levels of religiosity to be significantly independent predictors of SP hallucinations with a supernatural theme (ps

Psychotherapeutic group work with children diagnosed with Asperger’s Syndrome or high-functioning Autism

Ann Janks South Africa

The article presents psychotherapeutic work done in groups with children who have been diagnosed with
Asperger’s Syndrome or high functioning Autism. Initially I worked with these children on an individual basis with limited outcome. I began to explore the interactions between children within a group context with exciting results, far superior to working on an individual basis. I shall present how the groups developed from the initial semi-structured, time-limited, closed group with a maximum of six youngsters to its current form of (max) four children in a semi-structured, open-ended and open group. I will explore the criteria of the diagnosis of Aspergers Syndrome (according to Gilbert). We will describe each of the participants and their developments within the group process. Vignettes of interaction will be discussed. Several worksheets will be made available. The article is focused on how to assist interaction between the group participants and so interactive questions will be encouraged.

Immune power personality and the somatic and mental health indicators in a general population sample
Konrad Janowski University of Finance and Management, Poland; Konrad Skrztek; Tomasz Jedynak; Martyna Piasecka

Immune power personality (IPP) is a term proposed by H. Dreher to describe seven personality traits which had previously been found in empirical research to be associated with better functioning of some aspects of the immune system. These traits included the ACE (attent-connect-express) factor, the capacity to confide, assertiveness, healthy helping, the affiliative trust, hardness and self-complexity. In this study, it was assumed that IPP would correlate better with immune function and the latter would lead to better health outcomes. Therefore, the objective of this study was to verify whether the IPP traits reveal the hypothesized associations with the health status in a general population sample. 300 subjects from the general population were recruited to take part in the study. The sample was closely resembling the structure of the general population with respect to such parameters as age, gender, level of education and place of residence. The IPP traits were measured by a previously developed psychometric instrument. The somatic health status was assessed by a self-report questionnaire gathering data on various aspects of health (frequency of various somatic symptoms, occurrence of different diseases, hospitalizations, use of medications, etc.).

The mental health status was measured by General Health Questionnaire-28. Additionally, sociodemographic life-style data (e.g. smoking, alcohol consumption, exercise, dietary habits) were controlled. The results showed statistically significant links between some of the IPP traits and various indicators of both somatic and mental health, with generally stronger associations for mental health indices.

Memory functions and general cognitive status in alcoholics remaining in abstinence
Konrad Janowski University of Finance and Management, Poland; Włodzimierz Gajeowski

Alcohol dependence and chronic alcohol abuse increase the risk of changes in the brain, which may translate into impaired cognitive functioning. Memory functions were reported to be particularly vulnerable and sensitive to chronic alcohol abuse. However, what happens with the alcohol-induced cognitive impairment when an alcoholic starts to maintain abstinence is not yet fully understood. Therefore, the objective of this study was to assess memory functions and general cognitive status in alcoholics who preserve abstinence from alcohol. Fifty-four alcoholics, who were abstinent at the time of the study, took part in research. They were assessed on a battery of memory tasks (Chownowskí’s Memory Scale) and Mini-Mental State Examination to measure cognitive functions. Additionally, they were interviewed, and the data were collected on a range of socio-demographic and clinical variables, including those relating to the history of alcohol abuse and abstinence. The results showed that the subjects’ scores were significantly different from the age-adjusted norms on only the two subtests of Chownowskí’s Memory Scale measuring verbal learning rate and memory for associate pairs. However, both the general cognitive status and most of the measured memory functions showed statistically significant negative correlations with the length of the period of alcohol abuse and statistically significant positive correlations, with the length of the period of remaining in abstinence. These findings suggest that chronic alcohol abuse is a risk factor for cognitive dysfunction, however, prolonged abstinence can lead to reversal of such impairment.

The complementary roles of cognitive behavior therapy and psychodrama in managing complex trauma
Umme Habiba Jasmine Scottish Livingstone Hospital, Bangladesh; Mohammad Rahman Scottish Livingstone Hospital, Bangladesh; Herb Propper

Cognitive Behavior Therapy (CBT) focuses on addressing distorted perceptions and modifying habitual responses to identified stimuli whereas psychodrama focuses on both making insights through the use of role theory, which provides some cognitive clarity and framework by identifying certain roles that include thoughts and emotions and facilitating cathartic emotional release. This paper aims to demonstrate the combined impact of using CBT and psychodrama on an acute trauma case, aged 31, female, through qualitative case study design. She was unpredictably stabbed by her partner causing permanent physical disabilities. 14 psychotherapy sessions were administered; the process starting with CBT. After eight sessions, psychodrama was introduced when the client became blocked by painful emotions, hindering her capacity to process emotions, to seek support from significant others and improvement in psychotherapy. CBT worked on managing traumatic symptoms, dealing with feelings of guilt, anger, insecurity, mistrust, sadness and dysfunctional thoughts. When CBT became inadequate to deal with her blocked emotions, psychodrama facilitated her emotional expression through being in different roles and role reversals with significant others. It also contributed in her sense of security, adequacy and power, and insight about separation of her different roles and the means to deal with emotions, especially anger. CBT and Psychodrama combined managed her trauma symptoms and dysfunctional thoughts.

Use of narrative therapy and reflecting team to empower Latino families
Aida Jimenez Carlos Albuix University, Puerto Rico

The purpose of this presentation is to share a theoretical model that shifts the focus of narratives that are charged with problems to a narrative of possibilities. Narrative therapy and the use of a Reflecting team are used as methods to enhance empowerment among Latino families. The principles of the theory will be discussed, as well as the use of a Reflecting team. This post-modern, constructivist perspective challenges the dominant discourses of our society that are reflected in the families’ dominant stories, saturated by problems, creating the space for the construction of alternative stories that are more empowering. We will discuss the use of a Reflecting team as a tool to facilitate and promote an alternative story among family members. The 11 reflections that are covered during the intervention are: (1) Offering a different perspective, (2) Emphasising something positive, (3) Normalising, (4) Casting in a positive light, (5) Defining a problem as dyadic, (6) Using metaphor, (7) Suggesting an experiment, (8) Suggestions for managing past situation, (9) Telling story about a reflector, (10) Telling story about other couple, and (11) Suggestion on how a past incident could have been managed in a different way. The reflectors as well as the therapist will identify the dominant narratives that constrain the relationships and organise their perceptions and behaviours, and will also identify the language and metaphors used by each family member, as a mean to create alternative narratives unnoticed or forgotten.

Follow-up of patients treated at an inpatient psychotherapy unit: Research challenges
Emma Johnston Town Hill Hospital, South Africa

Inpatient psychotherapeutic services for patients suffering high levels of psychological distress and trauma are scarce in South Africa. Furthermore, follow-up research with patients receiving this type of mental health care is also limited. The present study focuses on patients treated at an inpatient psychotherapeutic unit offering individual and group psychotherapies to adults, by assessing their experiences since admission to the unit. Patient’s experiences during their admission and since discharge from the unit, mental health status since admission, compliance in terms of outpatient mental health care, current quality of relationships with family and friends, and impact of patient’s mental illness on their work situation are examined. The results are discussed within the context of broader therapeutic, infrastructural and training challenges within the South Africa context. The challenges encountered in such research are also explored.

Pathological organisations and psychic retreats in eating disorders
Yaël Kadish Scottish Livingstone Hospital, South Africa

A set of characteristic symptoms allow for the relatively straightforward diagnosis of eating disorders. Simultaneously and paradoxically a wide
Perceptions of contributing factors to substance abuse: A family case study approach
Zuhayr Kafsa Stellenbosch University, South Africa; Alexis Haupt-Pullen

Substance abuse has debilitated social and interpersonal interactions, particularly in families. Recently, the importance of the familial context in terms of its impact on the user has been the focus of research. The typical forms that eating disorders take are based on the specific ways that food and the body are used i.e. symptom manifestation. These distinctive symptom manifestations appear to be related to Steinier’s (1982, 1993) notion of a psychic retreat. Pathological organisations and psychic retreats are latent until called upon either sporadically or continuously. When activated, these defensive structures operate like a complex psychic skeleton around which the unique psychodynamics of each patient becomes rearranged and thereby transformed.

A psychoanalytic consideration of the influence of culture in eating disorders
Yael Kadish University of the Witwatersrand, South Africa

A comprehensive understanding of eating disorders usually necessitates engagement with the role of modern culture and the media. Feminists and critical social theorists have made significant contributions in this regard. Using two clinical cases, this paper contemplates the influence of culture and psyche, proposing a psychoanalytic conceptualisation underpinned by John Steinier’s (1982, 1987, 1993) theory of pathological organisations and psychic retreats. Two conceptual terms will be introduced namely ‘the normalised body order’ and ‘the abject body object’ to develop the argument. One of the two clinical cases presented will be used to explore a particular kind of therapeutic impasse that can occur when therapist and patient are both female. In this particular case, the normalised body order emerged temporarily obstructing therapeutic progress; the impasse was understood to be an example of the so-called anti-analytic third (Straker, 2006).

A case study of the impact of substance abuse on relationships within a family with multiple substance abusers
Zuhayr Kafsa Stellenbosch University, South Africa; Alexis Haupt-Pullen

Research examining the impact of substance abuse on families is limited. Much of the literature examining families of substance abusers has been conducted with families of alcohol abusers. Family members experience “decreased psychological and social adjustment, deterioration of the relationship with the drinker, reduced family cohesion, more interpersonal conflicts and stress, increased prevalence of illness and increased domestic violence”. One should be circumspect in generalising these findings as there are distinct differences between the use of alcohol and that of illicit substances. Few researchers have explored how substance abuse in the family impacts on relationships within the family. This study explores the perceived impact of substance abuse on family relationships by utilising a case study approach with one South African family. Participants were asked about relationship dynamics before, during and after addiction. Thematic analysis revealed that substance abuse impacted on the family through: deterioration of relationships; ineffective communication; interpersonal conflict; domestic violence; maternal resentment; increased illness; marital discord and detachment from others. Two opposing views regarding familial relationships were evident after addiction, viz. that family functioning had improved and that family dysfunction had been reduced. These findings suggest that the family was instrumental in the rehabilitation of the user. It is evident that family therapy be indicated before, during and after rehabilitation as undressed dysfunctional family patterns may become entrenched, which may increase the risk of relapse.7

The actual state and prospects of the imagery communication psychotherapy in China now
Rong Kai Beijing Forestry University, China

This study observes the imagery communication psychotherapy overall. Imagery communication psychotherapy was set up in the early 90s and has been developed over twenty years. This branch of psychotherapy has become the hot spot in Chinese psychology circles. In the last two to three years, this psychotherapy has also spread abroad. This study attempts to expand its horizons, collect comprehensive documentation and conversational material in order to systemically unscramble and integrate this type of psychotherapy. We try to draw the outline of the development of imagery communication psychotherapy, analyse the main theoretical concepts and the problem of strategy in practice. This study also points out the State of the Field and dynamic state which promotes creative exploration and practice in the area. The paper has four parts. The first part introduces the correlation studies of imagery communication in China and proceeds to a general survey of the studies. The second part elaborates the early development of the imagery communication psychotherapy. The third part collates ideological systems and action research during rapid transmission stage. The fourth part generalises and summarises the whole article and proposes the orientation for the future.

The impact of life skills training on self efficacy of couples in Iran
Mohammad Bagher Kajbas University of Esfahan, Islamic Republic of Iran; Amir Ghamariani; Mojgan Arefi; Setareh Kousha

The present study aims to investigate the effect of life skills training on couple’s self efficacy in Iran. Twenty couples completed the Shere and Madox Self Efficiency Questionnaire in pre and post test, and attended nine sessions of life skills training. The result of covariance analysis indicated that life skills training increased self efficacy of couples (p<0.01) was concluded that life skills training had good properties for use in counseling situations.

An assessment of the relationship between early maladaptive schemas and meta-cognitive states
Hamid Kazemi Zahrauni University of Esfahan, Islamic Republic of Iran; Sara Motahari; Hamid Kazemi University of Esfahan, Islamic Republic of Iran; Maryam Ghorbani

Cognitive therapists believe that early maladaptive schemas are the oldest cognitive components and even sometimes happen before a child’s language learning, and most of the times, apply their effect on the information processing under the consciousness threshold and has automatic mode. The aim of this study is to identify the relation between meta-cognitive components and different kinds of maladaptive schemas in third level high schools and guidance schools of Esfahan. The sample of this study consisted of third level students of a guidance school, first and second grade of high school students of Esfahan. 100 students (50 girls and 50 boys) in the range of 14-18 years were chosen randomly and filled out the meta-cognitive questionnaire (Onil and Abedi, 1996) and the Young questionnaire (205 form, 2007). The analysis of data shows that the total score of maladaptive schemas (R= -0.22 and P=0.05) has negative and meaningful relation with score of meta-cognitive states in students. Multi variable regression analysis shows that among 16 available schemas, Shame and Defection (R= -0.34 , p<0.001), Mistrust (R=0.39 , P< 0.05 ), Emotional Inhibition, ( R = , 0.45 , P<0.05 ) Unrelenting Standards (R=0.49 and P>0.05) show meaningful correlation. According to the mentioned findings, it seems that students who suffer more from these maladaptive schemas encounter deficits in meta-cognitive processing and have more cognitive and emotional distress during the learning process.
Prevalence of behavioural problems in school children

Waheda Khan Iamia Millia Islamia University, India

The mental health and well-being of children require our attention, as nearly one in five children and adolescents will have emotional and behavioural disorders at some point of time in their youth regardless of region or socioeconomic status. However, child and adolescent mental health has been largely a neglected area in India. Therefore, the present research was designed to study the nature and extent of behavior problems (i.e. neurotic, antisocial and undifferentiated) and type of school was observed to be a significant risk factor on the neurotic dimension. Government school children were 3.57 times more at risk to be neurotic as compared to public school children. However, on the undifferentiated category, government school children were 2.60 times more likely at risk as compared to public school children. Gender, age and school were significant risk factors in the case of antisocial behavioral problems. In view of the above findings, it is highly imperative that longitudinal epidemiological studies in early childhood be carried out for better preventive, curative and rehabilitative implications.

Effectiveness of teaching life skills to increase of communication skills in elementary school students in the second and third base in Tehran

Abolghasem Khoshkhehis University of Shahid Beheshti, Islamic Republic of Iran; Amene Sharifi

The purpose of this study was the effect of life skill education on enhancing communication skills and self-esteem in the second and third grade of primary schools. The method of the research was experimental and the population consisted of all primary school girls in the city of Tehran. Two primary schools were randomly selected as the sample of the study of which two groups of 15 students (control) and 15 students (experimental) were also randomly selected. Two tests, POP self-esteem (1989) and the Khamseh-assertiveness test (an Iranian test, 2002), were given to both groups as pretest and posttest. The girls in the experimental group received their life skill educating program during 10 weeks and over 10 sessions on focusing on Bandura theory. Results showed the experimental group performed significantly better than the control group. Thus, there was a significant effect of life skill education on enhancing self-esteem overall – social activities in the experimental group were more enhanced than the control group.

Whiteness revisited in psychoanalytic psychotherapy in South Africa: The Other and potential space

Zelda Knight University of Johannesburg, South Africa

In this paper I explore the subtleties of racialized subjectivities (a psychodynamic category) as opposed to race (a social category) in psychoanalytic psychotherapy. The paper takes the form of the author’s response to the contemporary writings within psychoanalysis regarding racialized subjectivities as well as an exploration of the experience of racialized selves in therapy when the client is Black and the therapist is White. It is suggested that the honest exploration of the racialized (inter)subjectivities with its unconscious communication, can lead to a deeper understanding of identifications, difference and the Other. The context is South Africa and the broader theme is one of the Other or difference and the dynamics of potential space as a source of transformation and healing.

Psychosocial rehabilitation: Are we all on the same page?
Anne Kramers-Olen Fort Napier Hospital, South Africa; Anthony Pillay

The concept and practice of Psychosocial Rehabilitation (PSR) has been gaining increasing recognition in mental health facilities providing care to patients with chronic mental disorders. However, the extent to which such programs are implemented in poorer countries is of concern, given the financial and training implications. In this context the authors investigate various aspects relating to mental health professionals’ perceptions, training, attitudes and beliefs regarding PSR programs. The study is being conducted at a state psychiatric hospital for long-term chronically mentally ill patients in South Africa. Staff in the departments of nursing, clinical psychology, psychiatry, social work, occupational therapy and pharmacy will be surveyed to examine some of the following issues: understanding of PSR, perceived aims and goals of PSR, adequacy of their professional training to implement PSR, availability of resources to facilitate PSR, and views of chronic mentally ill patients, including their functional skills, needs and prognosis. The results will be presented and discussed in the context of such national issues as economics, training and mental health service development.

Opinions of health care professionals who treat patients admitted for non-fatal suicidal behaviour.

Anna Kritzinger Medunsa University, South Africa; Linda Blokland Medunsa University, South Africa

Suicidal behaviour is a concerning phenomenon that continues to place increasing demands on the time and resources of health care professionals in South Africa and abroad. Research shows that a non-fatal suicide attempt increases the risk of a possibly fatal suicide significantly. Therefore, interventions at health care facilities providing care for patients admitted for the reason of non-fatal suicidal behaviour (NFSB) are crucial in the attempt to decrease alarmingly high suicide rates. However, health care professionals in South Africa struggle with multiple obstacles in terms of staff shortages, a lack of facilities and resources, as well as other limitations. The aim of this study will be to record the views and opinions of health care professionals who treat patients admitted for NFSB. By means of a qualitative investigation, the researchers hope to clarify the perceptions of medical doctors, nurses, clinical psychologists and social workers at a tertiary level hospital in Ga-Rankuwa, with regard to their experiences and feelings about NFSB admissions. Ideally, the availability of this information might have a positive impact on policy development and medical management in terms of enabling a health care environment that treats such admissions more efficiently; possibly contributing to a decrease in fatal suicide statistics.

Youth’s perception of family functioning as a predictor of suicide risk
Jennifer Kyle Queens College, United States of America

Family and social support are protective factors for minority youth at risk. The reason for living inventory (RFLI), a standard clinical instrument for the assessment of protective factors, has been used to predict risk in clinical and non-clinical samples. However, RFILI does not directly assess the quality of social or family support as it relates to suicide risk. Therefore, this study examined protective factors in a diverse non-clinical sample of youth to address the following questions: (1) Can social support and family functioning in addition to RFILI predict suicidal behaviours? (2) With regard to family functioning, is there a difference in youth’s perception of family functioning that predicts suicide risk? Participants (n = 243) completed self-report instruments to assess the following variables: Suicidality, social support, family functioning, and reasons for living. Participants’ age ranged from eighteen to fifty-six. The largest ethnic groups represented were Hispanics followed by Asians and Middle Easterners. Logistic regression was used to investigate the relationship between the predictor (independent) variables and to estimate the probability of the outcome variable i.e. suicidal behaviors. Data analysis shows that a comprehensive model of protective factors, including reasons for living, family functioning, and social support can be effective for predicting those at risk. Further, suicidal youth perceived their family as controlling, stressing the adherence to values and/or perceived their family as lacking in emotional involvement. These findings suggest that prevention and clinical intervention strategies need to address youth’s perception of available support to assure risk.

Treatment of anxiety disorder in a university clinic of psychology

Francisco Labrador Complutense University of Madrid, Spain; Laura Gomez; Ignacio Fernandez-Arias; Pablo Alonso; Francisco Ballesteros; Manica Berndalde de Quiros; Carmen Blanco; Francisco Estupia

 Anxiety disorders are problems which usually lead to sufferers asking for psychological help. The objective of this study is to identify the characteristics of the patients who demand psychological help, and the clinical variables referred to this demand and its treatment. Descriptive and quasi-experimental study of a group was undertaken. The group comprised an incidental sample of patients, with assessment performed in pre-treatment and post-treatment. A sample of 292 patients who sought aid at the psychological clinic of the Complutense University was studied. The typical profile of patients was that of young unmarried women with university studies, and having received a previous treatment, especially of a pharmacological type. The three more frequent diagnoses of anxiety were: Non-Specific
Anxiety Disorder, Social Phobia and Panic Disorder with Agoraphobia, which include 50% of the cases. The average length of the assessment was 3.5 sessions, and the average length of the treatment was 14 sessions. The percentage of discharges was of the 70.2%. The average cost of the treatment was approximately 840€. The results are discussed, highlighting the value of empirically supported treatments for anxiety disorders.

Does adding pharmacological treatment improve the results of psychological treatments in anxiety disorders?

Francisco Labrador Complutense University of Madrid, Spain; Francisco Estupía; Carmen Blanco; Ignacio Fernandez-Arias; Pablo Alonso; Laura Gomez

The goal of this work is to determine whether, in a welfare clinical context, the use of the empirically supported psychological treatments (ESTs) combined with pharmacological therapy (PT) has any beneficial effect compared with the use of ESTs only, in anxiety disorders (AD). A descriptive, quasi-experimental study of two groups (ESTs + PT, and ESTs), without random allocation, made up of an incidental sample, was performed. Participants were 287 patients of a psychology clinic who were diagnosed with AD. 25.1% received ESTs+PT, and 74.9% received EST. The sociodemographical, clinical and treatment variables of both groups were analyzed using t-tests. Those susceptible to covariation were included in a general linear univariate model to control for their influence on the analysis of intergroup differences in attendance and punctuality, task performance, and successful treatment outcome. Significant differences appeared in age and percentage of married patients (higher in group EST+PT). Also, the group EST+PT received more previous treatments (40% more than EST). The treatment in group EST+PT was significantly longer (16.58 vs. 13.04 sessions). The percentages of discharges, compliance with treatment and task performance were similar in both groups. The dubious benefits that PT might add to ESTs for AD and its implications in terms of efficiency are discussed.

Clergy sexual abuse: Facts, myths and questions

Hugh Lagan South Africa

A sustained and meaningful public dialogue about the sexual victimisation of children in faith communities, and in wider society, has emerged in recent years, resulting in part from revelations of child sexual abuse by clergy. Within an area of public interest wrought with emotion, and driven by preconceived assumptions, empirical research has helped to objectively deconstruct the complexities of clergy sex abuse, and open up much-needed understanding. Clarity of terminology, and accuracy of understanding, remain essential prerequisites in communicating effectively about the problem of clergy sexual abuse. The more the facts of clergy sexual abuse are permitted to inform clinical and pastoral thinking, the better able preventative and treatment strategies can hope to respond effectively to the multiple needs of survivors and offenders. This paper will provide an overview and synthesis of the most current empirical research within the field of clergy sexual offending. It will explain how clergy sex offenders are similar to, and different from, general populat-

A unique betrayal: Childhood sexual abuse by clergy

Hugh Lagan South Africa

The sexual abuse of minors remains a worldwide criminal and public health problem, with grievous harm often perpetrated against the victim’s long-term psychological well-being. When one’s perpetrator is a trusted spiritual leader and exemplar, the effects of childhood sexual abuse cut to the core of one’s raison-d’être. The sexual abuse of children and adolescents by ordained clergy entails an added violation of meaning as well as persons. As such, clergy abuse engenders not only physical, emotional, and psychological trauma, but also a profound existential and spiritual crisis that reverberates through their entire lives. It is this existential and theological crisis which sets clergy abuse apart from other forms of sexual abuse. This paper will seek to give voice to the experiences of survivors of clergy perpetrated childhood sexual abuse, their families and others impacted by this profound betrayal. It will also seek to advance our understanding of the unique traumatic impact of clergy perpetrated sexual abuse. Utilising culturally informed research studies with clergy sex abuse survivors from USA, Europe and Africa, this paper will examine best practice in the domains of intervention, assessment, treatment and prevention.

Guilt and shame in PTSD: A review of the dynamics

Tania Lambert NMMU, South Africa; Kempie van Rooyen NMMU, South Africa; Tanya Dutton NMMU, South Africa

The Diagnostic and Statistical Manual of Mental Disorders (DSM-IV) does not include guilt and shame in the diagnostic criteria for posttraumatic stress disorder (PTSD). However, a growing body of literature discusses the influence of these two self-conscious emotions on the dynamic development of PTSD. These self-conscious emotions are proposed to be included in the DSM-V and it is therefore important to understand how they might influence the disorder. The presentation discusses findings from a review of the last twenty years’ research findings on the influence of guilt and shame on the dynamics of PTSD. While the overall methodology is not that of a fully-fledged systematic review, articles were only incorporated if they contained information on how shame and guilt dynamically influence the various elements of PTSD. While findings indicate that both shame and guilt may have a significant influence on the aetiology, maintenance, symptom severity and treatment of PTSD, research in this important area is sparse and inconsistent. The information that is available is contextualised against a cognitive model of PTSD in trying to delineate how these emotions may impact the development and expression of PTSD. Recommendations (based on this synthesis) are made regarding practitioner vigilance the therapeutic management of shame and guilt in PTSD. Finally, ongoing empirical research on shame and its relationship with cognitive vulnerabilities is presented as an example of how future research in this area can be designed.

Physical and social functioning as mediators between stress and depression in multiple sclerosis patients

Sylvia Lara University of Barcelona, Spain; Teresa Kirchner

Multiple Sclerosis is a chronic neurodegenerative disease that provokes physical disability and emotional disorders. For many people the diagnosis of MS brings with it a great deal of stress. Depression symptoms have a high prevalence among these patients and have been associated with several quality of life indicators, especially physical and social functioning. The aims of the study were as follows: (1) To analyse the extent to which the quality of life indicators explain depression symptoms among multiple sclerosis patients, (2) to analyse the mediating role of the loss of social functioning between depression symptoms and the stress linked to the disease. Participants were 103 Spanish patients with a diagnosis of Multiple Sclerosis. Quality of life indicators were assessed by means of the Spanish adaptation of the SF-36 Health Survey. Depression symptoms were assessed using the Spanish adaptation of the Symptom Checklist 90 Revised. The low degree of social functioning had greater explanatory power on depression symptoms than did physical functions. It was also found that social functioning had an important mediating effect between stress and depression symptoms among these patients. Specifically, 52% of the relationship. The loss of social functioning has an important role in the psychological adjustment. These results may have noteworthy implications when designing prevention and treatment programs aimed at improving their quality of life.

Group intervention for reducing depression and anxiety in clinical menopausal women: A cognitive-behavioural treatment

Cristina Larroy Universidad Complutense de Madrid, Spain

Menopause occurs in Spain to 270,000 women annually. At least, in 50% of the cases, it results in an upheaval or problems of health for the women who suffer it. The treatment by means of hormone therapy, besides causing undesirable indirect effects, does not seem effective to reduce the depressive or anxious symptoms. For that reason, a cognitive-behavioural intervention has been designed. 28 women, recruited in diverse city councils of Madrid, received a group intervention to reduce symptoms related to menopause, including depression and anxiety, and to improve their quality of life. They all showed clinical symptomatology. They received a group intervention with cognitive-behavioural techniques in eight weekly sessions of two hours each, including: Psycho-education, relaxation, exercises of Kegel and sexual re-education, identification and control of excessive worries
Reducing symptomatology in menopause: Results of a psychological intervention
Cristina Larroy, Universidad Complutense de Madrid, Spain; Sonia Gutierrez
For an elevated percentage of women, menopause is associated with an important variety of physical and psychological symptoms. Diverse studies have demonstrated the efficacy of behavioural techniques to reduce several menopausal symptoms, such as hot flushes. For that reason, a cognitive-behavioral intervention has been designed and tested. Method: 28 women, recruited in diverse city councils of Madrid, received a group intervention to reduce symptoms related to menopause, and to improve their quality of life. All showed clinical symptomatology. They received a group intervention with cognitive-behavioral techniques, in eight weekly sessions of two hours each, including: psycho-education, relaxation, exercises of Kegel and sexual re-education; identification and control of excessive worries and irrational beliefs; training in problem-solving and time-management. Symptoms were measured by the Kupperman and Blatt Menopausal Index (BMI), which provides information about several menopausal symptoms, as hot flushes, myalgia, melancolia, anxiety, insomnia, etc. Quality of life was measured by a questionnaire specifically designed to evaluate quality of life in Spanish middle age women (EPQ). The control group consisted of 25 women, with no treatment. Measures were made pre- and post treatment and after a 6 months follow-up. Women in the experimental group reduced significantly their scores in BMI and EPQ and post-treatment and follow-up compared to the baseline. Besides, the percentage of women suffering clinical level of symptomatology (n≥ 20 in BMI) in the experimental group decreased significantly after treatment. Women in control group did not experience changes.

Menstrual pain: Differences depending on age
Cristina Larroy, Universidad Complutense de Madrid, Spain
Studies of prevalence of menstrual pain yield very different results, with percentages oscillating between 25% and 90% of the studied samples. This variability can be explained by various factors: The size and the homogeneity of the samples used, the age of the women of these samples, the measuring instruments used, the different symptoms considered in each study, the diversity of decision-making criteria about the intensity of the pain, and, ultimately, the lack of a clear, unambiguous and explicit definition of what menstrual pain is. The aim of the present study is to investigate how this disorder affects women in the state of Madrid, and, depending on their age, how it affects them. 1387 women aged between 13 and 52 years (M = 23.99; (SD = 9.24) answered the Menstrual Pain Questionnaire (Larroy, et al., 2001) referring to their menstrual period in the last year. The sample was divided (according to the age of the women interviewed) into four groups: Adolescents, youths, adults and elderly. The studied variables were: Prevalence of pain, intensity, duration, location, and strategies to combat pain. The results indicate differences in all the studied variables depending on the samples. Prevalence, intensity and duration of pain are higher in the group of adolescents and youths, but present high level data in the other two groups.

Correlation study between symptoms of personality disorders and childhood traumatic experiences in Chinese college students
Hui Ling, Hunan Normal University, China; Jian-ren Zhang
The aim of this study is to explore the relationship between symptoms of personality disorders and childhood traumatic experiences in Chinese college students. Personality Diagnostic Questionnaire-4 (PDQ-4+) and CECA.Q was administrated to 320 college students by layered sample. Significant correlations existed between several factors of personality disorders and childhood emotional abuse experiences. The personality disorders group showed severer childhood abuse than the normal group. There was significant correlation between symptomatic level of personality disorders and childhood emotional abuse experiences.

The response style and psychopathological symptoms in subjects with cognitive vulnerability to depression
Yu Ling, Hunan Agriculture University, China
The aim of the study was to explore the characteristics of response style, depressive and anxious symptoms, stress level in subjects with cognitive vulnerability to depression. The Chinese versions of the Cognitive Style Questionnaire (CSQ), the Mood and Anxiety Symptom Questionnaire-Short Form (MASC-SF), the Response Style Questionnaire-Ruminating (RSQ-R) and the Students Hassles Scale (SHS) were completed by 1201 undergraduate students. Every participant’s weakest-link score for all participants being 0.48 (SD = 0.86), the Cognitive Vulnerability (CV) group included 151 participants who scored over 1.34 (one SD above the mean of the whole group, 0.48 + 0.86), while the control (NCV) group included 192 participants who scored under -0.38 (0.48-0.86=-0.38). Results indicated that there were no significant differences on average age and gender between the CV group and the NCV group. However, there were significant group differences on scores of MASC-SF, RSQ-R and SHS. The CV group had higher scores on general distress anxiety symptoms, anxious arousal, general distress depressive symptoms, anhedonic depression, rumination, reflection and hassles level than the NCV group (p≤0.05). Subjects with cognitive vulnerability to depression experience more hassles in daily life, they tend to adopt negative response styles, and have more depressive and anxious symptoms, which suggested intervention for subjects with cognitive vulnerability should include strategies improving their negative response style.

Clinical psychology and private practice: is it still possible to earn a comfortable income?
Rafia Lockhat, South Africa
In general Clinical Psychology is regarded as a ‘calling’ by those who choose to enter the profession. The profession is also generally regarded as highly interesting and personally rewarding. However as a ‘calling’ or not, one still has to earn a living from one’s profession. In South Africa it takes seven years to qualify (including community service) and only then may you enter into private practice, although usually most Psychologists work for a few more years first, in order to gain the necessary experience. Is it worth it? The author argues that it is still possible to maintain a high standard of living but the challenges are many. With the current state of the economy, an increasingly small group of people are able to pay cash for psychological services with more and more practices becoming dependant on medical aids for pay-ment. Medical aids however, are constantly shrinking psychological benefits, e.g. the Government Employees Medical Scheme, pays for 9 consultations per family per year making the most basic long term therapy impossible. So what is to be done? The author proposes that Clinical Psychologists will have to become experts in a range of shorter, quicker and highly effective interventions for a wider range of psychological difficulties. In this regard, universities will have to adjust their training programmes to more adequately prepare students for the real world challenges of private practice.

The effect of Ritalin on sustained attention
Dubi Luft, Yezreel Valley Academic College, Israel
The purpose of this study was to assess the effect of Ritalin (brand name Methylphenidate or MPH) upon sustained attention using a computerized test, the Continuous Performance Test (MATH-CPT). Twenty-seven Israeli adolescents, with a mean age of 13.78 years old, who were diagnosed as having ADHD participated in the study. Before the study, the teachers of each child completed the DSM-IV ADHD Behavior Checklist (Robin, 1998) in order to assess ADHD symptoms. Each participant was then tested twice with the MATH-CPT (Luft, 2006), a computerized CPT-type test aimed at assessing attention. There was a span of one week between the administration of the tests. In one administration, the participants took medication 1.5 hours prior to being tested. In the second administration, the MATH-CPT was conducted without participants ingesting the medication prior to testing. The results of the DSM-IV ADEQ Behavior Checklist showed that, as a group, the mean total of symptoms was 14.64. In order to be diagnosed as having ADHD, there is a need for 12 or more symptoms. These findings showed that the participants were diagnosed correctly as having ADHD. The results of the MATH-CPT showed that treatment with MPH improved the overall attention formula in ‘attention’ and ‘impulsivity’ measures. However, MPH did not improve the performance of children who were diagnosed as
having ADHD in the three measures of sustained attention: ‘attention level,’ ‘reaction time,’ and ‘variability of the reaction time’. The authors will discuss the implications of these findings.

A study of a clinical population of schooled children

Ana Luzzi Universidad de Buenos Aires, Argentina
Sara Slapak

We present the results of a study from an epidemiological perspective of a clinical population of 1804 schooled children. Children attended a Children Clinical Psychology Unit of an Argentine public university along 1999-2008. Socio-demographic variables were gathered and their behavioural problems were analysed. The Achenbach Child Behaviour Checklist (CBCL) was applied at the time of admission and a Socio-demographic Survey was administered to the adults in charge of the children. We carried out descriptive studies on frequency distribution and associations among variables through the analysis of variance (ANOVA). The female clinical population was found to have an average of total scores slightly higher than the male one at the CBCL. Statistically significant associations were found between some syndromes and socio-demographic variables: gender, age of children and parents, father’s level of education, marital status of parents, the quantity of children in the family and levels of hoarding. We did not find variations on the behavioural problems and on the socio-demographic variables, but statistically significant associations throughout the studied period.

Irrational beliefs in depressed and non-depressed college students

Debra Machando Women’s University in Africa, Zimbabwe

Irrational beliefs are at the core of most psychological problems, including depression. The majority of affected individuals do not receive adequate treatment, even though depression has been ranked as the fourth most disabling disorder worldwide. It is reportedly on the rise in college students, yet several studies on irrational beliefs and depression have focused on clinical samples using exclusively Western populations. This study sought to investigate the relationship between irrational beliefs and depression in college students, using a non-clinical local sample. The researcher predicted a statistically significant relationship between irrational beliefs and depression. A descriptive correlational design with systematic sampling was utilised to obtain a sample of (N= 258) from a Women’s University in Africa. They were screened for depression with the Beck Depression Inventory, and assessed for irrational beliefs with the Irrational Beliefs Questionnaire which measures three subscales: Perfectionism, Need for Approval and High Self-expectation. Results indicated that there was a statistically significant positive relationship between irrational beliefs and High Self-expectation subscale, but a statistically significant negative relationship with Perfectionism, at 0.05 level of significance (F =31.288, p = 0.000 0.05). These findings contribute to the body of knowledge in psychology, and can be used in prevention and treatment interventions for local samples especially in Zimbabwean colleges, as well as for further research.

When three is a crowd: Working from a Mastersonian perspective in a psychiatric hospital

Daleen Macklin University of Pretoria, South Africa

In the context of a psychiatric hospital, patients are treated by a multidisciplinary team consisting of various disciplines, such as psychiatry, psychology, occupational therapy, social work and nursing. The approach to treatment also varies as a result of the theoretical perspective of these disciplines. At the beginning of 2011 a unit focusing on psychotherapy was introduced at Weskoppies Hospital. The patients admitted in this unit frequently presented with a co-morbid diagnosis of a personality disorder. The aim of this paper is to discuss the appropriateness and viability of working from an analytic stance when multiple team members are involved in the treatment. The therapist working in this unit worked analytically from a Mastersonian perspective. Masterson describes the different disorders of the self, as well as therapeutic strategies when working with these patients. Having multiple professionals involved in the treatment seemed to pose difficulties as a result of different treating modalities and theoretical understandings. It seemed that when more than one perspective was involved in the treatment, the defensive splitting was reinforced supporting the false self. It may be useful if a common conceptualisation is employed when understanding the patient. These difficulties will be explored by focussing on the therapeutic process of a patient in this unit.

Childhood abuse as a risk factor for drug dependence

Srarama Majumdar Jamia Millia Islamia University, India

Substance abuse is a complex phenomenon that can be related to various psycho-social pre-conditions. This study aimed at evaluating the significance of childhood abuse as a risk factor for drug dependence. The relationship between the two was assumed to be along the theoretical proposition of the Cognitive-Affective-Pharmacological Control Theory. Drug rehabilitation and community intervention centres across the city were accessed, and 40 male adolescent and adult drug users were interviewed. T-test was administered to analyze the level of significance. The results of the study show that childhood abuse is highly implicated among drug users being present in most of its forms in the history of more than half of the sample. However, there is not enough evidence to say that childhood abuse is a significant risk factor for drug dependence. The study also reviewed the main assumptions of the CAP Control theory and found that in a relatively high number of drug users who have a history of abuse, the associated feelings were helplessness and lack of control. The exact nature of affective repercussions of abuse as related to drug use needs to be further explored. The findings emphasize on the cognitive and affective component of dependence that can help in enhancing treatment procedures and making therapy more client centred and definitive. Childhood abuse as a risk factor in dependence simultaneously highlights the need to strengthen socio-legal provisions governing child abuse.

Adaptive behaviour functioning in young children with Autism: Evidence from India

Prabhjot Multi PGIMER, India

The objective of the study was to compare the adaptive behavior functioning of children with autism spectrum disorders (ASD) with age and IQ matched controls. 44 children less than five years with ASD (Mean age: 3.46 years, SD= .77) and age and IQ matched control children were recruited from the psychology clinic of the Department of Pediatrics of a tertiary care hospital in India. The adaptive behavior functioning was measured by the Indian adaptation of the Vineland Social Maturity Scale (Malin, 1971) and IQ was assessed by the academic sub-scale of the Developmental Profile II (Alpern et al., 1986). No significant differences among cases and controls on the IQ as measured by the VSMQ were found for children older than 3 years. However, ASD children younger than 3 years had significantly (t= 2.77, P=.01) higher IQs (M= 74.40, SD= 15.87) than controls (M= 54.90, SD= 20.57). A significant positive relationship between the IQ and SQ, SQ and age, and a non-significant correlation between SQ and severity of autistic symptomatology was found for children with ASD. Multiple regression analysis revealed that IQ and age accounted for 63% of variance in the SQ of children with ASD (F=28.57, p=.000). ASD children thus have better adaptive behavior functioning relative to their IQ as compared to the controls; however, the difference between IQ and SQ declines for older children. Besides targeting core symptoms and cognitive functioning in children with autism, there is also a need to improve their daily living skills.

When the blind lead the deaf: Towards a psychotherapeutic method for disabled patients

Majoape-Butaka Mapula University of South Africa, South Africa

Conventional psychotherapy does not sufficiently equip psychotherapists with skills to deal with special needs patients, such as patients who are severely physically disabled. Most conventional approaches to psychotherapy rely heavily on a conversation between the therapist and the client. This mode of providing therapy presents challenges when psychotherapy is being conducted with a client who cannot, for example, talk due to a disability, cannot hear due to disability, cannot use body language, voice tone, facial expressions and other gestures that aid communication, during a therapeutic conversation. Using an actual single case study, this paper will explore, illustrate and demonstrate some of the difficulties of conducting psychotherapy with a deaf and speechless client. This will include the process, content and challenges encountered. In this paper we will also analyse the therapy skills used as well as evaluate these skills in terms of effectiveness when judged against the perspective and responses of the client. Based on these analyses and evaluations, we will venture to make a few tentative findings, suggestions and recommendations for more effective therapy when dealing with disabled clients.

Re-creating self in schizophrenia: The value of art in the context of mental health

Trudy Meehan Rhodes University, South Africa; Kirsten Farquharson; Minnon Holtzhausen

Clinical
This paper examines the issue of self construction in Schizophrenia. It explores the role of exhibiting one’s art work in a public space. It is argued that the practice of ‘being an artist’ is beneficial to inpatients with a diagnosis of schizophrenia by providing the opportunity to develop alternative and richer identity positions. The study highlights the importance of the exhibition and discusses this in relation to narrative therapeutic theories of ‘performing’ and ‘witnessing’ alternative identity constructions. The research uses a qualitative design, presenting a discourse analysis of the self construction of eight people with a diagnosis of Schizophrenia who are members of an inpatient art group in South Africa. Transcripts from semi-structured interviews are analysed, wherein focus falls on how participants construct the self in talk. The findings indicate that both the practice of making art and the process of exhibiting and having this art ‘witnessed’ by the public, make important contributions to the construction and maintenance of an alternative identity position to that of ‘psychiatric patient’. The paper suggests that self construction in Schizophrenia can be supported by rehabilitative practices which provide opportunities for the ‘patient’ to practice and demonstrate alternative identity constructions in a public setting where these can be witnessed and responded to.

The national perinatal depression initiative: Adances in screening and early intervention as public health policy in Australia

Jeanette Milgrom Parent-Infant Research Institute, Australia

A national collaboration of key experts investigated the feasibility of antenatal depression screening across Australia between 2001-2006 (with support from beyondblue). This resulted in current Federal government commitment of $85M for universal screening of perinatal depression. The National Perinatal Depression Initiative is now at the implementation phase with three main activities: screening, promoting pathways to care and workforce training. The task is to develop a framework for universal screening in consultation with key stakeholders and government departments and gain national support at all levels. The findings of the national collaboration, including the largest published study on antenatal risk factors for postnatal depression, will be presented together with a description of the screening program and acceptability findings. The ability to treat depression is a necessary pre-requisite for advocating universal screening and a review of treatment efficacy will also be presented including some of our research in developing tailored interventions: (1) Individual and group CBT-informed treatment of maternal depression shown in randomized studies to be effective when delivered by a variety of professionals. (2) An internet programme for treatment of postnatal depression. (3) Parent-infant interventions which are necessary due to the impact of maternal depression on early brain development. We have demonstrated in randomised trials both the effectiveness of prevention and early intervention in reducing parenting difficulties postnatally. The results of the public health initiative will also be discussed in the context of the debate around screening, and the challenges of training and access to services. The policy, training and models proposed will be described.

Male homosexuality and psychoanalysis: The war is over, what now?

Gareth Mitchell University of the Witwatersrand, South Africa

Historically, homosexuality and psychoanalysis have not been happy bedfellows. In fact their relationship was at best a rocky one. Following on from Freud’s (1905, 1935) somewhat confused musings on the nature of homosexuality (ranging from homosexuality being a ‘developmental arrest’ to suggesting that there is no shame or illness in being homosexual), homosexuality was routinely pathologized and labeled a deviation from the normal path of psychosexual development. The last three decades have seen a radical shift in the standpoint of psychoanalysis towards the psychopathological nature of homosexuality. Despite these positive shifts, from a theoretical point of view, there still exists a vacuum of knowledge regarding the normal psychosexual development of the homosexual male. This has led to what Phillips (2003) has called the “constructual confusion” existing in the psychoanalytic world with regard to homosexuality. This paper will explore this conceptual confusion, beginning with an interrogation of how Freudian and neo-Freudian psychoanalytic theory is limited in its capacity to account for normal psychosexual development in the homosexual male. Following this, the paper will examine contemporary theorizing around the notion of normal psychosexual development in the male homosexual. The paper will argue that this emerging theory requires elaboration and extension.

The risk of depression and the prevalence of suicidal thoughts among university students in Poznan, Poland.

Ewa Mojs Poznan University of Medical Sciences, Poland; Elzbieta Skorupska; Wlodzimierz Samborski

The goal of the study was to evaluate the prevalence of depression and suicidal thoughts in first year university students in Poznan, Poland and to assess whether they were connected with demographic factors such as age, having brothers or sisters, social background, living arrangements, majors and the mode of study. Method: 1500 freshmen, who were 18 – 28 years old (M=19.81; SD=1.18) anonymously answered a questionnaire on the risk of depression (KADS) and a demographics survey including questions about age, having brothers/sisters, background, place of residence, living arrangements and their major. The analysis showed that 16.4% were at risk of depression and 7.3% had suicidal thoughts. Among analysed factors such as age, having brothers or sisters, social background, living arrangements, study and the mode of study, only financial status and age were statistically significant influence on both susceptibility to depression and suicidal thoughts. It is suggested that financial status and age – younger students are more prone to depression – but other factors leading to depression in students, were not clearly identified or taken into account in the screening tools for depression. There was a relationship between age and mode of living as a interconnecting factor in the risk of depression.

Group cognitive-behavioural intervention for social anxiety in first-episode psychosis

Tina Montreuil Douglas Research Institute, Canada

Anxiety symptoms in patients with schizophrenia have been traditionally overlooked. In the case of First Episode Psychosis (FEP), even fewer studies looked at this association. Based on scientific literature, evidence points to the possibility that social anxiety may contribute to poor clinical outcome in FEP which has been associated to poor quality of life, unemployment, increased risk for relapse, hospitalisation and suicide. We developed a brief psychotherapeutic intervention aimed at improving symptoms of social anxiety in FEP. This study was to investigate the efficacy of group-based cognitive–behavioural therapy (CBT) for social anxiety designed to improve clinical outcome in FEP. Fourteen patients with schizophrenia and comorbid social anxiety attended a group-based cognitive behaviour (CBGT) intervention. The CBGT was provided weekly for 14 weeks in 1.5-hour sessions. Baseline and post-treatment ratings of social anxiety were measured using the Brief Social Phobia Scale, the Social Interaction Anxiety Scale; and Social Phobia Inventory. The Scale for the Assessment of Negative Symptoms and Positive Symptoms were also administered. Pre- and post-treatment measures were subjected to statistical evaluation. All outcome measures displayed significant improvements on all anxiety ratings in the intervention group respectively [F(1, 10) = 9.91, p = .010], [F(1, 10) = 5.64, p = .039], and [F(1, 10) = 15.32, p = .003]. CBGT for social anxiety in FEP was demonstrated to be effective as an indispensable treatment for this population. Reductions in symptoms severity of social anxiety appears to be associated to the attainment of clinical remission.

The role of spirituality in dealing with life stressors

Nirveda Moodley UNISA, South Africa

The purpose of this qualitative study was to explore the role of spirituality in dealing with life stressors. A social constructionist perspective guided the framework of the study. Four participants were interviewed based on their experience with adversity and their commitment to spirituality. Participants were expected to respond to open-ended questions based on spirituality and adversity. The method of analysis of the information procured was thematic analysis. The four themes co-constructed by the researcher and participants were spiritual coping strategies, regulation of the mind (emotions, thoughts and behaviour), spiritual support and spiritual growth from adversity. Thematic co-constructions showed that participants employed multiple spiritual activities as coping strategies such as relationship with God, scripture reading, chanting, belief in the Law of Karma, belief in the spirit soul, allotting a purpose to suffering, surrender to God and attraction to Deities. Regulation of the mind was brought about by chanting (mantra meditation), redirection of time and energy towards scripture study and/or preaching activities. Spiritual support was obtained from senior members and/or spiritual masters. Thematic co-constructions also showed that spiritual growth in the form of enhanced psychological and coping skills, stronger relationships and interactional abilities, deeper existential meaning, emotional maturity, expansive viewpoints, more compassion, empathy and tolerance for others, a deeper sense of spirituality and an elevated consciousness emanated from the adversity.
Parenting: Risk and protective factors for mothers with a history of exposure to family violence
Sheereen Moolla
University of Cape Town, South Africa

This study assessed the influence of intimate partner violence and early childhood abuse on women’s current parenting, and to identify other factors which aid or interrupt positive parenting. Women from the greater Cape Town region who had a child between the age of 3 and 8 years were recruited from agencies contexts serving battered women or providing child care. Interviews were conducted with 203 women, and measures included the Conflict Tactics Scale, the Parent-Child Conflict Tactics Scale, the Alcohol, Smoking and Substance Involvement Screening Test, the Parent Stress Index, the General Health Questionnaire, International Child Abuse Screening Tool, the Parenting Sense of Competence, and the Eyberg Child Behaviour Index. Ninety-five percent of the participants had experienced intimate partner violence or had a history of childhood abuse. Results indicated that family violence (intimate partner violence and mother’s history of child maltreatment) was significantly associated with child behaviour problems. Results indicated that maternal mental health and maternal substance abuse were not significant mediators of child behaviour and that social support did not moderate the effects of family violence on child behaviour. Parental stress, parental incompetence and parent-child conflict were identified as the key mediators of child behaviour problems in the context of family violence. Children of mothers who have suffered family violence are at high risk of behaviour problems. Mothers face challenges due to the risk factors associated with family violence such as parental stress, parent-child conflict, substance abuse, mental health difficulties, parental incompetence and inadequate social support.

A meta-analysis about researches on effect of group logo therapy on depression of elderly in Iran
Azam Moradi
Payame Noor University, Islamic Republic of Iran; Soghra Taheri

The object of this research was a meta-analysis of research on the effect of group logo therapy on Depression in the elderly in Iran, and four studies were selection for meta-analysis. Based on the results, the effect size of efficacy of group logo therapy on Depression in the elderly of Iran was r=0.244. Results of this meta-analysis indicated that group logo therapy has a moderating effect on Depression in the elderly of Iran (based on Cohen’s criteria for interpreting effect size).

On becoming a mother in the face of psychotherapy
Marissa Morkel
University of Pretoria, South Africa; Daleen Macklin

Pregnancy is a unique experience in a woman’s life. As therapists, we are confronted with the merge of this personal experience with the therapeutic space. By exploring the experience of an expecting therapist against the background of psychodynamic and attachment thinking, we hope to unmask the impact of being pregnant on one’s therapeutic process with patients. Whilst being pregnant, the therapist worked in an adolescent inpatient treatment facility. The patients admitted presented with a variety of psychiatric disorders, as well as disorganised attachment. In working with this population the therapist found that their internal representations of ‘mother’ matched her own fears of not being a ‘good-enough’ mother, as described by Winnicott. She strongly identified with the internal representation of the inadequate parental part-object, experiencing herself as inadequate, not just as mother but as therapist. In therapy she experienced not being able to meet the emotional needs of her patient. Possibly in an attempt to avoid the experience of being an ‘inadequate mother’ she became preoccupied with her maternal ideal. These narcissistic preoccupations, made it difficult to hold and contain intolerable affects for her patient. Instead, she felt attacked by her patient’s projections experiencing them as potentially harming her unborn child. Pregnancy introduced a blunting of boundaries between the therapist’s anxieties and the internal world of her patient. These experiences may potentially lead to anti-therapeutic enactments contaminating the therapy if not understood.

Workplace safety for nurses, from awareness to sustainable action
Babak Motamedi
Islamic Azad University, Dehag, Islamic Republic of Iran

This research aimed to explore the situation, contributing factors and management of workplace violence among nurses in the health sector of the Isfahan, Iran. A total of 250 nurses were assessed from all the health care services available in Isfahan. Quantitative and qualitative data were collected through questionnaires and interviews. Nurses were asked a series of questions about their personal experience of workplace violence in addition to their views and perceptions of violence in the workplace more generally. This can include verbal aggression or abuse, threat or harassment as well as physical violence. Violence is a problem in the workplace for almost half of all nurses. Among hospital nurses, those working in Psychiatry, Drug abuse and Screening units are more likely to report violence as a problem in their workplace. The majority of nurses experienced a form of verbal abuse and a third of them reported physical violence or abuse. Females, younger nurses, working in night shifts, having physical contacts with patients, working in crowded units and poor working experience nurses were more likely to experience violence. Dissatisfaction of service provided and with diagnosis or planned treatment was the most frequently stated reason for workplace violence. Psychological backgrounds, inability to pay for hospital bill, low social security conditions were the indirect factors. Improved training, better security measures, including provision of a safe environment to treat known or potentially violent patients, prevention programmes, and health services for both nurses and patients should be provided.

Alienation, coping strategies, defence style and expression of aggression of male to female transgenders
Tillottama Mukherjee
Calcutta University, India; Akansha Mohta

Human rights violations against transgenders are on the rise in India. Transgenders are physically abused, harassed and generally discriminated against in society. In addition, they have limited access to healthcare services and are deprived of jobs despite being skilled. The present study attempts to investigate the degree of alienation, the coping strategies, defense style and expression of aggression within a transgender group (n=15; age-18-30) compared to a control group (n=15; age-18-30). The tools used were the Dean Alienation Scale (DAS), The Coping Checklist (CC); The Defense Style Questionnaire-40 (DSQ-40) and the Rozensweig Picture Frustration Study (RPFS). The mean values and standard deviations were calculated and the t-test was applied. The results show that the transgender and non-transgender groups significantly differ from each other with respect to their subjective feelings of alienation across all domains of powerlessness, normlessness and social isolation. The two groups also differ with respect to emotion focused and problem focused coping strategies, immature defenses, group conformity rating (GCR) and across all dimensions of direction of aggression. The presentation will discuss the relevance of these results in planning therapeutic and rehabilitative interventions among transgender subjects.

Breaking down the silos: Mental health issues among the Kenyan workforce
Solomon Mumah
Kenyatta University, Kenya; Agatha Ogwo; Chinwe Ifeacho

This study assessed the prevalence and extent of the severity of mental health cases among a selected cohort of the Kenyan workforce. The participants (academia, bankers, actuarial scientists, researchers, air transport staff, national security staff, IT specialists and workers in the hospitality industry) who presented themselves to a health facility following referral by a medic were each screened for psychosis, stress, depression, anxiety, PTSD, suicide, hallucinations, BMD and alcohol withdrawal syndromes. Results indicate that Kenyan workers exhibited high rates of depression (3-month prevalence for major depressive disorder amongst 18-52 year olds is 27%, compared with 5.7% for the entire population); stress (21%); BMD (20%); and anxiety (14%). These workers tended neither to seek professional help for mental health issues, nor use phone help lines. Could this be the long-overdue call to action? PsycheHealth, based on these findings, is implementing internet-based options to provide a more effective approach for reaching the working class. Online advertising together with media communications strategies are considered in this initiative in order to design and promote a site where all cadres of workers experience depression and other mental health issues, nor use phone help lines. Could this be the next new webinar service, based on structure problem solving. This will enable workers with serious illness to be picked up, who might not otherwise be helped.

Stress and coping among adolescent orphans
Julia Mutambara
Midlands State University, Zimbabwe

This study assessed the prevalence and extent of the severity of mental health cases among a selected cohort of the Kenyan workforce. The participants (academia, bankers, actuarial scientists, researchers, air transport staff, national security staff, IT specialists and workers in the hospitality industry) who presented themselves to a health facility following referral by a medic were each screened for psychosis, stress, depression, anxiety, PTSD, suicide, hallucinations, BMD and alcohol withdrawal syndromes. Results indicate that Kenyan workers exhibited high rates of depression (3-month prevalence for major depressive disorder amongst 18-52 year olds is 27%, compared with 5.7% for the entire population); stress (21%); BMD (20%); and anxiety (14%). These workers tended neither to seek professional help for mental health issues, nor use phone help lines. Could this be the long-overdue call to action? PsycheHealth, based on these findings, is implementing internet-based options to provide a more effective approach for reaching the working class. Online advertising together with media communications strategies are considered in this initiative in order to design and promote a site where all cadres of workers experience depression and other mental health issues, nor use phone help lines. Could this be the next new webinar service, based on structure problem solving. This will enable workers with serious illness to be picked up, who might not otherwise be helped.

Stress and coping among adolescent orphans
Julia Mutambara

Could this be the next new webinar service, based on structure problem solving. This will enable workers with serious illness to be picked up, who might not otherwise be helped.
The aim of this study was to assess stress levels among adolescent orphans, as well as to investigate how these young people cope with stress. Usually when parents die, children become vulnerable and prone to hardships, especially with the disintegration of the extended family system which used to absorb most of the orphans. Previous studies have confirmed that adolescence is a period of storm and stress, and therefore being an orphan at this critical stage can be psychologically traumatising. One hundred and eighty (180) adolescent orphans from six high schools in Gweru’s High Density Area participated in the study. A quantitative research survey method was used in this study. Questionnaires were used to elicit information on the participants’ stress levels and coping skills. The study revealed that there are gender, age and educational level differences in reported stress levels as well as coping skills. Females were mainly found to have low stress thresholds compared to their male peers. Period of orphanhood and nature of guardianship was also found to be positively related to reported stress level and coping skills. Overall, stress levels were also found to be related to coping skills (emotion and problem focused coping skills).

Family health strategy work team training to deal with mental health
Camilla Muylaert Universidade de São Paulo, Brazil; Alberto Olavo Reis; Meoeyr Bertolino Neto; Isabel la Bastos; Michelle Vasconcelos
The work teams from Family Health Strategy - ESF - are generalists and have to be prepared to attend different issues and resolve them. We aim to characterize the training of these professionals in order to deal with mental health problems. We applied a questionnaire of closed questions to 729 professionals from 122 ESF work teams in São Paulo State. We investigated the participation of managers, nurses, nurse auxiliaries, nurses and community health agents in training to cope with mental health issues by ESF work teams; whether or not they feel able to deal with these problems and the reasons attributed to these feelings. The doctors and nurses declared that they have received more and better qualification than community health agents and nurse auxiliaries. However, all of the professionals qualify the conditions for dealing with psychological distress as regular and the main reasons for this are lack of training and development. The quality of training received was analyzed. We discuss how the vertical, the fragmentation and the technical trends in the health field influence the subjective perspective which is necessary to cope with mental health problems.

Psychotherapy in Asia
Kumaraswamy Narasappa University Malaysia Sabah, Malaysia
Psychotherapy is a form of therapy where psychological principles are used as part of treatment. Mainly psychotherapy will be applied to treat psychological and psychiatric disorders. Psychotherapy is not very successful in Asian countries as the majority of patients still rely on Medical model. In addition most of the Asian countries still cling to the deep rooted beliefs. Still stigma towards mental illness is prevalent. Mental illness in the family is seen as a curse from God and the first consultation will be with a traditional healer. Mental health refers to the individual’s capacity for harmonious relationship with others in the environment. However, this is possible only if s/he is comfortable and happy about himself/herself. WHO recognises health as a state of physical, mental and social well-being and not merely an absence of a disease or infirmity. Psychologists have recognised that “positive health” accompanies many more dimensions, which are interdependent, and a defect in any dimension could interfere with the integration of personality. When we talk about psychotherapy in Asian countries, culture and belief play an important role. Each society has its own “belief system” which is deep rooted. Hence, in the psychotherapy sessions, the therapist should be well versed with cultural beliefs. Integrating these with the therapy will be of much benefit to patients. A few cases where “belief system” has played a significant role in the treatment will be discussed, with special reference to cases seen at Malaysia and Brunei.

Factors responsible for the onset of depression in young adulthood
Farheen Nasir University of Karachi, Pakistan
The aim of the study was to determine the factors responsible for the onset of depression in young adulthood, which could assist in designing remedial measures. The study was based on the case history of a male client aged 28 years, who experienced onset of depression at the age of 20 years. Material: Projective tests, namely Human Figure Drawing, Thematic Apperception Test and Rorschach. Method: The method applied was the single case study, where the client had initially started with catharsis, followed by free association, and cognitive-emotive exploration. Result: The responsible factors which appeared for the onset of depression were lack of parental support, lack of communication, need for perfectionism, and economic downfall, all resulting in a lack of confidence. Cognitive behaviour therapeutic techniques were finally applied for treatment. Implication: The study can help the mental health professionals, especially clinical psychologists and psychiatrists to identify the basic factors responsible for depression in young adulthood and thus to educate adolescents, young adults, parents and teachers about what measures to take in order to prevent the onset of depression.

The effect of spiritual group therapy on the reduction of depression, anxiety and stress of substance-abusers
Ghasem Naziry Islamic Azad University, Islamic Republic of Iran; Mohammad Reza Yabandeh
The aim of the present study was to determine the effectiveness of a spiritual group therapy approach on the reduction of depression, anxiety, and stress among male substance abusers who voluntarily attend drug-abuse therapy centers in Shiraz, Iran. The sample consisted of 20 participants selected from male abusers who attended Drug Abuse Therapy Centers in Shiraz, Iran. The participants were randomly assigned to two groups, an experimental (n=10) and a control (n=10) group. All participants were asked to complete the Depression Anxiety Stress Scales (DASS-21) and Spiritual Well-Being Scale (SWBS-20), in a private environment as pre-test and posttest. Participants in the experimental group underwent the spiritual group therapy for 12 sessions. Data analysis showed that there were significant reductions in anxiety (p<0022) and stress (p<0004) among the members of the therapeutic group and there were improvements in scores on Spiritual Well-Being Scale (p<0001). Therefore the spiritual group therapy approach can be used as an effective treatment approach for the reduction of anxiety and stress among male substance abusers. Meanwhile it can improve the spiritual-well being of substance abusers.

Training future psychotherapists to become more reflective about patients with personality disorders
Lina Normandin Universite Laval, Canada
This study examined whether training targeting mentalisation can increase the Reflective Functioning of predoctoral psychology students regarding patients with Borderline Personality Disorder. A total of 48 predoctoral students in clinical psychology were randomised to mentalisation training or to didactic training as commonly used in academic settings and reflective functioning was assessed on three occasions: before training, midway through the training programmes and post-training. Change in reflective functioning was measured using video vignette material of patients with borderline personality disorder. Students’ responses to vignette material were rated for reflective function, using the TMCS (Normandin & Ensink, 2009) a coding system of therapists’ mental activity that differentiates between reflective, reactive and rational mentalising. The results of independent mixed model repeated measures analyses showed that trainees assigned to the mentalisation programme, significantly improved their reflective functioning capacities whereas those who received traditional didactic training did not. However, trainees assigned to didactic training significantly increased their effectiveness in forming diagnostic impressions and proposing treatment plans whereas those participating in the mentalisation programme, did not. The strengths and weaknesses of both programmes are discussed.

Hypnosis, music and psychotherapy
Richard Oxtoby South Africa
Given that music is a language which can be used to arouse emotions, I shall explore the possibility that it can have an important place in reinforcing the verbal communications of a therapist. One area in which this has particularly powerful application is in the induction of hypnotic trance states, where the attention-focussing power of music can be used to good effect with susceptible subjects. The use of pieces such as Debussy’s En Bateau and Eric Satie’s Gnossienne no. 3 in enhancing the effects of a hypnotic intervention for stress-management will be demonstrated. Another rather different area of application to be examined is where the therapist is working with Jung’s concept of therapy as a process of healing the splits within the psyche. Visual and verbal symbolism is widely used by therapists in their attempts to achieve this state of mental health. This paper reports preliminary research into the effects of suggesting to the client listener that different parts of some musical works be regarded as symbols for warring parts of their own psyche, and
that experiencing the composer’s skill in blending disparate themes and melodies into a harmonious whole will transfer to a similarly harmonious unification of warring parts of their own psyches. This process will be demonstrated using short extracts from Beethoven’s Seventh Symphony and his Fourth Piano Concerto.

Physiological measurement of the process of perspective shift in the imagery of depression

A. Kodir Ozer Dogus University, Turkey; Emel Kromer; Ekin Erensoy

Previous studies on the effect of imagining an event from a field vs. observer perspective on emotional experience have mostly relied on the subjective and retrospective self-reports of the participants. The present study aims to measure and justify the effects of the process of perspective shift on the experience of depression by using physiological responses. Eighty-six participants were asked to imagine themselves in a situation in which they have experienced high levels of depression. Once the original perspective they used during imagery process was established, they were asked to shift to the other perspective and then back to the original one. Gender differences were found only in surface electro- myography responses of observers. Gender collapsed results indicated that heart rate responses decreased significantly when those starting with an observer perspective shifted to a field perspective. A similar but nonsignificant trend was detected for those starting with a field perspective. Again for fields, electromyography responses tended to decrease when they were asked to shift to an observer perspective. However, for observers, electromyography responses were not influenced by perspective shift. This result may indicate that in case of depression, irrespective of the original perspective of the imagery, changing the perspective has a decreasing effect on intensity of emotional experience. In general, the findings provide physiological evidence that perspective shift effects emotional experience. However, the effects of perspective shift in imagery of depression were quite different than the effects observed in test anxiety and anger.

CBT to treat anxiety in Parkinson’s disease

Nancy Pachona University of Queensland, Australia; Sarah Egan; Ken Laidlaw

Parkinson’s disease (PD) is a relatively common neurodegenerative disorder with significant disease burden. Anxiety symptoms are common in PD, with prevalence estimates ranging between 30 and 40%. Depressive symptoms and disorders frequently co-occur with anxiety in patients with Parkinson’s disease. Such co-morbid presentations increased functional impairment. In addition, anxiety symptoms in PD may stem from reactions to the illness, may stem from a pre-existing anxiety disorder, or may reflect underlying neurochemical changes which occur during the course of PD. There has been little research on the efficacy of CBT for the treatment of anxiety in PD. Adaptations to CBT for specific neurodegenerative disorders may increase efficacy of interventions. PD-specific modifications to CBT include psychoeducation about the interaction of anxiety and PD symptoms. In this presentation modifications to a standard CBT protocol for use specifically with older adults with PD are discussed, including coping with uncertainty about the future and concerns over disease progression, coping with grief and loss reactions in the adjustment to the diagnosis of PD, and developing active problem-solving strategies to enhance quality of life. Modifications specific to the presence of anxiety disorders include targeting strategies for dealing with PD specific anxiety concerns (e.g. social anxiety due to embarrassment over motor symptoms such as tremor when eating in public, fear about off periods with the consequent social withdrawal). Anxiety reactions to ‘on/off’ phases and side effects of medication will also be addressed.

Schizophrenia pathological or existential problem? The onto- psychological view

Gabriella Palumbo AEO and ISS, Italy

The authors will focus on two aspects of schizophrenia: manifest or pathological, and latent. For the first aspect, to better explain theory and method, a video will be shown. Methods for enhancing positive urges of the patient will be shown, as well as teaching strategies of how to cope with daily life, improve quality of life, and psychological well being. For the second aspect (latent schizophrenia) the paper will focus on the analysis and application of its method to social problems. It is well-known that consciousness, the historical Ego, is formed after the historical elaboration from infancy to adulthood, thus, very often, it is based on prejudices acquired right from infancy, that is, on opinion, learning, affectivity and dependence not centred on the natural identity (being). For this reason, it is particularly important to verify if the person has adequate maturity to act for social wellbeing, rather than unconsciously institutes aggressiveness and destruction. These days, proposing such “authentication” is a big challenge. We will therefore discuss the main results of two important International congresses: ‘Education and Politics’ and ‘Education and Politics: Creativity’ (organized by the International Ontopsychology Association) in which the role of authentication was discussed.

Interational pattern analysis: A development in family therapy beyond narrative therapy

Warwick Phipps University of Limpopo, Medunsa, South Africa

Within the field of family therapy, postmodernism has been associated with the emergence of narrative therapy. This approach incorporates an emphasis on the interpretation of the individual’s subjective experience. Such emphasis is consistent with the intrapsychic perspective—an earlier development—that is distinct from the later interspsychic perspective adopted in general system theory (GST) and which served as the foundation for family therapy. The intrapsychic perspective, however, is not a logical or necessary consequence of postmodernism. Consequently, the return to this perspective—as in narrative therapy—represents a deviation in the logical line of development. It is thus necessary to go beyond narrative therapy and to reconsider the development from the intrapsychic to interspsychic perspective, as incorporated by GST. Accordingly, a new development has emerged in family therapy—the interactional pattern analysis (IPA). Pioneered by Charl Vorster and overcoming the limitations of the earlier interactional approach, the IPA represents the integration of developments in communicative theory, GST, and the humanistic approach. The basis of the IPA is that the client’s presenting problem serves as the context for interpreting the meaning of interactional patterns of behaviour and, furthermore, that it is possible and necessary to observe these patterns in a systematic and trained manner. Drawing on the notion of trained—as opposed to the misconception of objective—observation, the IPA also highlights the potential value and role of trained observation in grounding future developments in family therapy.

Doors in the unconscious: A culturally sensitive approach to brief trauma resolution

Anna Maria Pi Carlos Albuiz University, United States of America

A method for brief trauma resolution is presented. This technique is based on the notion that the mind has the ability to heal through self regulatory processes and does not require an invasive therapeutic action to establish or re-establish an adaptive balance. It comprises hypnosis, relaxation techniques, guided imagery and symbols. This therapeutic approach is useful in the treatment of PTSD, Depres-
A developmental perspective on childhood psychological maltreatment
Nia Prude
HKHSS, University of Hong Kong, Hong Kong

Psychological maltreatment is considered to be a core issue in all childhood maltreatment, and its association with adult mental health sequelae has been well documented. In this paper, a developmental perspective is adopted with a view to understanding this association. It builds upon the results of a study of cognitive, affective and interpersonal phenomena in a non-clinical sample of young adults who experienced psychological maltreatment as children. Ninety participants in three groups of less severe, moderate and severe psychological maltreatment were compared on self-report measures of interpersonal and intrapersonal characteristics. The data were subject to a series of multivariate and bivariate analyses. Severely maltreated individuals were found to be distinguished by significant object-relations deficits, a high level of internalised shame, low self-esteem, and an immaturity dyadic style. The discussion highlights the effects of psychological maltreatment on the emerging sense of self and self in relation to others, as well as the avoidance of painful emotion through the regulation of affect. Some implications for psychotherapy are considered.

Psychotherapy outcome under outpatients conditions in China
Min Qin
Southwest University, China

The authors develop a psychotherapy outcome scale and a client satisfaction questionnaire, and both have good internal reliability, content validity, empirical validity, and clinical utility. We use the client satisfaction questionnaire to evaluate the effect of outpatients' psychotherapy. Most patients are satisfied with their psychotherapy. Patient’s variables, such as gender, employment, diagnosis, history of previous psychotherapy, and meditation have no statistically significant difference on client satisfaction. In terms of the patient’s age, it shows the younger the better. In terms of education, it shows the lowest the worst. In terms of family status, the satisfaction of patients living on their own are worst. In terms of income, the lowest the worst. Using dose-effect design, survival analysis indicated that 25% of patients attain clinically significant change (CS) in 5 sessions, 50% of patients attain CS in 9 sessions, and 75% of patients attain CS in 17 sessions. Psychotherapists who negotiate with outpatients about length of treatment can refer to these data.

Suicide in Botswana: Need for developing a national suicide research and prevention centre
Mohammad Rahman
Princess Marina Hospital, Bangladesh; Umme Jasmine Princess Marina Hospital, Bangladesh

Suicide is quite common among the teenagers, youths, and younger adults in Botswana. There is a close link between suicide ideation and suicide attempts with the mental health status of the individual, family and community. Botswana National Policy on Mental Health (2003) acknowledges that within the Southern African region, 20% of all patients who attend general outpatient clinics, have mental health problems that often remain unrecognised. Such unrecognised and untreated mental health problems, along with high HIV positive status cases, might be the cause of the high frequency of suicide in Botswana, as HIV positive status and its consequences, have a high mental health burden. The purpose of this paper is to critically review suicide, and its associated phenomena in Botswana, which causes immense suffering to the victims and their family, resulting in high financial loss, either directly or indirectly. Based on secondary sources of published reports, personal communication, professional observation and judgements, the paper will attempt to construct a theoretical model of suicide phenomena and its prevention in Botswana, and will evaluate the existing service delivery system in this regard. In conclusion, arguments will be placed in favour of developing a comprehensive "National Suicide Research and Prevention Centre" in Botswana, in close collaboration with similar quality centres available in the world, with an aim to strengthen cross-cultural understanding of suicide phenomena around the globe in general, but with a special mission to reduce suicide attempts, and improve the mental health and quality of life of people living in Botswana.

Clinical

The evaluation of a culturally sensitive programme to prevent and treat depression in women in the year following the birth of their baby
Rosanna Rooney
Curtin University, Australia

The aim of the current research was to evaluate a culturally sensitive support group programme to assist Iraqi women in the year following the birth of their baby (CSGG-B) in Perth, Western Australia. Participants were twelve Iraqi Arabic speaking women, who had a baby less than twelve months of age. The programme was based on Iraqi women’s explanatory models (DiCiano, Rooney, Wright & Robinson, 2010; Kleinman, 1978) of the birth and motherhood experience. A one-group pre-posttest design was used to determine if depressive symptoms had decreased during the course of the intervention and social support had increased. Results indicated that Iraqi Arabic speaking women found the support group intervention acceptable and relevant and there was a significant decrease in scores on the Edinburgh Postnatal Depression scale from pretest to posttest. These results suggested that the culturally sensitive group intervention was culturally acceptable and was associated with decreased levels of depressive symptomatology. A small randomised controlled trial of the CSGG-B was also carried out to determine whether a treatment effect was found in a different sample of Iraqi women. Preliminary results will be discussed. The potential to utilise the CSGG-B in a range of different culturally diverse groups in the year following the birth of a baby with further modifications will also be discussed.

Using the university student depression inventory (USDI) to investigate the effect of demographic variables on students’ depression in Iran
Zeinab Rostami
University of Isfahan, Islamic Republic of Iran; Nigar Khawaja; Mohammad Reza Abedi

The main purpose of this study was to investigate the Using the University Student Depression Inventory to investigate the effect of demographic variables on students’ depression. The population of the study was all of the University of Isfahan female students. For this purpose, 238 of the female students were selected by simple random sampling method and the University Student Depression Inventory (USDI) and a demographic form that measured student age, year-level, academic field, employment status, financial position, parents literacy, marriage status, and average were completed. The USDI was used because it’s the only standard, valid and reliable tool that up to now is known for measuring students’ depression. For analysis of the results, the statistical program SPSS 15 and correlation and regression analysis (stepwise methods) were used. The results showed that there is no significant relationship between student depression and demographic variables and none of the demographic variables predict students’ depression in Iran. Notwithstanding previous research that asserted there was a relationship between depression and demographic variables, according to the findings of this research it can be concluded that Iranian college students’ depression has no relationship with demographic variables. It’s recommended for future research the study of other variables that may predict students’ depression in Iran.

The effectiveness of a drug-attention control training program on reducing detoxified drug abusers’ attentional bias
Javad Salehi Fadardi
Ferdowsi University of Mashhad, Islamic Republic of Iran; Zarrin Barefon

Attentional bias for drug-related stimuli (DA) has been shown to play an important role in the substance abuse. We tested the feasibility of attentional retraining with a Drug Attention Control Training Program (DACTP). Participants were a sample of detoxified drug abusers (N=87), who were randomly divided into a group of controls and a group of trainees, who received three sessions of training with the DACTP. All participants completed Temp-
Parental tolerance and behaviour and emotional problems in children: A cohort study

Virginia Samaniego
Universidad Catolica Argentina, Argentina

In the scope of Developmental Epidemiology longitudinal studies evaluate the continuity of mental health problems in children and the factors influencing them. Parental tolerance has been one of the features that better predicts the presence of a greater degree of behavioural and emotional problems in school age children (Samaniego, 2004). The objective of this study was to determine if changes in the degree of behavioural, and emotional problems, and in the parental tolerance across time, exist and the relationship among those factors in children. An analytic cohort design study was carried out. The sample included 507 children from Buenos Aires City, Argentina whose parents responded questionnaires in three instances (Time-1-T1, Time 2-T2 [3 to 6 months from T1], and Time 3-T3 [12 months from T1]). Methods of data collection were the Parental Tolerance Scale (Samaniego, 2010) and the Child Behaviour Checklist (Achenbach, 1991 adapted by Samaniego, 2008). Results indicated that behavioural and emotional problems dropped across time (CBCL total score T1 = 37.25; T2 = 31.32; T3 = 27.15, p < .000). The level of symptoms is the better predictor of the appearance of new symptoms. Parental tolerance is stable. The decrease of the CBCL figures may reflect a developmental effect. Parental tolerance turns out to be a more stable characteristic which reflects more a trait than a state.

Discrepancies between adolescent and mother reports of maternal rearing behaviors (embu): A study conducted with Turkish adolescents and their mothers

Dilek Saritas METU, Turkey; Saritas Dilek; Gencoz Tunil

The aim of the present study was to explore the difference between mothers’ reports of maternal rearing styles and adolescents’ reports of perceived maternal rearing styles (EMBU). 595 first-grade high school students (300 females and 295 males, mean age of 15) and 365 mothers (mean age of 42) were administered EMBU. In order to examine possible gender and informant differences on EMBU, namely, warmth, rejection, overprotection, and comparison, 2 (Gender) X 2 (Informant) mixed design ANOVA with repeated measures on the last factor was performed. MANOVA results indicated significant Informant main effect (Multivariate F [4,316] = 28.44, p < .05, Wilks’ Λ = 0.99, n2 = .01) and the interaction effect were not significant, (Multivariate F [4,316] = 0.44, p > .05, Wilks’ Λ = 0.99, n2 = .006). To study which of the parenting rearing behaviors were responsible for the significant difference between adolescents’ reports and mothers’ reports, univariate analysis with Bonferroni correction was performed, thus for univariate analysis only the alpha scores lower than .0125 were accepted as significant. This analysis indicated significant informant difference for warmth [F [1, 319] = 91.80, < .001, η2 = .22], rejection [F [1, 319] = 33.13, p < .001, η2 = .09], and comparison [F [1, 319] = 26.94, p < .001, η2 = .08] subscales. Results indicated that adolescents rated their mothers as significantly less warm to them (M = 70.15) in terms of difficulty in emotion regulation as compared to their mothers report for adolescents difficult in emotion regulation. Moreover, this difference was particularly salient for the female adolescents. Thus, mothers tended to underestimate the experienced emotion regulation difficulties of their children, particularly for their daughters. Findings were discussed in line with the literature.

Differences between adolescent and mother reports of maternal rearing behaviors (embu): A study conducted with Turkish adolescents and their mothers

Dilek Saritas METU, Turkey; Saritas Dilek; Gencoz Tunil

The aim of the present study was to explore the difference between mothers’ reports of maternal rearing styles and adolescents’ reports of perceived maternal rearing styles (EMBU). 595 first-grade high school students (300 females and 295 males, mean age of 15) and 365 mothers (mean age of 42) were administered EMBU. In order to examine possible gender and informant differences on EMBU, namely, warmth, rejection, overprotection, and comparison, 2 (Gender) X 2 (Informant) mixed design ANOVA with repeated measures on the last factor was performed. MANOVA results indicated significant Informant main effect (Multivariate F [4,316] = 28.44, p < .05, Wilks’ Λ = 0.99, n2 = .01) and the interaction effect were not significant, (Multivariate F [4,316] = 0.44, p > .05, Wilks’ Λ = 0.99, n2 = .006). Parental tolerance and behaviour and emotional problems in children: A cohort study

Virginia Samaniego
Universidad Catolica Argentina, Argentina

In the scope of Developmental Epidemiology longitudinal studies evaluate the continuity of mental health problems in children and the factors influencing them. Parental tolerance has been one of the features that better predicts the presence of a greater degree of behavioural and emotional problems in school age children (Samaniego, 2004). The objective of this study was to determine if changes in the degree of behavioural, and emotional problems, and in the parental tolerance across time, exist and the relationship among those factors in children. An analytic cohort design study was carried out. The sample included 507 children from Buenos Aires City, Argentina whose parents responded questionnaires in three instances (Time-1-T1, Time 2-T2 [3 to 6 months from T1], and Time 3-T3 [12 months from T1]). Methods of data collection were the Parental Tolerance Scale (Samaniego, 2010) and the Child Behaviour Checklist (Achenbach, 1991 adapted by Samaniego, 2008). Results indicated that behavioural and emotional problems dropped across time (CBCL total score T1 = 37.25; T2 = 31.32; T3 = 27.15, p < .000). The level of symptoms is the better predictor of the appearance of new symptoms. Parental tolerance is stable. The decrease of the CBCL figures may reflect a developmental effect. Parental tolerance turns out to be a more stable characteristic which reflects more a trait than a state.

Discrepancies between adolescent and mother reports of maternal rearing behaviors (embu): A study conducted with Turkish adolescents and their mothers

Dilek Saritas METU, Turkey; Saritas Dilek; Gencoz Tunil

The aim of the present study was to explore the difference between mothers’ reports of maternal rearing styles and adolescents’ reports of perceived maternal rearing styles (EMBU). 595 first-grade high school students (300 females and 295 males, mean age of 15) and 365 mothers (mean age of 42) were administered EMBU. In order to examine possible gender and informant differences on EMBU, namely, warmth, rejection, overprotection, and comparison, 2 (Gender) X 2 (Informant) mixed design ANOVA with repeated measures on the last factor was performed. MANOVA results indicated significant Informant main effect (Multivariate F [4,316] = 28.44, p < .05, Wilks’ Λ = 0.99, n2 = .01) and the interaction effect were not significant, (Multivariate F [4,316] = 0.44, p > .05, Wilks’ Λ = 0.99, n2 = .006). Understanding self-injurious behavior: Affect regulation and pain in borderline personality disorder

Christian Schmauli C. I. of Mental Health, Germany; Sarah Reitz; Inga Niedtfeld C. I. of Mental Health, Germany; Teresa Knorz

Patients with borderline personality disorder (BPD) display a high prevalence of self-injurious behavior (SIB), e.g. cutting. Patients are reported to engage in SIB because of its immediate relief effects on emotional tension. To investigate the potential role of pain as a means of affect regulation in patients with BPD, we conducted two studies: (1) an event-related fMRI study using negative picture stimuli followed by thermal stimuli. (2) A study using incisions after a stress induction to model tissue damage and its influence on tension regulation. In study (1), results showed that both negative and neutral pictures led to stronger activation of the amygdala, insula, and anterior cingulate cortex (ACC) in patients with BPD than in HC. During thermal stimulation, we found decreased amygdala and ACC activation, which was independent of painfulness. Connectivity patterns between limbic and prefrontal regions differed between patients and controls. In study (2), the incision resulted in an
increase of subjective stress levels in HC, while stress levels decreased in the BPD group. In the BPD group, heart rate increased after a sham treatment, but decreased after the incision. Insula activity decreased, while DLPC activity increased after incision in BPD patients. Our data lends support to a mechanism of stress-reduction by pain in BPD. Also, we could demonstrate that incision-induced pain may be suited as a model for the mechanism of tension reduction in the context of SIB.

A training of learning skills for adolescents with ADHD - LeJa evaluation
Satyam Schramm C. v. O. University Oldenburg, Germany
Attention-Deficit/Hyperactivity Disorder (ADHD) is one of the most often diagnosed disorders in childhood and adolescence. Problems for adolescents with ADHD occur mainly in the fields of learning behaviour and organization. In most countries there is no empirically validated specific programme to treat this special group. To close this gap, "LeJa" - a learning skills training for adolescents with ADHD - has been developed on the basis of empirical evaluation studies. The concept of "LeJa" emphasises cognitive behavourial therapy and coaching elements, but is also based on empirically identified overall efficacious psychotherapeutic methods. Goals of the training are an increase of effective learning behaviour and supporting the adolescents in coping with normative developmental tasks. Concept and results of the empirical evaluation of "LeJa" in a large scale study in pre-post-follow-up Multi-Trait-Multi-Method-Design (n = 107) with two control groups (wait-list control and alternative intervention) will be presented.

Personality traits, nature of aggression and frustration tolerance in children with conduct disorder: A study in India
Amrita Sen University of Calcutta, India; Maria de Pinto; Damaris Estrella; Hector Rubio
The essential features of Conduct Disorder are the repetitive persistent patterns of behaviour in which the basic rights of others or major age-appropriate societal norms are violated. The present study involved an in-depth probe into the selected personality variables of children with conduct disorder (CD) and comparison to their normal counterparts (NC) to provide a better understanding of their personality traits, nature of aggression and frustration tolerance in the Indian set-up. A sample of 30 children with conduct disorder (following ICD 10 criteria) without any co-morbidity and 30 children without any behavioural problems between the ages of 9 and 13 years were assessed. The children’s personality traits, expression of aggression and frustration tolerance were evaluated using the Junior Eysenck Personality Inventory (JEPQ) and Rosenzweig Picture-frustration Study (RPFS) – Child Form. The mean values and standard deviations of the variables for each group were calculated and the t-test was used to find out whether there is any significant difference between the two groups. Statistically significant group differences were found between the children with CD and their control counterparts with respect to psychoticism and neuroticism (JEPQ). Children with CD and their control counterparts showed marked differences in the domains of ego defense and extrapunitiveveness in dealing with frustrating situations. Findings suggest that higher psychoticism and neuroticism scores along with lower ego defense and higher extrapunitiveveness are important factors in CD.

An exploration of help-seeking pathways followed by patients seeking mental health care services in Polokwane-Mankweng hospital complex
Matlou Shai University of Limpopo, South Africa; Tholene Sodi
A number of studies have indicated that help-seeking pathways followed by individuals suffering from mental disorders and other conditions of ill-health are not random, but are structured by a range of psychosocial and cultural factors. The quality and seriousness of the distress provide the impetus to the pathway, but its direction and duration is shaped by the convergence of psychosocial and cultural factors. This study explored the help-seeking pathways followed by patients receiving mental health care services in Polokwane-Mankweng Hospital Complex (PMHC) in the Limpopo Province (South Africa). A qualitative approach was followed and participants were selected through purposive sampling. Ten participants (males = 5; females = 5) who are receiving mental health care services at PMHC were aspychotic at the time they were recruited to the study. Data was collected using semi-structured interviews and analyzed using content analysis. Various themes emerged such as the knowledge of mental illness, perceived causes and management of the illness. The study revealed that various agencies and providers of health care are visited by individuals suffering from mental illness and that there is also some evidence of concurrent use of these services, i.e. Western and African. The findings emphasize that help-seeking pathways are mainly determined by the perceived causes of the illness, which are derived from cultural ideologies.

School connectedness overcomes the impact of adversity on adolescents: A longitudinal community prediction study
Ian Shochet Queensland University of Tech, Australia; Coral Smith; Rachael Bellair
Connectedness or a sense of belonging to a range of social contexts is emerging as a powerful protective factor in the domain of mental health promotion. It appears that the nature and strength of our connections to our communities, our workplaces, and our schools can have a significant effect on our ability to maintain positive mental health in the face of adversity. This paper presents a study focussing on connectedness within the school setting and the development of adolescent depressive symptoms. A sample of 483 Australian grade 7 and 8 students completed a battery of questionnaires at three time points, each six months apart. School connectedness was found to moderate the relation between negative life events and subsequent depressive symptoms. Moreover, this relation was no longer significant at higher levels of school connectedness. Students experiencing negative life events in the past six months were four times more likely to go on to develop clinically significant depressive symptoms if they initially had low as opposed to high school connectedness. Connectedness would seem to have the ability to mitigate the effects of adverse life events on adolescent depressive symptoms. These optimistic findings emphasise the potential of connectedness to more widely promote mental health in our communities. Interventions that enhance connectedness seem likely to increase the likelihood of community members following a positive trajectory despite the presence of adverse life events.

Reproductive health status and mental health of adolescent girls in rural areas of Varanasi district
Punam Rani Shukla Kayachikitsa, I.M.S., B.H.U., India
In India, adolescent girls are at high risk for reproductive problems because they move rapidly from childhood to marriage and motherhood within the brief span of adolescence. To study the reproductive health status and mental health of adolescent girls in rural areas of the Varanasi district, a community survey was done in the Kashi Vidyapeeth block of the Varanasi district. From this community, a few villages were selected by means of simple random sampling. In selected villages, a total enumeration of adolescent girls was done. A sample of 400 adolescent girls from the age group 10-19 years was then taken in proportion from these villages by the method of simple random sampling. A semi-structured interview schedule, Mental Health Inventory and Middle Sex Health Questionnaire were administered to these adolescent girls. The results indicated that the percentage of various types of menstrual problems was high in adolescent girls of rural areas of the Varanasi district. The mean score of mental well-being was low in these adolescent girls in comparison to the normal population. In addition, they showed high mean scores of phobic and somatic anxiety in comparison to the normal population. On this basis it can be concluded that the adolescent girls of rural areas suffer from various types of menstrual problems and a low level of mental well-being.

Poverty, social grants and intellectual disability examinations
Ev Terressah Siyothula Department of Health, South Africa; Anthony Pillay
The high rates of poverty in sub-Saharan Africa and several other countries are associated with desperate attempts by individuals and families to access social grant systems, where available. This paper examines the relationships between poverty, social grant applications and the role of state-employed Clinical Psychologists. While Clinical Psychologists may not wish to view this specific function as a significant component of their work, given their greater preference for psychotherapy practice, it is a reality of psychological work in poorer countries. The authors are involved in the provision of Clinical Psychology services at state-funded health care facilities in South Africa, and are regularly faced with clients or families seeking psychological examinations primarily aimed at confirming intellectual disability. In these cases families are usually hoping to receive reports that can support their applications for social grants. These include (i) disability grants, in the case of adults whose health status impairs their occupational ability, and (ii) care dependency grants for children whose health status demands constant care and supervision. The paper discusses the issues of poverty, intellectual disability and cognitive examinations, in the context of the limited clinical psychology services available in South Africa.
poverty alleviation programmes, and insufficient psychological services in poor communities.

Depression in adults with congenital deafness or acquired profound hearing loss
Evan Smith NOVA Southeastern University, United States of America; Marta Tobenas; William Dorman; John Lewis

Research suggests that deaf adults are at higher risk for developing depressive symptoms than adults without hearing impairment. As a cultural minority, deaf adults face greater difficulties and challenges that include language barriers, stigmatization, discrimination, inadequate access to mental health services, and under-trained practitioners that may not appropriately address their mental health needs. As such, we hypothesize that congenitally deaf adults and adults with acquired profound hearing loss (APHL) will report more depressive symptomatology than adults with no hearing impairment in a community sample, and deaf adults with APHL will report higher levels of depressive symptomatology than congenitally deaf adults. This study will utilise a community sample of congenitally deaf adults, adults with APHL, and adults without hearing impairment. We will recruit participants from local organisations for the deaf and hearing impaired. Participants will complete a demographics questionnaire to determine study groups by etiology of hearing loss and the BDI-II to measure depression in each participant. Results may suggest that deaf adults with APHL report higher levels of depression than congenitally deaf adults and adults without hearing impairment, possibly because deaf adults with congenital onset are more adept at forming adaptive coping mechanisms that moderate the relationship of deafness and depression. Secondary analyses using information from the demographics questionnaire may provide more insight to factors affecting depression in this underserved population. This research has explorable implications for therapeutic practice in the deaf community.

Expressive arts group therapies in psychiatric settings
Anita Solomon Spring Grove Hospital Center, United States of America

The author proposes to demonstrate an understanding of group therapies in in-patient hospital setting. Participants from different countries and obtain socialization skills and self-awareness through group therapies. These patients were encouraged to attend and increase their attendance to group psychotherapies which emphasized problem solving through effective communication, conflict resolution and cognitive methods, rather than violent means. This resulted in reducing seclusions and restraints and harmful punitive measures. The study is theoretical and non empirical in view of the many variables such as movement of patients to other wards and difficulty of conducting research in this setting. However study concludes and argues for more helpful and effective techniques to demonstrate that music and poetry can lead to nonviolence.

Effectiveness of psychiatric inpatient care
Ove Sonesson University of Gothenburg, Sweden; Tomas Tjus; Hans Arvidsson

The aim of this study was to investigate the outcome of psychiatric inpatient care. The Global Assessment of Functioning scale (GAF) was used as a measure of outcome. Patients treated in 2009 at the Sahlgrenska University Hospital, Göteborg, Sweden, made up the studied group (N = 816). Background variables consisted of ICD 10 diagnoses, age, gender, length of stay and ward affiliation. The total mean value concerning GAF at admission was 32.55 (SD = 10.80) and the corresponding value at discharge reached 53.29 points (SD = 13.80). This resulted in an overall GAF change of 20.74 (SD = 15.95) and an effect size using Cohen’s d of 1.67, 95% CI 1.56-1.79, corresponding to a large effect. Group of diagnoses was significant concerning GAF change. Persons with other mood disorders than bipolar disorders showed the highest improvement (M = 25.16, SD = 15.00, d = 2.33) and persons with schizophrenia the lowest, (M = 12.09, SD = 12.23, d = 1.12). The effect size spectra including all groups of diagnoses ranged from 1.03 (Substance related disorders) to 2.33 (Other mood disorders), corresponding to a large effect (>0.80). Length of stay and ward affiliation showed significant changes. The results indicate that the studied inpatient care units contribute to a clinically significant improvement of the patients overall level of functioning.

Cue-reactivity in females with pathological buying and healthy controls
Katrin Starcke University of Duisburg-Essen, Germany; Tobias Schaller; Debora Domass; Berenike Schlereth; Matthias Brand

It is currently under debate whether pathological buying can be considered as a behavioral addiction. Addictions have often been investigated with cue-reactivity paradigms in order to assess subjective, physiological and neural craving reactions. In the current study, 66 females (mean age = 22.93, SD = 4.34) were screened for pathological buying with the Compulsive Buying Scale and for baseline shopping craving. Thereafter, they rated shopping cues (pictures of shopping scenes) with respect to valence, arousal and subjective craving. The cues were individualized according to the participants’ shopping preferences prior to the rating. Results indicate that eight participants can be considered as “pathological buyers”. Correlational analyses indicate a significant relationship between the cue-ratings on the above mentioned dimensions and scores in the Compulsive Buying Scale even after controlling for baseline shopping craving (r’s = .27 to .32). Additionally, in a subgroup of 30 participants electrodermal reactions were assessed during cue exposure. In this subgroup, three of the eight “pathological buyers” were represented. These “pathological buyers” had higher electrodermal reactions compared to the “non-pathological buyers”, which slightly failed to reach significance. However, the group difference had a medium effect size (d = .43). Shopping cues are considered to be suited for future studies in which subjective, physiological and neural craving reactions should be assessed in a clinical sample of females suffering from pathological buying. The results of the current study provide further support for the assumption that pathological buying can be regarded as a behavioural addiction.

Excessive gaming as a psychopathological disorder? Relating MMPI-2 addiction subscales to excessive gaming
Marloes Spekman VU University Amsterdam, Netherlands; Peter Roeofisma; Heleen Riper; Elly Konijn

Should excessive gaming behaviour be considered an addiction in terms of a psychological disorder? Most voices in this heated debate tend to propose that excessive gaming behaviour should not be considered a psychopathological addiction, although it might be detrimental to one’s psychosocial life. Various studies have attempted to tap game addiction, however, thus far no study explicitly related excessive gaming to the well-established addiction subscales of the Minnesota Multiphasic Personality Inventory-2 (MMPI-2). Therefore, this was the goal of the present study. We selected three MMPI-2 addiction subscales generally used to measure addiction and substance abuse: the MacAndrew-Revised (MAC-R), the Addiction Potential Scale (APS), and the Addiction Admission Scale (AAS). Furthermore, we adjusted the relevant MMPI-2 addiction subscales to be used among (lower educated) adolescent boys because the extant literature indicates that they seem the most susceptible to game addiction. A questionnaire presenting relevant items in mixed order was distributed among 824 adolescent boys (M age = 14.14; SD = 1.39). Results show significant correlations between psychological symptoms of excessive gaming and MAC-R, APS, and AAS (r’s = .106, .126, and .634, respectively; all p’s < .01). Likewise, physical symptoms are significantly related to the three subscales MAC-R, APS, and AAS (r’s = .221, .290, and .213, respectively; all p’s < .001). Results are discussed within the context of excessive gaming as a psychopathological disorder among adolescent boys and psychopathological personality disorders more in general.

Treatment of couples experiencing domestic violence
Sandra Stith Kansas State University, United States of America; Eric McCollum

Domestic violence has devastating effects on all members of the family as well as the larger society. This manuscript discusses a treatment approach for couples who chose to stay together after mild-to-moderate domestic violence has occurred. The manualised treatment programme and the research regarding this programme were developed from funding made available through the National Institute of Mental Health in the U.S. and are available in a book written by the speakers published by the American Psychological Association, Couples Therapy for Domestic Violence: “Finding Safe Solutions”. The programme includes 18 weeks of treatment (six weeks are single gender and twelve weeks are conjoint). The treatment programme is based on a solution-focused perspective. The focus of the programme is on finding solutions and building strengths. Integral to the programme is a mindfulness meditation component beginning each session, a brief motivational interview to address substance abuse issues when necessary and a focus on individual responsibility. Eighty-three couples were randomly assigned to an 18-week multi-couple group or a single couple treatment programme. The programme has been translated into Spanish and implemented in the
Issues and challenges in the practice of play therapy in the Philippines

Maria Caridad Tarroja De La Salle University, Philippines; Louise Dey; Ma Aurora Catipon; Washington Garcia

Whereas play therapy is one of the most popular therapies employed when working with children, many play therapists in the Philippines are confronted with a lot of challenges. Through an online survey, practicing Filipino play therapists were asked about the issues and challenges they encounter in their play therapy practice and strategies they have explored to address these challenges. Their responses were analyzed qualitatively, looking into common patterns and themes. The first part of the study looked into the personal qualities and theoretical orientation of the 34 Filipino therapists who were surveyed. For the challenges and problems, three themes emerged in their responses, namely, challenges in working with parents, working with allied professionals, and the professional fees. Many play therapists admit the difficulty of explaining the process and the value of play therapy to parents. Some therapists feel frustrated when parents do not seem to value play therapy and expect quick results. With allied professionals, the main difficulty is the lack of coordination between the play therapists and the professionals. What has helped many therapists is their regular communication with the child’s parents, consultations and collaboration with allied professionals and supervision. The implications of these challenges and issues to clinical practice are discussed.

Exploring sleep problems among youth internationally

Mark Terjesen St. John’s University, United States of America

Evidence suggests that up to 43% of children ages 2 to 14 years may suffer from a significant sleep disturbance (Archerbold, Pitsch, Panahi, & Chervin, 2002). Research has shown that children with sleep problems are more likely to experience academic failure (Fredriksen, Rhodes, Reddy, & Way, 2004). Participants will learn about the major sleep disorders affecting school-age children, the cognitive and behavioral consequences of poor sleep and the impact of sleep disorders on both academics and behavior. Participants will be able to directly apply the knowledge gained from this presentation to their practice.

Delivering evidence-based treatment for youth with serious behavioral problems on a large scale

Dagfinn Theoegersen Norwegian Center Child Behavior, Norway; Bernadette Christensen

Since 1999 the Norwegian Center for Child Behavioral Development has led a national implementation of Multisystemic Therapy (MST), Functional Family Therapy (FFT) and Multi-dimensional Treatment Foster Care (MTFC). Currently the Center supports and oversees 30 teams using these evidence-based treatments (EBPs) in state welfare. The aim of this presentation is to provide a framework for successful, long-term and large scale implementation. Experience-based knowledge on key factors for success will be presented along with the results from a recent study on implementation components. In the study, 218 therapists, supervisors and agency leaders in Norway working with EBPs completed the Implementation Components Questionnaire. The psychometric quality of the questionnaire was supported by measures of internal consistency, factor analyses of the implementation components and the comparisons of implementation profiles between programs and respondents. The factor analysis confirmed our implementation framework in separating an individual clinical-level factor and an organisational system-level factor. The results also indicated differences in the importance of certain implementation components, across respondent groups and programs. In general, factors relevant to development of therapist clinical competency are relatively salient, while organisational factors are more often overlooked or ignored. These results underscore the importance of monitoring implementation components. Experience-based knowledge can inform how and when to work on improving these components throughout the process of implementation. Clinicians, researchers and policy makers should make use of this knowledge to provide quality services that reach out to more of those who need them.

Predicting depression and anxiety: The role of emotional and cognitive processing styles

Georgina Tolan Australian Catholic University, Australia; Rachel Grieve; Kate Witteveen

It is well established that emotion can facilitate positive or negative outcomes. How individuals cognitively process and engage with emotions contributes to the adaptive or maladaptive nature of emotion. Given the prevalence of depression and anxiety, identification of the factors that enhance and maintain these conditions is paramount. This study examined the role of emotional and cognitive processing styles as risk and protective factors for depression and anxiety. Using a cross-sectional, correlational design, participants completed measures of emotional regulation, emotional intelligence, alexithymia, emotional self-efficacy and cognitive processing style, as well as depression and anxiety, via self-report. It was predicted that better emotional processing and rational thinking styles would be negatively associated with depression and anxiety. Support for these hypotheses was mixed, with varying aspects of emotional and cognitive processing contributing differentially to depression and anxiety. Future research could strengthen the operationalization of emotional and cognitive processing and regulation through the use of ability rather than trait measures. It is concluded that the role of emotion and cognitive processing in depression and anxiety is complex and multifaceted, and highlights the importance of considering individual differences as risk and protective factors for these debilitating conditions.

Exploration of adolescents’ perceptions of gambling

Carey Upham Stellenbosch University, South Africa; Charnmaine Louw

In recent years the rapid expansion of legalised gambling has been associated with an increase in the rate of problem gambling and gambling disorders amongst both adults and the youth. The youth of today are raised in a society where legalised gambling is readily available, socially acceptable and presented in the media to a large extent. In a recent report, compiled in affiliation with the National Responsible Gambling Programme, it was revealed that 6% of South African adolescents gamble regularly. Adolescence is a developmental stage which is marked by an increase in risk taking, exploration and discovery. Gambling is often romanticised in popular culture. Adolescents are therefore unaware that harmful gambling can escalate to a degree whereby it could lead to decreased quality of life, addiction during their adolescent years or in later life and even other comorbid addictions. Common forms of gambling amongst South African adolescents are betting on sports games, scratch cards, flipping coins, cell phone gambling, internet gambling, dice and casino gambling. The bulk of both international and South African research has focused on adult gambling, most of which has been quantitative in nature. Limited research has been conducted on the youth as the legal age to gamble has often been utilised as an exclusionary factor for participation in various studies. The study shall take the form of a qualitative interpretive design. Data collection methods include focus group and individual interviews with grade 10, 11 and 12 adolescents. The research is still in progress.

Sabr’ (patience), ‘shalat’ (praying), and ‘dhikr’ (remembrance) as spiritual intervention for reducing psychological symptoms in region of Merapi eruption in Yogyakarta, Indonesia

Qurotul Uyun University of Leipzig, Germany

This study examined the role of spiritual intervention including ‘sabr’ (patience), ‘shalat’ (praying), and ‘dhikr’ (remembrance) to reduce psychological symptoms (somatization, depression, anxiety, and panic) on people in the region of the Merapi eruption in Yogyakarta, Indonesia. The intervention consisted of eight class sessions for one week, and each session ran for two hours. The
participants of the study were 68 refugees from two shelters of Merapi eruption survivors. They were between 18 and 50 years old, and were classified into two groups. One group (n = 37) received the spiritual intervention as the experimental group and the other (n = 31) served as control group (waiting list). The Brief Symptoms Inventory (BSI) was completed by each participant to measure psychological symptoms. A pre-test was given before the intervention and a post-test was given immediately after the treatment. A follow up test was given two weeks later. T-test analysis indicated that the participants who were trained performed significantly better than the control group on the measure of BSI. Based on the results it was concluded that spiritual intervention is effective in reducing psychological symptoms (somatization, depression, anxiety, and panic). Future investigations may lead to the incorporation of spiritual practices in psychological interventions.

**Keeping it personal/professional: The importance of differentiation of self of the psychotherapy trainee**

_ Sasja Van Der Merwe UNISA, South Africa; Ricky Nysders_

Psychotherapy is an interpersonal encounter where a therapist collaborates with clients to facilitate a healing process. Due to the personal nature of this encounter, the therapist not only needs the necessary skills and knowledge but also a differentiated sense of self. Bumberry and Whitaker (1988) define differentiation as a balance between belonging and individuation, while Bowen (1978) explains differentiation as the ability to choose whether to be guided by one’s emotions, or one’s intellect. Andolfi (1983) claims that it is who we are in our relationship with the client that facilitates the healing process. Research about psychotherapy training in recent years has focused on the respective paradigms and models used at different training institutions, while the importance of supporting the psychotherapy trainee’s own differentiation process has been neglected. In contemporary South Africa there is growing pressure to select larger groups of trainees which has the risk that the training would become less personal. I believe that this could bring about about mechanical therapists with reduced efficacy and culturally appropriate manner (crowne & marlowe, 1960). Questionnaires will be administered to the children, parent and peers as separated entities. From an eco-systemic viewpoint it is recommended that the children, parent and peers are prepared for the developmental tasks of the puberty years.

When grandiosity and vulnerability collide: Implicit and explicit self-esteem in patients with narcissistic personality disorder

_Aline Voter Free University Berlin, Germany; Astrid Schuetz; Jennifer Bosson; Claas Lammers; Kathrin Ritter; Stefan Roepeck; Michela Schroeder-Abe_

Narcissistic personality disorder (NPD) is characterised by feelings of grandiosity including exaggerated illusions of superiority and entitlement (DSM-IV-TR, APA, 2000). Based on clinical theories (e.g., Kember, 1975), many researchers argue that high explicit self-esteem in narcissists masks underlying implicit vulnerability. Conversely, based on opposing theoretical assumptions on narcissism (i.e., milton, 1981), one could assume that patients with NPD possess implicit grandiosity. This issue has not been investigated in patients with NPD. The present study examined the level of implicit (using an Implicit Association Test) and explicit self-esteem (using a self-report questionnaire) in patients with NPD in comparison to a non-clinical and a clinical control (Borderline Personality Disorder, BPD) group. According to our results, patients with NPD score higher on explicit and implicit self-esteem than patients with BPD. In comparison to non-clinical controls, NPD patients have lower scores on explicit self-esteem. Moreover, within the group of NPD patients, damaged self-esteem (i.e., low explicit, high implicit) is associated with higher narcissistic psychopathology. Our study is limited. We included patients seeking psychiatric treatment, which might be accompanied by insight into problematic behaviour. Our findings are indicative of vulnerable facets in patients with NPD (i.e. low explicit self-esteem). Furthermore, damaged self-esteem is connected to specific psychopathology within NPD patients. Further implications for research on NPD are discussed.

**Puberty, parents and peers: Tril(y) coping with bullying**

_Ronel Van Der Watt University of the Free State, South Africa_

The dynamics of bullying in puberty are complex. The upsurge in information technology and social media adds to the broadening of the social environment. These social networks can easily and anonymously be accessed to display uncensored content. Victims of bullying on school grounds may also access mobile phones to bully their perpetrators. Parents are uncertain as to how to cope with the impact of social media and the change in their relationship with their child. Consequently, parents become prone to exert relationships that resemble bullying. Coping becomes imperative. The research method included 192 children who were admitted at a private psychiatric clinic’s adolescent unit and 160 parents of these children who attended parental guidance group therapy sessions. The children attended a two-week multi-disciplinary programme. Data was gathered from the parents and children through semi-structured focus group discussions over a period of one year. The results of thematic analysis of the data reflected that parents experienced being bullied by their children. The adverse impact of authoritative parental styles and social media on children’s relationships with their parents and peers was highlighted. It was concluded that the dynamics of bullying are multi-faceted. During puberty, support to the children, parents and peers may reduce their vulnerability to bullying. It is a matter of ‘tri-coping’ instead of ‘trying to cope’ as separated entities. From an eco-systemic viewpoint it is recommended that the children, parent and peers are prepared for the developmental tasks of the puberty years.

**Risk factors for suicidal behaviour among grade 8 learners in South Africa**

_Naseema Vawda University of KwaZulu-Natal, South Africa_

Research on suicidal behaviour among youth focuses on developed countries. Less is known about the prevalence of suicidal behaviour and associated risk factors among youth who do not present for mental health care in developing countries. This study investigated the prevalence of suicidal behavior among grade 8 learners and associated risk factors in one school in South Africa. A school where a learner in grade 8 has committed suicide was asked to participate. Demographic questionnaires and various psychological scales were administered. Of the sample of 224 learners who had reported suicidal behaviour (thoughts, plans or made attempts) had higher levels of depression, perceived stress, hopelessness and anger (p < .01) than those who did not report any suicidal behaviour. Learners with suicidal behaviour also reported lower self esteem and perceived social support from family (p < .01) than those who had not reported any suicidal behaviour. Logistic regression indicated that a friend’s suicidal thoughts (OR 4.27, p< .01); alcohol use (OR 3.08, p< .01); perceived stress (OR 1.05, p < .01) and depression (OR 1.04, p<0.01) were strong predictors of suicidal behaviour. The study concludes that suicidal behaviour is prevalent in youth in a developing country and risk factors are similar to those of developed countries. These factors should be considered when assessing for suicidality and planning interventions.

**Evaluation of the capacity a gay and lesbian psychotherapeutic intervention training has to change attitudes and knowledge towards this population**

_Miguel Vazquez-Rivera Carlos Albizu University, Puerto Rico; Sean Sayers-Montalvo; Juan Nazario-Serrano_

Studies on negative attitudes towards the gay and lesbian (GL) community have been made more relevant especially in the population of psychologists and soon to be psychologists who are going to render services to the community. There are a small percentage of studies in Puerto Rico that study homophobia or negative attitudes in clinical settings. This fact can be alarming since the GL community is more prone to solicit psychotherapy services (Balsam et al., 2005). Some studies have found that psychologists’ perceptions after professional opinion towards the therapy’s goals (Green, 2003). Specifically in psychotherapy, the psychologist’s emotions and behaviors affect the therapeutic process at its core (Jones, 2000). The purpose of this research is to evaluate the capacity that GL psychotherapeutic intervention training has to change attitudes and knowledge towards intervention with the GL population in a group of psychology interns. Measures include the AGLP (Attitudes towards GL in Psychotherapy), CAIGL (Knowledge on Issues and Intervention with GL) Scale, and MCSDS (Marlowe-Crowne Social Desirability Scale). The MCSDS will evaluate if the interns answered using a more acceptable and culturally appropriate manner (Crowne & Marlowe, 1960). Questionnaires will be administered to a sample of 50 clinical psychology interns of a private university. The research design will be a pre-post-test with chronological series of one group (Herández-Sampieri, Fernández-Collado & Baptista-Lucio, 2003). Results on the effect of the independent variable (the LGBT intervention training) on the dependent variables (attitudes and knowledge) will be analyzed using an analysis of variance.
The relationship of suicide ideation and unawareness of the illness, hopelessness, and auditory hallucinations
Miguel Vázquez-Rivera; Carlos Alibiu University, Puerto Rico; Jordi Obiols-Llandrich; Sean Sayers-Montalvo; Francesc Arrufat-Nebot

One of the greatest health risks for schizophrenic patients is the high incidence of suicide attempts (Altamura, Bassetti, Bignotti, Pioli & Mundo, 2003). This study’s objective is to explore the relationship between hopelessness (BHS), unawareness of illness (SUMD), and auditory hallucinations and suicidal ideation (BSSI). The sample consisted of 49 schizophrenic spectrum patients from the Vic Hospital Consortium in Spain. Group assignment produced a control group of 27 participants and a suicide-history group of 22 participants. The research design is a cross-sectional correlational design. BHS was the only scale that revealed statistically significant differences in measures between the two groups (t[43.65] = 3.53, p=.001). Statistically significant correlations were found between the BSSI and the BHS (r = .32, p = .02), and the BSSI and the SUMD (r = .36, p = .01).

Two prediction models proved to be significant according to the Homer and Lemeshow significance test [Model 1: \( \chi^2(1) = 11.60, p = .001 \); Model 2: \( \chi^2(2) = 21.45, p = .001 \)]. Findings suggest that patients who are unaware of their illness have a lower likelihood of presenting suicidal ideation and that a negative view of the future has a significant role in the decision to end their lives. Professionals should focus more attention on therapies that concentrate on the development of awareness of the illness in these patients since they could increase the presence of suicidal ideation.

**Attrition retraining group therapy for outpatient patients with major depressive disorder, generalised anxiety disorder, and obsessive-compulsive disorder: A pilot study**

Chun Wang Nanjing Brain Hospital, China; Ning Zhang; Jie Zhang; Yalin Zhang

The aim of this present study is to examine the efficacy of attribution retraining group therapy (ARGT) and compare the responses in outpatients with major depressive disorder (MDD), generalised anxiety disorder (GAD) and obsessive-compulsive disorder (OCD). We carried out a prospective uncontrolled intervention study with an 8-week ARGT of sixty three outpatients with MDD, GAD or OCD. The Hamilton rating scale for depression, Hamilt-on Rating Scale for anxiety, Yale-Brown obsessive-compulsive scale, attribution style questionnaire, self-esteem scale, index of well-being, and awareness of illness scale were administered before and after treatment. Significant improvement in symptoms and psychological and social functions from pre- to post treatment occurred for all participants. The changes favoured MDD patients. Our study suggested that ARGT may improve symptoms and psychological-social functions of MDD, GAD, and OCD patients. MDD patients showed the best response.

**Clinical study on thought imprint psychotherapy in lower resistant state for depression**

Weidong Wang Guang’anmen Hospital, CACMS, China; Lan Hong; Yingna Lin; Xueyu Lu

Thought Imprint Psychotherapy in lower resistant state (TIP) is an indigenous psychotherapy which is suitable for Chinese culture. It was established and applied to Chinese patients with psychological disorders. It was used in our clinic for more than 20 years, and its efficacy for different types of mental disorder is satisfying. To assess the clinical efficacy and safety of TIP for depression, a randomised controlled study was adapted. 60 patients with depression were randomly divided into two groups according to different means of intervention: TIP group and paroxetine group. The trial was done in 12 weeks. 24 items Hamilton Rating Scale for depression (HAMD), Minnesota Multiphasic Personality Inventory (MMPI) and treatment emergent symptoms scales (TESS) were used to evaluate the efficacy and adverse effects. Evaluation was done before treatment, 2 weeks after treatment, 12 weeks after treatment. The results do not show any differences at the baseline between the two groups before treatment. After 2 weeks, the response rate was different: 23 cases in TIP group responded positively to treatment (76.7%), while 20 cases in the paroxetine group responded positively to treatment (66.7%). After 12 weeks, the total effective rate was 78.6% and 74.1% in the TIP group and paroxetine group respectively. In terms of safety, the TIP group complained of much less discomfort after treatment. TIP is an effective and safe intervention for depression which brings new insights, however, further studies are needed to prove its efficacy and to explore its mechanism.

The ripple effect of ADHD

Judith Wiener OISE/University of Toronto, Canada

Attention-deficit hyperactivity disorder (ADHD) is a neurobiologically-based disorder characterized by a chronic pattern of symptoms of inattention, impulsivity and hyperactivity. Individuals with ADHD have a substantial negative impact on society. Their usage of the health and mental health systems is inflated and they are more likely to have a lower likelihood of presenting suicidal ideation and that a negative view of the future has a significant role in the decision to end their lives. Professionals should focus more attention on therapies that concentrate on the development of awareness of the illness in these patients since they could increase the presence of suicidal ideation.

The problem of suicide in India: Preventive measures

Rahul Yadav RNGL, PATIALA, India

Suicide is the act of intentionally causing one’s own death and is often committed out of despair and/or due to an underlying mental disorder. Pressures or misfortunes, financial difficulties, and/or troubles with interpersonal relationships play a significant role. Considering the seriousness of the problem, the author would like to highlight the main causes of suicide, particularly in the context of India’s youth. More than 100 000 lives are lost every year due to suicide in India. Some of the factors that play a crucial role in suicide, particularly in terms of women, are: poverty, unemployment, debts, educational problems, divorce, dowry, mental disorders, love affairs, cancellation or inability to get married (due to the system of arranged marriages), illegitimate pregnancy, extra-marital affairs and conflicts relating to issue of marriage, and domestic violence. In India, attempted suicide is a punishable offence under section 309 of the Indian Penal Code. Emergency care to attempted suicide cases is denied as hospitals/doctors hesitate to provide treatment due to legal formalities. Obtaining exact data for attempted suicides is a difficult task as many attempts are described merely accidental. The following should be emphasized as preventive measures of suicides: the role of mass-media and NGOs, guidance and counseling of children, regular games/recreational activities, effective Parent-Teacher-Associations in schools, women’s education/adult education, poverty alleviation programs, effective employment policy, checking on drug abuse, etc. The law aims to prevent suicide by legal means but suicide is a multifaceted problem and suicide prevention programs should therefore be multidimensional. Collaboration, coordination, and cooperation are needed to develop and implement a national plan.

The effectiveness of Schema Therapy on patients with body dysmorphic disorder

Sagol Yadollahi University of Isfahan, Islamic Republic of Iran; Mohammad Reza Abedi; Hamid Taher Neshat Dust; Ahmad Abedi

This study investigated the effectiveness of Schema Therapy on body image and self esteem and body esteem patients with body dysmorphic disorder. The present study has a single-subject method with multiple baselines across participants. In this study, four participants that were selected by purposeful sampling were studied through sixteen individual sessions of schema therapy. Afterwards, they were given follow up tests after 2 successive weeks of treatment. Research instruments were early maladaptive Schemata scale and body dysmorphic, body image, self esteem and body esteem inventories. The results of the data chart analysis were based on descriptive statistics’ and visual analysis. Results revealed that...
the intervention has been effective on the four individuals. Findings of this study showed that the scheme therapy approach can effectively increase self esteem and body esteem and results in the make correction body image in these kind of participants.

**Risk factors for adolescent nonsuicidal self-injury: Variable- and pattern-centred approaches to change**

**Jianing You** Chinese University of Hong Kong, Hong Kong; **Freedom Leung; Kei Fu**

This longitudinal study examined adolescent personality, behavioral, emotional, cognitive, and inter-personal predictors of variations in nonsuicidal self-injury (NSSI) over a one and a half year period. Variable- and pattern-centered approaches were used, with the latter focusing on different trajectories of NSSI. Data were collected at 6-month intervals from three waves of assessment. Participants came from eight secondary schools in Hong Kong and completed the same battery of questionnaires in all three waves. At Wave 1, 5412 Chinese adolescents participated in this study. At Wave 2, 3999 (73.9%) students successfully followed. The final sample used in this study consisted of 3600 (56.6%) female students who had complete data in all three waves. The variable-centered approach showed that depression, dissociation, emotion reactivity and behavioral impulsivity were significantly associated with the current engagement in NSSI. In contrast, unstable interpersonal relationship and behavioral impulsivity predicted the increase in NSSI over time. The pattern-centered approach, on the other hand, suggested the predictive values of behavioral impulsivity and self-criticism in the increase in NSSI, as well as the protective values of lack of behavioral impulsivity and premeditation in the decrease in NSSI. These findings highlight the impulsive nature of NSSI and partly explain why NSSI is specifically chosen for emotional/cognitive regulation. Future directions and clinical implications are discussed.

**Internet-related behaviour characteristics of adolescents with internet addiction**

**Shjie Zhou** Central South University, China; **Zhihong Tang**

The aim of this paper is to explore the internet-related behaviour characteristics of adolescents with internet addiction. A total of 490 and 606 college students were collected in Yongzhou city and Changsha city, Hunan province, and were assessed by Internet Addiction Diagnostic Questionnaire (DQ), Internet Addiction Test, and Internet behaviour questionnaire. The addicted group begin to use the internet significantly earlier than the non-addicted group. The addicted group spent significantly more time online than the non-addicted group. Whereas the addicted group spent an average of 23.73 hours per week online, the non-addicted group spent 7.57 hours online. The addicted group used predominately two-way communication functions such as chat rooms, role-playing games or email. The addicted group spent more time searching cybersexual pages. The addicted group experienced higher level of internet anxiety, and internet gratification, and made more negative evaluations about the internet than the non-addicted group. The number of hours spent online and the internet content preference are predictors for determining Internet addiction.

**The experience of persons diagnosed with schizophrenia of their first admission to a South African psychiatric hospital ward for acute psychosis**

**Yumna Zubi** University of Witwatersrand, South Africa

Schizophrenia is said to be one of the most critical and severe mental illnesses affecting one percent of the population globally (Torrey, 2001). First time admission to a psychiatric hospital has been reported to be extremely traumatic and has not been adequately researched, more so in the South African context. Thus, this study explored the experience of persons diagnosed with schizophrenia of their first admission to a South African psychiatric hospital ward for acute psychosis. Semi-structured individual interviews with seven participants diagnosed with schizophrenia were conducted. These were analyzed using thematic content analysis. From the analysis it was evident that each participant had a different experience of their first hospitalization. While some had more positive experiences, the majority of the participants had frightening, distressing, emotionally painful or traumatic experiences during their first hospitalization. The first hospital admission was also described as having huge implications for the person with the diagnosis of schizophrenia as it makes them feel isolated and stigmatized which further hinders them from recovering
from symptoms and reintegrating into society. This study therefore draws attention to further research projects that may illuminate areas of intervention in the first admission process to psychiatric wards in South Africa.

Session Type: Posters

Psychopathology masking abnormal personality traits, dilemmas to success: A psychotherapy case study
Japneet Ahluwalia; Kasturba Hospital, Manipal, India; Shweta Rai; Eun Yeon
A 20 year old single female with predominant personality traits of emotional instability, low frustration tolerance, impulsivity, dramatic emotionality and anxious traits, with a history of multiple episodes of sexual abuse, presented in September 2010 with complaints of feeling increasingly anxious in the presence of strangers, excessive vigilance and scanning of the environment, autonomic arousal and panic attacks, a vague sense of apprehension and restlessness, occasional use of alcohol and tobacco, with one attempt of intentional self-harm in the past year. She also reported feeling sad with occasional crying spells for about a year. The symptoms left her experiencing a fluctuating self image, anxious cognitions, mood swings, decrease in self-worth, thereby affecting her ability to cope with educational, occupational and interpersonal demands of life. She was diagnosed with Anxiety NOS and Mixed Personality Disorder (Cluster ‘B’: Emotionally Unstable and Histrionic). Psychotherapy targeted the anxiety symptoms, but eventually these were found to be over dramatised, attention-seeking and a self-pity attempt. Considering this, the childhood dynamics of the patient, and the nature of the complaints, Cognitive Analytical Therapy was conducted. A total of 20 sessions were carried out followed by a follow-up after 4 months. The patient has benefited in all her presenting complaints as she reported a significant decrease in her anxiety and depressive features. She is able to plan her life ahead and is amenable for the further intervention plan for her maladaptive personality traits.

Effects of a school-based depression prevention programme for Japanese adolescents
Ogata Akiko Hiroshima University, Japan; Hiroshi Sato; Shin-ichi Ishikawa; Yasuko Togasaki; Shoji Sato; Yoko Sato
Adolescence is probably the optimal period in which universal prevention programmes to treat depression can be implemented. The present study evaluates the short- and long-term effects of a school-based depression prevention programme for Japanese adolescents. Participants were 176 students from the seventh to ninth grade. The eight-session cognitive-behavioural programme comprised social-skill training, cognitive restructuring, and problem-solving skills training. Students completed Children’s Depression Inventory (CDI; Kovacs, 1983), Social Skills Scale (Fujieda & Aikawa, 2001), and Children’s Cognitive Error Scale (Ishikawa & Sakano, 1993) before and after intervention. The CDI scores of 578 students from the seventh to ninth grades were used to compare depression symptoms with those of the intervention group. The result showed that depression in the intervention group decreased significantly from the pre- to post-intervention stage. Moreover, compared to the normative group, those in the intervention group showed fewer depression symptoms at post-intervention, although this finding was not statistically significant. Cognitive error and social skills improved significantly from the pre- to post-intervention stage. Improvement of social skills and cognitive error had an effect of reducing [A1] depression. Furthermore, as maintenance procedure, 24 students of the seventh grade, from the intervention group, participated in four booster sessions in each of the two years following intervention [A2] . Compared with the normative group, those in the intervention group showed significantly fewer depression symptoms one year after intervention. Our study partially validates the prevention effectiveness of universal prevention programmes for depression.

Prevalence and extent of internalising and externalising disorders among elementary school boys
Mahnaz Aliakbari Dehkhordi Payame Noor University, Islamic Republic of Iran; Asad Sadeghkhani; Aliasghar Jooybari
This study explored the prevalence and extent of internalising and externalising disorders among elementary school boys in Ilam city. This study used a descriptive and cross-sectional design. The statistical population consisted of male students educated in elementary schools within Ilam city, during the educational year 2010-2011. The sample consisted of 342 students who were selected by random categorical sampling methods among four schools. The Child Behaviour Checklist (parents reporting form) was used as a selector tool. Among the total of 342 students, 5/6% had internalising disorders and 5/6% externalising disorders. The prevalence of internalising and externalising disorders at boundary level were 12/3% and 9/6% respectively. The most epidemic internalising disorders were stress (6/7%) and physical disorders (6/7%). The most epidemic externalising disorders were Conduct Disorder (5/6%). In sum, the findings show that internalising and externalising disorders in Ilam city as compared with available research have a middle prevalence. However, the extent of internalising and externalising disorders at boundary level have a high prevalence. These conclusions show that the prevention or treatment of internalising and externalising disorders in elementary schools requires medical services and consultation.

Parenting practices of mothers of children with oppositional defiant disorder and mothers with normal children
Mahnaz Aliakbari Dehkhordi Payame Noor University, Islamic Republic of Iran; Asad Sadeghkhani; Aliasghar Jooybari
This current research intends to compare the parenting practices of mothers with children with oppositional defiant disorders and mothers with normal children. The current study is comparative post – incidence research in which about 60 mothers of children with oppositional defiant disorders and mothers with normal children were chosen using random categorising and sampling in Ilam city. The child behaviour list (reporting form for the parents and the teacher) was used as the selector tool. A questionnaire of parenting practices (Diana Bam Rend) for the survey of mothers’ parenting methods was used. The results of this research showed that there is a significant difference (p<.05) between the methods of parenting of mothers with children with oppositional defiant disorders and mothers of normal children in terms of powerful, autocratic and satisfying educational patterns. The methods that parents use to parent their children play an important role in providing for the mental health of their children and it is under an accurate relationship that we can recognise the needs of our children and try to supply and meet their needs. So, we should inform parents about methods of parenting and their effects on children.

Investigating the effect of behavioural - motor therapy on decreasing ADHD symptoms in children
Ali Akbar Arjmandnia University of Tehran, Islamic Republic of Iran; Gholam Ali Afroz; Keivan Kaka Baraei
This research is a 2-group experimental study with pre- and post-test, to investigate the influence of Behavioural - Motor Therapy on decreasing the symptoms of Attention-Deficit/Hyperactivity Disorder. The sample group consists of 18 male children (8 in experimental group & 10 in control group) between the ages of 6 to 11, who had been diagnosed with ADHD. They were chosen by available sampling and placed randomly in the research groups. The Long form of Conners’ Parent Rating Scale-Revised was administered before and after the treatment. The experimental group participated in 16 sessions (16 hours) of the therapy, twice a week, supervised by a trainer. To answer the research questions, data were analysed by Mann-Whitney U-test, paired and independent sample t-test and ANCOVA statistical methods. Results show that core symptoms of attention-deficit and hyperactivity-impulsivity were decreased significantly as a result of motor-behaviour therapy. Also, there was a significant decrease in comorbid symptoms. Symptoms of attention-deficit and hyperactivity-impulsivity were affected in the same way as motor-behaviour with no significant difference. According to the results, the use of Behavioural - Motor Therapy would be beneficial for decreasing symptoms of ADHD. Further research is required to assess academic performance and to compare other treatments with Behavioural - Motor Therapy to aid in the expansion of these results.

Prevalence of domestic violence and differential profile in addicted patients
Alfonso Arteaga Universidad Publica de Navarra, Spain; Javier Fernandez-Montalvo; Jose J. Lopez-Goni Universidad Publica de Navarra, Spain
The main objectives of this study were to determine the prevalence rate of intimate partner aggressors among users of a drug addiction treatment programme, and to establish the differential profile between addicted patients with and without associated gender violence. A sample of 125 addicted patients (95 male and 30 female) in the Proyecto Hombre addiction treatment programme in Pamplona, Spain, was assessed. Information about socio-demographic variables, presence of intimate partner violence (assessed by the Conflict Tactics
Scale and Inventory of Distorted Thoughts about Woman and Violence), socio-demographic and addiction related variables (EuroAsi), psychopathological symptoms (SCL-90-R) and personality variables (STAXI-2, BIS-10 and Inadaptation Scale) was collected at participants’ entry to the therapeutic programme. The prevalence rate of gender violence was 33.6% (94.9% of them with psychological violence, 84.6% physical violence, 43.6% sexual aggression, and 71.8% had caused injuries to their partner). Violent addicted patients showed higher severity than nonviolent patients in psychopathological (depression, anxiety, hostility) and personality (sate-anger, motor impulsivity) variables. The results of this study showed a high prevalence rate of intimate partner violence among addicted patients, as well as a significantly higher score on psychopathological and personality variables in patients with domestic violence. These findings indicate the need to assess the presence of gender violence problems in addicted patients, and to study the effectiveness of treatment programmes for drug addicted patients who present this kind of violent behaviours.

Does stress management intervention affect depression, anxiety, stress, obsessive and compulsive symptoms in patients with psychosomatic dizziness?
Neda Asemi University of Isfahan, Islamic Republic of Iran; Kourosh Namdari; Ahmad Chitsaz

We hypothesise that stress management intervention would be an effective treatment for symptoms of depression, anxiety, stress and obsessive-compulsive symptoms in patients with psychosomatic dizziness. 30 patients with psychosomatic dizziness were randomly selected from those who were referred to neurology clinics in Isfahan city. They were randomly assigned into two groups: an experimental and a control group. Each group consisted of 15 patients. Ten sessions of stress management intervention were performed for the experimental group; the control group received no treatment. Instruments DASS-42 scale and obsessive-compulsive subscale of SCL-90-R were performed on both groups before and after treatment. The data were analysed by ANCOVA. Statistical analysis revealed a significant difference in the scores of depression, stress, anxiety, and obsessive-compulsive symptoms between two groups after intervention. Findings of this study suggest that stress management intervention can significantly, and effectively, decrease psychological symptoms in patients with psychosomatic dizziness.

Correlation between attitude to mortality and psychological symptoms in students of Isfahan University
Neda Asemi University of Isfahan, Islamic Republic of Iran; Kourosh Namdari

This study was aimed to study the correlation between attitude to mortality with psychological symptoms in students of Isfahan university of 1388 students. 100 students were selected by a simple sampling method. Short form of SCL-90-R questioner (25 items) and Jean Louise mortality questionnaire were completed by students. The data were analysed by SPSS-16 in descriptive and inferential parts. The results, using Pearson correlation coefficient revealed that attitude to mortality has a significant correlation with all of the sub-scale of SCL-90-R except paranoia and somatisation. Also, the result of stepwise regression analysis showed that Interpersonal sensitivity and depression are the best predictor for attitude to mortality. Findings of this study revealed that mental health and the absence of psychological symptoms are related with attitude to mortality in people. Also psychological symptoms are less in people who have a logical attitude to mortality than in others.

The effectiveness of spiritual group therapy on the treatment of depression and anxiety in people with love trauma syndrome
Sara Bagheri Research and Science University, Islamic Republic of Iran; Ghasem Naziri Research and Science University, Islamic Republic of Iran; Jafar Bolhari

Love trauma syndrome is a collection of symptoms that appear after a broken relationship. The sample consisted of 20 university students referred to the investigator, because of a love relationship failure. The subjects were randomly assigned to two groups: experimental (n=10) and a control (n=10). All subjects were asked to complete the LTI , BDI, BAI as pre- and post test. The subjects in the experimental group underwent 10 spiritual group therapy sessions. Data analysis showed that there were significant reductions in depression (p<002) for the members of experimental group, while there was no significant difference between two groups’ anxiety scores (p>07). The results suggest that spiritual group interventions such as prayer, resigning to the will of God, and forgiveness have significant positive therapeutic effects on the treatment of depression in people with love trauma syndrome.

Psychosocial factors in the lives of mothers of children with an autistic spectrum disorder
Claudia Baxter Midrand Graduate Institute, South Africa; Lynn Hendricks

Mothers of children with a diagnosis on the autistic spectrum, are under a large amount of strain and the pressures of daily life sometimes prove unbearable. Social support systems have been shown to relieve some of the burden of stress that mothers perceive, which in turn may influence the coping mechanisms enlisted by these mothers. The purpose of this study was to explore the stressors, systems of social support, coping mechanisms and needs of mothers of children diagnosed with an autistic spectrum disorder. In depth qualitative investigations into the needs of mothers of children with autistic spectrum disorders are limited within the South African context. This study reports the findings of individual interviews with eight mothers. Findings show that the main causes of stress for mothers were financial, familial, leisure-time, social-life, medical, educational, grieving of parents, behavioural, and world-view stressors. In terms of social support systems, most mothers viewed their significant others and friends as unsupportive, with the parents of the mothers playing a more supportive role. Additionally, the results of this study showed the unique ways this sample adopted emotion-focused and problem-focused coping strategies. Mothers reported challenges in the provision of financial assistance from the government and educational facilities for them to receive parental guidance.

Evidence of improved quality of life and communication ability with Autism in a long-term intervention programme
Silvia Blatter Uni Innsbruck, Psychology, Austria; Barbara Juen; Harold Bliem

The purpose of this study is to analyse the efficiency of an intervention programme for autistic people which is characterised by a structured and increasingly complex communicative behaviours to better understanding between caregiver and client. Assessment of improvement was done by a detailed observation tool. Four years ago the institution for people with intellectual impairment started up special interventions for autistic people. One of the main-interventions was to enable autistic people to use and understand a simple way of visual communication, with the aim of a steady increase in communication complexity. The intervention was based on the hypothesis that a gain in specific communicative features of the interaction between autistic persons and caregivers, results in an increase in the quality of life of the autistic people. Quality of life was defined by an increase in positive, and a decrease in negative aspects of behaviour. The daily caregivers assessed different aspects of behaviour for each client and scored them several times a day over the whole period of four years. The results show an increase in the scores on aspects of the quality of life of autistic people, derived from studies of Schalock (2002) and Saldana et al. (2009). The autistic persons, as well as the caregivers, could improve their specific communication skills. In most cases there was also a significant decline in negative factors of behaviour, e.g. compulsive behaviour.

Internet sex addiction: The role of sexual arousal, subjective craving and internetsex preferences
Matthias Brand University Duisburg-Essen, Germany; Christian Laier; Frank Schulte

It is still under debate whether the anticipation of sexual arousal and gratification motivates individuals to excessively consume pornography on the Internet or whether they aim at compensating limited sexual activities in social reality (Young, 2008). Here, we investigated potential predictors of excessive consumption of Internet pornography in 176 heterosexual males (mean age 24.37, SD = 5.15 years). A 12 - item version of the Internet Addiction Test (IAT; Young, 1998) modified for Internetsex (IATsex; Brand et al., 2011), as well as questionnaire assessing craving, Internetsex preferences, sociosexual activities, and personality were administered. Additionally, 100 pornographic pictures were rated by all participants with respect to how much these pictures trigger sexual arousal, emotionality and overall attractiveness (all scales’ reliability Alpha > .8). While rating the sexual arousal, the viewing times were recorded. The mean IATsex score was 18.73 (SD = 6.21). In a hierarchical regression analysis, the sexual arousal while watching pornographic pictures in combination with the viewing times (R2= .096, p=.001), the current need to masturbate after watching the pictures (changes in R2=.05, p=.002), and the range of preferred sexual practices when consuming Internet pornography

Clinical
An experience of clinical supervision in the person-centered approach
Fernanda Bruck Faculdade Nobre, Brazil; Rosenei Moura; Jamie Dias; Angelide Costa; Gabrielle Batista; Nadilasara Marques; Olivia Correa

The supervised training in clinical psychology at the Faculty Noble - Feira de Santana - Brazil, during the second half of 2011, consisted of five students of the eighth semester of psychology and one student of the 10th semester of psychology. The stage consisted of various activities such as role-play, videos developed by Carl Rogers’ calls, reading and text production, awareness and supervision of clinical cases. Based on Person-Centered Approach of Carl R. Rogers, concepts such as empathic understanding, unconditional positive acceptance and consistency needed in a helping relationship, were worked out in theoretical terms but also in the experiential group supervision. As these concepts were better understood, so experiential, for each trainee in the group and the relationships between them, there was a significant learning effect, giving support to the theory of Person-Centered Approach. The theory was presented and meaningful to the trainees when they could experience it and not only understand it rationally. While trainees, therapists deepening their reflections to their customers in the therapeutic setting occurred concomitantly with changes in their self-concepts, a greater understanding of the human being and development of a more sensitive listening capacity, were generated and nourished in group supervision. The Person-Centered Approach of Carl Rogers makes sense, as to the applicability in clinical psychology intern, when it is experienced in the subjectivity of the trainee.

Psychological effects on male victims of domestic violence by female partners
Paul Campbell Paul Campbell Psychology, Australia; John MacDonald; Andrew Day; Jeanna Sutton

While there is little dispute that male victims of domestic violence exist, there is disagreement about the number of victims, the severity of the abuse, and extent to which specialist services are required, or how those services screen for male victims of domestic violence. This review examines the evidence relating to the prevalence of male victimisation, the attitudes of clinicians, and service providers, towards domestic violence, and discusses the effects of domestic violence on male victims, before raising some possibilities for service provision in this area. The conclusion of the review is that additional services may be required to meet the needs of the small, but largely unrecognised, group of men who most appropriately can be regarded as victims of violence.

A national survey on the professional backgrounds of the practitioners of psycho-counselling and psychotherapy in China
Yu Ping Cao Mental Health Institute, China; Ya Lin Zhang

To explore the professional backgrounds of the practitioners of psycho-counselling and psychotherapy in China, multi-stage sampling by regions and cities combined with cross-control quota by disciplines were used, and face-to-face interviews were conducted. According to the administrative divisions by Chinese government, the whole of China was divided into 6 regions. In each region, the sampling cities were divided into 3 city-levels such as A for the developed, B for the medium developed and C for the underdeveloped, based on the developmental level of psycho-counselling and psychotherapy. A quota sample of 200 practitioners was selected from each region. Because of uneven development by the region, sampling number of the practitioners was based on city-level. Each discipline covered one third of sampling both in each region and each city-level. A total of 1232 practitioners were face-to-face interviewed. Of them, only 49.6% of the practitioners had a professional background in psychology. In non-psychologists, 61.7% of them learned psychological knowledge from a training class, 22.2% learned from a conference, 39.6% from a refresher course, 27.7% from a supervisor, 19.6% from web-based training, and 51.4% learned by themselves. It can be seen less than half of the practitioners of psycho-counselling and psychotherapy in China have a background in psychology, and more than half of them learned by themselves. It is suggested that the practitioners of psycho-counselling and psychotherapy in China need more normalised guidelines and training.

Assessment of an adolescent living with intellectual disability and Prader-Willi syndrome
Charlotte Capri Lentegeur Psychiatric Hospital, South Africa

This study underscores the importance of in-depth assessment when attempting to better understand those who live with intellectual disability (ID). The study reports on the assessment of a 15 year old girl from a low-income community in the greater Cape Town area living with ID, Prader-Willi Syndrome (PWS), and past sexual abuse. Severe behaviour problems and life threatening obesity prompted a crisis admission to a psychiatric facility.

Language capabilities, little performance anxiety on neuropsychological tasks, acute personal sensitivity during projective testing, and a need for external structuring. These are in keeping with the described PWS behavioural phenotype, and encouraged further diagnostic considerations. By collecting quantitative and qualitative assessment data, the study illustrates how a systemic approach to assessment can facilitate diagnostic and treatment recommendations. In doing so, it contributes to knowledge of assessment and therapeutic work with children and families living with ID and PWS in lower-income communities.

Professionals’ perceptions on the role of support among individuals diagnosed with anorexia nervosa
Yihan Chen University of Witwatersrand, South Africa; Leonie Human

Anorexia Nervosa has shown to be the most dangerous disorder amongst the eating disorders because of its highest mortality and suicide rates (Arcelus, Mitchell, Wales, & Nielsen, 2011). Professionals websites have begun to emerge over the Internet in recent years. Such websites may motivate or enable the continuation of disordered eating behaviour. Individuals diagnosed with Anorexia Nervosa are often attracted to these websites because they tend to isolate themselves and they lack support systems in the real world. Given that medical professionals are the primary support persons in the treatment process, this research explored medical professionals’ perceptions on the role of support among individuals diagnosed with Anorexia Nervosa. A convenience sample consisting of four psychologists and one professional nurse were interviewed using semi-structured interviews. Thematic content analysis was used to analyse the results. From the results it was evident that Pro-anorexia websites have a dual role to play. This is discussed with reference to dealing with individuals diagnosed with Anorexia Nervosa in professional practice.

College athletes’ competitive stress coping processes
Lizhong Chi Beijing Sport University, China; Wenwen He

The Scenario Test of College Athletes’ Competitive Stress Coping Processes was used to explore the cognitive appraisals, coping strategies, coping effect and their relations on college athletes, when they faced the three specific stressors. The results revealed a notable difference between male and female in individual-item athletes, while the collective-item athletes showed differences in sex and skill level. Additionally, there were notable interactions among sex and skill level for collective-item athletes. The stepwise discriminant analysis method was also used in the study, to predict the coping strategies by using stressor’s and cognitive appraisal’s observational variables, and to anticipate the coping effect by using the variables of stressor, cognitive appraisal and coping strategies. Finally, the whole coping process of college athletes was examined with SEM method.

Parental stress in families with children with cognitive disabilities: Links with sibling relationships
Blanka Colneric Faculty of Arts, Slovenia; Maja Zupančič; Mojca Petric Faculty of Arts, Slovenia

Research suggests that families with children who have cognitive disabilities (CD) experience extended child care problems, related to higher levels of parental stress, compared to families with normative
children, or those with a chronically ill child. However, the quality of sibling relationships in families with a child with CD was not found to be significantly lower. The present study investigated the links between sibling relationships in families with a child with CD and parental stress. Parents of 95 children with CD (Mage=7 years; CD of different etiology and level) having an older normative sibling (Mage gap=3.4 years) reported on their parental stress separately, employing the measures of general (Abidin, 1995) and specific parental stress related to child disability (Friedrich et al., 1983). Both parents also provided views on the quality of their children’s sibling relationships, using the PEPC-SRQ (Kramer, 2001). Parent-perceived warmth, agonism and rivalry/competition in sibling relationships were considered. The child’s level of CD was predictive of general and specific parental stress in both parents. Parental defensive scores (a component of general parental stress) were also linked to specific parental stress. Controlling for the same rater-bias, ratings of sibling relationship dimensions were associated with parental stress; the perceived warmth between siblings was associated with lower levels of parental stress. Except for place of residence, demographic characteristics of the family were not significantly related to parental stress. The parents living in cities reported on higher levels of specific stress than those residing in towns or rural areas.

What makes a preventive stress management work?
Ana Carolina Conceicao BRB, Brazil; Samia Abreu BRB, Brazil

Stress associated with genetic factors and health risk behaviours may trigger physical and mental illness. In a Brazilian private health care facility, called “Saúde BRB”, more than half of its workers are vulnerable to diseases due to stress, according to a survey of their health profiles. As a preventive and health promotion, the institution implemented a preventive stress management programme for its employees. The programme’s goal was to reduce the symptoms of stress and to identify the mediators of behavioural change involved in the expansion of both physical and mental health. It offered psycho-educational intervention, with eight sessions, lasting 1 hour and 30 minutes weekly. At the end of each session, the facilitators completed a Process Evaluation Form (PAF), assessing organisational context variables, participants’ progress and limitations. 18 employees completed the intervention and, from a PAF content analysis, the following mediators were found: (a) the importance of integration of the group, (b) shared experiences, (c) cognitive restructuring of maladaptive beliefs and (d) social skills development. The results indicated changes in physical symptoms, self-care practices, beginning physical activity and leisure, emotional control, decreasing impulsiveness and increasing tolerance, and positive feelings about the company. The programme presented satisfactory results, however ergonomic and occupational changes would greatly assist in the prevention of stress.

The use of evidence based practice amongst therapists with patients who have post-traumatic stress disorder

Michelle Cordero-Soto Carlos Albizu University, Puerto Rico

This exploratory study consisted of a qualitative design, known as Grounded Theory. The purpose of this study was to investigate if a group (n=10) of psychologists, (both Psy.D. and Ph.D.) with current clinical practice, use evidence based practice when treating patients with Post-Traumatic Stress Disorder (PTSD). Since 2006, APA’s Task Force on Evidence Based Practice (EBP), has made an effort to disseminate and implement the use of clinical practice, that has been demonstrated to fully benefit the patient’s psychotherapy process (with a size effect of over.80). Research shows that there are a number of therapists, in the USA, who reject EBP. Until now, there are few studies in Puerto Rico that demonstrate if these patterns of rejection are the same amongst Puerto Rican psychologists. This study explored the attitudes, knowledge and use of EBP among these psychologists. The sample, which was obtained by availability, showed few psychologists had a clear definition of EBP and a majority of psychologists who were resistant and reluctant to use EBP when treating PTSD.

Comparing coping strategies among Puerto Rican adults
Melody Coste Carlos Albizu University, Puerto Rico; Tamara Martínez Carlos Albizu University, Puerto Rico; Angela Crespo; Michelle Cordero; Melany Ruiz; Sean Sayers

Over the years it has been documented that the concerns and priorities of each individual change throughout the years. Scientific literature indicates that people who are in middle and late adulthood have more coping strategies than those in young adulthood (Márquez et al., 2006). On the other hand, older people tend to adapt major strategies of appreciation at the time of dealing with any situation (Clemens, Florence, & Stefan, 2009). The objective of this research is to evaluate how each developmental stage of our lives influences the appropriate use of coping strategies in different life-event situations as well as a person’s self-esteem. A secondary data analysis will be performed using a pre-experimental design of group comparisons. Eighty-five Puerto Rican adults between the ages of 21 and 78 years were administered a 10 item Coping Strategy Scale (CSS) validated for the Puerto Rican population. Analysis of variance will be performed using the IBM SPSS Statistical Package, version 19.0. Participant’s scores on the CSS will be compared by gender, age groups, civil status, highest level of education, and religious denomination. Results from this study will permit us to have a better view on how Puerto Rican adults manage particular situations in their daily lives and what factors influence particular coping skills.

A study of the integrated cognitive model of depressive symptoms among Chinese adolescents
Lixia Cui Capital Normal University, China; None

The objective of the present study was to test the validity of the integrated cognitive model (ICM) of depression proposed by Kwon and Oei (1994) with a Chinese-adolescent sample. The model was developed for Western Europeans such as Americans and Australians and the validity of this model has not been tested on Chinese adolescents. With the two-wave panel data we hypothesized that the interaction between dysfunctional attitudes and adolescents’ negative life events experienced measured at Time 1 would predicts the frequency of automatic thoughts between Time 2, which in turn would predict the severity of depressive symptoms at Time 1. Participants were 329 Chinese junior high school students from three middle schools in Beijing. As a contrast we also tested three competing models also including the linear mediation model, the alternative etiologies model, and the symptom model. All participants completed the Adolescent Life Events Questionnaire, Dysfunctional Attitudes Scale, Automatic Thoughts Questionnaire and Center for Epidemiological Studies Depression Scale twice - 5 months apart. Path analysis was used to test all the models. The results of the path analysis indicated that the ICM model only fits the Chinese adolescent data. At the developing or increasing phase of adolescents’ depressive symptoms dysfunctional attitudes can be a common cognitive moderator of depression, whereas automatic thoughts can be specific cognitive mediators of depression.

Psychotherapists’ creativity and openness to experience: quantitative and qualitative analysis
Ervins Cikurs University of Latvia, Latvia; Sandra Sebe

The aim of this study is to quantitatively examine the relationship between measures of the psychotherapist’s personality and expressions of creativity, as well as to qualitatively explore the meanings which psychotherapists attribute to creativity and personality aspects within the psychotherapeutic process. This quantitative and qualitative analysis will be provided in regard to information from 30 professionally practicing psychotherapists in Latvia. They have completed a measure of creative expression, the Test for Creative Thinking – Draw- ing Production (TCT-DP, Urban & Jellen, 1995) the personality measure Big Five Inventory (BFI, John & Srivastava, 1999), and have responded to open-ended interview questions regarding the meaning and use of creativity and personality aspects within their professional work as psychotherapists. Quantitative analysis shows that the psychotherapists’ mean scores on creativity and Openness to Experience are higher than for a control group matched for gender, age and level of education. Psychotherapists with higher creativity scores indicated greater Openness to Experience. This presentation also will include results from the thematic content analysis of the predominant meanings and practical usefulness which psychotherapists attribute to both creativity and openness to experience within the psychotherapeutic process.

The relationship between fear of positive evaluation and social anxiety: Beyond fear of negative evaluation
Iran Davoudi Shahid Chamran University, Islamic Republic of Iran; Fateme Veisy

Cognitive theories propose that fear of negative evaluation (FNE) is the core feature of social anxiety disorder. Recently, it is discussed that fear of positive evaluation (FPE) is also a cognitive component of social anxiety. The aim of the present
study was to investigate the relationship between fear of positive evaluation and social anxiety, with control of FNE. The participants included 176 Chamran University Students (88 males, 88 females) who were selected through random multi-stage sampling. The instruments used in this study were: The Social Anxiety Scale and the Fear of Positive Evaluation Scale. The findings showed that FPE was positively associated with Social Anxiety, and its component- Social Self Concept, but not with Anxiety Symptoms (AS) and FNE. Three hierarchical regressions indicated that FPE accounted for significant variance in Social Anxiety and Social Self Concept beyond that already accounted for by FNE. The FPN couldn’t explain significant variance of anxiety symptoms after control of FNE. An explorative factor analysis provided additional support for the distinction between FPE and FNE. All of two scale items loaded on separate factors. It appears that FPE and FNE have distinct roles in social anxiety, and are probably associated with different types of anxiety symptoms. The theoretical and therapeutic implications of the findings for social anxiety are discussed.

Narrative drawing in exploring children’s attachment bonds in emotional connectedness Channelle De Beer UNISA, South Africa; Khmoetsile Modutla In this study children were provided with a unique opportunity to make their voices heard through narrative drawing. The research paradigm that formed the foundation of this study, narrative drawing, was found to be a valuable tool in inquiring into children’s thoughts, based on Cacioppo and Petty’s (1981) Thought, based on the Boston University Program. The instrument was Psychological SCL_90_R scale. Data was analysed by Multivariate Covariance analysis. Mean scores of somatization, in the post test (P<003) and follow up, was significantly lower in the experimental group than in the control group (P<003). The results showed the emotional regulation effects on the reduction of somatization of epileptic girls.

The efficacy of emotional regulation on the somatisation of epileptic girls (14-18) in Isfahan Leila Esmaeili; Dhorasoon(Isfahan)Branch,I.A.U, Iran, Islamic Republic of; Morteza Mirzaei; Aghaei Afsar; Fereshteh Afsar; Mozhde Loeipour The aim of this research was to assess the efficacy of emotional regulation on the somatization of epileptic girls (14-18) in Isfahan. In order to administer this study, 30 epileptic adolescence girls were selected from the population of epileptic adolescence girls, via the random cluster sampling method. The design of the study was comparative experimental and control group in pre-test, post-test and after 3 month follow-up. The intervention was emotional regulation training, based on the Boston University Program. The instrument was Psychological SCL_90_R questionnaire. The design of the study was a comparative experimental and control group in pre-test, post-test and 3 month follow-up. The intervention was emotional regulation training, based on the Boston University Program. The instrument was Psychological SCL_90_R scale. Data was analysed by Multivariate Covariance analysis. Mean scores of somatization, in the post test (P<003) and follow up, was significantly lower in the experimental group than in the control group (P<003). The results showed the emotional regulation effects on the reduction of somatization of epileptic girls.

The efficacy of mood induction on the psychological well-being in daughters of veterans with PTSD Maryam Esmaeili University of Isfahan, Islamic Republic of Iran; Mehrdad Kalantar; Leila Esmaeili University of Isfahan, Islamic Republic of Iran; Saeideh Mahdavi; Zahra Esmaeili Children of war veterans with PTSD have higher rate of emotional disorders. The aim of this research was to determine the efficacy of mood induction methods on the psychological well-being of the daughters of veterans with PTSD. The subjects were high school female students in Isfahan City who were assigned to two groups randomly (each group consisted of 15 adolescents). The experimental group was subjected to 8 sessions of mood inductions. We performed pre-test, post-test and follow-ups for both the experimental and the control groups, using the psychological well-being questionnaire of Borumand, Molavi and Ryft’s demographic information questionnaires. Manova analysis showed that there were significant differences between experimental and control groups: mood induction effects were found in the psychological well-being in daughters of veterans with PTSD (P=0.004).

The efficacy of emotional regulation on the somatisation of epileptic girls (14-18) in Isfahan Leila Esmaeili Dhorasoon(Isfahan)Branch,I.A.U, Iran, Islamic Republic of; Morteza Mirzaei; Mozhde Loeipour; Aghaei Afsar; Fereshteh Afsar The aim of this research was to assess the efficacy of emotional regulation on the somatization of epileptic girls (14-18) in Isfahan. In order to administer this study, 30 epileptic adolescence girls were selected from the ages of 14-18 years from the population of epileptic girls in Isfahan city via random cluster sampling method, and assigned randomly to experimental and control groups (each group had 15 people). The design of the study was comparative experimental and control group in pre-test, post-test and after 3 month follow-up. The intervention was emotional regulation training. Training was based on Boston University Program. The instrument was SCL-90-R questionnaire. Data was analyzed by Multivariate Covariance analysis of variance. Mean scores of somatization (P
Isfahan city via random cluster sampling method and assigned randomly to experimental and control group (each group15 people). The design of the study was comparative experimental and control group in pretest, post-test and after 3 month follow up. The intervention was emotional regulation. Training was based on Boston University Program. The instruments were SCL-90-R questionnaire. Data was analysed by Multivariate Covariance analysis of variance. So was mean scores of Somatisation (P

A comparison of interpersonal sensitivity and anxiety of dermatitis out-patients and normal group
Maryam Esmaeili University of Isfahan, Islamic Republic of Iran

Psychological factors have an important effect on the skin. Skin is a system with primary tasks in tactile response and direct reaction to emotional stimulants. Statistical population of this research was all dermatitis out-patients in 2011. Experimental group was 111 dermatitis out-patients which were from 18 to 50 years old, selected randomly. The control group was 93 healthy people in the same age group, also randomly selected. SCL-90-R was used in interpersonal sensitivity and anxiety item, and demographic questionnaire was administered to all subjects. The results of this study showed that the mean scores of interpersonal sensitivity and economical status of patients (13/69) was significantly more than the mean scores of the control group (11) (p<.003). The results of this study, didn’t show a significant difference between anxiety and educational level of experimental and control groups. The results of this study were similar to previous research on the relationship between stress and dermatitis. Findings of this study can show dermatologists that they should mention psychological factors to make a complete diagnosis.

Psychologists’ perceptions of the ICD-10 and DSM-IV: World region and country income level as predictors of clinical utility
Spencer Evans University of Kansas, United States of America; Joao Correia; Geoffrey M. Reed; Michael Roberts University of Kansas, United States of America; Jared Keelley

Previous research suggests that individuals maintain ‘folk taxonomies’, in which common concepts (e.g., plants, animals) are mentally arranged into groups within a hierarchical classification scheme based on similarity. Recently, a novel card-sorting methodology has been used to investigate how psychologists, psychiatrists, and students conceptualise relationships among mental disorders. Using this approach, this study aims to elucidate how clinicians around the world organize mental disorders into folk taxonomies. Five hundred eighteen psychologists and psychiatrists were asked to sort 60 cards, each containing only a diagnostic category label (e.g., ‘schizophrenia’), into groups based on their clinical similarity. Next, participants were asked to complete two more sorts, in which they would either combine or divide the original groups, resulting in a hierarchical taxonomy with three levels. The data were aggregated in a frequency matrix showing (a) how many times two cards were paired together relative to the total possible, and (b) the resultant disorder cluster groups, with varying degrees of agreement. Substance-use, mood, and personality disorder clusters had the highest rates of agreement, whereas bodily, impulse control, and childhood disorders had the lowest. Lower rates of agreement were found for disorders characterised by mixed symptom profiles, prominent developmental considerations, or concurrent psychological and physiological symptoms. Internationally, psychologists and psychiatrists share a relatively consistent folk taxonomy of mental disorders, but with disagreement regarding the nosological placement of particular disorders. Revisions to classification systems should improve clinical utility through incorporating research on how clinicians conceptualise relationships among mental disorders.

Intolerance of uncertainty and excessive reassurance seeking in depression
Lyndsay Evraire University of Western Ontario, Canada; David Doozoo; Erin Lowe

To develop a comprehensive understanding of depression, it is important to examine the dynamic interaction between an individual with depression and his or her social environment. Excessive reassurance seeking (ERS), the stable tendency to excessively and persistently seek assurances from others, regardless of whether such assurance has already been provided, is an important interpersonal behaviour to examine within the context of depression. Given the unique role that ERS plays in the development of depressive symptoms and in the deterioration of interpersonal relationships, it is critical to gain a more comprehensive understanding of this behaviour. A dearth of research has examined the cognitive origins of ERS. Although excessive reassurance seeking (ERS) and intolerance of uncertainty (IU) are conceptually linked and have both been found to occur in depression and anxiety disorders, previous research has failed to examine the association between these two variables. In the current study, two hundred undergraduates completed self-report measures of depression, ERS, and IU. Subsequently, participants read an imagery prime specifying a negative ambiguous or non-ambiguous event and completed a self-report measure specifying how they would engage in ERS following the event described. Results indicated that IU and ERS were significantly and moderately positively correlated. Furthermore, IU predicted ERS above and beyond depression and partially mediated the relationship between ERS and depression. The results of this study suggest that IU is an important variable in the prediction of ERS and that further research is needed in order to clarify the relationship between these two constructs.

Violence in drug addiction: Differential profiles of addicted patients with and without violence problems
Javier Fernandez-Montalvo Universidad Publica de Navarra, Spain; Alfonso Arteaga; Jose J. Lopez Goni Universidad Publica de Navarra, Spain

This study explored the prevalence of violent behaviours in patients who are addicted to drugs. A sample of 252 addicted patients (203 male and 49 female) who sought outpatient treatment was assessed. Information on violent behaviours, socio-demographic factors, consumption factors (assessed by the EuropAsi), psychopathological factors (assessed by SCL-90-R) and personality variables (assessed by MCMI-II) was collected. Drug-addicted patients who were associated with violent behaviours were compared on all variables to patients who were not associated with violent behaviours. The rate of drug-addicted patients with violent behaviours in this sample was 39.68% (n=100). There were significant differences between the numbers of patients who did and did not demonstrate violence on some variables. Patients with violence problems were younger than those without violence problems and were more likely to report having been a victim of abuse. Moreover, they were significantly more likely to have experienced an overdose and showed a significantly higher score on several EuropAsi, SCL-90-R and MCMI-II variables. According to these results, patients with violence control problems present with both a more severe addiction and several comorbid problems. The implications of these results for further research and clinical practice are discussed.

Polycrime among Catalan adolescents: Relationship with affective and anxiety problems
Maria Forns University of Barcelona, Spain; Laia Soler; Claudia Paretillà; Teresa Kirchner
The experience of multiple victimisations has an impact on anxiety and affective problems and on the perception of positive qualities. The objectives of this study are twofold: (1) to provide descriptive data about affective and anxiety problems and self-perception of positive qualities among Spanish adolescents; and (2) to establish the relationship between these variables and the degree of victimisations experienced. By means of a consecutive case method, 835 Catalan adolescents (36.65% boys and 63.35% girls) aged between 13 and 18 years were recruited from several secondary compulsory schools of Barcelona (Spain). The number of victimisations was assessed with the Juvenile Victimisation Questionnaire (JVQ). Anxiety Problems and Affective Problems were assessed with the Youth Self Report (YSR) DSM-Oriented Scales, and the perception of positive qualities with the scale of Positive Qualities (YSR). The results showed a high level of affective and anxiety problems among Catalan adolescents in comparison with data from multitudinal studies. In boys and girls, positive and moderate correlations were observed between the occurrence of victimisation and both anxiety and affective problems. Only in boys, a negative low correlation between victimisation and Positive Qualities was also found. The main conclusion of the present study is that the higher the number of traumatic experiences the higher is the intensity of affective and anxiety problems and the lower is the perception of positive qualities in boys. These results may contribute to a better understanding of the impact of traumatic experiences in adolescents’ psychological well-being and may have clinical value.

An approach to the study of punishment in therapy: A case study
Maria Xesus Frojan-Parga Autónoma de Madrid, Spain; Elena Ruiz-Sancho; Rebeca Pardo-Cebrian; Nerea Galvan-Dominguez; Isabel Izquierdo-Alfaro
The aim of this study is to analyze how the therapist’s punitive utterances have an influence on those emissions of the client that are in opposition to the therapeutic goals. In order to do this, ten sessions of a clinical case have been coded. The client was an adult with couple issues and low mood. The psychologist is a behavioral therapist with more than 20 years of experience in the field. Clinical sessions were coded using the Observer XT software and categorized using two tools specifically designed for categorizing verbal behavior. The first one is focused on the client, and it is built to classify his/her verbal content according to the therapeutic goals. The second one is focused on the therapist’s utterances, in order to register punishing utterances in therapy. The result was that punishment is presented in a contingent way to the anti-therapeutic conditions model than a necessary conditions model. In turn, change through the therapeutic process. This work allows us to advance further the research on processes in therapy, therefore helping us to clarify the process of clinical change during therapy.

A study of the relation between the client’s utterances and the emission of motivational utterances by the therapist in clinical settings
Maria Xesus Frojan-Parga Universidad Autónoma de Madrid, Spain; Ricardo DePascual-Verdu; Ana Calero-Elívira; Carlos Marchena-Giraldez
This study is undertaken in the broader context of a research program focusing on therapeutic change as a process. The program’s previous and current research spearheads the analysis of the learning processes that happen in clinical settings. In this particular study, we tried to find and clarify situations in which the therapist emits motivational utterances, in order to promote a relation between these and the client’s utterances. In order to do this, 92 sessions belonging to 19 cases treated by 9 different therapists with varying degrees of experience were coded using The Observer XT. The categorizing system was the SISC-INTER-CVT, developed and refined in previous studies conducted by the group. The results show a relation between the emission of anti-therapeutic utterances by the client and the emission of motivational utterances by the therapist.

Replication of an observational study of verbal behavior of the psychologist for the analysis of the therapeutic process
Maria Xesus Frojan-Parga Universidad Autónoma de Madrid, Spain; Isabel Izquierdo-Alfaro; Nerea Galvan-Dominguez; Elena Ruiz-Sancho; Ivette Vargas-De la Cruz
Previous studies of the current research group allowed analysis of verbal behavior in therapeutic interventions. Given the interest in the results found in this study, we performed a replication of the study with a new sample and an improved categorization tool. For this purpose, we recorded 92 clinical sessions from 19 patients treated by 9 behavior therapists with varying degrees of experience. The clinical work was conducted with adults and psychological treatment was individual. The instruments used were the Observer XT software for encoding sessions and Therapists’ Verbal Behavior Categorization. When performing a cluster and discriminant analysis, the new data was found to replicate the results from previous studies by the research group. These results allow us to demonstrate that the therapist’s verbal behavior changes throughout the therapeutic process, and that these variations are not explained by the therapist, the client or the case; in fact, the data show the therapist’s verbal behavior to be related to the kind of activity being undertaken. Specifically, we have found four clinically relevant activities of the psychologist: Evaluating, explaining, treating and consolidating changes. We consider this kind of analysis of the therapist’s performance in sessions to be the key to a better understanding of therapy as a process.

Improving treatment adherence: A study of therapists’ instructions in clinical settings
Maria Xesus Frojan-Parga Universidad Autónoma de Madrid, Spain; Ricardo DePascual-Verdu; Fran Linares-Carmona; Carlos Marchena-Giraldez; Ana Calero-Elívira
One of the definitions of treatment adherence has been related to the non-compliance of therapeutic prescriptions and this is related with a lower effectiveness of psychological treatments. The aim of the present study attempts to describe the therapist’s instructions during clinical intervention and to establish hypotheses about how the typologies of instructions influence treatment adherence. 20 fragments of video-taped sessions of clients attending counselling in a private psychological clinic in Madrid (Spain) were analysed. Using an observational methodology and a coding system, the clinical sessions were registered according to the instrumental categories previously defined. The Observer XT software was used for coding. We found some differences in the typologies of instructions used by the therapists depending on their clinical expertise and the activities they were carrying out in sessions. Results will be useful to establish hypotheses about the importance of the way the therapists emit instructions in order to improve therapeutic adherence and the treatment results. We need to confirm these preliminary results in future studies with a larger sample.

Coding system for the study of rules emitted by the therapist during the clinical process
Maria Xesus Frojan-Parga Universidad Autónoma de Madrid, Spain; Fran Linares-Carmona; Rebeca Pardo-Cebrian; Ivette Vargas De la Cruz
We consider that the rules emitted during the therapeutic process have a fundamental role in the correspondence between what is said inside the session and what is done outside the session. However, there are few studies about the rules emitted by the therapist and a few processes research in this field. The aim of this study was to present a coding system for the rules emitted by the therapist along the therapeutic process. The sample consisted of 57 sessions proceeded of 18 therapeutic cases conducted by a behavioural therapist. The Observer XT software instrument was used to code, register and analyse these recordings. The definitive coding system for the study of rules emitted by the therapist is presented, with 7 categories and 3 sub-categories. Adequate levels of inter- and intra-rater reliability were obtained in both cases. The potential applications of this coding system to clinical and research areas are discussed as well as the future research that could be implemented.

Psychopathology and selfconcept in schizotypy modulated by schizophrenic symptoms
Ascension Fumero Universidad de La Laguna, Spain; Adelia De Miguel
The current schizophrenia research has led to the detection of vulnerability markers in people at risk for developing the disorder. This vulnerability called schizotypy can be identified in people who are clinically unaffected. This study seeks to establish whether schizotypy predicts the presence of psychopathological symptoms and affects self-concept. From a population of 495 students, a sample was selected, including the 20% higher and lower scores for the factors corresponding to positive symptoms (cognitive-perceptual), negative symptoms (interpersonal) and thought disorder (disorganized) characteristics of schizophrenia that were combined into 8 different groups. Moreover, the existence of psychopathological symptoms and the effect on self-concept in each group was evaluated. It was noted that schizotypy dimensions differentially affect both psychological characteristics. This effect appears to conform more to a sufficient conditions model than a necessary conditions model. We conclude that the choice of mixed groups sup-
ports the prediction of specific effects on self-concept or symptomatology.

**Assessing the cognitive basis of everyday risk-aversion in OCD: The multi-dimensional risk assessment scale**

*David Garratt-Reed, Curtin University, Australia; Robert Kane; Clare Rees; Lyndall Steed*

Obsessive-compulsive disorder (OCD) is characterized by poor treatment response and high rates of symptom relapse following therapy. These problems appear to be linked to the avoidance of everyday risks. This research aimed to create and validate a measure, the Multi-Dimensional Risk Assessment Scale (MDRAS), which can be used to enhance understanding of everyday risk-aversion in OCD and inform potential cognitive-behavioural strategies to target it. Threat perception largely determines risk-averse or risk-approach responses. The MDRAS assesses the related, although separate appraisals that form overall situational threat perceptions—the probability and cost of potential negative events, and the ability to cope with those events. MDRAS items were derived from the Everyday Risk Inventory – Australian Revision and from the Life Events Stress Scale. Items were unrelated to typical OCD concerns and elicit quantitative perceptions of probability, cost, and coping ability in hypothetical daily situations and potential future negative events. Principal components analyses and confirmatory factor analyses among 222 non-clinical individuals indicated that the MDRAS Probability, Cost, and Coping scales could be separated into Everyday and Future subscales, but could also be interpreted as unitary constructs. The internal consistency of the MDRAS scales was high and the convergent and discriminant validity of the MDRAS scales were demonstrated through the pattern of correlations with a measure of negative affect, a measure of obsessive beliefs, and a measure of perceived control. The MDRAS appears to be a psychometrically sound instrument with the potential to inform treatments in OCD.

**An experimental study of gratitude and optimism in Iranian adolescents**

*Amir Ghamarani, University of Isfahan, Islamic Republic of Iran*

Gratitude can be conceptualised as a virtue or as an emotional state (Froh et al., 2008). This study investigated the effectiveness of gratitude intervention on adolescents’ optimism. Participants consist of 160 adolescents who were randomly assigned to either a gratitude, or control condition. Results indicated that gratitude intervention was associated with enhanced self-reported gratitude and optimism. Positive intervention, such as gratitude intervention, is suitable to use for adolescents in Iran.

**The relationship between perfectionism and anxiety: The mediating role of maladaptive cognitive schema**

*Fatima Ghanbari Jahromi, Science & Research Branch Azad University, Islamic Republic of Iran; Majid Barzegar; Ghasem Naziry*

The purpose of the present study is to determine the mediating role of maladaptive cognitive schema in the relation between socially prescribed perfectionism and anxiety, besides presenting a model of these relationships by path analysis. In order to collect data a nonclinical sample of 200 students was chosen by stratified random sampling (160 males and 40 females). Instruments used to achieve the objectives of the study were Hewitt and Flett Multidimensional Perfectionism Scale, depression anxiety stress scales, and Young schema Questionnaire - short form. In order to analyse data, given models of path analysis were examined. Results have shown that the initially hypothesised model had not enough fitness to be confirmed, even though revised models had a better fitness. The findings show that anxiety model did not definitely approve, after adding the path from abandonment schema to vulnerability to harm and illness schema, the revised model of anxiety showed improvement. Therefore vulnerability to harm and illness may play the role of mediator in relationship between socially prescribed perfectionism and anxiety. Perfectionism has been a difficult problem to treat and change, so exploring the mediating mechanisms that influenced the relationship between perfectionism and anxiety can be very important to provide information relevant to understanding effective components of treatments. (Department of Psychology, science and research branch, Islamic Azad University, Fars, Iran)

**Depressive symptoms in adolescents: A cross-sectional study among four major ethnic groups in Sarawak, Malaysia**

*Siti Raudzah Ghazali, University of Malaysia Sarawak, Malaysia*

The increasing prevalence of depressive symptoms among adolescents worldwide has been reported in many studies. The major objective of this study is to survey symptoms of depression in adolescents from different ethnic backgrounds in Sarawak, Malaysia. A sample of 162 adolescents aged 12 to 18 years old were randomly selected from different villages of which 43.8% were males. Of the sample, 23.5% were Malay, 28.4% were Chinese, 16.7% were Iban, and 31.5% were Bidayuh. In this study, the Center for Epidemiological Studies Depression Scale for Children (CES-DC-M) was translated and used to measure depressive symptoms. As recommended by Weissman, Orvaschell, and Padian (1980) to have a stronger discriminating score for clinical depression, the cutoff score of 21 was used to categorise the group who exhibited depressive symptoms. Results showed that the prevalence of depression was high. Eighty four adolescents (59.1%) exhibited depressive symptoms. Chi-square analysis has shown that both gender and ethnicity are not significantly associated with depressive symptoms among these adolescents. Implications of the findings and future research recommendations are discussed.

**A taxonomy of adjustment difficulties in Slovenian 3-year-olds: Dimensions, classes and associated risk-factors**

*David Gosar, UKC Ljubljana, Slovenia; Rok Holtnaner*

Based on extensive research, different empirical taxonomies of childhood psychopathology have been proposed. Using data from a Slovenian psychological screening instrument developed for detecting pre-schoolers at risk in their social, cognitive and emotional development, we aimed to confirm previously established dimensions and/or categories of childhood psychopathology such as externalising and internalising difficulties. Furthermore, we wanted to investigate the associated genetic and environmental risk-factors to establish the degree of overlap with data on previously established taxonomies. Using exploratory and confirmatory factor analysis on data from a group 22946 3-year-olds we identified nine dimensions of adjustment difficulties including internalising difficulties, externalising difficulties, ties and stereotypical behaviour, sleeping difficulties, eating difficulties and hypoactive behaviour. Additional analysis using latent class models indicated that some sets of adaptation difficulties were best described as dimensions, while others, such as externalising disorders were better described as distinct categories. Using data from 46 monozygotic and 164 dizygotic twin-pairs we also established genetic effects for internalising disorders relatively consistent with previous reports (h²=.49). In addition, we found that the genetic effects for externalising difficulties were mainly associated with inattention and hyperactivity (h²=.55), rather than with symptoms of oppositional behavior or a conduct disorder (h²=.08). Together with previous findings, our data seems to indicate that the underlying structure of childhood psychopathology is relatively robust and may be recovered using different parent-completed measures administered in different languages.

**The mediating role of thought-action fusion between the relationship metacognition and psychological distress symptoms**

*Ismail Gulum, Hacettepe University, Turkey; Nil Adali*

Thought action fusion (TAF) is a cognitive bias which researchers mostly linked with Obsessive compulsive disorder (OCD) (i.e. Piri & Kabaci, 2007). Theoretically TAF has two basic components. Metacognition is simply defined as ‘thinking about thinking’. Theoretically metacognition has five different domains (Cartwright-Hatton & Wells, 1997). There are some research about metacognitive beliefs’ role in OCD (Gwiliam, Wells, & Cartwright-Hatton, 2004; Solen, Haland, Vogel, Hansen, & Wells, 2009; Moritz, Peters, Laroi, & Lincoln, 2010). Although these two variables were previously studied separately, we think that these two variables are linked to each other. And also that these variables were previously studied mostly in OCD. In this study we examine these variables with OCD, depression and social anxiety symptoms. For this purpose, we reached 214 (125 women and 89 men, mean age is 24.46 SD=5.48) people via the Internet. We used the Metacognition Questionnaire, TAF Scale, Maudsley Obsessive Compulsive Inventory, BD1 and Liebowitz Social Anxiety Scale. There is a significant relationship between metacognition and psychological distress symptoms and TAF mediates this relationship. We have tested the mediating role of TAF (and subdomains) between the relationship metacognition (and subdomains) and psychological distress symptoms according to Baron & Kenny’s (1986) method via a series of regression analysis and Sobel’s Test. We have found that only the TAF-Likelihood has a mediating role and this role has changes between metacognition subdomains and psychological distress symptoms.
The suicide ideation and adjustment in risky high school students

Habib Hasani Shahid Beheshti Teacher Training, Islamic Republic of Iran; Behrouz Cheraghi; Akbar Mahdloo Shahid Beheshti Teacher Training, Islamic Republic of Iran; Sedigheh Nazari

One of the serious bio-psycho-social health-threatening factors in youth is suicidal ideation and behavior, which imposes irreversible losses on persons, family, and society. In this regard, identifying risk factors for suicide in this age is important. The present study with aims to prevent suicide, investigated suicidal ideation and adjustment conditions in risky high school students and its associated factors in high-risk high school students in Zanjan (Iran). To collect data from 141 male students with high-risk behaviors, the method of screening interviews, and High School Students Adaptation Questionnaire, Suicide Ideation (SSI) and Demographic Questionnaire were used. The sample selection criterion was having two or more risk factors such as: depression; bipolar disorder; conduct disorder; self-harming behavior; drug and alcohol use; violence; escape and absence from school; dead/separated/addicted parents. The results suggest that: There is a significant relationship between the divorce/death of parents suicide ideation in high risk students; negative significant relationship appears to exist respectively between emotional, social and academic compatibility and suicide ideation in high risk student; suicide ideation was not related to other variables significantly. Dead or divorced parents had positive correlation with suicide ideation however, the output regression analysis showed that, variables of emotional, social, educational adjustment were the most important predictors for suicidal thoughts, that was explained 54% of variance of suicide ideation. It can be inferred that, increased adaptation skills (emotional, social, and educational) may be inclined to reduce suicidal ideation and behavior in high-risk students.

Predictive factors of suicide trends in opioid-dependent individuals under methadone treatment

Habib Hasani Shahid Beheshti Teacher Training, Islamic Republic of Iran; Ali Reza Aghajanlou; Mohammad Reza Eskandari; Soghra Karami

This study investigated factors affecting suicide trends in opioid-dependent patients covered under methadone treatment. The study sample included 157 opioid-dependent subjects, referred to Zanjan Addiction Treatment centres, selected by random sampling, responding to the Maudsley Addiction Profile (MAP), and the researcher-designed questionnaire. To extract the results, correlation tests, independent samples T test, analysis of variance, and stepwise regression analysis were used. Findings showed that: 1) factors of age, occupation, age at onset of substance abuse, type of drug used, methods of drug abuse and psychiatric disorders in drug abusers have a significant positive relationship with tendency to suicide; 2) rates of suicide trends in opioid-dependent individuals are found in younger, unemployed or part-time employed people; beginning at ages under 20 years, type of drug consumption, including by injection, and in people with psychiatric disorders, more than other groups; 3) regression analysis showed that respectively, age, occupation, age at onset of drug abuse, risk of psychiatric disorders, the type of drug consumed, explained most of the variance of tendency to suicide. The study highlights the importance of variables as age, occupation, age of onset of use, risk of psychiatric disorders and substance use in opioid-dependent people who have suicidal tendencies, and emphasises the complementary therapies that reduce suicide risk factors.

Comparative study of anxiety in the three stages of pregnancy and its association with demographic determinants

Habib Hasani Shahid Beheshti Teacher Training, Islamic Republic of Iran; Alireza Aghajanlou; Sedigheh Nazari

The study aimed to evaluate the comparative study of anxiety in pregnant women during the first, second and third trimesters of pregnancy, and its relationship with demographic variables in Zanjan province. The research subjects included 226 pregnant women for the three stages of pregnancy. For this purpose, subjects responded to the Spielberger State-Trait Anxiety Inventory (STAI-Y) and Demographic questionnaire. To extract the results, statistical methods of correlation, independent sample T test and ANOVA were used. Results showed that: 1) anxiety levels in the first trimester of pregnancy are higher than the second and third trimesters; 2) there is an inverse relationship between the age of pregnant women and their pregnancy anxiety level; 3) there is an inverse relationship between the educational level of pregnant women and their pregnancy anxiety level; 4) with increasing frequency of pregnancy, maternal anxiety decreases; and, 5) anxiety level in pregnant women doesn’t significant relate to their family income. Overall, these results indicate that the level of anxiety in the first trimester of pregnancy is more than the second and third trimester and demographic factors such as age, educational level and frequency of pregnancy affect this relationship.

The relationship between ways of coping and anxiety in pregnant women in Zanjan

Habib Hasani Shahid Beheshti Teacher Training, Islamic Republic of Iran; Behrouz Cheraghi; Alireza Aghajanlou; Seydeh Mozghan Dehghan; Fariba Taheri; Sedigheh Nazari

This study investigated the relationship between ways of coping and anxiety, in pregnant women in Zanjan. Data were collected from 164 pregnant women. All subjects responded to demographic, anxiety Spielberger State-Trait Anxiety (20 Measures) and Lazarus-Folkman ways of coping (66 Measures) questionnaires, including 9 subscales of confrontive coping, distancing, self-control, seeking social support, accepting responsibility, escape-avoidance, planful problem-solving and positive re-appraisal. To extract the results, statistical methods of correlation and multiple regression analysis were used. Results showed that: 1) There is negative relationship between coping strategies and the anxiety rate of pregnant women. 2) Pregnant women anxiety showed a positive significant relationship with distancing, self-control, seeking social support, planful problem-solving, positive reappraisal, subscales of ways of coping. 3) Pregnant women anxiety has a positive relationship with escape-avoidance and confrontive coping subscales of coping. 4) There was no significant relationship between anxiety and accepting responsibility as well as escape-avoidance subscales ways of coping. Considering the high prevalence of anxiety among pregnant women and the negative effects on mother and foetus, we suggest that, at this critical period, training and change of dysfunctional coping strategies can play an important role in reducing anxiety, and reducing the risks in pregnancy on the foetus and the mother.

Examining the constructs of meta-emotion philosophy in mothers of children with Oppositional Defiant Disorder

Michelle Hendrickson University of Kansas, United States of America; Julie Dunsmore; Thomas Ollendick

Many aspects of parental emotion socialisation have demonstrated importance in the development and maintenance of children’s externalising behaviours. The purpose of this study was to examine whether indices of emotion socialisation cohered, forming distinct groups of parents of children with Oppositional Defiant Disorder (ODD). Identification of such groups may have important implications for intervention and prevention. Parents’ meta-emotion philosophy is comprised of attitudes about, and reactions to, emotional experience and expression (Gottman, Katz, & Hooven, 1997). It has been theorised to be a core belief structure that organises the parenting system. Therefore, these indices of emotion socialisation were hypothesised to cohere in a way that is consistent with the meta-emotion construct. The sample included 63 children diagnosed with ODD and their mothers. Mothers completed questionnaires, and mother/child dyads participated, in an emotion-talk task to measure aspects of emotion socialisation. A K-means cluster analysis revealed two significantly different groups. One parenting group was characterised by high levels of both positive and negative monitoring, and low levels of attention to negative emotions. Parents in the second group were relatively uninvolved in monitoring and discipline, but displayed high levels of attention to negative emotions. Contrary to hypotheses, these
groups were not consistent with the meta-emotion typologies. However, with further study, these cohesive groups may have implications for treatment. Results indicate that variation in parent emotion socialization profiles exist within a population of mothers of children with ODD. Treatment approaches may benefit from considering parent characteristics, such as involvement and emotion socialisation.

A therapeutic intervention with a neglected child utilising attachment theory and theraphlay

Lorryn Herbst; Nelson Mandela Metropolitan Uni, South Africa; Greg Howcroft; Louise Stroud

The extensive amount of research conducted internationally in the field of John Bowlby’s attachment theory indicates an insecure attachment between a child and the primary caregiver has a detrimental effect on both social and emotional development in childhood, as well as having a profound effect on psychological development and functioning in adulthood. The present study aimed to explore and describe the therapeutic process of an eight year old child with an insecure-ambivalent attachment style and how nurturance and feelings of safety impact the attachment style. The therapeutic process was embedded within Ann Jernberg’s Theraphlay framework and the case was further contextualized within Bowlby’s attachment theory. The case study method was utilised and specific inclusion criteria were used to identify the participant. Irving Alexander’s content-analytic framework was employed for data analysis. It was found that Theraphlay provides an appropriate therapeutic process to intervene when the child has a prominent need for nurturance.

Relationships between parental mental distress and functional somatic symptoms in children: An investigation of the moderating effects of parenting style

Ye Huang, Nankai University, China; Xinjian Wang; Bin Zhang

The aim of the study was to examine whether parenting style mediates the relationship between parental mental distress and children’s functional somatic symptoms. 306 junior school students, aged from 13-15 years, and their parents participated. Children completed the Children’s Somatization Inventory-24 (CSI-24), Depression Self-rating Scale for Children (DSRSC), The Screen for Child Anxiety Related Emotional Disorders (SCARED) and Short-Form Minnen av Bamdums Uppfostran (s-EMBU). Parents completed the SCL-90. Parental anxiety and depression subscales were significantly associated with their children’s functional somatic symptoms. Parenting style partially mediated the relation between children’s functional somatic symptoms and parent’s mental distress for depression and somatization. However, protective parenting fully mediated the relationship between children’s functional somatic symptoms and parent’s anxiety, indicating that parent anxiety did not uniquely contribute to children’s functional somatic symptoms. The results suggest that parenting style needs to be addressed when treating children with functional somatic symptoms.

Social, behavioural, familial and parenting variables in ADHD and ODD pre-school children

Aylin Ilden Kockar; Istanbul Kemerburgaz University, Turkey

The aim of this project is to understand the early symptoms of Attention Deficit Hyperactivity Disorder (ADHD) and Oppositional Defiant Disorder (ODD) and define the problems that may arise in terms of the child-parent relationship. In this study three groups of children, namely, children at risk for preschool ADHD and ODD, preschool children who have been diagnosed as having ADHD and ODD, and a control group and their parents will be compared in terms of the children’s social and behavioural features as well as parenting styles and family functioning. It is expected that family dysfunction will be related to the child’s ADHD and ODD symptoms. In parents of preschool children with symptoms of ADHD and ODD, more depression, anxiety, and burnout should be observed, their coping skills will be less effective, and they will perceive less social support than parents of normal controls. It is also expected that in parents of preschool children with symptoms of ADHD and ODD, a more controlling and negative child rearing style will be observed compared to parents of normal controls. Parents of ADHD and ODD children will have lower acceptance towards their children, as well as having less perception of competence about their parenting. Through this study, it is expected that some of the problems that the risk group of ADHD and ODD children and their parents will be understood and measures of intervention and prevention can be taken.

Theory of mind deficit in patients with schizophrenia

Osamu Imura; Osaka University, Japan

It is well known that patients with schizophrenia have difficulties in social relationships. One of the reasons why they have such disorders is supposed that the ability to infer other’s intention and emotion is deteriorated. In other words, patients with schizophrenia have a deficit of “theory of mind (ToM)”. Several researchers have revealed that they showed lower scores in the ToM tasks compared with normal controls. However, the relation between ToM deficit and social adaptation in patients with schizophrenia is not clear. Patients with schizophrenia (n=31, mean age=45.8) and normal controls (n=11, mean age=47.3) participated in the study. Smart type ToM task (first order ToM) was performed to assess their ToM ability. BPRS (Brief Psychiatric Rating Scale) and Life Assessment Scale for the Mentally Ill (LASMI) were used to measure their symptoms (BPRS) and social adaptation levels (LASMI). Patients with schizophrenia showed lower correct score (35.5%) on the ToM task compared with that of normal controls (90.9%). Patients who failed the ToM task showed higher scores in BPRS (general psychopathology, anxiety and tension) than those who did not. Positive symptoms did not differ between the two patients groups. The correlation between ToM and LASMI was not clear in this study, because the values of point biserial correlation coefficient were low. The results of this study confirmed the former researches. Patients with schizophrenia have difficulties to infer other’s mental state. However, the correlation between ToM ability and social adaptation was not clear. Further studies will be needed.

A comparative study of psychological well-being dimensions of parents with oppositional defiant disorder (ODD) children and parents with normal children

Ye Jamal; Islamic Republic of Iran; Somaye Jamal; Ahmad Abedi

The aim of the current research was to compare the psychological well-being dimension of mothers with Oppositional Defiant Disorder (ODD) children and mothers of normal children, using the ex-post facto method. The statistical population was the third grade class of a school in Isfahan city, during 2010-2011. The sample consisted of 30 students with Oppositional Defiant Disorder and 30 normal students. They were selected by multi-stage cluster sampling method. Tools were Oppositional Defiant Disorder Rating Scale, Ryft’s Psychological Well-being Survey, and Competitive Interview. The results showed that there is a significant difference between the psychological well-being of mothers with Oppositional Defiant Disorder children and mothers with normal children. Mothers with Oppositional Defiant Disorder children have lower levels of well-being than mothers with normal children.

Dysfunctional beliefs, rumination and severity of depressive symptoms in primary care patients

Konrad Janowski; Uni. of Finance and Management, Poland; Tomasz Jedynak; Joanna Zakrzewska; Konrad Skrzetek

Cognitive theories of depression postulate that thought processes are a primary cause of depression leading to secondary affect changes. Among different thought processes, dysfunctional beliefs about oneself, the surrounding world and the future, as well as ruminative thoughts were most strongly implied as of key importance in the etiology of depression. The objective of this study was to assess the contribution of both dysfunctional beliefs and rumination to severity of depressive symptoms. Seventy-nine primary care patients were recruited to the study. They completed measures of depressive symptoms (Beck Depression Inventory), rumination (Ruminati Questionnaire) and dysfunctional beliefs (Dysfunctional Attitudes Scale-A). The severity of depressive symptoms (as measured by BDI) was varied in the sample and ranged from 0 to 33 (M=9.19, SD=6.91). Stepwise regression analysis was carried out with the severity of depressive symptoms as the dependent variable, and basic sociodemographic variables, rumination and dysfunctional beliefs scores – as independent variables. The resulting regression model contained the dysfunctional beliefs total score, and rumination about oneself as the only variables significantly contributing to explanation of the scales and in Clinical symptoms severity. These two variables explained about 31% of the variance in depressive symptoms. Significantly higher variance in depressive symptoms was explained by rumination than by dysfunctional beliefs. These findings provide only partial support for the claim about the importance of dysfunctional
believes and emphasise the role of ruminating in the etiology of depression.

Using virtual reality exposure therapy treatment with social anxiety disorder

Rong Kai, Beijing Forestry University, China; Wang Guang

The main goal of this study was to offer data about the efficacy of virtual reality exposure therapy (VRET) in the treatment of social anxiety disorder (SAD). VRET is a new treatment modality that places the individual in a "virtual" world by using real-time computer animation, audio input, and so on. Social anxiety disorder has become a highly frequent problem in our society. The study aimed to explore the effectiveness of a set of virtual reality environments for emotionally significant responses in Chinese people with high levels of social anxiety. A sample of 120 people with high social anxiety participated in this study and were randomly assigned to an imagination exposure group, a virtual reality exposure group and a waiting list group. Also, repeated measures (pre-treatment, post-treatment and 3 month follow up) were taken. The improvement achieved using virtual reality exposure therapy was better than for the waiting list group (F=21.231, p<0.01), which supports the efficiency of VRET for the treatment of social anxiety disorder.

The effectiveness of cognitive-behavioural stress management therapy on relapse prevention

Negar Karimian, University of Allame Tabatabii, Islamic Republic of Iran; Mahmoud Golzari; Ahmad Borjali

The role of stress at the beginning of addiction, its persistence and relapse after treatment, has been shown in several studies, and also that stress doesn’t spontaneously trigger substance dependence, or relapse after treatment, but that it is related to a lack of appropriate coping skills in dealing with stress. The purpose of this study was to investigate the effectiveness of cognitive-behavioural stress management therapy on relapse prevention in men who are substance dependent. In an experimental study, 30 individuals who settled in Esfahan therapeutic community center were randomly divided into experimental (15 subjects) and control (15 subjects) groups. The experimental group underwent ten 90-minute sessions of cognitive-behavioural stress management, and the control group didn’t receive any particular treatment. All participants underwent urine tests at the beginning of the study, completion of treatment, and three months after the completion of treatment. Data were analysed using descriptive statistics and tests. Test results showed a significant difference in relapse rates of two groups in the follow-up stage (P<0.05). Cognitive-behavioural stress management therapy is effective in relapse prevention in men who are substance dependent.

Does stress management affect the promotion of quality of life in substance dependents

Negar Karimian, University of Allame Tabatabii, Islamic Republic of Iran; Guo-Xiu Tian; Alexandra Restrepo; Sergio Christiano

This study investigated the effectiveness of cognitive-behavioural stress management therapy on promotion of quality of life in men who are substance dependent. 30 individuals who settled in Esfahan therapeutic community center were randomly selected. They were randomly assigned into an experimental and a control group. Each group consisted of 15 persons. 10 sessions of cognitive-behavioural stress management were performed on the experimental group, but no intervention was done on the control group during this period. All participants completed the quality of life inventory (sf-36) at the beginning of the study, on completion of treatment, and three months following the completion of treatment. Data were analysed using descriptive statistics, analysis of covariance. Analysis of covariance test results showed a significant difference between the two groups in promotion of quality of life in the post test stage and following stage (P<0.05). Findings of this study revealed that cognitive-behavioural stress management significantly and effectively increase quality of life in men who are substance dependent.

Comparing the effectiveness of buprenorphine and methadone in preventing relapse in Iranian substance abuse patients

Hamid Kazemi Zahrani, University of Esfahan, Islamic Republic of Iran; Hamid Nane, University of Esfahan, Islamic Republic of Iran; Seyyed Hossein Abdollahi; Mahnaz

Substance abuse is one of the most common psychiatric problems. It interacts with environmental and genetic factors such as abnormality and sociocultural conditions. These disorders can occur in the form of poisoning, dependence and abuse (Abosaleh, 2006). Finding a way to treat and prevent relapse on patients is one of the clinician’s fundamental concerns. Current treatments are divided in two basic groups: Medical treatments and psychological treatments. The aim of this study was to compare the effectiveness of maintenance treatment with Buprenorphine and Methadone on changing substance related beliefs, substance tempting ideas, self efficiency, emotional regularity and prevention of relapse in patients. For this aim, 60 samples of patients with diagnosed as addicts have been selected and randomly assigned to one of two groups. Either to maintenance treatment with Methadone or with Buprenorphine. Participants of each group completed questionnaires that relate to substance related beliefs, substance tempting ideas, self efficiency and emotional intelligence before and after the treatment. The data analysis showed that maintenance treatment with Buprenorphine differs significantly from treatment with Methadone. (F=39.4, P<0.01). In particular, there was a significant difference in relapse rate variables. This can be explained in terms of the fact that treatment with Buprenorphine, because it has a different impact on neurophysiological mechanisms of addiction, reduces substance tempting ideas, increases the client’s sense of self control, and the capacity for emotion regulation associated with the temptation.

The simple and multiple relationships between health and emotional maturity of gifted and non gifted students

Abolghasem Khoshkonesh, University of Shahid Beheshti, Islamic Republic of Iran; Roghayeh Rahimi

The aim of the present study was to assess the simple and multiple relationship(s) between mental health and emotional maturity among the gifted and non gifted students. The method of the research was descriptive. 280 gifted intelligent high school students (138 males, 142 females) and 280 non gifted ordinary high school students (138 males, 142 females) were selected from a community of students in the second grade of high schools through cluster random multi-step sampling. Participants in this study responded to mental health (SCL25) and emotional maturity scale (EMS) questionnaires. Results showed there were meaningful and positive relationships between mental health and emotional maturity in gifted and non gifted male and female high school students. The mean of the scores of mental health in gifted and non gifted males were more than the mean of scores in gifted and non gifted females. So non gifted females had less mental health than gifted females. Gifted males had less mental health than non gifted male high school students. Gifted and non gifted males and females were different in emotional maturity and mental health. Thus, gifted males and females were better than ordinary male and female students in general. So, it may be due to family care of them.

Study and compare irrational beliefs and relationship beliefs of women requesting divorce in Boukan

Abolghasem Khoshkonesh, University of Shahid Beheshti, Islamic Republic of Iran

This paper aims to study and compare irrational beliefs and relationship beliefs of women requesting divorce from a family court with that of women willing to keep their marriage in Boukan. Samples included 100 individuals; 50 women requesting divorce and 50 women willing to keep their marriage, that have been selected by sampling from an available population. Both groups answered the questionnaires of personal traits (compiled by the researcher), relationship beliefs (RBI), and irrational beliefs (IB). The data were analyzed by descriptive statistics (mean, standard deviation, and so on) and inferential statistics (multivariate analysis of variance (MANOVA) and LSD test. Analysis of the inferential statistics indicates that there is a difference between the two groups regarding the total number of irrational beliefs and subscales of demand of approval, blaming, emotion irresponsibility, anxious over-concern, dependency, despair about changing, perfectionism and that they are meaningfully higher in women requesting divorce. The total number of relationship beliefs is lower than that of its subscales; disagreement is destructive, mind regarding is expected, partner can’t change, sexual perfection, and the sexes are different, is different and they are meaningfully higher in women requesting divorce. Generally speaking, some of the reasons for divorce among the women of Boukan are ineffective relationship beliefs, cognitive distortions, and irrational expectations of partners in marital relationships. Partners’ irrational thinking and beliefs affect their marital satisfaction and may lead to a breakdown of their relationship.

The effect of teaching communicative patterns of pluralistic family on couples’ happiness

Clinical
Sadrollah Khosravi (IAU, Firoozabad, Islamic Republic of Iran; Sara Ahmadi)

One of the basic elements of positive psychology is happiness. People who are happy feel more secure. They find it easier to make decisions and they feel more satisfied. The purpose of the present research is to measure the efficacy of teaching pluralistic family communication patterns on couples’ happiness. Some experiments, including pre test and post test were designed with a control group. The research comprised clients from consultation centers in Shiraz. Forty couples were selected randomly according to the revised version of Koernner and Fitzpatrick’s family communication patterns. Two factors, namely laissez-fair and protective family patterns, were taken into account through the process of selection. The Oxford Happiness Inventory was administered to the couples. Ten 90 minute training sessions were held to expose the experimental group to pluralistic communication patterns. Three couples declined and 34 couples participated. The test was run for again for both groups and the data was analyzed with covariance. The results of the present study show that there is a meaningful difference between both groups (p<0.005). The communication patterns and its interaction with the group did not reach a meaningful level. Based on the findings, it can be concluded that listening to and speaking with each other play a key role in happiness. Therefore pluralistic communication methods based on high levels of listening, speaking and interaction can be an effective way to increase couples’ happiness.

Gender differences in reasons for alcohol and drug use in Kenya

Faith Kimunya American University in Cairo, Egypt

The use of alcohol and other drugs has been largely associated with and even condoned in men, while being met with social disapproval when it comes to women. In addition, women have been found to attach more stigma than men to alcohol and drug use. Despite this stigma, the rate of substance use in women has generally been low in comparison with men. However, reports from Australia, United States, Canada and countries in the European Union show merging in the rate of use of some illicit substances among young men and women and increasing rates of use among women in general in some European countries (United Nations Office on Drugs and Crime [UNODC], 2004). Research designed to understand why women are increasingly using alcohol and drugs has revealed that men and women cite different reasons for initiating and continuing use. Most of this research however, has been conducted on Western populations and may not be applicable to Kenyan men and women. This paper will highlight the ways that both gender and culture can affect alcohol and drug use, and discuss the implication of these differences for prevention and treatment.

Preschool-age children’s executive functions, and parent-child interaction relationships

Iliona Krone University of Latvia, Latvia; Leva Bite

At the pre-school age, children develop the basic elements of executive functioning, which influences their interaction with the environment, self-regulation and academic success later in life. The research indicates that variations of executive dysfunction may manifest as attention deficit and hyperactivity disorders, autism, Asperger’s syndrome, learning disorders etc. Although a large part of these studies emphasise the role of neural maturing in the development of executive function, it is also found that social interaction could be one of the factors influencing development. Research should thus also be concentrated on the role of parenting in the development of children’s executive functioning. The goal of the research was to establish the interconnection of children’s executive functioning and parent-child interaction. The sample included 40 4-year-olds and their mothers (from Latvia). The preliminary results (n=30) show that there is a positive correlation between the Marte Meo elements (waiting, naming and conformation) and EF functioning, and the child’s verbal abilities. Also, the MM elements in mother-child interaction predict (by regression analysis) the child’s executive functioning.

Does religion work here? A comparison of RCBT and CBT in substance abuse therapy

Charlotte Kwakye-Nuako Methodist University College Ghana, Ghana

Religion has always been a part of the healing process for most Africans, but its effects in psychotherapy for substance abuse have not been fully explored and the role that the individual’s own level of religiosity plays in the healing process has not been studied at all. This study was a clinical 3-group study with a pre-/post-treatment design involving a sample of 75 patients admitted for the abuse of marijuana, cigarettes and alcohol. Measures used included a modified version of the Religious Position Scale by King and Hunt (1972a) and Jennings (1972) to measure their level of religiosity, a Stress Inventory to measure their level of stress, and the Beck’s Anxiety and Depression scales to measure their levels of anxiety and depression respectively. The results for the treatments showed that Cognitive-Behavioural Therapy (CBT) alone was effective in reducing alcohol use, but where religion was used with Behavioural therapy (RBCBT), the treatment had no effect on any of the substances. Neither CBT nor RBCBT had any significant effect on stress, anxiety and depression after treatment. Church attendance had no significant effect on the rate of substance abuse and stress. Denominational differences were found only for marijuana abuse but not for the other substances. Results were discussed and recommendations made for future research.

Improving sexual response and quality of life for climacteric women: Preliminary results

Cristina Larroy Universidad Complutense de Madrid, Spain; Marta Perandones

The climacteric is a stage when different changes in the female gonitourinary system (as a lack of lubrication or vaginal dryness, or genital atrophy) appear. These changes may cause inconvenience and difficulties in the sexual relationships of women, and as a result, impair their sexual life and the quality of life for couples. The present work shows the results of a group cognitive behavioural intervention program for the improvement of sexual response and quality of life for couples in a sample of climacteric women. 18 women (the experimental group) received a cognitive-behavioural intervention in a group program of eight weekly sessions of two hours each, including: Psycho-education on sexuality, exercises of Kegel, sexual re-education and training, and training to improve quality of life for couples. 18 women were assigned to a control group. Women in the experimental group improved their sexual response after the intervention (increased arousal, lubrication and overall sexual response) as in a one month follow-up (increase of desire, arousal, lubrication, satisfaction and overall sexual response, and decrease pain), related to baseline period. They also improved their quality of life in couples and their quality of life in general. No changes occurred to the control group.

Adaptation and proposal of an improved program of cognitive-behavioural therapy in bulimic adolescents

Cristina Larroy Universidad Complutense de Madrid, Spain; Natalia Macias; Guadalupe Moreno

The objective of the study was to improve a well known program of cognitive-behavioural therapy in bulimic adolescents. Five patients were selected from the Eating Disorder Center in Hospital Niño Jesús. A five month study was done, with patients and their families in two hour weekly sessions.
Body Shape Questionnaire (BSQ), State-Trait Anxiety Inventory (STAI), Beck Depression Inventory (BDI) and Eating Disorder Inventory (EDI) were used pre and post intervention. SPSS19.0 was used for Statistical analysis. Bulimia nervosa is an important eating disorder, more prevalent in young patients. There are some validated therapies that improve symptoms. We combined well validated therapies, to verify if it could improve the treatment. It was divided in 3 modules. The first one becomes from a Castro’s adaptation (2007) of the technique developed by Fairburn. The second one focuses on the body image, based on the Raich’s program (1997), adapted from Rosen and Cash. It includes strategies to work on body image perception, to face the fear and discomfort created by that fact, to modify desadaptive thoughts and behaviour; and to prevent relapses. The last one, focuses on diaphragmatic respiration, so the patient could be relaxed. Results were encouraging, as all patients showed improving symptoms, supported by statistical analysis. It is hoped this program can be applied for this pathology in young patients with acceptable success.

The mediating role of emotional awareness between trauma, psychological distress and negative life events

Olivier Laverdière Universite de Sherbrooke, Canada; Louis

Psychological traumas are well-known to have deep and lasting effects on psychological health and on life conditions. Developmental and clinical literature has recently seen an upsurge of interest in the role of emotional awareness in the resolution of traumatic experiences. Some of these formulations emphasise the role of emotional awareness in mediating the impact on psychological distress of various risk factors, such as temperament dimensions, attachment insecurity, and early traumas. Few multivariate studies looked at the complex interplay of these variables and their impact on psychological distress and exposure to negative life events. The current investigation examines these relations in a structural model, with 385 nonclinical participants who completed a questionnaire package. Results revealed the contributions of risk factors in the prediction of psychological distress, and exposure to negative life events, and also the mediating effect of emotional awareness. Finally, results gave insights about the psychological variables associated with emotional awareness, as well as their mediation by attachment dimensions. The discussion pertains to the role of emotional awareness in psychological distress and proneness to negative events.

Delay aversion and impaired time perception in attention deficit/hyperactivity disorder (ADHD)

Patrick Leung Chinese University of Hong Kong, Hong Kong; Liao Ho

Children with ADHD (Attention Deficit/Hyperactivity Disorder) were known to suffer from delay aversion and impaired time perception. This study aimed at investigating whether these two deficits were related. Twenty-seven boys with ADHD and 26 gender-, age- and IQ-matched controls (age range=6-10 years) participated in a Choice Delay and Time Estimation Experiment. The children were provided with their favourite snacks: shrimp crisps, at the beginning of the experiment. They were then told if they could wait, they would be given one additional piece for every minute that they waited. When the children finally gave up waiting and consumed the crisps, they were asked to estimate how long they had actually waited. The boys with ADHD were found to stop waiting significantly earlier. However, they also significantly overestimated the duration of their waiting. There was a significant negative correlation between accuracy of duration estimation, and the duration of actual waiting, i.e., the severer the participants overestimated their waiting duration, the earlier they stopped waiting. The hypothesis that the deficits of delay aversion and impaired time estimation were related was supported. Children with ADHD, while choosing to stop waiting earlier, overestimated their waiting duration. Perhaps, they might have perceived themselves to have waited long enough for a reasonably large reward (a good number of shrimp crisps) and thus stopped waiting.

Criminological profiles of patients in addiction treatment

Jose Lopez Gori Universidad Publica de Navarra, Spain; Alfonso Arteaga; Javier Fernandez-Montalvo

This study explored the prevalence of criminal behaviours in patients who are addicted to drugs. A sample of 252 addicted patients (203 male and 49 female) who sought outpatient treatment was assessed. Information on criminal behaviours, socio-demographic factors, consumption factors (assessed by the EuropAsi), psychopathological factors (assessed by SCL-90-R) and personality variables (assessed by MCMI-II) was collected. Drug-addicted patients who were associated with criminal behaviours were compared on all variables to patients who were not associated with violent behaviours. The rate of drug-addicted patients with criminal behaviours in this sample was 60.3% (n=150), and it was mainly related to traffic vehicles, followed by drug dealing crimes. There were significant differences between the numbers of patients who did and did not demonstrate criminal behaviours on some variables. Patients with criminal problems were mainly men and single. Moreover, they were more likely to report poly-consumption and they showed statistically significant differences in some scores on several EuropAsi, SCL-90-R and MCMI-II variables. According to these results, patients with criminal problems present with a more severe addiction problem. The implications of these results for further research and clinical practice are discussed.

Cognitive appraisal, belief in just world and coping self-efficacy in predicting depressive symptoms in unemployed

Maruta Ludane University of Latvia, Latvia; Leva Bite

The aim of this study is to explore the applicability of the transactional stresses model (Lazarus & Folkman, 1984) of job loss situations. It is tested how such personal beliefs as Coping Self-efficacy (CSE) (Chesney, Neilands, Chambers, Taylor, & Folkman, 2006) and Personal Belief in Just world (PBWJ) (Dalbert, 1999) influence the cognitive appraisal of job loss and the role that those more general beliefs and cognitive appraisal play in the development of depressive symptoms after job loss. The impact of these cognitive factors is compared with situational factors: length of unemployment, age, income, previously discussed as important depression related factors in unemployment literature. Preliminary results from a sample of 120 unemployed people aged over 45 years show that such dimensions of cognitive appraisal as Loss and Challenge combined explain about 13% of variance in depression. When controlled for dimensions of cognitive appraisal, PBWJ explain additional 4% and CSE additional 16% of depression variance of unemployed. The influence of PBWJ, CSE and such variables as age, income, length of unemployment on Loss and Challenge appraisal are explored. Results deepen the understanding of mechanism through which job loss influence the development of depression and give implications for specific preventive interventions.

Trajectories of resilience: Distinguishing whether childhood-onset conduct disorder desists

Tamara Maccon University of Michigan, United States of America

Although some developmental pathways of antisocial behavior are established theoretically and empirically, less scholarship considers what distinguishes those with disorders limited in childhood from those with life-course persistent psychopathology. Research examining differentiating mechanisms most often is limited to individual factors, such as callous-unemotional traits and family history of externalising behaviors. In this paper, an alternate theoretical approach for distinguishing developmental trajectories of psychopathology is proposed. The approach draws on transactional frameworks emphasizing the relationship between child and context, and on resilience frameworks, which inform the interactions between individual characteristics and environmental stressors and supports. While individual risk factors may help us identify children in need of the most targeted intervention, going beyond the predictive validity of children’s traits to understand the mechanisms of action, or transactions, that explain why that trait presents the child with an elevated risk is useful in targeting more effective interventions. Furthermore, this paper asserts methodologies that should be undertaken to better capture child-context transactions, including microgenetic designs and modified latent class analyses that determine similar groups based on dynamic cross-legged associations. In sum, this line of research exemplifies Pasteur’s quadrant of “use-inspired basic research” by seeking to understand the underlying transactional processes that link traits that differentiate between childhood-limited and persistent conduct problems, which will aid our understanding of etiology and pathogenesis of antisocial behavior as well as inspire more informative diagnoses and appropriate prevention and intervention opportunities.

Burnout in police officers: Results of mixed methods

Barba Magdalena University of Lausanne, Switzerland
Several studies have shown that burnout is caused by multiple factors. The purpose of this study was to explore the predominant causes of stress leading to potential burnout in four Swiss cantonal police institutions. A one-hour semi-structured interview was conducted with thirteen Swiss cantonal police officers who volunteered to talk about the professional difficulties they experienced. Participants were asked open-ended questions regarding their career. Preliminary results show the following difficulties: Insufficient staffing, lack of recognition for the job they do and lack of meaning in their job. Participants’ experiences are compared to major themes in the literature. Quantitatively, a panel of questionnaires was used to measure participants’ well-being, engagement, job strain and risk for burnout. Analyses are still in progress. By applying the findings of this research, prevention programs will be developed in order to suggest changes that reduce the risk of burnout for current and future police officers and their subsequent resignation from the field.

The genogram in family therapy
Daniel Martinez Carlos Albizu University, Puerto Rico; Daniel Martinez-Ortiz

The genogram in family therapy workshops will promote the development of an intergenerational perspective of therapy and facilitate conceptualization that use means of a dynamic, visual and systemic analysis. The participants will learn how to implement the genogram while being culturally sensitive to non-traditional families. The therapeutic implementation of the genogram will be analyzed alongside with multigenerational maps, family life cycles, reconstructed families and multicultural families. The genogram structure, symbols, and intergenerational relationships will be described. Participants will be involved in exercises and role-playing using real clinical cases. Specific themes to be presented will be: The history of the genogram, systemic, structural and strategic theory, scientific investigations, advantages of the genogram, and genogram structure and interpretation.

Relationship between the reality-shock and mental health among first-year teachers
Miki Matsunaga Hiyama University, Japan
Although it has been established that Japanese teachers’ mental health worsens over time, few studies have investigated the mental health of teachers in their first few years of teaching. We examine the relationship between the first-year teachers’ mental health and the reality shock they experience. One hundred and forty-eight first-year teachers (51 men, 97 women, mean age: 26.1 years) were assessed with the Reality shock scale, the Stress Response Scale (SRS-18), and the Job Satisfaction scale. One hundred and forty-eight women, mean age: 26.1 years) were assessed with the Reality shock scale, the Stress Response Scale (SRS-18), and the Job Satisfaction scale. Preliminary findings show that the high reality-shock group was significantly more stressed than the low one (p < .001). Moreover, the members of high group were significantly more dissatisfied with their jobs than those of the low group (p < .001). These findings suggest that those who change their perception of their jobs after being employed, experience mental stress response and their job satisfaction is low. Further research should examine the factors that promote changes in perception and those that reduce reality shock.

The comparison of impulsivity between responsive and non-responsive obsessive-compulsive patients to selective serotonin reuptake inhibitors
Mahnaz Mehrizadeh Honarmand Shahid Chamran University, Islamic Republic of Iran; Majid Ghafari; Rahim Koochaki

In recent years, there has been a growing interest in the interrelationships among obsessive-compulsive disorder, impulsivity and serotonin, although previous studies produced mixed results. This study aimed at investigating the comparison of impulsivity between responsive and non-responsive obsessive-compulsive patients to selective serotonin reuptake inhibitors (SSRIs). In an ex post facto design, using Sadowski and Sadowski’s (2007) definition, and through convenience sampling, 27 obsessive-compulsive patients were divided into two groups (responsive and non-responsive to SSRIs) and were examined through 11th Bartlett Impulsivity Scale, Yale-Brown obsessive-compulsive Scale (symptom checklist), and Structured Clinical Interview for DSM-IV. The mean scores of impulsivity and its components in responsive patients were higher in comparison with non-responsive ones. Centroids of responsive and non-responsive groups were significantly different regarding impulsivity, attentional, motor, and non-planning impulsiveness (p < .009). Among the four variables, there were significant differences only in impulsivity (p < .01), attention (p < .01) and impulsiveness between responsive and non-responsive groups (p < .05). The findings of this research show that there is a significant difference in impulsivity level between responsive and non-responsive obsessive-compulsive Patients to SSRIS, and the mean score of impulsivity in non-responsive patients is higher. However, attending to some provides a comprehensive theoretical explanation for the interrelationships among impulsivity, OCD, and responsiveness to SSRIS.

Attachment and early maladaptive schemas in autobiographical memory recall
Babola Michele Institute of Applied Psychology, Portugal; Liseta Vieira; Michele Babola; Victor Claudio; Lina Raimundo

In this investigation we studied the influence of attachment and early maladaptive schemas in recall of autobiographical memories. Autobiographical memories are central to the human function, contributing to self-representation, the ability to guide, and also to search for targets in view of past experiences (Williams, et al., 2007). Early maladaptive schemas, in turn, may be regarded as stable cognitive structures, influenced by information processing. These act as organizers of external experiences of the individual and arise directly in relation to the encoding, evaluation, storage and retrieval of information, determining the responses of the individual to an external event (Stopa & Waters, 2005). Early experiments, established with parenting figures, determine the formation of early schemas, which develop in the course of life. These schemas would consist of early memories (implicit or explicit) of emotional experiences. The methodological design points to a correlational study with a sample of 52 participants aged between 18 and 52 years. A battery of clinical and experimental instruments was used: Brief Symptom Inventory (BSI), Beck Depression Inventory (BDI), State-Trait Anxiety Inventory (STAI), Autobiographical Memory Task, Schema Questionnaire and Adult Attachment Scale (EVA). We applied the Portuguese version of all instruments. The results indicate a greater recall of autobiographical memories for positive valence when compared with negative valence. We correlated these results with early maladaptive schemas scores and attachment styles. The results are discussed emphasizing the importance of attachment styles and early maladaptive schemas in information processing in the individual.

The effectiveness of schema therapy on depression and anxiety patients with OCBD
Mohammad Sadegh Montazeri Isfahan University, Islamic Republic of Iran; Mohammad Abedi; Hamid Neshat Doost; Ahmad Abedi

The schema therapy model of psychotherapy was developed by Young and Associates for treating more complex cases, such as anxiety disorders and other long term characterological conditions within a cognitive behavioural framework (Young, 1999, 2003). This study investigated the effectiveness of schema therapy on depression, perfectionism and anxiety in patients with Obsessive Compulsive Personality Disorder. The present study has a single-subject method with multiple baselines across participants. In this study, four participants, selected by purposeful sampling, were studied through sixteen individual sessions of schema therapy. Afterwards, they were given follow up tests after 2 successive weeks of treatment. Research instruments were early maladaptive schema scale and depression, anxiety and perfectionism inventories. The results of the data chart analysis were based on descriptive statistics and visual analysis. The obtained results revealed that the intervention had been effective on all four individuals. Findings of this study showed that this intervention (schema therapy approach) can effectively decrease of anxiety, depression and perfectionism in these kinds of participants.

A meta-analysis about researches on relationship between mental health and social support
Azam Moradi Payame Noor University, Islamic Republic of Iran; Soghra Taheri; Fatehbeh Javanbakht

The purpose of this study was to meta-analyse research on the relationship between mental health and social support in Iran. Among research on the relationship between mental health and social support which have been done in Iran, 8 studies were acceptable in terms of methodology and inclusive criteria, and were selected for meta-analysis. Based on results of this meta-analysis the effect size of the relationship between mental health and social support was 0.369 in Iran. Results of this Meta – analysis showed that the effect size of the relationship between mental health and social support is above of moderate in Iran (based on Cohen’s criteria for interpreting effect size). This topic makes the importance of preparing the ground for strengthening social support.
The relationship between depression and social support: A meta-analysis study in Iran
Azam Moradi Payame Noor University, Islamic Republic of Iran; Azam Moradi; Fatemeh Javanbakht; Soghra Taheri

The purpose of this research was to determine the relationship between depression and social support through meta-analysis of research done on this topic in Iran. Research was conducted on the relationship between depression and social support. 6 studies with inclusive criteria were selected for meta-analysis. These studies contained 9 effect size reports about the relationship between depression and social support. Results showed that the effect size of a relationship between depression and social support is 0.456. The effect size of a correlation between depression and social support is above moderate (based on Cohen’s criteria for interpreting effect size). This makes clear the importance of providing room for strengthening social support.

Relationship between quality of marital relationship and depression: A meta-analysis study
Azam Moradi Payame Noor University, Islamic Republic of Iran; Maryam Molavi; Razieh Fatahi

The purpose of this research was to meta-analyse research on the relationship between quality of marital relationship and depression in Iran. From previous research on this relationship that has been undertaken throughout Iran, 4 studies were found to be acceptable in terms of methodology and had inclusive criteria. These were selected for the meta—analysis. Based on results of this meta—analysis, the effect size of the relationship between quality of marital relationship and depression was 0.894 in Iran. Results of this meta—analysis showed that the effect size of the relationship between quality of marital relationship and depression is above average in Iran (based on Cohen’s criteria for interpreting effect size).

Precision of visual working memory capacity in trait and state anxiety
Jun Moriya Ghent University, Belgium; Yoshinori Sugiuara

Visual working memory capacity is one of the most important cognitive functions to maintain task-relevant information in a highly active state, and it varies across individuals. In the present study, we investigated the effects of trait and state anxiety on visual working memory capacity. To assess visual working memory capacity of quantity, we used an orienting change-detection task. A brief array of red oriented rectangles randomly selected from a total of 36 orientations, was presented for 100 ms, and participants were asked to remember the orientations of items. Memory for these red items was tested 1000 ms later with a test array that was either identical to the original memory array or differed by one orientation, which varied by 15° or 30°. After the experiments, the participants completed questionnaires about trait and state anxiety. Under 30° rotation condition, individuals with high trait anxiety and low state anxiety showed high visual working memory capacity, whereas individuals with high trait anxiety and high state anxiety showed low visual working memory capacity. Low trait anxiety did not affect working memory capacity, regardless of the degree of state anxiety. These results suggest that individuals with high trait anxiety have potentially high visual working memory capacity. However, under high state anxious condition, their working memory resources are diminished.

Effectiveness of group child parent relationship therapy (CPRT) on 8-11 years olds with ADHD
Ragayeht Mousavi Shaded University, Islamic Republic of Iran; Amin Nejati; Rasoul Roshan

The aim of this study was to investigate the effectiveness of group Child-Parent Relationship Therapy (CPRT); based on filial therapy on decreasing of Symptoms of ADHD among. In this experimental design, 30 Children with ADHD aged 8-11 years who medicating with drug and their mothers; aged 20-45, were selected randomly in two phases and assigned to two experiment and control groups. The instrument for data gathering in this study was “Comers Parents Rating Scale” (CPRS-48), which was completed by the subjects (mothers) both before and after child-center play therapy skills training. Data were analysed with nonparametric tests algorithms (Mann-Whitney U Test). Group CPRT training significantly decreased the symptoms of ADHD (except of hyperactivity-impulsive) in the patients of the experimental group (p<0.01). This change was not observed in the control group. Group CPRT training is effective in decreasing the symptoms of ADHID in the Iranian populations. This study supports the use of filial therapy as an effective training model for improving parenting of mothers’ empathic behaviour with children. Filial therapy training offers significant possibilities for future use in the Iranian populations to facilitate the development of healthy parenting attitudes and interactions between future parents and children.

Effect of a prevention programme in help-seeking in dating violence
Marina Munoz-Rivas Autonoma University of Spain, Spain; Carmen Almendros; Jose Granda-Gomez; Liria Fernandez Gonzalez; Maria Zamarron Cassinello

Youths involved in violent dating relationships usually react passively and those seeking help commonly choose informal resources instead of formal services. Consequently, prevention efforts should address this issue. In this study we examined the adolescents’ responses to physical aggression by a current or ex-dating partner and we evaluated the effect of an eight-session dating violence prevention program on adolescents’ help-seeking behaviour. The sample was composed of 7,196 Spanish youths (ages 14-26). A 1,058 participants subsample that reported having been involved in at least one episode of physical violence were used for analyses. The results show that the most prevalent response was “doing nothing” (41.3%), followed by informal help-seeking (four categories being the highest 31.1%), break up (9.2%), aggressive behaviour (2.9%) and formal help-seeking (less than 1%). After participating in the prevention program the use of formal helping sources and breaking-up increased, while the use of informal resources tended to remain the same. The dating violence prevention programme shows promise to improve adolescents help-seeking skills, although future research with a bigger sample is needed.

Group scribble and squiggle for psychiatric inpatients
Akane Nagashima Gakushuin University, Japan

This study covers an example of “Group Scribble and Squiggle” which is one of the art programs of hospitalised group psychotherapy. The main purpose of this therapy is to allow schizophrenic patients to interact with others by non-verbal communication with providing sense of security. Primarily doctor had given permission to have participation from patients with the desire to take part (during the 6 sessions conducted, grand total of 27 patients and staffs participated). There was “Group Scribble” session and “Squiggle” session which staff and patients working in pairs. Mr. A did not identify the line drawn by the staff but with the staff changing the line into a powerful picture and with caring the uneasiness of Mr. A, Mr. A was able to finish the session feeling safe. Eventually, Mr. A was able to connect the pictures shared in the sessions to the line he had drawn himself. Ms. B and Ms. C was passive and showed denial in intertwining with others due to fear or lack of confidence. To those two patients, staff had changed their expression into a positive one through non-verbal approach, “Squiggle”. Through the “Squiggle” approach there is a possibility that the patients had felt that their expression or their presence was “taken-in” by others. Thus it is assumed that these approaches play a supplementary role in curing the disorder.

Post traumatic growth in people living with HIV in Singapore: Recommendations for best practice in psychological care
Nenna Nduwe James Cook University, Singapore; Poaja Kumar; Jaiying Soon

Receiving a diagnosis of human immunodeficiency virus (HIV) is regarded as a traumatic experience and is often associated with psychological distress. Hence supporting individuals to manage the overwhelming demands of a diagnosis, including the change to their lives, is of optimal importance. A key question for clinicians concerned how to facilitate positive adjustment (also known as post traumatic growth [PTG] in individuals living with HIV. Existing studies have described the general role of clinical psychologists in HIV services. However, the specific role with regards to facilitating PTG is yet to be defined. Although PTG continues to be a topic of interest for researchers, the picture is relatively unknown in South East Asia where rates of HIV diagnosis continue to increase. Understanding PTG in people living with HIV cross-culturally would help to inform the development of recommendations for psychological intervention and service policies. Further research is required in order to develop a better understanding of best practice for psychological care in enhancing PTG. This poster presentation summarises a literature review and puts forward a proposal for cross-cultural HIV related research using a Singapore sample. The research aims to investigate the phenomenon of PTG in people living with HIV in Singapore, and to understand whether there is a role for psychology in facilitating growth.

Development and standardisation of a military stress inventory
Damian Osa-Affana Nigerian Defence Academy Kaduna, Nigeria
Over the years, the Nigerian military has participated in many peacekeeping operations throughout the world. In each of these cases, the men of the armed forces were never evaluated or screened both before and after the operations to determine their psychological state. In the development and standardisation of the Military Stress Inventory (MSI), an item pool created from a list of situations related to military operation and profession was used. A 36 item inventory was obtained and administered to 600 participants made up of 150 Army, 150 Navy, 150 Airforce personnel and 150 civilians. A total mean score for MSI of 89.30 and a standard deviation of 24.13 was obtained. The mean score and standard deviation for military personnel was 88.71 and 22.08 respectively. Analysing data with Cronbach alpha, Gutman’s split-half and Pearson Product Moment statistics, the reliability coefficients, both coefficient alpha and split-half range in the 80s. The concurrent validity of MSI is satisfactory with .64. The results were discussed in terms of how the development of the MSI met the objective of the study.

Prevention and early Intervention in post-partum depression risk
Gabriella Palumbo AEO and ISS, Italy; Fiorino Mirabella; Isabella Cascavilla ; Antoanna Gigantesco; Emanuele Tarolla
Routine screening of post-partum depression has been shown to be effective. The efficacy of specific psychological interventions for the prevention and treatment of post-partum depression has been addressed recently by several studies. In October 2011, the Mental Health Department of the Italian National Institute of Health (ISS) received a grant from the Ministry of Health to assess, in Italy, the feasibility and efficacy in actual practice of the demonstrably effective approach based on clinical work and research evaluated by Milgrom J. at the Infant Clinic of the Parent-Infant Research Institute, Austin & Repatriation Medical Centre, in Melbourne, Australia (Milgrom J, Negri LM, Gemmill AW, McNeil M, Martin PR., 2005). Post-partum depression prevention, through an intervention based on the promotion and development of positive potential (Meneghetti A, 2007), has several strengths: it is empowering, in that it is mostly an effort to facilitate learning among women after childbirth and on the improvement of their strengths; it is likely to be more cost-effective than other interventions that are not conducted in group sessions, such as individual and home-based sessions; it is innovative because it is an actual psychological intervention not limited to education/ information and/or psychological support.

Characteristics of children with mental retardation presenting at Polokwane/Mankweng Hospital complex in Limpopo Province: An archival study,
Molepo Poodedi University Of Limpopo, South Africa; Tsholene Sodi
The aim of the study was to profile the characteristics of children with mental retardation presenting at a clinical psychology unit in a hospital complex in Limpopo Province (South Africa) over a five year period (i.e. January 2005 up to and including December 2009). Using the archival data method, the clinical files of all children presenting with mental retardation at this facility were retrieved and studied. A total of 326 (male = 169; female = 157) files covering the period under review were retrieved. The Statistical Package for Social Sciences (SPSS) was used to analyse the data. Categorical data were analyzed by using frequency tables, descriptive statistics and crosstabulations. The study revealed that a significant number of cases (99.4 %) were diagnosed with mental retardation. It was also found that 45.4% of the cases were diagnosed with comorbid clinical conditions such as epilepsy, Down’s syndrome, visual problems etc. The majority of the children were referred to the clinical psychology unit to be assessed for school placement (50 %) and disability grant (38.7%).

Therapeutic efficacy in families with violent adolescents and parents with personality disorders
Susana Queiroga Universidad de Buenos Aires, Argentina; Griselda Grubisch; Glenda Cryan; Tais Carmo
The objective of the study was to show how weekly psychodynamic group therapy of a Violent Unit, attended by early adolescents with antisocial and self-destructive behaviours and their parents, works. This unit is included in the Programme of Buenos Aires University. Due to difficulties such as lack of bonds and high drop-outs in the treatment of these pathologies, new techniques had to be planned in both psychodynamic group’s therapy to improve the therapeutic efficacy. The first step is a Setting Group, which consists of about 10 sessions to establish the framework and to foster verbal communication. The second step is a ten-session Short-term Focused Psychotherapy Group with a parallel psychotherapy group for parents, each with a different therapist. It includes two multi-family sessions at the beginning and at the end. The third step is a six-month Definitive Therapy Group to stabilise bonds and identification. The sample consisted of 27 adolescents with antisocial and self-destructive behaviours of both sexes, aged 13-15, and their parents, referred by schools or courts. The outcomes of pre-post tests for anxiety and depression of both adolescents and their parents and the relationship between these symptoms in both groups; the parents’ personality organisation; and the family structure will be shown. For patients with lack of mentalisation and verbalisation and risky behaviour, a planned psychodynamic therapy group with pre-established objectives and a parallel parents’ group psychotherapy shows a higher efficacy.

An investigation into the public’s attitude towards seeking professional psychological help (psychotherapy) in Trinidad
Karen Ramcharitar ITAP, Trinidad and Tobago
The public’s attitude toward seeking professional psychological help, in Trinidad, were investigated, using the short form of the Attitudes Toward Seeking Professional Psychological Help (ATSPPH) Scale, developed by Fischer and Farina in 1995. A total of 225 male and female adults over age 20 were randomly recruited from various locations throughout Trinidad and surveyed via telephone.

Adult psychopathology: Is there any agreement between self-reports and other informants?
Virginia Samaniego Universidad Catolica Argentiniana, Argentina; Natalia Vazquez
In adult psychopathology, assessment self-reports have been an essential source of information. To determine how well self-reports agree with reports by informants who know the person being assessed, Achenbach, Krukowski, Dumenci & Ivanova, (2005) examined 51 000 articles finding that qualifying correlations were found in 108 (0.2%) of the

Characteristics of children with mental retardation presenting at Polokwane/Mankweng Hospital complex in Limpopo Province: An archival study,
Molepo Poodedi University Of Limpopo, South Africa; Tsholene Sodi
The aim of the study was to profile the characteristics of children with mental retardation presenting at a clinical psychology unit in a hospital complex in Limpopo Province (South Africa) over a five year period (i.e. January 2005 up to and including December 2009). Using the archival data method, the clinical files of all children presenting with mental retardation at this facility were retrieved and studied. A total of 326 (male = 169; female = 157) files covering the period under review were retrieved. The Statistical Package for Social Sciences (SPSS) was used to analyse the data. Categorical data were analyzed by using frequency tables, descriptive statistics and crosstabulations. The study revealed that a significant number of cases (99.4 %) were diagnosed with mental retardation. It was also found that 45.4% of the cases were diagnosed with comorbid clinical conditions such as epilepsy, Down’s syndrome, visual problems etc. The majority of the children were referred to the clinical psychology unit to be assessed for school placement (50 %) and disability grant (38.7%).

Therapeutic efficacy in families with violent adolescents and parents with personality disorders
Susana Queiroga Universidad de Buenos Aires, Argentina; Griselda Grubisch; Glenda Cryan; Tais Carmo
The objective of the study was to show how weekly psychodynamic group therapy of a Violent Unit, attended by early adolescents with antisocial and self-destructive behaviours and their parents, works. This unit is included in the Programme of Buenos Aires University. Due to difficulties such as lack of bonds and high drop-outs in the treatment of these pathologies, new techniques had to be planned in both psychodynamic group’s therapy to improve the therapeutic efficacy. The first step is a Setting Group, which consists of about 10 sessions to establish the framework and to foster verbal communication. The second step is a ten-session Short-term Focused Psychotherapy Group with a parallel psychotherapy group for parents, each with a different therapist. It includes two multi-family sessions at the beginning and at the end. The third step is a six-month Definitive Therapy Group to stabilise bonds and identification. The sample consisted of 27 adolescents with antisocial and self-destructive behaviours of both sexes, aged 13-15, and their parents, referred by schools or courts. The outcomes of pre-post tests for anxiety and depression of both adolescents and their parents and the relation between these symptoms in both groups; the parents’ personality organisation; and the family structure will be shown. For patients with lack of mentalisation and verbalisation and risky behaviour, a planned psychodynamic therapy group with pre-established objectives and a parallel parents’ group psychotherapy shows a higher efficacy.

An investigation into the public’s attitude towards seeking professional psychological help (psychotherapy) in Trinidad
Karen Ramcharitar ITAP, Trinidad and Tobago
The public’s attitude toward seeking professional psychological help, in Trinidad, were investigated, using the short form of the Attitudes Toward Seeking Professional Psychological Help (ATSPPH) Scale, developed by Fischer and Farina in 1995. A total of 225 male and female adults over age 20 were randomly recruited from various locations throughout Trinidad and surveyed via telephone.

Adult psychopathology: Is there any agreement between self-reports and other informants?
Virginia Samaniego Universidad Catolica Argentiniana, Argentina; Natalia Vazquez
In adult psychopathology, assessment self-reports have been an essential source of information. To determine how well self-reports agree with reports by informants who know the person being assessed, Achenbach, Krukowski, Dumenci & Ivanova, (2005) examined 51 000 articles finding that qualifying correlations were found in 108 (0.2%) of the
articles. So the question arises if self-reports can still be applied as the only source of psychopathological assessment. Achenbach & Rescorla (2003) developed the Adult Self Report (ASR) and the Adult Behavior Checklist (ABCL) that allow not only obtaining self-reports but others’ perception of the adults’ functioning. This study aims to establish some psychometrical properties of the ASR and the ABCL, to examine correlations between self reports and collaterals and to establish levels of psychopathology in an urban adult sample in Argentina performing a cross-sectional descriptive study. The ASR 18-59 and the ABCL 18-59 were applied to a sample of 825 adults. Both instruments showed adequate levels of reliability and content validity. Total problem scores means for both instruments were in a similar range in the Argentine sample than in the U.S.A population (Argentina 29.01-43.06 vs. U.S.A. 27.9-43.4). Correlations between self reports and collaterals were of high magnitude and statistically significant. Higher correlations were found in this study than in the USA sample which might mean that in Argentine people have better understandings of others.

Depression in adolescents living in Puerto Rico: Differences by perceived social status

Idamari Santiago Universidad de Puerto Rico, Puerto Rico; Patricia García-Diaz

The scientific literature documents that adolescents with low socio-economic status (Low-SES) usually report higher depressive symptoms than those from high socio-economic status (High-SES). Low-SES is related to a higher psychiatric morbidity, disability, and poorer access to health care. The Hispanic Health and Nutrition Examination Survey found that among Puerto Ricans, the possibility of being diagnosed with major Depression was higher for those who reported Low-SES. The purpose of this study is to evaluate possible differences in depressive symptoms in adolescents of different socio-economic status living in Puerto Rico. Participants were 443 students between the ages of 12 and 18 years attending private and public schools in the San Juan area, from medium-high/low socio-economic status (G1) to low/medium-low socio-economic status (G2). We compared the mean scores on depressive symptoms for both groups using independent-samples t tests (p ≤ .05). In the INENESD Total Scale, adolescents in G2 scored significantly higher than adolescents in G1, both for the last two weeks and for the last six months. We also observed significant differences in all subscales of the instrument. The adolescents in G2 reported more depressive episodes in their lives (p ≤ .001) as well as less confidence in asking for help to manage Depression in the past six months (p ≤ .05). These results support findings regarding the relationship between youth depression and socio-economic status. It is important to examine whether variables such as family cohesion and conflict moderate this relationship.

Suicide experiences, attitudes, training and intervention skills of university health professionals

Jose Serra-Taylor University of Puerto Rico, Puerto Rico; Maria Jimenez-Chafey

There has been a lot of concern in the field of mental health over suicide risk in the college student population over the last decade, as well a community and research efforts directed towards prevention. One of the main prevention strategies is to have university personnel well trained in identifying and managing suicide risk. The specific goals of this study are to describe the experiences, attitudes and training of mental health professionals in university settings in relation to suicide behaviour. An online questionnaire was developed to explore variables of interest. Once approval of the IRB of the University of Puerto Rico, Rio Piedras Campus was received, the questionnaire was sent via email to 100 professionals (counselors, psychologists and social workers) who work with college students at the universities in Puerto Rico. 52 responses were received. The results showed that almost all (91.0%) believed suicide is preventable, most (66%) felt comfortable with their level of training and capable of intervening with suicide risk; however, 41% rarely or never assess for suicide risk in initial interviews. Also, over half (70%) reported seeing students with suicide risk only once or twice a year, yet studies show that a significant number of college students present suicide ideation and attempts, which could suggest inadequate screening practices. Results suggest that university mental health professionals need further training in suicide assessment to reinforce knowledge of comprehensive risk assessment of suicidality as an early intervention strategy for prevention.

A comparison of efficacy of monotheistic integrated therapy and cognitive therapy on reduction of criminal behaviour of prisoners

Mohammad Hussein Sharifinia Research Institute of Hawzah, Islamic Republic of Iran

One of the major problems in prisons is the high rate of criminal behaviours, including aggression and pugnacity, violation of prison regulations, carrying and using illegal drugs, suicide and self-tor- ture, disturbance seeking, upsetting the order of prison and destruction of public property. For a comparison between efficacy of 2 methods include monotheistic integrated therapy and cognitive therapy on the reduction of the aforementioned criminal behaviours, 90 prisoners of Qom ,Iran, were randomly chosen and organised into 3 groups: Monotheistic integrated therapy group, cognitive therapy group, as experimental groups, and a control group. Groups 1 and 2 underwent monotheistic integrated therapy and cognitive therapy for 6 months while group 3 was left without any interference except for critical cases. For 15 days, all groups were unnoticeably put under clinical observations by trained observers both before and 2 weeks after the therapeutic interventions, while their illegal behaviours were recorded. The analysis of data showed that in...
both treatments, the rate of criminal behaviour was reduced, but in monothestic integrated therapy the reduction was more considerable.

Depression investigation in a low-income population under hemodialysis in Brazil
Geraldo Silva Junior University of Fortaleza, Brazil; Joao Santana; Ana Paula Buosi; Francisco Emmanuel Monteiro; Eveline Silva; Elizabeth Dach; Minaugela Lima
Depression is the most common psychiatric illness in patients with end-stage renal disease (ESRD). The aim of this study is to investigate the presence of depression in ESRD. This is a prospective study conducted in two hemodialysis clinics in Fortaleza, Brazil, to investigate the occurrence of depression in patients with ESRD under hemodialysis. Depression was investigated using the Beck Depression Inventory (BDI-II). A total of 148 patients were included, with an average age of 46 ± 13 years, and 54% were male. The mean time in dialysis was 5.3 ± 5.2 years. Depression was found in 101 patients (68.2%), and it was mild in 50 (49.5%), moderate in 42 (41.5%) and severe in 9 (9%). Only 23 patients (15.5%) had previous diagnosis of depression. Follow-ups with a psychologist or psychiatrist were made by only 48 patients (32.4%). The comparison between patients with and without depression was found to be similar in age, gender and time on dialysis. Patients with depression were taking medications more frequently, such as anti-depressants (20.7% vs. 4.2%, p=0.01) and benzodiazepines (33.6% vs. 8.5%, p=0.001). Improvement of symptoms were reported by 40 patients among 46 who were taking medications in the depressive group (86.9%). Depression is frequent and underdiagnosed among ESRD hemodialysis patients. The investigation of depression must be part of the routine evaluation of these patients.

The experience of consultants as containers to the Robben Island Diversity Experience
Madeleine Smit IOPsychotherapy UNISA, South Africa; Frans Cilliers; Michelle May
Consulting from a systems psychodynamic stance to the Robben Island Diversity Experience (RIE) is different to other training events. Consultants found it difficult to take up their roles as consultants and containers. The aim of the research was to explore the experience of consultants as containers in a group relations training event with specific reference to the Robben Island Diversity Experience (RIE). Qualitative research, using the hermeneutic paradigm, was done. A form of non-probability sampling, purposive sampling was used, focusing on consultants who worked as staff to RIDE. A focus group was conducted. The data obtained were analysed through thematic analysis. The findings indicated that consultants found it difficult to take up their role as consultants and containers. They were not prepared for the impact of the island on the event and especially on them as consultants. Consultants had to work harder in containing their own feelings and anxieties in order for them to take up their role. They experienced that the tumultuous/symbol-laden setting of RIDE predetermined that the diversities of race and gender were worked with, while other diversities were greatly shut out. However, consultants found that they had never experienced such an enriching experience as they had during RIDE. Robben Island as venue, with its symbolic value, had a direct influence on the event and the performance of the consultants as containers, and made it different from other training events.

The impact from rearing styles on anxiety symptoms in a medical high risk sample
Mikaela Soehmann University of Copenhagen, Denmark
This paper delineates the effects of parenting behaviour of the potential impact from being very prematurely born (VPB) with very low birth weight (VLBW) in a national cohort of VPB/VLBW survivors. Several studies indicate that individuals born VPB/VLBW have higher prevalence of psychiatric disorders and psychiatric symptoms, including anxiety. Also, parents of VPB/VLBW born are reported to have PTSD like symptoms to a greater extent than normal population. In this prospective longitudinal data (baseline + 5 year + 17 year) from the national Danish birth cohort of VPB/VLBW survivors born in 1994 and 1995 is analysed. Preliminary results suggest that taking into account rearing behaviour, which is moderated by self-reported PTSD symptoms, around time of birth eliminates the seemingly over representation of anxiety symptoms in this medical high-risk cohort. Other factors taken into account are intelligence measures collected at age 5.

Poly-victimisation and risk for self-injurious behaviour and suicidal ideation
Laia Soler Universitat de Barcelona, Spain; Anna Segura; Claudia Paretell; Teresa Kirchner
This study aims to provide evidence concerning the effects of experiencing multiple forms of victimisation (poly-victimisation) on mental health in adolescence, the specific focus being self-injurious behaviour and suicidal ideation. A total of 877 adolescents were recruited from eight secondary schools in Catalonia, Spain. The Youth Self Report (YSR) and the Juvenile Victimation Questionnaire (JVQ) were employed to assess psychological distress and victimisation, respectively. Participants were divided into three groups (non-victim, victim and poly-victim groups) according to the total number of different kinds of victimisation experienced lifelong. Results showed girls report significantly more self-injurious behaviour and suicidal ideation than boys (OR = 2.93). On the other hand, as much as 37.7% of adolescents in the poly-victim group report self-injurious behaviours or suicidal attempts, compared with 10.9% in the victim group and 5.4% in the non-victim group. Only the poly-victim group displayed significantly more self-injurious behaviour or suicidal ideation than the other two. In conclusion, while experiencing moderate levels of victimisation does not seem to significantly increase the risk of suicidal behaviour (suicidal ideation or self-injurious behaviour) over and above the absence of victimisation, the experience of high levels of victimisation (poly-victimisation) significantly does. These results add evidence supporting the need for research to take account of the full burden of victimisations to which individuals are subjected, since focusing on the impact of just one kind of victimisation may overestimate its relationship with other variables disallowing the effects of suffering multiple kinds of victimisation.

How we integrated different approaches in treating Borderline Personality Disorder
Manuela Spigno; Simona DeFazi
A case study describing the treatment of a Borderline Personality Disorder case, moderate in severity, and complicated by occasional drug use. Assessment was made by using the following instruments: Cognitive Behavioural Assessment 2.0 (CBA 2.0), Millon III, Structured Clinical Interview for DSM-IV Axis II Disorders (SCID-II). The main approach was Cognitive-Behavioural Therapy (CBT), with specific regard to the therapeutic relationship and acceptance promotion, with the aim of promoting emotional regulation skills. We also took into account different considerations, in and out of CBT, that we describe in the paper. In addition, APA’s guidelines (2001) highlight the importance of the case’s flexible management of Borderline Personality disorder, with a complex treatment, including the integrated use of different skills and resources in the personal life environment. Therapeutic strategies included definition of the main problems and specific interventions for each problem. At the end of treatment, lasting about one year, we repeated the evaluation using the same instruments used in the assessment phase. The results showed an improvement in emotional regulation, greater planning capacity regarding her life and objectives, and a reduction in the critical scores. Occasional drug use had completely stopped. Positive results were maintained in the two follow-ups.

Specificity of rumination as a vulnerability to depression in the context of adolescent life stress
Jonathan Stange Temple University, United States of America; Lyn Abramson; Lauren Alloy; Jessica Hamilton
Response styles theory contends that individuals who ruminate, or repeatedly think through, the causes of their low mood, are at risk for experiencing depression. Recent research has indicated that rumination may be especially harmful when individuals encounter life stressors. For example, a recent longitudinal study of adolescents indicated that rumination moderated the relationship between life stress and the onset of major depressive episodes (Abela & Hankin, 2011). Although previous research has indicated that rumination is associated with depressive and anxiety disorders, the extent to which rumination confers specific risk for depression versus anxiety is unknown, particularly when evaluated in the context of life stressors. The present study prospectively evaluated the relationship between rumination, negative life events, and symptoms of depression and anxiety in a racially-diverse community sample of 195 early adolescents (mean age = 12.4 years). Results indicated that rumination interacted significantly with negative life events, peer victimisation, and emotional neglect, to predict increases in depressive symptoms eight months later. The form of these interactions was such that negative events predicted increases in depressive symptoms more strongly among adolescents with higher levels of rumination. Rumination did not interact with any of these stressors to predict increases in anxiety symptoms at follow-up. These results are consistent with a vulnerability-stress model and provide evidence that rumination may confer risk specifically to depression when adolescents encounter life stress.
Dependency, self-criticism traits and depressive symptoms
Qiuping Tang Department of Clinical Psychology, China; Xiongzhao Zhu; Sha Liao; Zhenhui Zhou
The object of this study was to explore the relationship between dependent, self-critical depression-linked personality traits, and depressive symptoms. A total of 290 depressive outpatients were recruited in the current study. Structured Clinical Interview, Center for Epidemiological Survey Depression Scale (CES-D) and Depressive Experiences Questionnaire (DEQ) were administered to all participants. The total score showed somatic and depressed affect scores of CES-D in those who had high self-critical and dependent traits were significantly higher than that in those who had low self-critical and low dependent traits \((t = 3.796, p < 0.01; t = 2.524, p < 0.05; t = 3.723, p < 0.01)\). Both the dependent \((r = 0.203–0.249, p < 0.01)\) and self-critical traits \((r = 0.211–0.297, p < 0.01)\) were positively correlated with the total, somatic and depressed affect scores of CES. These findings indicate an increase of hypervigilance in a clinical sample of patients suffering from Narcissistic Personality Disorder (NPD). The goal of the present two studies was to examine the usefulness of self-report inventories in a clinical sample of patients with NPD. We used an extreme-group approach by comparing patients suffering from NPD with non-clinical controls. In Study 1, we compared three self-report instruments, one developed for clinical settings (the narcissism subscale of the Dimensional Assessment of Personality Pathology, DAPP-BQ) and two used in social and personality psychology (Narcissistic Personality Inventory, NPI and Hypervigilant Narcissism Scale, HSNS). Patients with NPD scored higher than non-clinical controls on the DAPP-BQ, the HSNS, but not on the NPI. Study 2 aimed at replicating these findings and at analysing the role of self-esteem as potential suppressor. Specifically, we examined whether patients with NPD show higher NPI scores than non-clinical controls, after controlling for self-esteem. The results showed that patients with NPD scored higher on the DAPP-BQ, but not on the NPI, in comparison to non-clinical controls, unless one controls for the suppressing effect of self-esteem. Implications for research on normal and pathological narcissism are discussed.

Alexithymia in alcohol dependent patients: Gender differences, associations with craving and dependence severity
Fred Arne Thorberg Centre for Addiction Issues, Norway
Up to 50% of alcoholics have alexithymia, a multifaceted personality trait associated with emotion regulation difficulties. Although research has examined alexithymia and alcohol dependence, gender differences are yet to be explored. The objective of the present study was to determine gender differences in relation to alexithymia as well as the relationship with craving and dependence severity in a sample of alcohol dependent outpatients. Three hundred and seventy eight patients (66% male) aged between 18-71 years \((M = 38.92)\) undertaking Cognitive-Behavioral Therapy for alcohol dependence were recruited. Participants with a diagnosis of a co-morbid major psychiatric disorder, organic brain syndrome or alcohol-related medical complications were excluded. Participants were detoxified prior to assessment and completed the Toronto Alexithymia Scale (TAS-20), the Obssive Compulsive Drinking Scale (OCDS) and the Alcohol Use Disorder Identification Test (AUDIT), as part of a larger study. T-tests indicated that males scored significantly higher on Difficulties Describing Feelings and Externally Oriented Thinking compared to females. Chi-square test indicated that 34.5% of males were classified as alexithymic, 25.4% borderline alexithymic, 40.1% non-alexithymic compared to 26.4%, 26.4% and 47.1% for females. TAS-20 scales were significantly correlated with all OCDS scales for males, but not for females. In conclusion, the present study found a stronger relationship between alexithymia, craving and alcohol dependence severity for men. These findings highlight the importance of conducting gender specific research on alexithymia in alcoholic populations.

On the measurement of narcissism: Utility of self-report instruments for clinical research
Aline Vater Free University Berlin, Germany; Michele Schroeder-Abe; Kathrin Ritter; Stefan Roeske; Lars Schulze; Babette Renneberg
Research in social and personality psychology has used various self-report instruments for assessing narcissism. Until now, no study has assessed the utility of self-report instruments for measuring narcissism, in a clinical sample of patients suffering from Narcissistic Personality Disorder (NPD). The aim of the present two studies was to examine the usefulness of self-report inventories in a clinical sample of patients with NPD. We used an extreme-group approach by comparing patients suffering from NPD with non-clinical controls. In Study 1, we compared three self-report instruments, one developed for clinical settings (the narcissism subscale of the Dimensional Assessment of Personality Pathology, DAPP-BQ) and two used in social and personality psychology (Narcissistic Personality Inventory, NPI and Hypervigilant Narcissism Scale, HSNS). Patients with NPD scored higher than non-clinical controls on the DAPP-BQ, the HSNS, but not on the NPI. Study 2 aimed at replicating these findings and at analysing the role of self-esteem as potential suppressor. Specifically, we examined whether patients with NPD show higher NPI scores than non-clinical controls, after controlling for self-esteem. The results showed that patients with NPD scored higher on the DAPP-BQ, but not on the NPI, in comparison to non-clinical controls, unless one controls for the suppressing effect of self-esteem. Implications for research on normal and pathological narcissism are discussed.

Assessment of functional somatic symptoms in Chinese junior high school adolescents
Xinjian Wang Nankai University, China; Yi Huang; Bin Zhang
The aim of this study is to examine the psychometric properties of the Chinese version of the Children’s Somatisation Inventory (CSI-24) in 10-14 year old children in China. Furthermore, the study aims to present normative data on functional somatic symptoms among a multicultural sample of Spanish-speaking university students, and to assess the associations with school absenteeism records and emotional distress. A total of 2,623 students (11- to 15-years old) and 2,615 parents completed the CSI-24 and a number of personality and psychopathology questionnaires. The reliability (internal consistency) and validity of the CSI-24 was satisfactory. A factor analysis of the children’s data yielded one dominant general factor, which is not strictly unidimensional. Headaches, abdominal pain and feeling low in energy were the most frequently reported symptoms. The median CSI total score was 8. Girls scored higher than boys, and no gender effect was found. FSS were significantly correlated with school absenteeism records and emotional symptoms. Finally, highly similar psychometric properties were obtained for the Parent version of the CSI (i.e., PCSI). The Chinese version of the CSI-24 is an appropriate reliable and valid self-report measure for assessing functional somatic symptoms in adolescents.

A new indigenous approach for psychological disorders in China
Weidong Wang Guang'anmen Hospital, CACMS, China; Xueyu Lu; Fang Wang; Lan Hong; Hui Du
Thought Implant Psychotherapy under lower resistant state (TIP) was established by Professor Wang Weidong, who created the psychotherapy from his deep understanding of psychology, qigong, behavioral medicine as well as hypnosis. He integrates qigong into a psychological treatment system which makes full use of Chinese culture. The essence of TIP is thought imprint and lower resistant state which makes it avoid the resistance to psychological treat-
ment from Chinese patients. TIP has four main characterstics: lower resistance, reasonable authority and non-counseling style, doctor-dominance. TIP derived from clinical practice and has a long history over 20 years before its existence. And now, it is used to treat depression, insomnia, obsessive compulsive disorder, anxiety, etc. Regarding psychopathology, TIP’s view is based on abnormal development psychology. It considers that two core risk factors are trauma and protection which have strong implications in China. Also, they cause abnormal development manifested by elements missing or stages missing. The two types of abnormal development will lead to personality flaws and makes individuals prone to get mental disorders. TIP now has developed into an integrative system which is composed of basic, core and symptom-based techniques. The basic techniques include lower resistant state acquiring technique, reasonable authority acquiring technique, anti-disruption technique. Core techniques include emotion cusing, process analytic comprehension, impronted cognitive treatment, suggestive inductive imagination, personality remodeling, etc. Symptom-based techniques include imaginative desensitization, sleep regulation, interpersonal relationship adjustment, etc.

Attention bias training with word stimuli: An effective treatment for depressive symptoms

Wenhui Yang, Huinan Normal University, China; Zhirui Ding; Ting Dai

Attention bias training is a newly emerging, promising intervention for depression. A recent study (Wells & Beavers, 2009) suggested that modifying selective attention using picture stimuli reduced depressive symptoms, while another study (Baert, Raedt, Schacht & Koster, 2010) showed that attention bias training using word stimuli had little effect on depression. We investigated whether words could serve as effective stimuli in attention bias training to reduce depressive symptoms. With a double-blind, placebo-controlled, among-groups design, we examined the effect of the modified dot probe task, using word stimuli on attention bias and depressive symptoms. Mild to severely depressed college students (n=77) were randomly assigned to attention training, placebo training, or an assessment-only control condition. In training conditions, participants completed 8 sessions of training during a two-week period. All participants completed self-reported assessments of depressive symptoms at baseline, post-training, and follow-up. Participants in the attention training showed a significant improvement of depressive symptoms from baseline to post-training, as well as to follow-up. Meanwhile, they presented a significantly reduced attention for sad stimuli after the training. But these were not found in participants in placebo training and control conditions. The change of attention bias was negatively related to depressive symptoms assessed at post-training and follow-up. Attention bias training using word stimuli is an effective treatment for depressive symptoms. The biased attention may have a causal role in the maintenance of depressive symptoms.

Juan Yang, Hainan Medical College, China; Chenchun Zhang; Shuqiao Yao

There have only been a few studies that tested the interaction between rumination and stress in predicting levels of depressive symptoms and results are mixed. Treynor, Gonzalez, and Nolen-Hoeksema (2003) have identified two distinct subtypes of rumination - brooding and reflection - which explain the relationship between rumination and depression. More specifically, studies indicate that brooding, but not reflection, predicts the development of depressive symptoms over time. Accordingly, the aim of the current study was to examine whether rumination and its sub-types moderate the relationship between stress and depressive symptoms. During the initial assessment, 618 high school students (302 boys, 316 girls) completed measures assessing negative life events, rumination (including brooding and reflection) and depressive symptoms. Every three months for the next twelve months participants completed measures assessing negative life events and depressive symptoms. Data were analyzed using hierarchical linear modeling analyses. Hierarchical linear modeling analyses indicated adolescents who tend to ruminate in response to depressive symptoms did not report greater elevations in depressive symptoms following elevations in negative life events than other adolescents did. Additionally, brooding only showed the main effect on depressive symptoms and did not moderate the relationship between the occurrence of negative life events and depressive symptoms, while reflection did not predict the development of depressive symptoms. Stressful life events and brooding could predict the development of depressive symptoms, however rumination and its sub-types did not moderate the relationship between stress and depressive symptoms.

Mental health comparison of general university undergraduates and local university undergraduates

Jinhui Ye, Jiangxi Normal University, China

Exploring the state of mental health of undergraduates of universities run by local people was lower than that of the undergraduates of general university. A total of 315 undergraduates of university run by local people (170 males, 145 females) and 200 undergraduates of general university (100 males, 100 females) were selected and tested with the Symptom Checklist 90 (SCL-90). The total level of depressive symptoms of non-clinical addicts who have, or have not been successful in quitting their addiction. The sample was chosen randomly in the Tavâlod-e-Dobareh charity center comprising 90 individuals (30 successful addicts, 30 unsuccessful addicts, and 30 non-clinical individuals). The participating groups were controlled according to demographic factors such as gender, age and education. The sample groups took the general health questionnaire (GHQ) and Young Schema Questionnaire (YSQ). MANOVA statistical test and related post hoc were applied to analyse the data. The results indicated that there is a significant difference between primary maladaptive schemas such as Mis- trust/ Abuse, Deflectiveness/ Shame, Entitlement/ Grandiosity, Dependence/ Incompetence, Enmeshment/ Undeveloped Self, and Insufficient Self-Control/ Self-Discipline among addicts who were able to quit, with those addicts who were not able to quit, and the non-clinical population (p < 0.05). The difference effect was 0.278. Also, there was no significant difference among the Dependence/Incompetence and Enmeshment/Undeveloped Self between the successful and unsuccessful groups and non-clinical population. The overall statistical analyses indicated that the mean scores of the maladaptive schemas are significantly different among the successful, unsuccessful withdrawals and non-clinical population.

Secondary traumatic stress among mental health workers

Aytten Zara; Istanbul Bilgi University, Turkey

Due to its very nature, trauma constitutes one of the most challenging areas of work within the realm of psychology. Secondary traumatic syndrome is an integral part of engaging with traumatized clients professionally, which causes a shift in mental health workers’ cognitive schemas, values, and beliefs about self and the world. This shift does not happen due to only one therapeutic relationship, but due to repeated exposure to vivid traumatic material brought by clients. This study investigates the prevalence of secondary traumatic syndrome among mental health workers in Turkey, and professional, personal and demographic factors playing a role in its development. 205 participants from both Eastern and Western, urban and rural parts of Turkey took part in the study. Both mental health workers, who work with trauma cases, and those who do not, took part in the study. A survey consisting of 17 demographic questions, the Turkish version of Maslach Burnout Inventory, and the Trauma Attachment Belief Scale were administered to the participants. Data were collected through mailed and online survey methods. This research has found a high level of secondary traumatic stress syndrome in mental health workers. Mental health workers with personal trauma history, and who work in the East and South-East Region of Turkey reported more secondary traumatic stress. Specializing in working within the traumatic stress field and receiving supervision were found to have a preventative effect against secondary traumatic stress.

Do maladaptive schemas change as for withdrawal in addicts?

Mostafa Zarean; Shahid Beheshti University, Islamic Republic of Iran; Faezeh Pourshahla-Nobari; Anisi Khoshlahjeh

The purpose of this research was to compare the maladaptive schemas of non-clinical addicts who have, or have not been successful in quitting their addiction. The sample was chosen randomly in the Tavâlod-e-Dobareh charity center comprising 90 individuals (30 successful addicts, 30 unsuccessful addicts, and 30 non-clinical individuals). The participating groups were controlled according to demographic factors such as gender, age and education. The sample groups took the general health questionnaire (GHQ) and Young Schema Questionnaire (YSQ). MANOVA statistical test and related post hoc were applied to analyse the data. The results indicated that there is a significant difference between primary maladaptive schemas such as Mis-trust/ Abuse, Deflectiveness/ Shame, Entitlement/ Grandiosity, Dependence/ Incompetence, Enmeshment/ Undeveloped Self, and Insufficient Self-Control/ Self-Discipline among addicts who were able to quit, with those addicts who were not able to quit, and the non-clinical population (p < 0.05). The difference effect was 0.278. Also, there was no significant difference among the Dependence/Incompetence and Enmeshment/Undeveloped Self between the successful and unsuccessful groups and non-clinical population. The overall statistical analyses indicated that the mean scores of the maladaptive schemas are significantly different among the successful, unsuccessful withdrawals and non-clinical population.

Differential association of basic temperaments with cognitive emotion regulation strategies
sdPsychopathological symptoms stem from fundamental temperaments as declared in recent theories (e.g., Gray, 1999; & Clark, 2005), while others continuously endeavour to clarify its common features such as emotional dysregulation (Brown & Barlow, 2009; Warner & Gross, 2010). In the present study we aimed to investigate the complex associations between basic temperaments and broad strategies of cognitive emotion regulation. In a descriptive cross-sectional study, 232 undergraduate students from Tehran universities enrolled in the project and completed the Behavioural Inhibition/Activation System (BIS/BAS) and Cognitive Emotion Regulation Questionnaires. Primary results indicated that positive strategies correlated with the dimensions of the activation system: reward responsiveness, drive, and fun-seeking. However there was significant correlation among dysfunctional strategies and an inhibitory system (r=0.01). Also, these temperaments could predict the valuable amount of cognitive emotion regulation strategies’ variance. As the core entity of temperament is inherited and has predictive value in psychological interventions, evidence from the present study supports the idea that the development of psychopathology can be controlled due to the detection of temperamental aspects as well as prevention through functional emotion, regulation strategies training within the community.

**Effect of parenting style on the development of functional somatic symptoms in adolescents**  
**Bin Zhang Nankai University, China; Yi Huang; Xinjian Wang**

The aim of this study is to determine whether parenting style affects the development of functional somatic symptoms (FSS) in young adolescents. In addition, the mediation effect of parents’ psychological factors, namely, anxiety, depression and dysfunctional strategies were assessed. FSS were assessed in 600 11-to-14-year-old adolescents using Children Somatization Inventory-24. Anxiety, depression and self-esteem were examined in 401 young adolescents using SCARED, DSRSC and Rosenberg Self-Esteem Questionnaire. Parenting style was measured by e-EMBU in 299 adolescents. 299 young adolescents’ parents’ anxiety, depressive and somatic symptoms and disorders were assessed by SCL-90. The results showed that maternal overprotection was a predictor of the development of FSS in both male and female young adolescents (β=0.862, p<.001), while parental emotional warmth and rejection has no significant effect on the development of FSS in adolescents. Stratified analysis revealed that beside maternal overprotection, paternal rejection was also a predictor of the development of FSS in boys (r=0.938, p<.05), but not in girls. Significant mediating effect of parental psychological factors in the relationship between maternal overprotection and FSS were found. Maternal over-protection contributes to the development of FSS in young adolescents. Paternal rejection predicts the development of FSS in boys.

**Amelioration of self-schema vulnerability in cognitive therapy for depression**  
**David Dozois University of Western Ontario, Canada**

Three primary levels of cognition are emphasised in Beck’s theory of depression: Cognitive products (e.g., negative automatic thoughts, dysfunctional attitudes), processes (e.g., attention and memory biases) and structures (i.e., well-organised and interconnected internal representations of self). In this presentation, a programme of research is described showing that negative cognitive structures show sensitivity and specificity to depression. The interaction of cognitive structure and negative life events also appears to predict future depression. Although the products and processes associated with depression appear to fluctuate with concurrent mood (i.e., this negative thinking improves when an individual remits from an episode), the organisation of negative interpersonal content related to self appears to be temporarily stable. Given that cognitive therapy (CT) is highly effective for treating the acute phase of a depressive episode, and that this treatment also reduces the risk of relapse and recurrence, it is possible that CT may alter this stable vulnerability factor. Some data will be presented that supports this idea. The implications of these results for understanding mechanisms of change in therapy and the prophylactic nature of cognitive therapy will be discussed.

**Self-harm in the context of trauma, violence and disconnection**  
**Gillian Straker University of Sydney, South Africa; Gill Straker**

This presentation explores associations between trauma and violence, including harm against the self, via the concepts of dissociation and disconnection. The pathways by which trauma promotes disconnection at the neuropsychological, interpersonal and social level are discussed. There is a particular focus on the disconnection between words and meaning. Within this psychoanalytically inflected paper, this disconnection between words and meaning is explored within attachment theory, and the notion of the alien self. It is argued that when words do not function as containers for affect, enactments frequently ensue. Enactments can involve attacks on the body of the self, or the other, with a gender bias affecting which body will be chosen for attack. Women are more likely to attack themselves, and men more likely to attack someone else, but there is an overlap in the dynamics that inform these behaviours. This presentation focuses on women and self-harm, and how some women use their own bodies to express their distress. Self-harm is refracted through the lens of two new concepts, auto-mirroring and provoked affect broadcasts. The inner experiences of those who self-harm are conveyed in their own words to illustrate their experiences of disconnection, and their attendant need for auto-mirroring and provoked affect broadcasts, as these serve to compensate for deficits in reflective function and feelings of disconnection on multiple levels.

**The portrayal of psychopathology in films**  
**Danny Wedding Alliant International Univ., United States of America**

This presentation will review the ways in which psychopathology has been portrayed in the cinema, illustrating five common myths: traumatic etiology; schizophrenogenic parents; harmless eccentricity; the healing power of love; and the belief that people with schizophrenia have split personalities. Film clips will be used to illustrate these myths. The role of media in establishing and maintaining the stigma of mental illness will be covered. In addition, this presentation will examine the portrayal of psychologists and other mental health professionals in movies, illustrating five recurring motifs: the psychologist as learned and authoritative; arrogant and ineffectual; seductive and unethical; omniscient and dangerous; or kindly and well intentioned. Films illustrating the core principles of positive psychology will be briefly discussed, and the use of films in the classroom and in therapy will be examined. Finally, the use of films for personal growth will be explored. The presentation will be based on the books Movies and Mental Illness (Wedding, Boyd, & Niemiec, 2010) and Positive Psychology at the Movies: Using Films to Build Virtues and Character Strengths (Niemiec & Wedding, 2008).

Genetic and environmental influences on behavioural and emotional problems in 7-17 years old Russian-speaking twins: age and gender differences  
**Elena Gindina Tomsk State University, Russian Federation; Marina Lobakova; Sergey Malykh; Elena Sabirova**

Behavioural and emotional problems in childhood and adolescence are a strong prognostic indicator for poor adult mental health. Thus, information about its etiology is needed. To date, most behavioural genetic research of behavioural and emotional problems has been conducted on European and American samples. We investigated the relative contributions of genetic and environmental factors to behavioural and emotional problems in Russian-speaking school-aged twins (7-17 years). Sample was recruited in the cities of Moscow, St Petersburg, Izhevsk, Tver (Russia) and Bishkek (Kyrgyzstan). Measures of behavioural and emotional problems were obtained from maternal CBCL (Achenbach T., 1991, Manual for the Child Behavior Checklist/4-18 & 1991 Profile, Burlington: University of Vermont, Department of Psychiatry) data and included data from 737 twin pairs. Structural equation modelling was employed to obtain genetic and environmental estimates in three age groups of 7-10 (216 pairs), 11-13 (201 pair) and 14-17 (270 pairs) years old twins. Results showed there are important environmental, as well as genetic factors which contribute to phenotype variance of maternal reports of behavioural and emotional problems in school-aged Russian speaking children. Differences in heritability across age and gender were found.

**Symposium title: Engaging young people and their families in evidence-based services: Challenges and Innovations**

Evidence-based services for young people and their families: How can psychologists help?

Catherine Lee, University of Ottawa, Canada

Worldwide, one in five children and youth suffer from emotional and behavioral disorders. These problems are neither trivial nor transitory. Epidemiological data demonstrate that the majority of disorders of adulthood first appear during childhood or adolescence. Untreated, these disorders are associated with diverse negative consequences that accumulate and persist into adulthood. Only a small fraction of those in need receive any type of services. Many who begin services do not complete them, and there is limited evidence that ‘service as usual’ is effective. Although there are now efficacious treatments for a wide range of disorders, current models of service delivery are unable to reach the vast majority of those who require services. Marginalised people, who are in the greatest need, may be least likely to engage in, complete, and benefit from traditional services offered in a psychologist’s office. Some psychologists are therefore considering the best way to maximise the impact of their knowledge and skills in order to help the greatest number of young people. The Triple P suite of programs is designed to offer services to help the greatest number of young people. The Triple P suite of programs is designed to offer services to promote positive parenting. Asgary-Eden and Lee surveyed service providers, supervisors, and administrators about implementation of this program in their agency in the Canadian province of Ontario. Despite overall positive results and openness to offering this evidence-based program, the majority of agencies faced some resistance in implementing the program. Psychologists are in an ideal position to facilitate the adoption and maintenance of evidence-based services by training, supervising, and evaluating these services.

Rabeja: A clinical case of Bipolar Disorder
Claudia Burroni, HSA, Jamaica; Aimee Ferreira

This work is a detailed and systematic extract of a whole cognitive behavioural psychotherapy (CBT), lasting eleven months, of a patient with diagnosis of Bipolar Disorder. The script describes the rationale that led the therapist to choose the most appropriate intervention in relation to the disease presented and the therapeutic phase. In the work, are included extracts from the clinical interview, result of psychodiagnostic test used during Assessment process (CBA 2.0, MMPI II), and the tools used to achieve a better psychological compensation. Rabeja is a 35 year old woman, married for 16 years with three children aged 17, 10 and 5. She accessed my private practice after heavy pressure and insistence from her psychiatrist. Rabeja is of Kurdish nationality. After her arrival in Italy, which occurred 3 years ago, after a lot of problems related to her husband’s as a political refugee, she has had to deal with economic, social and cultural problems. Although previous studies have shown that depression is more prevalent in Vaular Dementia (VaD) than in Alzheimer’s Disease (AD), the severity and profile of depressive symptomatology appear to be independent of etiology. Because of overlapping manifestations, depression may be misdiagnosed as apathy or behavioural disturbances and a correct diagnosis is sometimes quite arduous. Besides it is well known that depression itself may cause cognitive dysfunctions, as exemplified by Depressive Pseudo-dementia (DPP). The aim of this study was to assess whether the use of self-reporting depression scales, such as Beck Depression Inventory (BDI) and Beck Depression Inventory II (BDI II), would allow identification of symptoms clusters to better differentiate among dementias. The secondary aim of the study was to define whether the comparison between these two diagnostic instruments would highlight different results. The BDI was administered to AD, VaD and DPP patients matched for age, education and severity of dementia. For all subjects cognitive impairment was sufficiently mild to allow self-compilation of the scale. As suggested by literature, the BDI score is subdivided in three subscores corresponding to symptoms of dysphoria, apathy and somatic symptoms. The BDI II score and subscores were based on current Italian standardization of the inventory. Non-parametric analysis of data was performed. The use of different subscores in depression reporting seems to be a useful tool in discriminating among dementias, even if it is not too sensitive to apathetic disturbances. Results obtained by the two different instruments seem to overlap.

Session Type: Invited Workshops

Building capacity for mental health treatment in the developing world: developing and assessing the success of cognitive behavioral group treatment of anxiety disorders in a group of Tanzanian men
Rehman Abdulrehman, University of Manitoba, Canada

Psychology plays a very limited role in most of the developing world; many countries’ health systems are run without any mental health policy. According to the World Health Organization, developing countries have significantly fewer resources to treat mental health problems. Pharmacological treatment is the primary mode of treatment, but is difficult to access and costly. Since CBT is proven to be very effective treatment for the most common mental health problems (i.e., anxiety and depression), and is more cost effective than pharmacological treatment, a model to develop CBT in developing countries may prove useful. An alliance of psychologists from the University of Manitoba and the Muhimbili National Hospital (in Dar es Salaam, Tanzania) conducted a group CBT program for anxiety disorders. The program consisted of seven male outpatients from the university hospital who were diagnosed with an anxiety disorder and were open to exploring non-pharmacological treatment as the primary means of treatment. The group was run by a local psychologist, clinical psychology student, and remotely supervised by a psychologist who specializes in CBT of anxiety disorders, at the University of Manitoba, in Canada. This workshop presents the development of this project, the course of treatment, evaluation by the researchers and by participants, and challenges along the way. This method of training and treatment may serve as a possible model for future training of health care workers in developing countries for the treatment of common mental health problems, and therefore build capacity for overall availability of mental health treatment.

Brain-based therapy
John Arden, Kaiser Permanente Medical Center, United States of America

Proposed Preconference Workshop 4 hours This seminar will examine the role of attachment in development of affect regulation and hemisphere asymmetry. Apply a brain-based approach to treating depression, anxiety, OCD, PTSD, mood and attention deficit disorders. Understand which elements of traditional psychotherapy are relevant and which are counter-therapeutic. Discover how the synthesis of neuroscience, evidence-based treatment and attachment theory fosters optimum therapeutic outcomes. Understand the role of memory and attention in the therapeutic process. Understand how diet effects and can improve your brain. Applying the latest Developments in Neuropsychology to Everyday Practice Recent advances in the neurosciences have increased our knowledge of how and why people change. Brain-based therapy synthesizes neuroscience, evidence-based treatment, and attachment theory into a hybrid therapeutic model. This model helps identify which elements of theoretical psychology are relevant and which may be counter-therapeutic. Brain-based therapy envisions the therapeutic process as a method to change the brain in order to change mood and behavior, using evidence of brain function and activity and moving beyond the theoretical school paradigm. This seminar will examine the use of brain-based psychotherapy to enhance outcomes with a variety of client populations. Participants will identify the role that brain function plays in mood, memory and behavior. You will evaluate the latest research indicating certain aspects of traditional theoretical psychology that may be counter-therapeutic. Using a synthesized model of neuroscience, attachment theory and evidence-based treatment, you will learn how to more effectively treat clients with depression and anxiety disorders as well as PTSD and OCD. Participants will develop a new way of looking at the therapeutic process to move beyond the traditional theoretical school approach. You will learn how to use this information in the therapy session to educate your clients and make the goals of treatment understandable. Course Content Brain-Based Therapy: Brain-based therapy approaches to treating anxiety, depression, trauma and attention deficit disorders. Translate knowledge of the brain into client education and motivation strategies.

Narrative exposure therapy
Thomas Elbert, University of Konstanz, Germany

In narrative exposure therapy (NET), the patient, with the assistance of the therapist, constructs a chronological narrative of his life story with a focus on the traumatic experiences. Empathic understanding, active listening, congruency and unconditional positive regard are key components of the therapist’s behavior. The autobiography is structured according
to their chronological order with the help of the therapist. The aim of this procedure is to transform the generally fragmented reports of the traumatic experiences into a coherent narrative. For traumatic stress experiences the therapist asks in detail for emotions, cognitions, sensory information (visual, auditory, tactile, olfactory and gustatory) and physiological reactions, probes for relative observations and records this information. The patient is encouraged to relive these emotions while narrating without losing the connection to the ‘here and now’, using permanent reminders that the feelings and physiological responses result from memories, the therapist links the experiences to episodic facts, i.e., time and place. The exposure to the traumatic experience is not terminated until the related fear reaction presented and reported by the patient does show a significant diminution. In this way, the narrative is driven forward in a supportive but rather directly guiding style by the therapist, in order to counter avoidance and to recover the full implicit information of the traumatic experience. If requested by the client, a written report may be used for rights and human rights advocacy.

Psychological assessment and evidence-based practice in psychology
John Hunsley University of Ottawa, Fiji
The focus of the workshop will be on evidence-based assessment (EBA) as a key component of evidence-based psychological practice (EBPP). The workshop will begin with an overview of EBPP, including both treatment and assessment services. Following a general discussion of the purposes of EBA, the focus will be on three assessment purposes directly pertinent to treatment: diagnosis, case conceptualization and treatment planning, and treatment monitoring and treatment evaluation. After reviewing some of the key scientific and clinical issues involved in each assessment purpose, the final part of the workshop will involve an examination of the ways that decision-making aids can serve to reduce the negative effects of biases and heuristics in the provision of psychological services. Throughout the workshop the emphasis will be on building on knowledge and skills that professional psychologists already possess by virtue of their training. Practical strategies for maintaining and enhancing professional knowledge and practices will be presented in detail, and information on specific clinician-oriented EBPP resources will be provided.

Session Type: Symposia

Symposium title: Symposia

A comparison of stressors and resources reported by suicidal South African and British adolescents
Henriette Van Den Berg University of Free State, South Africa
A significant increase has been noted in adolescent suicidal behaviour in developed and developing countries. This presentation aims to compare the influence of contextual stressors and resources on the suicidal tendencies of a group of South African and British adolescents. A stratified sample of 678 adolescents from Surrey, England (N = 297) and Northern Cape, South Africa (381) were recruited from private and public schools. The age range of participants were 14 - 16 years. The Suicidal Ideation Questionnaire for adolescents, Life stressors and resources inventory and Cope scale were used to gather data. Descriptive statistics and stepwise regression analysis were performed for the two groups respectively. The British girls reported significantly higher levels of suicidal ideation and behaviour than their South African counterparts. Personal variables such as self-esteem played a very important predictive role for both groups, while alcohol and drug disengagement was a very important contributing factor for the British group (0.1% level of significance, moderate effect size). Support from family and friends played a significant role in the regression analyses. Problems related to financial resources and infrastructure played an important role in the South African group’s suicidal behaviour. Disengagement as coping style was another significant predictor. Recommendations are made regarding the role of interventions aimed at enhancing self esteem and effective interpersonal and coping skills.

The need for increased access to suicide prevention and intervention programs in South Africa
Henriette Van Den Berg University of Free State, South Africa
The Second South African Youth Risk Behaviour Survey showed a marked increase in suicidal behaviour amongst South African adolescents between 2002 and 2008. The South African Health System is characterized by a serious lack of mental health services. This is evident in the ratio of 1: 10000 psychologist to member of the public. Currently no national suicide prevention plan exists. Limited services are available to schools to deal with the increased incidents of suicidal behaviour of pupils. The aim of this presentation is to provide an overview of the services available to South African adolescents battling with suicidal behaviour. The presenter completed a survey in one province in South Africa, making use of key informants in a number of government departments, schools and private mental health facilities to gather information on the availability of mental health services, specifically suicide prevention and treatment services. Results highlighted the serious shortage of suicide prevention and treatment services. Schools in higher socio-economic groups make use of services of private psychologists and counsellors to debrief learners after suicide related incidents of pupils and teachers. The vast majority of schools unfortunately do not have access to any mental health services. Recommendations are made regarding the training of community psychologists and registered counsellors to establish a network of mental health support in schools and at community centres.

Symposium title: Applications of psychology to human service development in Africa
Convener: Robert Serpell

Resilience and adaptation in traumatised child survivors of terrorism: A Nigerian study
Robert Serpell University of Zambia, Zambia; Esther Akinsola
The resilience of children faced with extreme adversity calls for examination of specific ways in which they manage traumatic experience. This study investigated Nigerian children’s representations of their coping strategies following a terrorist attack in Lagos, Nigeria, where in January 2002, bomb explosions erupted in a military cantonment and its surroundings, leaving many people dead and countless displaced, and hundreds of severely traumatised women and children. Among the people displaced and traumatised were children who either lost a parent or other relative or whose houses were burnt. In June 2002, a group of professionals was assembled to assess the impact of the explosions on these children and provide short term intervention with medical treatment, counselling, psychotherapy, and art and drama therapy. Psychologists conducted various assessments, including a family relations drawing test designed to enable children to express their emotions and feelings through their drawings. The first part of this report analyses the children’s experience and coping strategies reflected in their drawings. The second part presents findings from a follow-up study ten years after the explosions, designed to re-assess the children, now adolescents, and determine their recovery level. The sample comprises teenagers that could be located within the cantonment and the surrounding secondary schools. Assessment tools include those used ten years earlier as well as distress and resilience inventories. Findings are discussed in relation to the literature on resilience and adaptation to adverse and traumatic conditions.

Symposium title: Beyond self-report: Objective indices of reactivity and arousal in the assessment of child psychopathology
Convenor: Candice Alfano

Polysomnographic sleep patterns of non-depressed children with generalized anxiety disorder
Candice Alfano University of Houston, United States of America

Subjective reports of problems initiating and maintaining sleep are a consistent finding among children with generalized anxiety disorder (GAD). Yet objective sleep data are lacking. Specific clinical features associated with sleep problems in this population also are unknown. Thirty non-medicated, pre-pubescent children (ages 7-11 years) were assessed including 15 children with primary GAD (without comorbid depression) and 15 matched healthy controls. All participants underwent structured diagnostic assessment and laboratory-based polysomnography (PSG). State anxiety and salivary cortisol were assessed at bedtime on the PSG night and correlations among clinical symptoms and objective sleep variables were examined. Children with GAD showed significantly increased sleep onset latency (SOL) and reduced latency to rapid eye movement (REM) sleep compared to controls. Sleep efficiency was decreased and percentage of REM sleep was increased at marginal levels in the GAD group. State anxiety and total concentrations of cortisol at bedtime were similar across the groups. While increased SOL was associated with a range of clinical symptoms, increased severity of worry was associated with increases in REM sleep. Results provide initial evidence of objective sleep abnormalities in children with GAD. Follow-up studies are needed to explore whether REM sleep characteristics might represent a neurophysiologic pathway from early GAD to later depression.

Cortical patterns of electrical activity that result from childhood traumas
Fleur Howells Department of Psychiatry, UCT, South Africa

Childhood trauma is associated with psychiatric disorders, yet the underlying physiological mechanisms are not well understood. The study of control adults and their correlates with levels of perceived childhood trauma may be particularly useful, to assist in understanding the long-term effects on physiological mechanisms. We hypothesized that control individuals would present with changed patterns of arousal at rest and during a task of attention that requires behavioral inhibition. Fifty-three control individuals completed the Childhood Trauma Questionnaire to assess a range of childhood traumas and perception of trauma. These individuals underwent cortical and peripheral physiological recordings at rest and during performance of a visual go/no-go task. They also completed several personality questionnaires. The results of the present study suggest that: Childhood neglect increases cortical arousal and enhances approach behavior circuitry. Childhood emotional abuse increased arousal when behavioral inhibition is required. Childhood physical and sexual abuse leads to more deliberate information processing. Underreporting of childhood trauma increases mental effort during activation and deactivation of inhibitory circuitry, which may be related to process of denial. Future studies should include multimodal physiological measures that will allow us to elucidate the physiological vulnerabilities that lead to the development of psychiatric disorders that have been strongly related to childhood trauma.

Peering into the living brain through fMRI to probe reward processing in the development of adolescent depression
Carla Sharp University of Houston, United States of America

At any given time, between 4-6% of adolescents are experiencing Major Depressive Disorder (MDD). Lifetime prevalence rates of MDD between the ages of 15-18 are estimated to be 14% with an additional 11% reporting minor depression. Reward processing shows promise as an important endophenotype, heritable mechanism and etiological factor in the development of depression. While several studies in adults and adolescents have demonstrated reduced reward activation in depressed individuals relative to controls, it is unclear whether these abnormalities precede (that is, cause a vulnerability to) MDD, or whether they are a consequence of recurrent illness. We used fMRI to examine brain activation in response to reward anticipation and outcome in three groups of mother-daughter dyads (N = 42): (1) Mothers-with-history-of-depression with never-depressed-daughters (depressed; n = 14), (2) mothers-with-history-of-depression with never-depressed-daughters (high risk; n = 14), and mothers and daughters with no history of depression (low risk; n = 14). Results showed similar reduced activation in the caudate for high risk and depressed teens, while the daughters of never-depressed mothers showed elevated reward processing in response to positive rewards. These findings support the notion that altered reward processing may be evident even before the onset of MDD in high-risk adolescent girls. Results will be discussed in the context of the value of fMRI that goes beyond self-report measures in the identification of endophenotypes in developmental psychopathology.

Clinical study on thought imprint psychotherapy in lower resistant state for depression
Lan Hong Guang’anmen Hospital, CACMS, China; Weidong Wang; Yingna Lin; Xueyu Lu

Thought Imprint Psychotherapy in lower resistant state (TIP) is an indigenous psychotherapy which is suitable for Chinese culture. It was established and applied to Chinese patients with psychological disorders. It was used in our clinic for more than 20 years, and its efficacy for different types of mental disorder is satisfying. To assess the clinical efficacy and safety of TIP for depression, a randomised controlled study was adapted. 60 patients with depression were randomly divided into two groups according to different means of intervention: TIP group and paroxetine group. The trial was done in 12 weeks. 24 items Hamilton Rating Scale for Depression (HAMD), Minnesota Multiphasic Personality Inventory (MMPI) and treatment emergent symptoms scales (TESS) were used to evaluate the efficacy and adverse effects. Evaluation was done before treatment, 2 weeks after treatment, 12 weeks after treatment. The results so no differences at the baseline between the two groups before treatment. After 2 weeks, the response rate was different: 23 cases in TIP group responded positively to treatment (76.7%), while 20 cases in the paroxetine group responded positively to treatment (66.7%). After 12 weeks, the total effective rate was 78.6% and 74.1% in the TIP group and paroxetine group respectively. In terms of safety, the TIP group complained of much less discomfort after treatment. TIP is an effective and safe intervention for depression which brings new insights, however, further studies are needed to prove its efficacy and to explore its mechanism.

Efficacy of tip treatment for primary insomnia: A randomised controlled trial
Weidong Wang Guang’anmen Hospital, CACMS, China; Xueyu Lu; Qian Diao

The objective was to evaluate the short-term efficacy of sleep regulation technique of Thought imprint psychotherapy in lower resistant state (TIP) for the treatment of primary insomnia. We adapted a randomised, single-blind study. 30 hospitalised outpatients with primary insomnia were included according to DSM-IV criteria. Outpatients from sleep medical clinic of Guang’anmen Hospital were randomised in a 2:1 ratio to TIP or Zopiclone (ZPL) group. In TIP Group, patients received sleep regulation technique of TIP twice per week. ZPL group
Dehumanised perception as a mechanism to facilitate human atrocities

Lasana Harris  Duke University, United States of America

Dehumanisation, a failure to spontaneously consider the mind of another person, may be a psychological mechanism facilitating inhume acts by people against other people — human atrocities. Spontaneous social cognition — considering someone’s mind — recognises the other as a human being subject to moral treatment. Social neuroscience has reliably shown that participants normally activate a social-cognition neural network to pictures and thoughts of other people. Our previous work shows that parts of this network uniquely fail to engage for traditionally dehumanised targets (homeless persons or drug addicts). This suggests participants may not consider these dehumanised groups’ minds. I describe evidence that participants do fail to spontaneously think about the contents of these targets’ minds when imagining a day in their life, and rate them differently on a number of human-perception dimensions. Furthermore, these human-perception dimension ratings correlate with activation in brain regions beyond the social-cognition network, including areas implicated in disgust, attention, and cognitive control. I discuss the role of disgust, attention, and cognitive control in moral decision that ultimately may be linked to perceived humanity. These results suggest that disengaging social cognition affects a number of other brain processes and hints at some of the psychological sequelae of torture, but still gives an indication of the complexity and gravity of reactions. The presentation will show the major findings in this preliminary, uncontrolled study and provide clinical examples from treatment sessions.

From victim to survivor: Net in treatment of the psychological sequelae of torture

Hakan Stenmark  United States of America

Studies on the treatment of the psychological sequelae of torture are sparse and with conflicting findings. Some studies have indicated limited effect of treatment whereas others have reported more positive findings. In this study we treated 16 torture survivors, diagnosed with PTSD, with 10 sessions of Narrative Exposure Therapy. Pre-testing was applied before and post-tests one and six months following treatment. Clinician Administered PTSD Scale and Hamilton Depression Inventories were used as primary outcome measures. The findings indicated improvement from baseline before treatment both with regard to PTSD and depression. Ten of the patients achieved clinically significant improvements in PTSD symptoms according to Jacobsen and Traux, 1991. Only one patient had a total severity score below 20, indicating full remission of PTSD symptoms. With regard to depression, the sample mean decreased from moderate to mild depression from pre-treatment to the six months follow up. The study thus supports the use of Narrative Exposure Therapy in treatment of the psychological sequelae of torture, but still gives an indication of the complexity and gravity of reactions. The presentation will show the major findings in this preliminary, uncontrolled study and provide clinical examples from treatment sessions.

Finding benefit in the experience of breast cancer: Issues and questions

Charles Carver  University of Miami, United States of America

A number of theorists have suggested that adversities, even traumatic experiences, do not lead exclusively to distress. Rather, at least some people react to such experiences with feelings of growth and benefit. These experiences do not necessarily take the place of distress, but they sometimes accompany the distress. There is no question that some people do report positive changes after traumatic encounters. Numerous studies verify the existence, even the widespread prevalence, of such effects. Some positive changes pertain to the way people think about the world and their own lives. Some of them pertain to the acquisition of new skills to use in dealing with future adversities in life. Other positive changes appear to pertain to the way people organize and prioritize their actions, or even their choices of what kinds of actions to engage in. This presentation will consider the phenomenon of benefit finding as it arises during the experience of being diagnosed with, and treated for, breast cancer. Several studies will be described which explore the processes that may underlie reports of benefit finding in this circumstance. This exploration consists partly of examining who has those experiences to greater and lesser degrees.

A social-contextual model of dyadic coping among couples facing adversity

Anita Delongis  University of British Columbia, Canada

Research presented will examine dyadic coping and support among married couples in which one or both members of the couple is facing adversity. Using a combination of longitudinal and daily process methodologies, couples were followed over time to examine coping and social support as a dyadic process in which spouses are mutually influential. Findings support a dyadic model in which...
Task prioritization among university students with different subtypes of future-oriented coping strategies

Yiqun Gan Peking University, China

This study aimed to explore subtypes of future-oriented coping profiles. It adopted the time discounting experimental paradigm to examine the influence of coping subtypes on task prioritization. A sample of 188 university students were clustered into four subtypes, namely, high future-oriented coping (HFOC), high preventive coping (HPVC), low preventive coping (LPVC), and low future-oriented coping (LFOC). Next, using a computer, 77 of the participants were asked to prioritize pairs of tasks that had been selected from 2 (long-/short-term) * 2 (challenging/threatening) tasks in six scenarios. The results indicated that, compared with students in other subtypes, those in the HFOC subtype demonstrated a stronger preference for important but not urgent tasks (p<0.01), whereas the HPVC subtype attended more to threatening tasks (p<0.01). Results of the study have theoretical and practical implications for the study of time management and future-oriented coping.

Health threat beliefs and coping in the context of genetic risk for cancer

Yiqun Gan Peking University, China

This study linked beliefs about the consequences of being assessed for genetic risk of cancer to specific coping responses and their impact on emotions and frequency of worry. Participants were 301 women undergoing genetic risk assessment based on family history. Patients were sent postal family cancer history questionnaires (time 1), which they returned approximately one month later (time 2). Based on these data, they were subsequently informed of their risk level (time 3). At each time point, participants completed questionnaires measuring their beliefs about the threat associated with risk assessment and the coping strategies they used in response to each belief, their emotional responses to the risk assessment process, and frequency of worries about their genetic status. Analysis involved exploration of the relationship between specific beliefs and use of coping strategies, changes in coping strategies over time, cluster analysis to identify groups using differing coping strategies, and the relationship between coping and changes in emotional and frequency of worry. Overall, the data show that participants used one dominant strategy for coping with each concern (limited to positive appraisal, acceptance, and seeking family/social support) and, while they also used other coping strategies, they used these much less often. Cluster analysis revealed four clusters of coping responses, including the use of positive appraisal as an almost unique coping response to 10 or the 11 beliefs explored to a much wider use of differing coping responses. The associations between coping and changes in emotions and worry were modest although significant.

The relations of career barriers to emotional and personality-related career-decision-making difficulties

Yiqun Gan Peking University, China

Emotional and personality-related career-decision-making difficulties represent emotional and personality-related aspects of difficulties in making career decisions, which could be organised into three dimensions: Pessimistic view, anxiety and self and identity (Saka, Gati, & Kelly, 2008). Problem-solving appraisal, which is assessed by Problem-Solving Inventory (Heppner, 1988), is suggested to be related to coping effectiveness, vocational adjustment and many other factors that reflect people’s well-being and adjustment (e.g. Heppner, Lee, Heppner, McKinnon, Multon, & Gyens, 2004). Based on these reviews, this study aimed at inquiring into the moderating effects of problem-solving appraisal on the relationship between career barriers and career decision making difficulties. Data were collected from undergraduates across 19 universities, 17 provinces in Mainland China. All students were administered with Chinese Career Barriers Inventory, Emotional and Personality Career Difficulties Scale and Chinese Problem Solving Scale. Hierarchical multiple regressions were done to see the moderating effects of problem-solving appraisal between career barriers and EPCD scores. Results showed a significant moderating effect. The regressions revealed that in the high problem-solving group, career barriers had a greater regression coefficient than in the low problem-solving group. This might be due to the fact that the high level of problem solving had shielded the influence of some possible existing variables which might predict emotional and personality-related career-decision-making difficulties, thus raising the contribution of career barriers.

Designing couple therapy based on general mechanisms of change

Mariann Grawe-Gerber United States of America

Empirical psychotherapy process research has found increasing evidence that change achieved by therapeutic procedures and interventions seems to be more influenced by general principles of change and common factors in psychotherapy approaches rather than by specific methods and techniques. Within cognitive-behavioral couple therapy researchers have also suggested examining general mechanisms of change across different evidence-based treatments for couples (e.g. Christensen, 2009). This presentation will introduce four empirically established therapeutic mechanisms of change and common factors in psychotherapy extracted by Grawe and his research team after years of studying findings from psychotherapy process research for their meta-analysis (Grawe 1997, 2004, 2007). These four general change mechanisms include: problem actuation, resource activation, master, and clarification of meanings. It will then be demonstrated how conceptualizing couple treatment optimizing these general principles enables the therapist to integrate therapeutic procedures and interventions from different approaches within an empirically sound framework.

Greater emotional arousal predicts poorer long-term memory of communication skills in couples

Kurt Hahlweg Germany

Many studies have examined the importance of learning skills in behaviourally-based couple interventions but none have examined predictors of long-term memory for skills. Associations between emotional arousal and long-term recall of communication skills delivered to couples during a behaviourally-based relationship distress prevention program were examined in a subsample of 49 German couples drawn from a larger sample of 58 couples. (The nine couples not included in analyses had dropped out of the study during the follow-up period.) Fundamental frequency (f0), a vocal measure of encoded emotional arousal, was measured during pre-treatment couple conflict. Poisson Hierarchical Generalized Linear Models were used to test associations between each partner’s f0 and skills remembered as well as sex differences in such associations. Higher levels of f0 were linked to fewer skills remembered 11 years after completing the program, and women remembered more skills than men. Implications of results for behaviourally-based couple interventions are discussed.

Symposium title: Empirical advances in couple-based interventions

Convenor: Douglas Snyder

Couple-based interventions for adult psycho-pathology

Donald Baocom University of North Carolina, United States of America; Cynthia Bulkin; Jonathan Abrahamowitz; Jennifer Kirby

Because adult psychopathology has traditionally been viewed as individual disorders, interventions typically have emphasized individual psychotherapy. However, these problems exist in an interpersonal context, and intimate relationships either can exacerbate or help to alleviate individual distress. Likewise individual psychopathology can impact the quality of relationship functioning. This presentation will present an overview of models for treating individual psychopathology from a couple-based perspective. Based on these models of couple-based interventions, the presenter will describe treatment results from two of his recently completed treatment studies, providing couple-based interventions for anorexia nervosa and obsessive-compulsive disorder. He will highlight the primary patterns of couple interactions observed in each of these disorders, that is, how couples have learned to interact around the disorder in both adaptive and maladaptive ways. In both of these investigations, the effect sizes for the couple-based treatment are notably larger than any previous individual treatment for the respective disorders. Implications for using couple-based treatments for other types of disorders will be discussed.
International dissemination of the prevention and relationship enhancement program (PREP): Challenges and future directions
Howard Markman, United States of America

Marriage Education is a novel response to the rising rates of divorce and relationship distress occurring in many countries around the world. This presentation begins by comparing relationship and marriage education to marital therapy and shows how education is a different approach to helping couples. In brief, research-based marriage education programs are designed to help couples by teaching the skills and principles associated with a healthy and happy marriage (e.g., effective conflict management, protecting and preserving positive connections). The presenters will focus specifically on PREP (Prevention and Relationship Education Program) as an approach to relationship and marriage education and briefly describe the research on the effectiveness of PREP. They will then discuss processes of disseminating PREP in other countries (e.g., Norway, Denmark, Israel, Chile, Sweden, and Estonia) and highlight the challenges associated with such dissemination efforts including forging and maintaining relationships with partners in other countries, adapting (including translating) content and delivery of the program, training trainers (and deciding who those trainers will be), guiding partners in best strategies to use the program in their own country and culture, basic research and evaluation issues and follow-up. Recommendations will be presented for future cross-national disseminations of research-based relationship education programs for couples.

Advances in couple-based interventions: An overview
Douglas Snyder, Texas A and M University, United States of America

Numerous controlled clinical trials over the past 30 years have confirmed the effectiveness of couple-based interventions for the prevention and treatment of general relationship distress. However, until relatively recently, receiving less empirical study have been questions regarding therapeutic mechanisms, couple interventions for individual psychopathology, or international dissemination of evidence-based approaches. This research symposium including an international panel of clinical scientists will discuss findings and implications of recent exemplary studies addressing these issues. In the first paper, Dr. Donald Baucom (USA) will present the results of multiple randomized controlled trials of couple therapy for individual emotional disorders. The second paper presented by Dr. Mariann Grawe (Switzerland) will discuss the design and conduct of couple interventions drawing upon an integrative model of general mechanisms of therapeutic change. The third paper, by Dr. Kurt Hahlweg (Germany), will describe the role of emotional arousal as a moderator of acquisition and retention of communication-skills in couple skills-training protocols. The fourth paper, by Dr. Howard Markman and Marcie Pregulman (USA), will discuss findings regarding the dissemination of a relationship enhancement and distress-prevention program across diverse countries and cultures. Collectively, these clinical trials and findings from similar lines of research offer far-reaching implications for clinical practice and for service delivery on an international scale. Dr. Kim Halford (Australia) will serve as discussant for this symposium.

Symposium title: Engaging young people and their families in evidence-based services: Challenges and Innovations
Convenor: Catherine Lee

Engaging parents with media-based, internet and minimally sufficient interventions: Maximising reach worldwide
Rachel Calam, University of Manchester, United Kingdom

Employing non-traditional means of engagement, delivery and retention offers important opportunities for increasing accessibility and uptake of parenting interventions worldwide. Effective media, internet-based, self-directed and large group approaches offer new possibilities for engaging parents who might not otherwise be attracted to or able to participate in evidence based programmes. The paper will describe a series of studies by our research group designed to reach families in different contexts and settings. Firstly, two UK based, online studies will be outlined. (1) The success of an online randomised controlled trial which ran alongside a networked television series on parenting will be described. (2) A web-based trial testing the impact of different advertisement content on uptake of an online parenting programme will be outlined. This illustrated the natural history of uptake and attrition in an online parenting programme in the absence of reminders or support, and indicates the issues that must be managed to reap the benefits of this potentially highly cost-effective strategy. A second area of study addresses the issues involved in reaching families in middle-low income countries in cost-effective ways. A study of 136 parents (94% mothers) of primary school children in Panama indicated parents found Triple P Positive Parenting Program materials highly acceptable and showed high levels of intention to take up parenting resources if offered, including self-directed materials. Examples of successful large group delivery approaches will also be given. Models for engagement and delivery to assist in dissemination of preventative strategies in cost-effective ways internationally will be discussed.

Engaging fathers in behavioural family interventions
Louise Keown, University of Auckland, New Zealand

An increasing body of evidence highlights the importance of fathers’ parenting and involvement for children’s development. However, fathers are typically underrepresented in behavioural family interventions (BFIs). Research has identified a range of obstacles that should be addressed in order to increase father involvement in BFIs. These include identifying and removing barriers to participation, and tailoring content and delivery methods to meet the parenting support needs of different father groups. This paper discusses the use of father preference data to identify how to engage and involve fathers in parenting programmes. Illustrations are provided from the author’s work to highlight fathers’ parenting challenges, parenting support preferences, and fathers’ opinions about methods of parenting programme engagement and delivery. The range of delivery options (group, individual, self help, web-based), that is needed to attract fathers will be discussed. A range of programme content issues that could be incorporated into behavioural family interventions to better suit the needs and interests of fathers will be highlighted, along with implications for practitioners for tailoring programme content. Work in progress, using consumer preference data to assess the cultural relevance and acceptability of the Triple P Parenting Program to indigenous Maori and Pacific Island fathers in New Zealand will also be described.

Symposium title: Enhancing clinical psychology training: Curriculum changes worth considering
Convenor: Nancy Pachana

Best practice guidelines and research in clinical supervision
Anise O'Donovan, Griffith University, Australia; Kim Halford, Griffith University, Australia

Supervision of clinical practice is generally agreed to be central in such training. Clinical psychology supervision is intended to serve three related, but somewhat conflicting, functions: (1) normative functions of monitoring and ensuring client well-being, and monitoring and evaluating supervisee competence; (2) restorative functions of supporting supervisee personal and professional well-being;
and (3) formative functions of educating and guiding the supervisees professional practice. Research suggests that while supervision may achieve restorative and formative functions, as currently practised, that ensuring competence for trainee psychologists is a more elusive goal. This paper presents data from a large Australian research project on clinical psychology training. Recommendations on how to enhance supervision practice are described, including systematic assessment of supervisee competence and client outcomes.

Enhancing clinical psychology training: Curriculum changes worth considering

Nancy Pachana University of Queensland, Australia
Clinical psychology training programmes are under pressure to increase the number of graduates they produce and to ensure that these graduates meet high standards of professional competencies. This Australian Learning and Teaching Council-funded research project aimed to better align clinical psychology training curriculums to competencies in several key areas including competency assessment, clinical supervision issues and strategies, and fitness to practise protocols. This set of presentations covers the data gathered in a national survey as relevant to these topics, and discusses modifications and adaptations to the curriculum to enhance training experiences for both staff and students. Overarching future considerations are also discussed.

Embedding clinical competency evaluations into clinical postgraduate training in psychology

Nancy Pachana University of Queensland, Australia; Theresa Scott; Kate Sofronoff; Edward Helmes
Debates over models of professional training have occurred in several clinical disciplines, including psychology. Currently, clinical competencies often form the backbone for the accreditation of such training programmes, with sample domains including ethical and legal issues, assessment, intervention, and experience with a diversity of clients across cultures and the lifespan. This paper presents data from a large Australian research project on clinical psychology training. We review key models for clinical competencies in the international literature and report on results of a survey of students undertaking clinical training as to the methods of assessment used in their training programmes. Results showed that direct competency assessment was less commonly used than expected from the stated accreditation standards. One factor behind the results may be that ways to assess such competencies remain elusive. In this paper, models of clinical competency assessment are offered, with practical considerations for embedding this and data on student outcomes when such a programme is firmly in place.

Fitness to practise in clinical psychology training

Kate Sofronoff University of Queensland, Australia; Edward Helmes
Assessment of Fitness to Practise (FTP) guidelines within clinical psychology training programmes requires balancing the individual student’s right to pursue their vocation of interest and the rights of others with whom that person comes in contact, most especially clients. The past decade has seen an international growth in policies related to formal FTP assessment built into clinical training programmes leading to professional qualifications. We draw on data from a large Australian research project on clinical psychology training in Australia. This national survey of 35 clinical psychology programmes explored views from both clinical directors and clinical students. Recommendations on realistic ways to move forward in this area are offered.

Symposium title: Hypnosis
Convener: Cecile Gericke

A hypnotherapeutic model of ericksonian and ego-states for the effective and successful therapy

Cecile Gericke South Africa
Hypnosis has been defined as a complex system of influence communication. It has extensively been used as the treatment approach for a variety of problems ranging from childhood abuse to empowering growth in people. Utilisation as the centre of Ericksonian theory is combined with the inner parts Ego-State therapy to illicit the inner resources of the client. The combination of these two theories epitomise the unique treatment. The therapist makes strategic use of any, or all, facets of the client or the environment when packaging the goal in a unique and acceptable way for the client. The presentation is illustrated with case studies to highlight the efficiency of the approach.

The problem with the unconscious is that it is unconscious: Might the marriage of hypnosis and depth psychology be a remedy?

Susanna Kriegler South Africa
Libido contains two opposite urges or instincts: To live and to die. All energy flows from a difference in potentials. However, the human ego perennially nurtures the childlike illusion that it can partake only of the positive pole, and banishing all that is deemed negative or bad into the unconscious, thus creating an enormously bloated Shadow (Carl Jung). So much of our religious teachings are rooted in the “Socratic fallacy” that earnestly pursuing the good will eliminate all evil. Many psychologies likewise skim the surface, treating behaviours, reinforcing ego strategies, and/or medicating. Yet, how is it that there are so many discrepancies between our professed values, our presumptive virtues, and our myriad destructive, behaviours? It is easy to deny, project elsewhere, or bury the Shadow complexes in us, but in the process we become most dangerous to ourselves, our families and to society. The problem with the unconscious is, of course, that it is unconscious. In serious therapy, we cannot afford to disregard the power of the unconscious, and we are obliged to approach the issue of the Shadow from the standpoint of Depth Psychology – thus named because of its effort to respect and to work with the dynamic powers on the unconscious. Hypnosis and Depth Psychology is a marriage made in heaven – that is, in the sacred space (the mandorla, as explained by Robert Johnson) where conscious and unconscious overlap, thus creating the fulcrum for profound healing.

Hypnotherapy, psychedelic drugs and holotropic breathwork: A critical reflection (25.2)

Rona Newmark Stellenbosch University, South Africa
The use of psychoactive plants is common in the Western Cape, South Africa. Psychedelic plant substances have been used in many cultures to induce non-ordinary states of consciousness. Research has shown ‘universality’ of psychoactive drug experiences across cultures and history. These substances are used to open up experiences of realities which are normally unconscious. There are many psychological and physical affixes linked with the use of these substances. Psychedelic drugs are viewed as powerful catalysts for personal insight, yet, they may cause individual and social disruption (Grace and Zarkove, 1985; De Korne, 2011). Based on his research in the 1970s, Stan Grof (1981) argues that transformation can occur in non-ordinary states of consciousness. He views psychedelic substances as the most powerful technique of inducing these non-ordinary states. Because of the risks involved in the use of psychedelic substances, Grof (1985) developed Holotropic Breathwork to reach non-ordinary states of consciousness in a safe manner. In this paper I present a critical reflection on psychedelic drugs, Holotropic Breathwork and the implications for hypnotherapy in Africa.

Ericksonian principles utilised in combination with the primordial connection of human beings with wild animals

Louise Olivier South Africa
This paper deals with a unique approach using the Ericksonian principles of utilisation, introjection, individualisation, interspersing and metaphors (Erickson & Rossi, 1979). Africa presents a special opportunity to the therapist to combine the principles of Erickson with the primordial connection that human beings have with the wild and the healing power of nature. In this presentation (highlighted with video material) the therapist and client find themselves within the greater arena of nature. The therapist utilises the behaviour of the wild animals to 1) effect an interactive trance 2) to individualise the experience for the client, 3) to imbued within a metaphor the suggestions which is beneficial to the client and to 4) introject new behaviour patterns and internal psychological resilience within the client. The way in which this technique can also be adopted in countries other than Africa is also discussed.

When wifey gets frisky, you don’t want your accountant part handling the matter

Michiel Opperman South Africa
This presentation will focus on sexual problems and the impact thereof in the relationship between couples. Case studies will be presented, including a wife that feels neglected by her husband, as when she wanted to feel loved by him and felt sexy, he would attend to the checklist: brush your teeth, take your vitamins, etc. By unpacking the internal ego states, identifying their respective roles, and determining which ego state would be the appropriate one to deal with the sexual matters in the relationship, we managed to save a relationship. In the presentation issues of sexual addiction in a relationship is explored and discussed according to another case study. The client
gets involved in random sexual encounters with strangers, with huge guilt feelings afterwards. His wife has no knowledge of these encounters, and is under the erroneous belief that they are in a monogamous relationship. In unpacking the ego states, there is a clown face, a mask of self-confidence and power, and horns for sexual conquests. Another part feels the guilt after the sexual encounters. There is a Nobody part, that has no identity if he does not put on the Sexual Predator clown face mask. In unpacking the different ego states and encouraging communication between the parts, the system is integrated and the sexual addiction healed.

**Symposium title: Linking cognition and psychopathology**

**Convenor: Elke Geraerts**

**Degrading anxiety-provoking flashbacks and flashforwards**

*Irís Engelhard United States of America*

Earlier studies have shown that eye movements (EM) during retrieval of disturbing images about past events reduce their vividness and emotionality, which may be due to both tasks competing for working memory resources. Many patients with affective disorders also suffer from upsetting future-oriented mental images: "Flashforwards". This study examined whether EM also reduce vividness/emotionality of flashforwards. A non-clinical sample was asked to select two images of feared future events, and rate image vividness and emotionality. Images were recalled again while making EM or without a dual-task, and after a break, vividness and emotionality were rated again. Relative to 'recall only', EM+recall decreased image vividness and emotional intensity. Apparently, EM reduce vividness and emotionality of visual images about past and future feared events. This is in line with a working memory account of the beneficial effects of EMDR, which predicts that any task that taxes working memory during retrieval of disturbing mental images will be beneficial. The findings were recently replicated in two studies of anxious students suffering from flashforwards. Potential clinical implications will be discussed.

**Memories of childhood sexual abuse: First do no harm**

*Elke Geraerts Erasmus University Rotterdam, Netherlands*

In this paper, I will present our latest findings on recovered memories of childhood sexual abuse. We distinguished two types of recovered memories: Those that were recovered spontaneously and those recovered in suggestive therapy. Results show that people with both types of recovered memories suffer from posttraumatic stress disorder and depressive symptoms. This presentation will highlight the dangers of suggestive therapy and will provide guidelines for memories of childhood sexual abuse.

Is there covariation bias in separation/social anxiety in primary school children?

*Birgit Mayer Erasmus University Rotterdam, Netherlands*

Covariation bias refers to the phenomenon of overestimating the contingency between certain stimuli and negative outcomes, which is considered as a heuristic playing a role in the maintenance of certain types of psychopathology. Most prominently, this type of reasoning bias is observed in adult patients with different sorts of anxiety pathology. As anxiety disorders frequently have their onset during childhood, it is important to investigate whether this maintaining bias is already playing a role in children. In the present research, covariation bias was investigated in normal school children in the context of separation anxiety symptoms (N = 324; 52.3% girls, mean age = 9.32 years) and social anxiety symptoms (N = 120; 58.3% girls, mean age = 9.50 years). In both samples, a priori and a posteriori contingency estimates were measured between positive, neutral and negative pictures relevant for the pertinent anxiety disorder (e.g., a child being united with the mother and a happy face or a child being separated from the mother and a disgusting face), on the one hand, and pictures of negative, positive and neutral outcomes (e.g., electric shock, candy, and nothing), on the other hand. Hypothesised is an overestimation of the contingency between fear-relevant negative pictures and negative outcomes being dependent on levels of anxiety disorder symptoms and age. Results of the research will be presented and discussed.

**Tackling depression: A working memory intervention**

*Sabine Wannmaker Erasmus University Rotterdam, Netherlands*

Increasing evidence shows that a deficit in working memory could be the cause of biases in attention, memory and interpretation in depression (Joormann, 2010). This results in rumination and sustained negative mood, the core symptoms of depression. This lack of working memory ability could be solved with a working memory training. Recent research has shown that a working memory training leads to an improvement in executive processes (Klingberg, Forssberg, & Westerberg, 2002). Moreover, Klingberg et al. (2005) showed that such a training resulted in a significant reduction in the severity of ADHD symptoms in children suffering from this disorder. In the present study a working memory training was performed to reduce depressive symptoms in patients with a major depressive disorder. Sixty patients with a major depressive disorder completed a 4-week working memory training which was adapted to their working memory deficits. The group was compared with a control group (N = 60) who performed the working memory training without an increasing memory load. On the post-test the experimental group showed less depressive symptoms and rumination, they were less affected by the mood induction and their working memory was improved. These results indicate that working memory is a crucial element in the treatment of depression. This easy intervention could be developed in a new therapy when more positive results are found. More research has to be done to the possibilities of this training by dysphoric, bipolar and individuals in remission.

**Sexual risk and substance use: Contributions of family and community contextual processes**

*Velma McBride Murry United States of America*

African Americans residing in resource poor communities have been hit hard by two critical issues—high prevalence of HIV/AIDS and increasing rates of illicit drug use among their sons, in particular, as they transition into emerging adulthood. Reasons why African Americans in general, and those in the South, in particular, are impacted disproportionately by HIV/AIDS (Wyatt, Williams, & Myers, 2008) and illicit substance use remain unknown (Brussick, 1999; French & Pitchall-French, 1999). The research questions focus on the effects of early experiences, the role of parenting as a buffer against stress and the different pathways that lead to HIV/AIDS vulnerability behaviours and substance use among rural African American adolescents. The study examines the effects of Community and Religious Social Support, parental nurturance and youth self-control on risky sexual behaviour and substance abuse.

**Maternal intrusiveness in infancy and early childhood: Effects on behavioural outcomes of African American boys**

*Amanda Clincy United States of America*

Among studies comparing parental intrusiveness and control and child outcomes across cultures, the positive associations between intrusiveness and negative child outcomes tends to be larger among European American families than African American families. This may be due to a de-coupling of intrusiveness and parental warmth and sensitivity within African American families as compared to European American families. The current study examines the prediction of maternal intrusiveness during the first three years of life, as well as the behavioural and psychological outcomes associated with intrusiveness over time. First, we examined the trajectory of maternal intrusiveness during the first 3 years of life (at 6, 15, 24, and 36 months of age), and the association between maternal intrusiveness and child. The findings indicate that, on average, mothers of African American boys increased significantly in their intrusive behaviours across the first three years of life; B = .086 (0.33), p < .01; however, there was significant individual variation in change over time across mothers as well. Next, we examined the contextual, psychological, and child level predictors of initial levels of intrusiveness and change over time. Neither family cumulative demographic risk, maternal psychological, nor difficult temperament predicted initial levels of intrusiveness (measured at 6 months of age). Collectively the current results suggest that there is not a strong de-coupling of intrusive and warm parenting behaviours during the first 3 years of life for mothers of African American boys and the effects of maternal intrusiveness across the first three years are associated with problematic outcomes for African American boys.

**Family functioning and adolescent coping skills that promote youth development in inner-city African American and Latino youth**

*Patrick Tolan United States of America*

The study examines the effects of Community and Religious Social Support, parental nurturance and youth self-control on risky sexual behaviour and substance abuse.

Family functioning and adolescent coping skills that promote youth development in inner-city African American and Latino youth
This study analyses eight waves of data from the Chicago Youth Development Study, a longitudinal study started in 1990 to research the development of young African American and Hispanic men and their children, partners, and parents in high crime, economically depressed neighbourhoods. The young men were recruited in fifth- and seventh-grade classrooms in 17 Chicago public schools located in high poverty communities. To ensure that half the sample was at “high risk” for serious aggression, half of the boys were selected based on teacher ratings on the Teacher Rating Form of students who had already displayed high levels of aggression. The other half of the sample was randomly selected from young men at low or medium risk for serious aggression. We tested the effects over time and identify promising links to successful outcome within this high risk environment. Our analyses examined the roles of coping strategies and family functioning on the relation between stressful events and positive youth development. In particular, we tested how family functioning (parenting and strong family relationships) moderated (protect against) the impact of stress. Stressful events will share a significant direct negative association with coping success, and significant positive direct relations to academic success and engagement in productive activities. Stressful events were inversely related to academic success. Successful Coping strategies and positive family functioning were positively associated with educational attainment and engagement in productive activities.

Symposium title: Marriage and cohabitation separation adjustment
Convenor: Kim Halford

Breaking up is hard to do? The impact of relationship dissolution on mental health and life satisfaction.
Kim Halford University of Queensland, Australia;
Scott Stanley; Howard Markman; Galena Rhoades
This study examined the impact of unmarried relationship break-up on psychological distress and life satisfaction using a within-subjects design. Among unmarried 18- to 35-year olds (N = 1295), 36.5% had one or more break-ups over a 20-month period. Experiencing a break-up was associated with an increase in psychological distress and a decline in life satisfaction (from pre- to post-dissolution). In addition, several characteristics of the relationship or of the break-up were associated with the magnitude of the changes in life satisfaction following a break-up. Specifically, having been cohabiting and having had plans for marriage were associated with larger declines in life satisfaction while having begun to date someone new was associated with smaller declines. An interesting finding, having higher relationship quality at the previous wave was associated with smaller declines in life satisfaction following a break-up. No relationship or break-up characteristics were significantly associated with the magnitude of changes in psychological distress after a break-up. Existing theories are used to explain the results. Implications for clinical work and future research on unmarried relationships are also discussed.

The trajectories of different dimensions of adjustment to couple relationship separation
Kim Halford University of Queensland, Australia;
Susie Sweeper
The current study describes the trajectories of different aspects of separation adjustment in people formerly married or cohabiting, and moderators of those trajectories. We assessed emotional attachment to the former partner, loneliness, psychological distress, and co-parenting conflict at two time points six months apart in 303 participants (169 women; 134 men) who had separated between 2 and 18 months previously. Multilevel modeling was used to estimate the trajectories of the different aspects of adjustment as a function of time since separation, marital status, gender, presence of children from the relationship, who initiated separation, social support and anxious attachment. Attachment to the former partner, loneliness, and psychological distress were initially high but improved markedly across the two years after separation, but co-parenting conflict was high and stable. Adjustment problems were similar in men and women, and in those formerly married or cohabiting. However, reported co-parenting conflict was higher in men than women, and in formerly cohabiting than formerly married individuals. Low social support and high anxious attachment predicted persistent attachment to the former partner, loneliness, and psychological distress. Co-parenting conflict is a common, chronic problem for many separated couples, and individuals with certain psychological vulnerabilities also experience chronic personal distress.

Coping eduction and family mediation outcomes
April O’Mara University of Queensland, Australia;
Kim Halford University of Queensland, Australia;
Megan Morris Australia
For many separating parents and children the separation is a sometimes a difficult transition but they adjust well reasonably quickly. However, for other parents and children they experience chronic poor separation adjustment, characterised by ongoing parental conflict, poor parental communication, low parental cooperation, poor parental adjustment, poor child adjustment, and poor child-parent relationships. Family dispute resolution (FDR) is a process in which a professional mediator seeks to assist the separating parents to negotiate a mutually acceptable co-parenting agreement, which serves the best interests of their child(ren). Under Australian Family Law most couples who cannot reach an agreement together on coparenting must attend FDR. A key assumption in FDR is that the key challenge to enhancing post-separation adjustment of children is for the parents to negotiate an agreement that is mutually acceptable. However, many separating parents lack crucial knowledge and skills to coparent effectively, and adding psycho-education to FDR could improve outcomes for children and parents. This paper reports on a randomised clinical trial of the effect of integrating psycho-education with FDR on child and adult adjustment post-separation.

Symposium title: Primary care psychology: An international perspective
Convenor: Robyn Vines

Primary care psychology in the United States
James Bray Baylor College of Medicine, United States of America
The practice of psychology is in the process of evolution and change to meet the needs for our population in the changing health care environment. Primary care psychology is an exciting new area for the profession. In the US, primary care providers treat over 70 percent of mental health problems, without assistance from psychologists or any other mental health providers. Primary care providers are the de facto mental health system due to policies and over-reliance on medications. Research indicates major health problems, such as diabetes, heart disease and obesity, are due to psychosocial and lifestyle problems - issues that are not effectively addressed by the medical profession. Psychologists are becoming increasingly involved in preventing and treating these problems as integrated health care is implemented. The opportunities in primary care psychology necessitate additional knowledge of primary care and different skills in caring for primary care patients that reflect the evolution of psychology from being a mental health profession to a full partner in the health professions. This presentation will discuss (1) the present status of psychologists working in primary care in the United States and its relationship to the health care reforms that are occurring; (2) practice opportunities in primary care in private and public settings; (3) how to market your practice to primary care providers; (4) the use of technology and electronic health records in primary care practice; and (5) future challenges in developing integrated health care systems and training models for the future of psychology practice.

Primary care psychology in Norway
Tor Høggaard Norwegian Psychological Ass., Norway
In Norway, psychologists started working in primary care many years ago. However, due to changes in health care legislation, most migrated to the secondary care system with few remaining in primary care. Although good for the secondary care system, the lack of psychologists in primary care was of concern. During a 10-year period of major mental health reform, many people still received no psychological help for mild/moderate depression and anxiety. There was also a huge rise in the prescription rates of anti-depressant and anxiety medication by primary care doctors. Since 2007, the Norwegian Psychological Association has put "primary health care psychologists" back on the agenda. User organisations, the Norwegian Medical Association, and government have agreed that this was necessary to address the mental health needs of the population. After four years, a status report can now be provided: all political parties now support early intervention in primary care; €12 mil has been allocated to pilot programmes to establish best ways to recruit and organise psychological services in the municipalities; new primary health care legislation defines mental health as equally important to somatic health; future funding of psychologists in public

Clinical
primary care is now being planned by the Director-ate for Health. This presentation will give an overview of the development of mental health services and reform ideology in Norway. It will focus on the political work of the Psychological Association, and strategies developed to change the understanding of what psychologists can contribute in primary care.

Primary care psychology in Great Britain/ the UK
Peter Kinderman The University of Liverpool, United Kingdom

This presentation will give an overview of the status and future direction of primary care clinical psychology in the UK. It will address four main areas, the growth of the profession of clinical psychology, and of a psychological ethos, over the past 20 years, the impact of the major Government investment and capacity-building programme - IAPT (Improving Access to Psychological Therapies Programme), the likely impact of reforms to the NHS commissioning framework, and finally the ethos of clinical psychology provision in the UK. Over the past 20 years, there has been rapid growth in the number of clinical psychologists employed in the UK, and a substantial increase in the centrality of psychological perspectives in planning. This, coupled with the driver to implement the recommendations of the National Institute for Health and Clinical Excellence (NICE), has led to a £1bn+ investment in psychological therapies, targeting CBT in primary care for mild-to-moderate depression and anxiety in adults of working age, and increasingly including children, young people, older adults, psychotic problems and comorbid medical conditions. The implications of this major programme will be discussed, together with current changes to the NHS commissioning arrangements which provide a focus on central government level on primary care physici-ans and an emphasis on well-being. The implications for psychology will be explored, including the tenet that the core purpose of clinical psychology, especially in primary care, must be to retain a focus on helping people maintain their functioning and well-being, rather than focus too much on treating mental illnesses.

Primary care psychology in Australia: Developments over the past ten years
Robyn Vines Primary Health Care, Monash Uni, Australia

In recent years, Australia has led the way in the provision of equitable access to primary care psychological services under the Public Health System. Australian primary mental health reforms have represented a substantial national investment in, and focus upon, improving access to early intervention for common mental disorders in the primary care setting. Since the advent of medicare rebates for these services in November, 2006 (after a 20 year campaign), approximately 2 million people have accessed primary psychological care, contingent on GP/family physician referral. The presentation will describe Australian primary mental health care reforms over the past decade, and the outcomes of current evaluations in relation to the Better Access to Mental Health and Better Outcomes in Mental Health Care programmes. Lessons from the Australian experience will be highlighted.

Primary care psychology: An international perspective
Robyn Vines Primary Health Care, Monash Uni, Australia; James Bray; Tor Hoffgard; Jean Grenier; Peter Kinderman

Primary Care Psychology is a growing area of practice and service delivery in a number of western countries. At the core of this new development lies a collaborative model of mental and general health care involving appropriately trained psychologists working with family physicians in general practice. Enabling early intervention for common mental health disorders (previously under-treated), chronic disease and its behavioural and mental health sequelae, the model minimises the stigma of help-seeking, facilitates more equitable access to care, and requires different approaches to those traditionally used in the hospital, community health and private practice sectors. The Symposium will focus on: evidence-based interventions for common mental disorders and chronic disease in primary care, models of best practice, and optimal funding frameworks for this mode of work. An emphasis will be placed on current research findings, changes needed for practitioners to adapt to new shared-care approaches to treatment, and how to enhance post-graduate training models to ensure that specialist psychologists and GP/family physicians are best prepared to work effectively together in the primary care setting. The Forum will provide an international perspective with speakers from Norway, the UK, USA, Canada and Australia – highlighting progress in primary care mental health in each of these countries. A “Report Card” will be provided for each country indicating “progress, threats and opportunities” relevant to primary care psychological service delivery. Problems unique to each country will be outlined from the perspective of the psychologist and the GP/family physician, as well as current dilemmas in health policy development.

Discredited psychological treatments with adults
John Norcross University of Scranton, United States of America

This presentation summarizes the results of two Delphi polls on discredited psychological treatments for adults. In the first poll, 101 experts rated 59 treatments with which they were familiar and rated them on a continuum from not at all discredited to certainly discredited. In the second poll specific to addictions, 75 experts rated another 65 treatments. The presentation highlights those psychological methods identified as strongly discredited and describes their common features. Such results can lead us to avoid the delivery of services that may be unnecessary, unproven, and sometimes harmful.
Discussant

John Norcross University of Scranton, United States of America

Dr. Suzanne Bennett Johnson, the 2012 president of the American Psychological Association, will serve as discussant for this symposium.

Discredited psychotherapies with children

Robert Resnick Randolph-Macon College, United States of America

Over the past several years, there has been a proliferation of psychological treatments for children suffering from a wide variety of mental health disorders. Children, who are not the decision makers for a course of treatment or the practitioner, are particularly vulnerable to exposure to discredited treatments. This is further complicated by parents who are stressed and anxious about their child’s difficulties and, thus more likely to be attracted to treatments that are frequently ineffective, not evidence based, and in some instances, lethal. The presentation will review 10 of these treatment methods and the risks they pose to children.

Symposium title: Social cognition in borderline personality disorder

Convenor: Inga Niedtfeld

Attention to angry faces in borderline personality disorder

Gregor Domes University of Freiburg, Germany

Patients with borderline personality disorder (BPD) often show difficulties regulating their emotions in social interactions. The present study investigated whether BPD patients show an attentional bias towards facial cues of anger. In a modified dot-probe task, happy, angry and neutral facial expressions were shown for 100, 600, or 1200 ms to assess covert and overt allocation of visual attention towards these social cues in three groups of participants: BPD patients, clinical controls, and healthy controls. The results so far suggest increased attention for angry faces might play a role in social interactions. The present study investigated visual attention to angry faces in line with their cognitive schemas, which is referred to as interpretation bias. Because both abandonment and anger are highly salient themes in borderline personality disorder, the current study assessed whether these patients are characterised by anger and abandonment-related interpretation bias. Fifty-one female participants with varying degrees of borderline personality disorder traits were presented with ambiguous emotional interpersonal scenarios, and asked for their interpretation of the situation. Both open and closed answers (rating the likelihood of predetermined anger, abandonment, negative and positive answers) were obtained. Results and conclusions: Analyses show that borderline traits were significantly related to increased likelihood ratings of both anger and abandonment-related interpretations. Possible clinical implications of these findings will be discussed.

Social perception in borderline personality disorder: Judgments regarding the trustworthiness of others

Inga Niedtfeld CIMH Mannheim, Germany; Andreas Gloeckner; Peter Kirsch; Benjamin Hilbig; Christian Schmahl

Borderline Personality Disorder is characterized by problems in social cognition and interpersonal behaviour. For example, patients show disturbed processing of facial expressions, or biased inference of other people’s mental states. It is assumed that these alterations can lead to dysfunctional behaviour in social interactions (e.g., unstable and intense interpersonal relationships, difficulties to control anger), resulting in impaired psychosocial functioning. In the current study, subjects had to make inferences about the intentions of others, and had the possibility to adjust their own behaviour accordingly. Preliminary data suggest differences between patients with Borderline Personality Disorder and healthy control subjects regarding the ability to form correct impressions of others, altruistic behaviour, and reactive cooperation. We will focus on different aspects that bear importance for the development, chronication, and therapy of Borderline Personality Disorder.

Social cognition in adolescent inpatients with borderline traits: Treatment effects

Carla Sharp University of Houston, United States of America

Sharp et al. (2011) demonstrated an association between excessive theory of mind (or hypermentalising) with borderline traits in adolescents. Whether hypermentalising and other forms of social cognition are malleable to treatment remains unknown. The current study aimed to examine whether (1) a reduction in hypermentalising is achieved between admission and discharge for adolescent inpatients, (2) the hypothesised reduction is more apparent in adolescents meeting criteria for borderline personality disorder compared with psychiatric controls, and (3) other forms of social-cognitive reasoning would also be malleable by inpatient treatment in the same way we expected hypermentalising to be. The “Movie for the Assessment of Social Cognition” Task, the Children’s Eyes Task, Mentalising Stories Test for Adolescents and the Basic Empathy Scale were administered to consecutive admissions in an adolescent in-patient unit at admission and discharge, alongside an interview-based measure of BPD and self-report measures of internalising and externalising problems (N = 163; 38% boys; mean age = 15.47; SD = 1.41; 28% meeting criteria for BPD). Results of a repeated measures factorial ANOVA demonstrated a main effect for hypermentalising as well as an interaction effect for hypermentalising with BPD diagnosis. No other social-cognitive task showed significant change between admission and discharge specific to a borderline diagnosis. Hypermentalising shows specificity and malleability in adolescent borderline patients. This study provides additional evidence that social cognition is a promising target for treatment in adolescents with borderline traits.

HIV/AIDS impact on parenting behaviour in South Africa

Jamie Lachman University of Oxford, United Kingdom

HIV-affected families experience significant risks of psychosocial problems. Positive parenting behaviour may buffer against risk factors associated with HIV/AIDS. Currently, there is insufficient evidence for the role of HIV/AIDS in developing countries. This paper aims to contribute to the evidence regarding risk and protective factors for positive and negative parenting in high HIV-prevalent communities of South Africa. Participants were caregiver-child dyads (n=2476) from a cross-sectional survey (39% HIV-affected) in KwaZulu-Natal, South Africa. Path analysis was used to test a hypothesised mediation model predicting positive parenting and parental supervision. The tested model showed a good fit ($z^2(8) = 12.78$). Familial HIV/AIDS had a direct negative effect on positive parenting (b = -.04) as well as indirectly through household poverty, caregiver depression, and social support (total effect, b = -.08). Familial HIV/AIDS was also indirectly associated with worse parental supervision through household poverty, caregiver depression, and perceived social support (total effect, b = -.02). The
final model accounted for 11% of the variance in positive parenting and 3% of the variance in parental supervision. This paper shows that HIV/AIDS has a significant effect on parenting behaviour that warrants consideration in future epidemiological and intervention research. Interventions focused on improving social support and caregiver mental health may promote positive parenting while buffering against potential risk factors for HIV-affected families.

Mental health outcomes for orphans by AIDS compared to orphans by other means
Carla Sharp University of Houston, United States of America; Lochner Marais; Molefi Lenka; Motsaathebe Serekoane
A major challenge facing South Africa as a result of the HIV/AIDS epidemic is the increase in the number of orphans and other vulnerable children (OVC). The devastating impact of this poses significant challenges for primary care services in addressing the mental health needs of children and adolescents affected by AIDS. Yet, very few studies have examined the mental health outcomes of OVC in South Africa. None of these studies have compared mental health outcomes of children orphaned by AIDS vs. children orphaned by other means. Against this background, we used parent- and self-report Strengths and Difficulties Questionnaires (SDQ; Goodman et al., 2005) which are well-validated screens of psychiatric problems in children and adolescents to examine the mental health outcomes of N = 187 orphans (mean age 9.14; SD = 1.3; 51.2% female) in the Mangawang township in South Africa, of which n = 87 were orphaned by AIDS and n = 100 were orphaned by other means. A series of one-way ANOVAs demonstrated no differences for orphans by AIDS vs. orphans by other means, except for parent-reported hyperactivity (F = 5.75; p = .01). These results are important because it suggests that orphan status by HIV/AIDS does not put children at increased risk compared with other means of becoming orphaned. Future studies need to compare this group with non-orphaned children and importantly, need to take into account whether poverty may be a more important correlate of poor mental health outcomes than orphan status per se.

Chronic illness in the home: Implications for the mental health and protection of children
Tonya Thurman United States of America
HIV and AIDS in South Africa have left many children facing the death and illness of caregivers. Devising effective interventions that promote resilience requires more information on their welfare as well as influential factors amendable to change. Survey information was collected in 2010 from 1782 child-caregiver dyads drawn from beneficiarys newly enrolled in community-based programmes for AIDS-affected children in South Africa. Multivariate logistic regression models explored the relationship between two AIDS-related impacts, orphanhood and chronic illness in the home, with children’s depression and experiences of maltreatment from adults in their home. Almost half the children (44%) were living with at least one chronically ill adult, 57% of children were orphaned (most of whom were double orphans). One-third of children reported depressive symptomology; the prevalence rose significantly when there was chronic illness in the home. Nearly half (43%) reported experiences of maltreatment from adults in their home and this too was significantly higher in households affected by illness. Caregiver reports of poor family functioning were more common in homes with an ill adult and this factor was a mediator of children’s depressive symptomology and experiences of maltreatment. Psychological studies of AIDS-affected children that focus on parental mortality may miss the impact of the preceding illness, when emotional and financial stressors are most acute. It is important to recognise the psychosocial consequences of familial AIDS for children, and ensure that much needed support is available for the whole family.

Symposium title: The relevance of applied psychoanalysis in community settings in South Africa
Convenor: Leonora Engelbrecht
The broken mirror: Difference and shame in South African psychotherapy
Leonora Engelbrecht SAPC, South Africa
This paper offers an outline of the challenges particular to intersubjective approaches to psychoanalytic psychotherapy in South Africa. It focuses on the possibility (and impossibilities) of empathic injury and the dynamics of shame when racial difference, and all its associated baggage, dominates - for a moment or for months - the interaction or the therapy dyad. It focuses on the limits of empathic immersion when difference centres a fluid, shifting but ever-present otherness on every encounter. It draws on the work of Allan Schore, in relation to affect regulation and self-development, of Philip Bromberg on dissociation, and of Andy Morrison and Melvyn Lansky on shame. The paper suggests that struggles with empathic attunement in radicalised contexts are often deeply affected by shame. This is associated with visceral experience of the social body, positioned by race and gender. Understanding the roots of shame experienced in therapies across the racial and cultural divides marks the beginning of shared subjectivity and mutual regulation.

Containing the containers: Container-psychotherapy with child and youth care workers
Lindsay Fredman South Africa
This paper explores the application of psychodynamic psychotherapy within a community setting. The recipients of the psychotherapy are child and youth care workers who provide services to vulnerable children and families in the Isibindi model designed by the National Association of Childcare Workers. Care workers in this programme face challenging contexts in their work and are drawn from the very communities they serve, adding unique stressors to their working situation. It is well documented that many in the helping professions are drawn to the work because of their own childhood pain, and a desire to make life better for the next generation. In order to overcome these emotional stressors and increase the ability of care workers to have the psychological stamina needed in this emotionally exacting work, a Caring for Carers programme has been developed. The programme offers child and youth care workers site based group and individual psychotherapy in order to meet their psychological needs. This presentation explores the provision of individual psychotherapy for the child and youth care workers focusing on some key principles of psychodynamic psychotherapy and how applicable these are in a community based context. The principles which will be examined are: Making the Unconscious Conscious, the use of Defence mechanisms and the use of another mind as a container and catalyst for change. Issues in relation to transference and confidentiality will also be explored. In addition the applicability of this model will be presented as well as its strengths and challenges.

Speaking (or not) about shame: Some small stories about the (im)possibilities of doing psychodynamic psychotherapy with impoverished patients
Lou-Marie Kruger Stellenbosch University, South Africa
Relatively little research has been conducted in South Africa regarding the availability and effectiveness of psychodynamic psychotherapies for low-income people. I will argue that shame is inevitable in all psychotherapies, but is particularly present in psychotherapeutic encounters between middle-class psychotherapists and their low-income patients. By citing several case studies of psychotherapy with low-income people from one semi-rural South African community, I will attempt to show how shame that is obscured and hidden or disavowed may evoke substitute affects such as rage or depression and may lead to anticipatory rejection, abandonment, ostracism, relegation to inferior status - and ultimately failed psychotherapies. Using the work of intersubjective psychoanalytic theorists such as Stolorow, Orange and Atwood I will argue that if shame is recognized in the psychotherapeutic space and the reasons for the shame remembered and made explicit there is potential for connection and healing.

Of poverty, power, psyche and survival – reflections of a community service psychologist
Lisa Padfield South Africa
There is scant literature on the training, experiences or efficacy of clinical psychologists completing their community service year in South Africa, despite the paucity of mental health services nationally. The paper comprises a narrative description of a clinical psychologist’s community service experience. The socio-historical context of the placement, clinical populations encountered, nature of psycho-social services provided, therapeutic opportunities and challenges are explored. Case material is drawn on to illustrate the helpful and limiting aspects of thinking about the clinical work from a self psychology perspective. The question “What makes psychotherapy, in this setting, therapeutic?” is interrogated, given the very real limitations of undertaking brief psychodynamic work at the primary health care level. Elements that emerge as significant include: Space, privacy, consistency, the therapist’s ability to bear witness, pay undivided attention, think in particular ways and take care of her/himself.
Research Area: Cognitive

Session Type: Papers

Mental representations underlying the unconscious thought effect
Marlene Abadie University of Toulouse, France; Laurent Waroquier; Patrice Terrier

The Unconscious Thought Effect (UTE) refers to an improvement in complex decision-making following a distraction period. Such findings have often been interpreted as evidence for beneficial unconscious thinking. Recently, however, it has been proposed that distracted participants may merely recall a judgment that was formed on-line during information acquisition. In the present study, an innovative methodology was used to prevent online judgment and constrain decision-makers to retrieve relevant information from memory. We manipulated the presentation format of the choice alternatives and the decision mode in order to a) investigate whether a detailed or a global presentation format elicited different mental representations and b) to examine its effect on decision quality following a distraction period, a conscious deliberation period or an immediate choice. Results revealed that, compared to a global presentation, a detailed format allowed participants to form more precise verbatim representations of alternatives’ attributes. When the format was detailed, a period of conscious deliberation resulted in better decisions than a period of distraction or an immediate choice. By contrast, a period of distraction improved decisions when the format was global. Us- ing an experimental procedure that promotes memory-based decisions, the UTE was replicated when participants had no precise verbatim memory but could still rely on gist memory of alternatives’ attributes. These findings strongly suggest that the UTE is dependent upon the level of precision of the representation elicited by the task.

Mental imagery and reading comprehension proficiency in ESL learners: An exploratory study
Aleksandra Ashton Wits, South Africa; Yvonne Broom

Reading comprehension proficiency is vital for academic success, but South African students have revealed that reading comprehension skills are often underdeveloped in secondary school learners. Local research has explored the factors such as multilingualism and deficits with the national curriculum standards. Fewer studies have examined the cognitive underpinnings that differentiate between ESL learners who are proficient at reading comprehension and those who are not. Multi-coding theories assert that the integration of mental visual imagery and verbal information is essential for establishing a comprehensive mental model which forms the basis of reading comprehension. This study explored the relationship between visual reasoning ability and reading comprehension in a group of 83 ESL learners from two urban Gauteng schools. The Non-Verbal Reasoning and 3D Spatial Manipulation of the Differential Aptitude Test Battery were used to determine the learners’ ability to reason using visual imagery, and the Verbal Reasoning test established their language skills. Items in the Reading Comprehension test of the Stanford Diagnostic Reading Test were assessed for concreteness effects. The relationships between the DAT tests and the SDRT-RC Total, Abstract and Concrete Items were explored using correlational and multiple regression analyses. The results are discussed and interpreted in terms of Multi-coding models of reading comprehension.

Beyond vision: Integrating sensory substitution devices
Malika Auvray LIMSI, France

Sensory substitution devices provide, through an unusual sensory modality (the substituting modality, for example audition), the kind of information that is normally accessed through another sensory modality (the substituted modality, for example vision). Since their inception in the 60’s various kinds of devices have been developed, tested, and shown to allow their users to behave to some degree as if they possessed the substituted sensory organ. These systems thus question the usual taxonomy of our sensory modalities and the characterisation of a perceptual experience. Through a set of behavioural studies involving localisation, recognition, and categorisation tasks with visual-to-auditory substitution devices, this talk addresses the question of which sensory modality the acquired perception belongs to. Though certain results might be taken to point to the conclusion that perception with sensory substitution devices belongs to the substituted modality, overall evidence leads to an alternative view. According to it, the experience after sensory substitution is a transformation, extension, or augmentation of our perceptual capacities, rather than something equivalent or reducible to an already existing sensory modality. This view will be developed by comparing sensory substitution devices to other ‘mind enhancing tools’ such as sketchpads or calculators. An analysis of sensory substitution in terms of mind enhancing tools unveils it as thoroughly transforming sensory experience and as giving rise to a novel form of interaction with the environment.

Crossmodal change blindness between touch, vision, and audition
Malika Auvray LIMSI, France; Alberto Gallace; Charles Spence

Change detection studies have revealed a striking failure by people to detect changes between two consecutively presented scenes, when they are separated by a distractor that masks the transients typically associated with change. This failure, known as ‘change blindness’, has been reported within vision, audition, and touch. We report a series of experiments investigating this phenomenon crossmodally. In particular, our studies revealed that participants’ performance in detecting changes in position between two tactile scenes is impaired not only when a tactile mask is introduced between the two to-be-compared displays but also when a visual mask is used instead. Interestingly, using a similar procedure, no effect of auditory masks on tactile task performance or of tactile masks on visual task performance has been reported. We have also investigated change detection performance when the two to-be-compared stimuli patterns were presented to different sensory modalities (one stimulus pattern was tactile while the other was presented visually or vice versa). The results showed that in the absence of masking, participants detected changes in position accurately, despite the fact that the two to-be-compared displays were presented in different sensory modalities. Furthermore, when a mask was presented between the two to-be-compared displays, crossmodal change blindness was elicited no matter whether the mask was visual or tactile. These findings suggest that certain of the processes underlying change blindness are modality-specific whereas others are multisensory in nature.

Thought process objective characteristics in time limitation problem-solving
Julia Babaeva Lomonosov MSU, Russian Federation; Pavel Sabadosh; Nataly Rotova

To find time limitation influence on thought efficiency and problem-solving temporal and energetic characteristics, 31 participants, 18–26 years old, performed Raven’s Standard Progressive Matrices with eye-tracking and pupil size fixation in free (odd tasks) and time limitation (even tasks) modes. Data were processed with ANOVA. The correct answers dependency on mode and task complexity, was mediated by subject’s intellectual power. In free mode, moderately and highly intellectual subjects’ efficiency differed only on moderately complex tasks. In time limitation mode this groups’ efficiency decreased only on the most complex tasks. Lower intellectual subjects’ efficiency decreased proportional to task complexity in both modes. In time limitation mode lower intellectual subjects, contrary to the other groups, decreased pupil size. Solving duration increased with task’s complexity and subject’s intellectual power. Time limitation influence on solving duration increased in complex tasks. Proportion “task condition’s eye fixation time/whole solving time” increased with task complexity and subject’s intellectual power for each mode. In time limitation mode this index decreased, especially in intellectual subjects. Time limitation influences various problem-solving process characteristics: efficiency, duration, task condition analysis, and pupil size. Thought efficiency reflects both intellectual power and involvement in task. Pupil size indexes involvement in task (D.Kahneman). Results show that less intellectual subjects abandon mental efforts when facing complex tasks, while more intellectual ones mobilise on complex tasks in free mode, and on moderately complex tasks in time limitation mode. Thus time limitation influence is mediated by subject’s intellectual power and involvement in the task.

The ‘Psy’ element as the core contributor to holistic human development
Felipe Bigesca AEV/FAESA, Brazil

Fenici (2009) states that “according to its etymology, Psychology is the discipline that investigates the psyche. However, the meaning of the term ‘psyche’ is not constant across time”. According to the Dictionary of Psychology of the American Psychological Association there are more than one hundred areas of study in Psychology. This paper discusses, on the basis of a bibliographical study, Psychology in its etymology and relates it to a proposed new
Psychological approach, starting with an examination of the fields of Educational and Mental Health in the State of Espírito Santo, Brazil. By taking into consideration the cognitive aspect of how Psychology is viewed nowadays and how the core aspect of Psychology may offer a collaborative conversation with the boundaries that delimit the study of Psychology, the paper explores how this new approach, that proposes the consideration of "soul", in the process of transformation by educating the person as a whole, can serve humanity, giving the person a new perspective of living and being. The start point is the myth of "Eros and Psyche". The argument that motivates this paper is the question: What if the true power of Psychology to serve humanity lies not only in the areas of actual studies of Psychology but in a brand new understanding of being a human being that generates a harmonic coexistence among all of them?

The integration and comparison of the dual-processing model of anchoring effects: Anchoring and adjustment heuristic and selective accessibility model
Li Bin Central China Normal University, China; Hongyu Ma; Wang Wei; Xu Fuming

Since the anchoring effect was proposed by Tversky and Kahneman in 1974, lots of research has been done on it. Now there are two main models accounting for anchoring effects: the anchoring and adjustment heuristic and the selective accessibility model. But the great mass of research is focused on the anchoring and adjustment heuristic and the selective accessibility model separately. This study is to try to explore the relationship between anchoring and adjustment heuristic and selective accessibility model when the self-generated anchor and experimenter-provided anchor show up at the same time. A total of 64 undergraduate or graduate students were recruited and paid for participation. Participants were invited to the laboratory, where they were placed in separate cubicles, each containing a computer, which was used to present the information and to register the dependent measures. Participants were told that the experiment was about how people make estimates. First, they had to estimate if there was predominance of capital or lower case letters in several letter combinations. After that, they had to make some probability estimates. The results showed that: (1) only without self-generated anchors is there a significant difference in participants’ estimates between those who were exposed to the high anchor and those who were exposed to the low anchor, and (2) only with self-generated anchors is there a significant difference in participants’ estimated response latencies between those who were exposed to the high anchor and those who were exposed to the low anchor. The results of our current study suggest that the anchoring and adjustment heuristic is more dominant than the selective accessibility model when the two show up at the same time. The consistency of anchor information would affect different processing mechanisms’ activation: anchor-consistent information would activate the anchoring and adjustment heuristic, which is making participants’ estimated reaction time longer than the former.

Experimental study of humour recognition in interrupted and uninterrupted texts
Irina Blinnikova Moscow State University, Russian Federation

In the three experimental series, the influence of certain parameters of cognitive organisation on humour recognition in texts was studied. 50 funny stories were divided into 2 parts: an introduction and a punchline. Then a non-funny ending for each story was designed so as to make banal versions of the stories. In the first series 25 texts, randomly chosen from the list, were presented in either a humorous or a non-humorous version, without repeating the stories. The task for the subjects (N = 60) was to establish if the story was funny, or not, as soon as possible. The percentage of correct humour recognition was 85.07. It was also shown that the time required for reading and evaluating a humorous version of a story was significantly more than for a non-humorous one. In the second and the third series, the separate exposure mode was utilised: first, the introduction appeared on the screen, upon reading it a subject pressed - "enter", either a humorous or a non-humorous ending randomly selected from the list appeared on the screen. Subjects performed the same task as in the first series. The percentage of humour recognition significantly decreased in comparison with the first series. In the third series the time gap between an introduction and an ending varied: it could be 100, 500 or 1000 ms. It was shown that an increase of the time gap resulted in the dehumorisation effect.

The rationality of human reasoning
Jean-Francois Bonnefon CNRS and Université de Toulouse, France

During the past decade, the psychology of reasoning has undergone a profound transformation, which has led to the instalment of what some have called a new paradigm. This new paradigm gives central importance to individual differences and uncertainty information, as well as decision-theoretic considerations. In the wake of this transformation, and in line with the overarching theme of ICP 2012, the time is ripe for leading figures of the new paradigm psychology of reasoning to consider how it will translate into the knowledge, skills, and tools that can enrich and improve human life.

Self-efficacy versus perceived behavioural control in the model of goal-directed behaviour
Jean-Paul Broonen Université Libre de Bruxelles, Belgium

In the Model of Goal-Directed Behaviour (MGB), the role of perceived behavioural control (PBC) is controversial. In previous research, PBC affected desires while in others it played a major role in influencing intention, depending on the nature of the behaviour. However, in those studies, PBC and self-efficacy items were aggregated into the same construct. This questionable confusion darkened structural links between the so-called PBC and behavioural desires or intention. To test the predictive power of the two constructs in an MGB, freshmen students (N = 203; women = 163) participating in a program of increasing studying motivation and volition voluntarily provided by questionnaire measures on attitude, anticipated emotions, subjective norms, PBC, self-efficacy, and behavioral intentions, with motivation control planning as the dependent variable. Data were analysed using structural equation modelling (LISREL 8.80). Reliabilities for PBC and self-efficacy scales were high (pc = |Σ2(1/2Σ)2 + Σ2(θ)| = .84 and .82 respectively). Correlation between the two scales was high (γ = .93), but discriminant validity supported (.90 < φ < .97). The structural model showed a good fit: R2(212) = 144.96, p = .059; RMSEA = .028; NNFI = .98. Self-efficacy influenced intention directly (γ = .16, t = 3.41) and indirectly through behavioural desires (γ = .18, t = 2.39). PBC had no significant influence neither on desires (γ = -.06) nor on intention (γ = -.04). These results demonstrated that, compared to PBC, self-efficacy was the most powerful in predicting behavioural desires and volition in an educational context.

Why cognitive deficits like congenital prosopagnosia are often overlooked and what we can do against this neglect
Claus-Christian Carbon Germany

Cognitive deficits in basic human skills are expected to draw attention. However, some dysfunctions in socially important cognitive tasks, such as recognising people’s faces, may not be apparent. The congenital type of prosopagnosia (cPA) or ‘face blindness’ — the impaired ability to recognise faces on an individual level — was considered to be a rare condition until very recently, though it has recently been found to affect about 2.5% of the general population in Germany despite the fact that it is generally not noticed in society. Exemplarily, the paper analyses cognitive dysfunctions which are typically accompanied by cPA (e.g., unseensure of unfamiliarity, strongly impaired visual imagery) and which have escaped attention so far. The paper underlines the need for sophisticated tests which particularly analyse developmental aspects and which integrate everyday life experiences. The inclusion of a variety of information sources will help to advance the development and to increase the validity of such tests. This will also help to develop a research framework of revealing further cognitive dysfunctions.

Working memory and attention interactions with complexity and difficulty levels in task performance
Eduardo Cascallar Katholieke Universiteit Leuven, Belgium; Mariel Musso Katholieke Universiteit Leuven, Belgium

Basic cognitive processes such as executive attention (ExAtt) and working memory (WM) have been shown to be quite significant in the explanation of performance in various tasks. This study extends the analysis to determine the interaction of those individual cognitive processing characteristics with tasks of high and low levels of complexity and difficulty. These effects were studied in a mathematics test administered upon entry to higher education. A total of 850 students participated in the study and they were divided into four cognitive groups corresponding to high and low levels of each cognitive resource, using results from two online instruments, the Attentional Networks Test, and the AOSSPAN (an automated test measuring
working memory capacity). Tasks were categorised in high and low for levels of complexity and difficulty, as determined by TIMSS descriptors, and difficulty obtained with an item-response theory analysis. Results comparing performance between the four cognitive ability groups with the four task characteristics groupings clearly show significant interactions of cognitive resources with the two task characteristics. They establish the independent effect of working memory and executive attention on complexity and difficulty, the two latter constructs also being differentially affected by the cognitive resources. While WM accounts for an overall stronger effect, high ExAtt levels increase the performance of low WM subjects for complex and difficult tasks, as well as for easy and simple ones. These and other results show a clear pattern of interactions with significant implications for cognitive theory as well as for the study of performance conditions.

The effect of second language proficiency and syntactic structure similarity between languages on Chinese-English bilingualists’ English passive sentence processing: Evidence from behavioural and ERP data

Xin Chang
Shanghai Normal University, China

To investigate the effects of second language proficiency and syntactic structure similarity between languages on processing English passive sentences, the present ERP study asked Chinese late learners of English to read sentences carefully and to judge whether or not they were correct. The results indicated that better performance was observed for literally translated sentences than for freely translated sentences. The former evoked larger P200 and P600, while the latter elicited enhanced N400. Compared to intermediate-proficient participants, highly proficient participants exhibited better behavioral performance and evoked larger than P600. Both behavioral and ERP data provided evidence for the structural similarity effect in sentence processing; this effect was more evident in intermediate participants than highly proficient participants.

A study on two imagery schemas of up-down directional words

Meirong Chen
China

The study examines whether different genders elicit different reactions to two image schemas of “shang xia” as location words. 34 subjects (male and female undergraduates, half in each) were selected and the experiment was conducted in three stages. First, practice stage: the subjects are asked to learn the meaning of Static Position, Dynamic Position and Metal Position of “shang xia” as locatives in Chinese. Among them, the Static and Dynamic Position are a spatial metaphor, namely “Natural Image Schema”(NIS). Mental Position as the Psychological metaphor, is Psychological Image Schema (PIS). According to the above three definitions, subjects identify four sentences containing “shang xia” by pressing one of three corresponding keys.

Second, test phase: with the same procedures, 15 similar sentences are presented for identification without a time limit. Finally, a recognition test: the participants are asked to recognize 20 mental position terms containing “shang xia” and press the button accordingly. The results show that: As to NIS, there is no significant difference between different gender in accuracy rate, but remarkable difference in reaction time t=4.615, p=0.032<0.05. However, different genders show significant differences in accuracy rate and reaction time with PIS - males do better than females F=8.946, p=0.000<0.001. Conclusion: There exist gender differences in Psychological Image Schema of “shang xia” as locatives.

Diabetes mellitus, hypertension and memory functioning

Dinesh Chhabra
University of Delhi, India; Amitra Yadava; Nov Rattan Sharma; Pawan Goyal

The objective of the study was to determine whether Type 2 diabetes mellitus and hypertension are associated with impairment of memory functioning. Memory functioning was examined in a group of 30 normal controls (mean age 53.2 ± 3.18 years), 68 patients with Type 2 diabetes (mean age 52.41 ± 3.96 years), and 58 patients with hypertension (mean age 52.26 ± 3.8 years). To obtain the demographic, self-reported health and subjectively perceived memory loss deficits related information, Personal Data Form (prepared by the investigator) was used. Wechsler Memory Scale – III was administered which provided scores on various memory indexes such as auditory immediate, visual immediate, immediate memory, auditory delayed, visual delayed, auditory recognition delayed, general memory, and working memory. Descriptive statistics and one-way Analysis of Variance (ANOVA) followed by Tukey’s HSD test were applied by using Predictive Analytics Software (PASS) 17.0 version. The results suggested significant memory deficits in diabetic and hypertensive patients as compared to normal controls. On all indexes of memory functions, normal controls significantly performed better (scored higher) than the diabetics and hypertensives. Comparisons between the disease groups revealed no significant differences from each other on any index. These results implicate a detrimental effect of both the diseases on global memory functioning. However, the nature of decline in memory functioning appear to be same in both diabetics and hypertensives when compared with each other.

Influence of decision-making style and risk preference on decision-making in badminton

Lizhong Chi Beijing
Sport University, China; Wei Shao

The level of athletes’ decision-making may directly affect their performance. Research on decision-making in sport might greatly improve the quality of training and performance in competition. Based on cognitive research approach and needs from training and competition of sport, this study tried to investigate the effects of decision-making style and risk preference upon the decision-making speed and accuracy of badminton players. 68 players (18 to 23 years old; 52 men, 16 women) from one badminton team of a sport university participated in the research. The whole study consisted of a two experiments. The first experiment explored the effect of decision-making style (4) and decision-making task (2) on the speed and accuracy of decision-making. The second experiment investigated the effect of risk preference (2) and decision-making task (2) on the speed and accuracy of decision-making. The results suggested that: (1) Decision-making style had a strong effect on decision-making. The response speed of intuitive-spontaneous players was slower than that of rational and dependent players, while the response accuracy of the rational players was higher than that of dependent and intuitive-spontaneous players. (2) Risk preference had a significant effect on decision-making. Those who preferred more risk had a lower reaction speed.

Influence of emotion on visual-external movement imagery

Lizhong Chi Beijing
Sport University, China; Wei Shao

Imagery usually plays an important role in motor learning and performing. Emotion is also an important factor affecting movement performance. This research tried to examine the relationship between emotion kinds and visual-external movement imagery. 30 sport college students majored in Tai-chi (a traditional Chinese sporting event) participated in the study. Different types of emotion priming (subliminal priming and subliminal priming) were performed with pictures from IAPS, and imagery performance was tested by recalling movement directions or rotations. The first experiment explored the effect of emotion on the efficiency of visual-external movement imagery activation, and the second experiment examined the effect of emotion on the representation quality of visual external movement imagery activation. The major results are as following: (1) Different kinds of emotions may have different effects on the quality of visual-external movement imagery. The quality of imagery under positive affective priming was better and faster than under negative affective priming. (2) The interaction between emotion kinds and affective priming types was significant on the speed of visual-external movement imagery activation.

Mirror illusions: Understanding individual differences

Giselle Christoffersen Denmark; Lars Arendt-Nielsen; Laura Petrini

Mirror illusions (MI) have been widely and successfully used in therapeutic settings to treat chronic pain. However, the individual differences in treatment outcome could indicate that the subjectivity in how mirror images are perceived is connected to cognition and personality. The aim of this study is to investigate a relationship between the subjective experience of MI, personality factors, and perceptive organisation. MI was induced through an Augmented Reality system designed to act as a mirror: An image of the hands in normal size was projected. 33 healthy right-handed volunteers participated in the study. A questionnaire assessed how the subjects perceived the MI using the following variables: Movement (agency of hand movements), Depersonalisation (level of detachment to the mirrored hands), and Location (perceived location of the mirrored hands). Personality was measured using the NEO Pi-r (long version) and perceptual organisation was measured using the Perceptual Organisation Index (POI) from WAIS-III. The results show positive significant correlations between: Movement vs. fantasy and actions (facets for Openness); Location vs. depression (facet for...
Language processing and motor representation
Yann Coello University Lille Nord de France, France

For a long time, language perception and comprehension have been considered as processes independent from executive functions and have mainly been thought to be based on amodal abstract symbols manipulation, though few attempts have been made to relate language production to language comprehension (e.g., the motor theory of speech perception). However, there is now growing evidence that suggests the existence of a large overlap between the processes involved in the control of body-environment interactions and the processes involved in semantic processing and language comprehension. Among the arguments, brain structures responsible for the production of intentional motor acts have been found to be also activated during language perception in a somatotopic way. Furthermore, recent data have suggested that the comprehension of words or sentences are affected by a concurrent motor activity and that, conversely, the control of goal directed action can be affected by a concurrent linguistic task with either facilitation or interference effects. Consequently, several authors have proposed that brain motor activations during language perception are necessary for language comprehension, and consequently, that language must be viewed as an embodied system. Within this context, the aim of the symposium is to present recent experimental findings and theoretical accounts of interactions between motor representations and language processing supporting this view. Scientific presentations will be made on several but complementary topics. First, language processing will be considered in the light of the theory of evolution. According to this perspective, language and action are viewed as sharing many common features suggesting that language has evolved through human evolution in relation to growing motor capacities and social interactions. The access to a biped posture, for instance, is thought to have provided more flexibility for upper-limb gesture and to have favoured the emergence of gestural communication. In parallel, the production of sounds accompanying gesture execution is thought to have led to the emergence of a vocal proto-language, which has progressively evolved to become the language we are currently using today. Thus, the production and comprehension of language are viewed as being fundamentally a motor process that appeared on the basis of gestural language, with the consequence that spontaneous gestures remain often associated to oral communication and that the hand/mouth system is supposed to play an important role in the development of speech. Second, recent data will be presented that suggest that not

The rhythm of life is a powerful beat: Sensitivity to auditory biological motion cues
David Cottrell James Cook University, Australia

Upon hearing footsteps in the hall one instantly recognises that a person is approaching. Exactly how we do this is unclear. It is well known that we can recognise a moving person from no more than lights attached to their joints, but comparable auditory biological motion research is lacking. Two sets of experiments explored recognition of auditory stimuli of biological and non-biological origin. First, 22 undergraduates (15 female, mean age 26.8) completed a series of 2AFC signal-detection tasks that compared sensitivity to three stimuli: footsteps, a bouncing ball and drumbeats. The ball traversed the same course as the walker thus controlling for translational cues. The drumbeats were matched to the walker’s cadence. When individual sounds were presented in noise, participants were no more sensitive to footsteps than to the non-biological sounds. In the second series of experiments we presented pairs of stimuli and asked a different set of 40 undergraduates (28 female, mean age 26.5) to discriminate between the stimuli. Under these conditions the biological stimuli were identified more easily that the non-biological stimuli whenever the cadence of the non-biological stimulus differed from that of a walker. Given that the sound a foot-strike makes depends on both the characteristics of the walker and the surface on which they are walking, cadence might be the most reliable cue to an unseen moving human. In this specific case it might approximate what J. J. Gibson termed “a perceptual invariant”.

Speaking and thinking about space: The past and future of research on imagery, language, and spatial cognition
Michel Denis LIMS-CNRS, France

The production and comprehension of spatial language has attracted increased attention on the part of researchers in cognitive science in the recent years. Not only does this field of research inform us on how people construct and handle mental representations of their environments and use them in navigational tasks, but it enriches our knowledge of the mechanisms by which people build integrated spatial knowledge from as different representational systems as the linguistic, visual, and locomotor systems. The talk will review the advances in this domain of research, revisiting the major contributions and assessing the prospects at the crossroads of cognitive psychology, neuropsychology, and neuroscience. The capacity of language to assist navigational performance in way-finding tasks will be emphasised, with a special attention to the devices intended to assist blind pedestrians.

An assessment of relationship between meta-cognitive states, problem solving and psychological wellbeing
Saeidmeysam Dibaji University of Isfahan, Islamic Republic of Iran

The current research examined the relationship between meta-cognitive states, problem solving and psychological wellbeing among students. For this purpose, 97 students (14 to 18 years) from Isfahan high schools and secondary schools were selected randomly (50 girls and 47 boys) and were given the students’ state meta-cognitive inventory (Onil and Abedi 1996), the Hepner and Peterson’s problem solving inventory (1982) and Ryff’s psychological well-being scale (1989). The findings of the current study indicated a positive and significant relationship between meta-cognitive components and psychological wellbeing on the one hand and a negative and significant relationship between the dimensions of problem solving and the students’ psychological wellbeing. The stepwise multiple regression analysis revealed that awareness and self-monitoring in meta-cognitive components and trust, personal control and approach-avoidance style in problem solving components could best predict the psychological wellbeing of the students. According to the present findings, students who are aware of their personal thoughts in facing learning problems and assignments, revise their performance, are confident in their own ability in solving problems and use avoidance style less often have better psychological wellbeing and adaptability in facing problems and assignments.

An assessment of relationship between self-efficacy and cognitive/emootive creativity
Saeidmeysam Dibaji University of Isfahan, Islamic Republic of Iran

One of the components involved in educational and learning processes is self-efficacy or sense of personal competency and adequacy about a person’s abilities that has influenced on how he/she deals with life problems and tasks. Self-efficacy is caused by 4 sources: individual success, alternative experience, verbal persuasion and emotional states when judging his/her ability. The fourth component is discussed in cognitive/emotional dimensions. In the present study the question follows of whether as it is predicted, self-efficacy on cognitive/emootive creativity in a group of middle schools and high schools girls in Isfahan. To investigate these relationship, 60 girl students from middle schools and high schools in Isfahan (aged 14–17) were selected randomly. Abedi creativity test (1993), Averill emotional creativity questionnaire (1999),
and Sherer et al. self-efficacy inventory (1982) were performed on the sample. Results showed that self-efficacy has a positive and significant relation to the total score of cognitive creativity. Results of stepwise regression indicated that self-efficacy is predicted by fluency and honesty. In this paper, research findings explain that efficacy sources are emotional and cognitive states, especially when a person evaluates himself/herself and every one that has higher level of self-efficacy can approve better cognitive/emotional creativity to counter the problem.

Brain correlates of composing major and minor music
Liudmila Dikaya Southern Federal University, Russian Federation; Igor Dikiy Southern Federal University, Russian Federation

Music composition is a spontaneous creative activity. Cognitive and emotional components are closely interconnected in it. At the same time there is insufficient research devoted to brain correlates of musical creative activity in relation to emotions induced by major or minor music. The purpose of our research was to reveal EEG-patterns of musical creative activity in musicians during the composing of major and minor music. The participants were 47 conservatory students aged 17 to 23 years. EEG signals were recorded during three types of internal musical activity (perceiving, reproducing and composing major and minor music) from 21 scalp electrodes according to the International 10-20 System. We analyzed EEG spectral power and coherence for delta, theta, alpha, beta-1, and beta-2 frequency bands (0.50–35.00 Hz). For statistical analysis we used ANOVA and post hoc analysis to compare features of the frequency-spatial organization of cortical bio-potentials in musicians during creative and other kinds of musical activity and during the composing of major and minor music as well. Conclusions were as follows: (1) Short-distance low-frequency coherence and the high-frequency creative axis (right frontal and left occipital cortex regions) are most relevant for the musical creative process. (2) Composing music is reflected in activity of anterior cortex regions. The major key is associated with right hemispheric correlates, and the minor key with left ones. (3) The most difficult creative musical activity is reflected in high-frequency coherence. The received results are used for creativity development by means of an EEG biofeedback.

Realistic expectations for a 21st century mind
Ramezan Dowlati Northern Virginia Community Coll, United States of America

The rapid change of the modern world has affected many aspects of human life including communication, education, and socialisation. Recent technological developments have widened generational gaps and increased the possibility of misconception and misunderstanding between the generations. Parents, educators, and public policy makers are faced with new questions and concerns about whether they know enough about the young generation’s minds and behaviour. Psychologists can serve humanity by investigating characteristics of the young minds of the 21st century and provide an updated knowledge base that is essential for understanding and helping each other. Research in social and behavioural sciences has revealed that human mind might go through changes and adjustments in response to new conditions. On this ground, this exploratory study has focused on cognitive capacities of the young generations to find some new developing features that were not present in the old generations in 20th century. The study targeted subjects understanding and performance of their attention, reasoning, and learning style. Data were collected using tests and surveys from a group of sixty young students (age 10- to 20-year-old) and twenty old students (age 30-year-old and higher). The analysis of the results pointed at generational differences in how attention is allocated. The differences in quantitative reasoning were not found to be significant. However, qualitative differences were found in learning styles. The follow-up discussion argues that such change, if verified by large-scale research, might lead us to redefine centuries-old concepts of knowledge, learning, and teaching.

Richness of encoding explains the survival processing effect
Edgar Erdfelder University of Mannheim, Germany; Meike Kronesien

Naime, Thompson, and Pandeirada (2007) discovered a strong and stable recall advantage for word material processed in the context of a survival scenario. The memory mechanism underlying this survival processing effect has been a matter of some debate. Kronesien and Erdfelder (in press) recently argued that it is not survival processing per se that facilitates recall but the richness and distinctiveness with which information is encoded. We tested this explanation by comparing different processing tasks for both the standard survival scenario and control conditions. Two experiments replicated the survival processing advantage, under standard conditions. They also showed that the memorial benefit of survival processing vanishes when participants evaluate (1) imagery of interacting with objects or (2) the irrelevance rather than the relevance of objects with respect to the scenario. These results are in line with the richness of encoding explanation of the survival processing effect and are difficult to reconcile with alternative explanations.

False memories: An explanation for alien abduction stories?
Saif Farooqi University of Delhi, India

In the past decade and a half, more and more people have come out in the open to share their traumatic experiences of being abducted by aliens. Skeptics have compared such narrations to a large number of child-sexual abuse cases that have no forensic evidence, and were later termed as resulting from false memories caused by hypnotherapy. A false memory is a fabricated or distorted recollection of an event that did not actually happen. False memories can be extended to such an extent within an individual that it may become a syndrome. This syndrome, known as the false memory syndrome, is the belief that one remembers events, especially traumatic and remote in time, which have not actually occurred. Along with hypnosis, false memories are caused in a number of ways, leading to false memory syndrome. This paper discusses how the traumatic experiences of alien abductions may actually result from false memory syndrome. The paper explores various causes of false memory syndrome such as hypnotherapy, fantasy proneness, memory dissociations, psychoticism, confabulation, temporal lobe abnormality, and movement of tectonic plates (Tectonic Strain Theory) in the light of alien abductions. Strong associations of false memories and false memory syndrome have been found with a number of alien abduction cases, which corroborate the claims of skeptics. However, some aspects of alien abduction are yet unexplained.

The influence of the emotion priming effect on perceptual dominance of binocular rivalry
Lirong Gao School of Psychology, CCNU, China; Chuang Gao; Bing Zhang; Lin Fang

When dissimilar images are presented to the two eyes, perception alternates spontaneously between each monocular view; a phenomenon called binocular rivalry. Previous researchers investigated the influence of several physical factors, such as spatial frequency, brightness, contrast and revolution on binocular rivalry, but they haven’t investigated the emotional factors of the stimulus. Experiment 1 examined the perceptual dominance of different types of emotional facial expressions in the binocular rivalry condition. The result demonstrated that emotional facial expressions predominate over neutral expressions, and positive facial expressions predominate over negative ones. Experiment 2 explored the emotion priming effect on perceptual dominance of binocular rivalry. The subjects’ positive or negative emotions were aroused by two types of video clips. Then those previous facial expression pictures were used to promote binocular rivalry and measure the influence of the emotion priming effect on perceptual dominance of binocular rivalry. The result indicated that the dominance of positive pictures weakened, while that of the negative ones increased in the negative priming condition.

Preferences aggregated for sequences of events
Tommy Garling Sweden

An issue in preference construction is how preferences for sequences of events are aggregated to an overall preference. In contrast to multi-attribute preferences, part preferences are separated by time. Depending on the length of the time separation different memory systems are activated to retrieve information about the events on the basis of which preferences are formed, semantic memory (schemas) for longer time intervals and episodic memory for shorter time intervals. An alternative is that part preferences are formed during the event sequence and remembered. Even if memory for part preferences is accessible, different aggregation rules may be used. One is the peak-end rule implying that the overall preference is the average of the highest preference and the preference for the last event in the sequence. It has been shown that this rule leads to inconsistencies such that a higher average of the part preferences is not preferred to a lower average if the preferences for the peak and end are higher. We tested whether the peak-end rule applies in the context of preferences for work commutes. In a survey of 713 work commuters in three
urban areas of Sweden, self-reports of overall preference for the most recent normal commute to and from work were collected by means of a multi-item measure. Self-reports were also made of preferences for the legs of the commutes. Results showed that the peak-end rule was outperformed by a duration-weighed averaging rule.

Heuristic decision-making
Gerd Gigerenzer Max Planck Institute for Human Development, Germany

Heuristics are efficient decision-making processes, conscious or unconscious, that ignore part of the information. Because using heuristics saves time and effort, the classical view has been that heuristics imply greater errors than do ‘rational’ decisions as defined by logic or statistical models. However, for many decisions, the assumptions of rational models are not met. How well cognitive heuristics function in an uncertain world is thus an empirical rather than an a priori issue. To answer both the descriptive question (‘Which heuristics do people use in which situations?’) and the normative question (‘When should people rely on a given heuristic rather than a complex strategy to make better judgments?’) formal models are indispensible. Research that tests formal models of heuristic inference in areas such as business, health, and law indicates that (a) individuals and organizations often rely on simple heuristics in an adaptive way, and (b) ignoring part of the information can lead to more accurate judgments than weighting and adding all information, for instance, in cases of low predictability and small samples. The challenge ahead is to develop a systematic theory of the building blocks of heuristics as well as the core capacities and environmental structures that these exploit.

Does listening to a preferred music genre affect your mood and task persistence? Michelle Godzinski Penn State Erie, United States of America; Chelsea Perry; Dawn Blasko

In general, people believe that music will enhance their performance on academic tasks. However, listening to music may also distract a person from their goal. Music may only be helpful when it is both familiar and enjoyable. In the current study, we examined whether listening to music would increase persistence at an impossible task (solving mazes). In a between subject design, some participants were allowed to choose a song from four genres, or were assigned a song. Music either had a fast (170 beats per minute) or slow (70 beats per minute) tempo. In a control condition, participants had no music as they worked on the task. Participants were randomly assigned to one of the five conditions. Participants were given a series of mazes to work on, one of which was impossible to complete. The dependent variable was the total number of mazes to work on, one of which was impossible to complete. The dependent variable was the total number of mazes to work on, one of which was impossible to complete.

Less is more: The effect of information brochures on students’ attitudes and perceptions towards e-learning in Zambia
Given Hapunda University of Zambia, Zambia

Many nations are adopting e-learning infrastructures as a strategy of increasing tertiary education enrolment. However, a robust body of literature suggests that many learners have negative attitudes towards and perceptions of e-learning compared to conventional classroom learning. Choi, Kim, & Kim (2006) argued that a person is likely to have a more positive attitude towards performing an action if he or she believes it will have major consequences and that these will be good. In an e-learning environment, the attitudes constructed could be general attitudes about e-learning or towards a specific system. The aim of the study was to examine the effectiveness of simple information brochures on e-learning on students’ attitudes and perceptions towards e-learning. 300 university students were subjected to a pre-test involving a Questionnaire without a brochure (QWOB) and a post-test involving a questionnaire with a brochure (QWOB), which examined the attitudes towards and perceptions of e-learning. The post-test included a summary description of e-learning, its advantages and disadvantages. A t-test analysis showed that attitudes and perceptions of students towards e-learning positively changed in the QWB condition rather than in the QWOB condition. These results suggest that positive attitude and perception to e-learning are closely connected to students’ knowledge and understanding of e-learning environment. Simple interventions such as information brochures on e-learning can be effective – ‘less is more’.

A study on the relationship of wisdom and emotional creativity
Soheila Hashemikoochaksaraei University of Mazandaran, Islamic Republic of Iran

This research was conducted with the goal of investigating the relationship between wisdom - in the process of real life problem solving - and emotional intelligence. By using stratified sampling 101 university students were selected. Wisdom data was collected through standardised interview based on Assessment Scale of Wisdom-related Performance of Berlin paradigm. Interviews data was scored based on five criteria: 1) Rich factual knowledge, 2) Rich procedural knowledge, 3) Life span contextualism, 4) Value relativism, and 5) Uncertainty. Emotional creativity including novelty, preparedness and effectiveness, i.e., authenticity, was assessed through Averill’s EC test. Findings indicated the correlation coefficient between wisdom and emotional intelligence was 0.23. Among EC sub scales only the correlation of novelty with wisdom (0.21) was significant. Regression analysis showed only 5% of variance in wisdom was accounted by EC. It can be concluded that in the process of real life problem solving instead of emotional awareness, expressing emotional experiences and having eagerness to explore emotions which are pivotal in EC, the enjoyment of sophisticated knowledge about ill-structured problem solving and metacognitive awareness seem more important. Investigating the relationship of metacognition and ill-structured problem solving ability with wisdom in an experimental design and also the correlation of creativity and wisdom are suggested in future research.

Relationship between cognitive functions and reading of Japanese kana characters in early childhood
Miyuki Hosokawa Ibaraki Christian University, Japan; Hiroaki Shoji; Yukihito Shinohara; Tamie Matsumura

To test the relationship between cognitive functions and the reading of Japanese kana characters in early childhood, 87 kindergarten children participated (4–6 years old, 45 boys and 42 girls) in this study. The following three phonological tasks and a visual task were applied, i.e., (1) syllable decomposition and extraction, (2) rapid picture naming, (3) syllable reversal, and (4) “position in space” in DTVP (developmental test of visual perception). The reading abilities were evaluated by reading KANA words and letters aloud. These tasks were individually conducted. Partial correlation coefficients were calculated between the reading abilities and the score of phonological and visual tasks, with the removal of the effect of age. The children over 5.5 years old could read almost all KANA characters correctly. Correlation analysis showed that the reading abilities were significantly related to the scores of the syllable decomposition and extraction task, and the syllables reversal task. On the other hand, the scores of KANA words and letters reading were not correlated to the scores of “position in space” in DTVP. Therefore, phonological manipulation skills might be the most crucial for the acquisition of Japanese KANA reading.

Role of recollection in episodic feeling-of-knowing accuracy in young and older adults
Michel Isingrini University of Tours, France; Celine Souchay; Audrey Perrotin; Laurence Toconnot; Badia Bouazzoual

In feeling of knowing (FOK) studies, participants predict subsequent recognition memory performance on items initially encoded, but that cannot be recalled. This study examined the hypothesis that FOK accuracy may be influenced by the recollection of contextual information related to the unrecalled target, by asking participants to indicate whether the information on which they based their prediction of future recognition was related, or not, to the contextual episode of learning. Such procedure enabled to distinguish two types of episodic FOK accuracy, associated to the recollection of the context information (R-FOK) or not (NR-FOK). In addition, we tested whether the episodic FOK accuracy deficit demonstrated by older adults could be reduced. Results confirmed that R-FOK accuracy was significantly higher than NR-FOK accuracy confirming that the recollection of contextual information enhanced episodic FOK. However, this was not the case for older adults indicating that, contrary to the younger adults, they do not benefit from this recollection effect. This suggests a lack in older adults in the quality of contextual details retrieved pertaining to the unrecalled target that are required to make accurate FOK judgments.

Exploring cognitive development with artificial neural networks
Chris Janeke University of South Africa, South Africa

Neural networks’ (a.k.a., ‘connectionist nets’, ‘parallel distributed processing models’) now constitute...
a vibrant research field within both psychology and cognitive science, and these models have also become popular as a theoretical framework for exploring and simulating aspects of cognitive development. In this paper I present a brief exposition of the neural network approach, and discuss how these models have been used in cognitive developmental research. The discussion focuses on a puzzle introduced by Piaget and Inhelder called the ‘balance-beam’ task. Developmental researchers have found that children appear to pass through a series of stages in their answers to the puzzle. During these stages, children are thought to gradually integrate information about the two dimensions of distance and weight in their judgments about the behaviour of the beam, until they eventually achieve an intuitive understanding of the concept of ‘torque’. I first describe two different neural network models that have been used to simulate children’s progress on this task, and then discuss some of the theoretical issues that have arisen regarding the strengths and limitations of such neural network simulations in cognitive developmental research.

Stress priming and syllable frequency interact while reading aloud
Remo Job University of Trento, Italy; Simone Sulpizio

In polysyllabic languages as Italian, both stress assignment and syllable computation play an important role in reading aloud. Previous studies have shown that while stress assignment may affect the advance of phonological encoding, syllable frequency may affect the following stage, that is the phonetic encoding and the articulation. However, it is an open issue what relationship exists between stress assignment and syllable computation and what is the relative timing of these two operations. In the present study, we address this issue in a reading aloud experiment. We adopted a priming paradigm, with three-syllabic words as primes and targets. In the congruent condition prime and target syllable frequency may affect the following stage, that is the phonetic encoding and the articulation. However, it is an open issue what relationship exists between stress assignment and syllable computation and what is the relative timing of these two operations.

The causal impact of control perceptions on emotions
Martina Kaufmann University of Trier, Germany

Appraisal models on emotions hold that cognitive appraisals cause emotions (Ellsworth & Scherer, 2003 for an overview). The present research was to test whether, over and above the value associated with an event, the perceived personal control plays a causal role in emotions. Results show that trying to control the onset of random light evokes more anger and sadness, when the absence of the light is associated with a loss. In contrast, when the light is associated with a gain, then the task reduces anger and sadness and even induces joy. Similarly, more anger and sadness can be observed, when the onset of the light becomes infrequent. This effect was demonstrated to be mediated by the belief of having less control over the light. These findings support appraisal models assuming an influence of the perceived control on emotion.

Everyday stress, locus of control, general self efficacy and prospective memory performance among adolescents
Azizuddin Khan IIT Bombay, India

Everyday stress is a potent modulator of working and long term memory (Lupien & Legaye, 2001; Joels et al., 2006). However, little is known about the role of stress in prospective memory performance. The present study explored the effect of everyday stress and locus of control on prospective and retrospective memory among adolescents. The research also investigated the relationships among general self efficacy, retrospective, and prospective memory. 244 adolescents (134 male and 110 female, Mean= 16.54, SD= 0.76) participated in the study. Everyday hassles were assessed by the Hassles Assessment Scale. The Locus of Control Scale, General Self Efficacy Scale and Prospective and Retrospective Memory Questionnaire were also administered on adolescent subjects. Analyses of variance and regression analyses were used to analyse the data. All the main effects were significant. Some interactions were also found to be significant. Results suggest that everyday hassles affect performance of prospective memory. Significant differential effects were observed among low, medium and high everyday hassles for memory, cue and task and various interaction between these variables. Similarly, there was significant difference between internal and external locus of control. Further, there was significant negative correlation between retrospective memory and general self efficacy. However, there was significant positive correlation between retrospective memory and prospective memory. Moreover, significant positive correlation was observed between prospective memory and general self efficacy. The findings of the study are discussed in light of the existing literature.

Memory distortions: Recalling an episode as analogy-making
Boicho Kokinov New Bulgarian University, Bulgaria; Neda Zoreva; Veselina Feldman

This paper presents a series of experiments on memory distortions, and more specifically, on blending of elements from various episodes. A classical example of this phenomenon is the misinformation effect studied by Elizabeth Loftus and her colleagues. In these studies two episodes (the original and the misinformation story) are highly similar and only a single element is varied (e.g. the hammer becomes a screwdriver). In the present experiment two completely different original stories are presented to adult, healthy participants and after two weeks they are asked to recall them. The original stories are highly dissimilar: they share neither the protagonists and objects, nor the plots, i.e. the two stories are superficially and structurally dissimilar. Still, if meanwhile (on day 7) the participants had to make a double analogy (an analogy between a third story and each of the two original stories), then it turns out that they will make a blending between the two original studies than in the control group. Thus the conclusion can be reached that the double analogy has connected the two original episodes and when trying to reconstruct them, we use building blocks from each of these original stories. The mechanisms of episode reconstruction suggested in the model are the same as for analogy-making: transferring elements from old representations to the new one based on structural mapping and semantic similarity. A second experiment provided further evidence in favor of the analogical reconstruction mechanisms: analogical stories are easier to blend than superficially similar ones.

Levels of processing and memory awareness when recognising own-race versus other-race faces
Ira Konstantinou Richmond American University, United Kingdom

The study employed the remember-know paradigm to investigate levels-of-processing effects in recognition memory for same- versus other-race faces. It was predicted that deeper processing would benefit accuracy in recognition and remembering for both own- and other-race faces. Moreover, the Cross-Race Bias (CRB) would be evident with participants more accurately recognising faces of their own race than faces of another race. No interaction between the 2 variables was expected. The experiment employed a 2 (face roundness vs face reliability judgment) x 2 (same vs different race to the participants’ own) within-Ss design. Recognition measures (hits, false alarms) and remember, know or guess judgements were recorded. Deeper processing benefited accurate remembering only. The CRB was evident with same-race faces being accurately recognised more than other-race faces, and more remember and know false positives being given to other-race faces. No interaction effect was found. The results do not support the depth of processing hypothesis for the CRB and have implications for the assumption that richer encoding could lead to a decrease in CRB by minimising false positives. Thus, in eyewitness memory richer encoding opportunities do not necessarily lead to less false cross-race identifications and care should be taken when dealing with these kinds of identifications.

Need and ability interaction as a predictor of pre-decisional information searching and decision strategy
Małgorzata Kossowska Jagiellonian University, Poland; Katarzyna Jako

The extent to which people seek and process information before making a decision can have important consequences in many everyday situations. It is then of theoretical and practical interest to identify the psychological variables that might influence the range and type of information that is sought before a decision is made. One variable that is widely studied in the context of knowledge formation and decision making is the epistemic motivation. This
approach concentrates on the factors determining a person’s need to complete the decision-making process. It is assumed that the scope of the information taken into account is a function of an individual motivational state, whether it is a dispositional or a situationally induced one. However, we suggest that motivation itself might not be enough to evoke behavior in accordance with one’s epistemic needs. One factor that may bear on this issue is working memory capacity (WMC) that is widely studied in the context of regulating the processes of attention. Thus the aim of the research is to explore the relation between epistemic motivation (i.e. need for cognitive closure, NFC) and cognitive ability (i.e. working memory capacity, WMC) in the context of decision making process. The results of these studies demonstrate the importance of WMC in regulating epistemic behavior that is determined by controlled motivational states. We discuss the possible future directions in research on an interplay between epistemic motivation and cognitive resources.

Emotional cues and the sequence of the stimuli affect accuracy in the 2-back memory task

Gerly Kukk
University of Tartu, Estonia; Kaili Kreigipuu; Jaanus Harro

Working memory is often defined as a complex multimodal executive temporary storage system, essential for a meaningful interaction with the environment. It has been proposed that the effectiveness of this system depends on several factors, such as the affect and the sequence of perceived elements, but the results have been contradictory. In everyday life, one of the most frequent and important stimuli that people encounter and often need to remember is the human face. In this study, the effects of the emotional schematic visual stimuli and objects, and the sequence of the stimuli on the accuracy and speed of working memory were studied on a large-scale population of the stimuli on the accuracy and speed of working memory were studied on a large-scale population. The effects of presentation of the stimuli on the accuracy and speed of working memory were studied on a large-scale population. The effects of presentation of the stimuli on the accuracy and speed of working memory were studied on a large-scale population. The effects of presentation of the stimuli on the accuracy and speed of working memory were studied on a large-scale population. The effects of presentation of the stimuli on the accuracy and speed of working memory were studied on a large-scale population.

The effects of stimulus dimensions on response conflict resolution

Yongna Li
Renmin University of China, China

Many tasks involve conflicts caused either by different stimulus dimensions or by characteristics of tasks. The previous studies suggested that both types of conflicts are resolved in a task-specific manner and processed by distinct networks. The present study was designed to investigate whether or not the conflict that was caused by either stimulus perceptual or semantic properties in the task was resolved by the same mechanism. Thirty seven undergraduate students (24 female) from Beijing Normal University participated in two experiments. The task in the first experiment was to judge whether or not the ink colour of the colour word was the same as the color patch that was presented above the word. Participants performed this task based on the perceptual property of stimuli. However, in the second experiment, they were asked to identify whether or not the ink colour of the colour word was indicated by the word presented above it. The results showed the congruency effect (the Stroop effect) in the task that required matching between perceptual properties of the two targets. However, in the task that required matching the semantic and perceptual properties between the two targets, there was an interaction between response and congruency (the congruency effect for the matching trials and the reversed congruency effect for the mismatching trials). These results suggest that different stimulus dimensions have different effects on conflict resolution.

The effects of bilateral eye movement and presentation modality on memory

Aik Meng Lim
SIM University, Singapore; Eun-Young Yeo

The combined effects of presentation modality (visual and aural) and eye movement (bilateral and central fixation) on true and false memory were investigated using a mixed factorial design. The participants were 140 SIM University undergraduates (Age = 20.52, M = 28.14, SD = 7.05) who were presented with visual and aural word lists from the Deese-Roediger-McDermott (DRM) paradigm. The participants then underwent one of the eye move- ment conditions. Lastly, they were asked to recogni- nise presented words from a printed word list contain- ing a mixture of presented, non-presented and critical lure words. They were also asked to make “remember” judgements on words that they recog- nised as presented. A two-way factorial ANOVA revealed no important effects of presentation modal- ity and eye movement on the proportion of falsely- recognised critical lures. No interaction effect was found as well. Significant effects of presentation modality and eye movement were found on the proportion of “remember” judgements of correctly- recognised words. However, no corresponding inter- action effect was found. The additional contextual information provided by visual presentation and facilitated by bilateral eye movements appeared to help participants in remembering details of pre- sented words but not in rejecting non-presented critical lures. Therefore, the distinctiveness heuristic appeared to be utilised only for remembering pre- sented words in this sample. The non-utilisation of the distinctiveness heuristic in the rejection of non- presented critical lures warrants future investigation.

Causal inference in young children at the gate of scientific enlightenment: Thinking about covariation and confounding

Wen-Ying Lin
Chung Yuan Christian University, Tai- wan, R.O.C.; Meng-Hua Tsai; Jenn-Wu Wang

Existing research has shown that preschoolers can implicitly understand that “there will be covariation between cause and effect” and that “causality can only be confirmed without confounding”. However, only when this implicit knowledge can affect causal judgments on the conscious level, can children begin to think in a scientific way, and in turn possess the ability to accept science education. This study conducted three experiments to test the causal thinking of young children in the elementary school. Experiment 1 asked the first-graders to probe for the reason of the diarrhea. The results showed that approximately half of the participants were already capable of predicting whether an effect would appear or not on the basis of the rela- tionship of covariation between cause and effect. Experiments 2 and 3 enlisted children from grades one and two respectively as participants, to test, by means of an imaginary story about “nourishing soup”, their judgments of causation in confounded and non-confounded situations. The results of the two experiments showed that the causal judgments made at the conscious level by most first grade and slightly older second grade children at the time when they are about to receive scientific enlighten- ment education, are incapable of reflecting their implicit understanding of the relationship between confounding and causal inference.

Memory-reference effect in Chinese adolescents

Hu Ling
Hunan Normal University, China; Lian Xiong

Using the R.K. paradigm, this study aims to investi- gate the self-reference effect in Chinese adolescents
and the effect of intimacy on it through a comparison between the self-reference conditions and other reference conditions (friend reference condition, mother reference condition, and semantic reference condition). In the experiment we employed a mixed design, four (reference conditions: self, friend, mother, semantics) x 2 (style of response: R response, K response), between-subjects variables were reference conditions and within-subject variables were style of response, the dependent variable was the correct response. The results of the experiment revealed that:

(1) There were significant main effects for reference conditions and R/K judgments. The correct R response of friend reference condition, mother reference condition, self-reference condition were significantly higher than that of semantic reference condition, and the correct R response of friend reference condition was significantly higher than that of mother reference condition and semantic reference condition. (2) The correct R response of the high intimacy reference condition was significantly higher than that of the low intimacy reference condition. This study suggests that:

(a) Self-reference effect, friend-reference effect, and mother-reference effect existed in the adolescent’s memory, and the friend-reference effect is bigger than mother-reference effect, and close to self-reference effect. (b) Intimacy has a positive effect on memory-reference effect, that is to say, the higher intimacy is, and the bigger reference effect is.

Influence of attention and expectation on interrupted timing behaviour
Ruiguang Liu
China

Two experiments were conducted to explore the influence of attention, and expectation of a break, on interrupted timing behaviour, and the relationship between duration production, and break position, by using a prospective paradigm and single-task programme. A geometric stimulus was presented on a VGA monitor, moving from the original locus to the final locus on the screen, during which the stimulus was interrupted, and after a few seconds, recovered. Target duration (10s in exp1, 1s-6s in exp2) containing a break was randomly formed. Subjects were asked to produce a duration by pressing the corresponding key, if they felt the time of stimulus moving was proportional to the target duration. The interrupted duration (also called break duration) is the result of subjects’ shifting of their attention from temporal processing to non-temporal processing. Break position equal to the waiting duration, reflects subjects’ expectation of a break in the timing task of pre-cue offered conditions. By conducting a set of two-, or three-way, repeated analyses of variance on the average of duration estimations and analysing the results, we drew three main conclusions: (1) Attention and expectation of a break are important factors which influence subjects’ interrupted timing behaviour; (2) Linear prediction between duration production and break position is not confirmed experimentally; and (3) this study will be important for developing time psychology and understanding of higher cognitive functions in humans.

The effects of aircraft noise on children’s memory and attention
Phillip Louw University of the Witwatersrand, South Africa; Joseph Seabi; Kate Cockcroft; Paul Goldschlag

Children have been shown to be particularly vulnerable to the effects of chronic exposure to noise and also aircraft noise. Children attending schools in the vicinity of airports have shown cognitive impairments in reading comprehension, different aspects of memory and attention. This cross-sectional study forms part of a larger longitudinal study conducted at schools in the vicinity of an airport in Durban, South Africa, that was decommissioned and moved. This study aimed to investigate the effects of chronic exposure to aircraft noise on children’s memory and attention before the moving of the airport. A purposeful sample of 834 grade 5 and 6 learners from five schools in noisy and quiet areas near the airport were assessed on aspects of long-term memory, working memory, prospective memory and attention with standardised tests in a classroom context. The results indicated increases in certain aspects of memory with increased noise which, although unexpected, may prove important in understanding the effects of chronic noise on different memory systems. The results and their implications are discussed in relation to previous studies as well as literature on the effects of noise on memory systems.

Working memory and incidental sequence learning: A fruitful connection
Markus Martini University of Innsbruck, Austria; Christine Unterrainer University of Innsbruck, Austria; Marco Furtner; Pierre Sachse

Working memory (WM) can be conceptualised as a system that temporarily holds and transforms a limited amount of information, within an activated subset of long-term memory units. Incidental sequence learning can be defined as the process through which we, unintentionally, perceive certain regularities in our environment. There has been great progress in the understanding of basic processes, within both domains in the last years, however, interaction between them is poorly understood. The aim is to integrate methodological and theoretical progress within the WM, and the sequence learning research fields. Furthermore, we specify the role of WM within (1) sequence learning, through which connections between content, context and procedures are set into a new structure and integrated into long-term memory and (2) sequence knowledge processes, i.e. retrieval of information from long-term memory.

Short-term retention of information from an emergent-processes perspective
Leh Woon Mok James Cook University, Australia

Postle (2006) proposed that working memory is an emergent property of the mind and the brain. That short-term retention of information is produced when attention is directed to neural areas that represented the particular type(s) of information. These neural areas are the very regions responsible for representing the same information in non-working memory situations, perception included. This view inadvertently includes the idea that information retained in working memory can comprise activated long-term memory. The present paper applied this view of working memory to the interpretation of short-term processing of information in a delay task, in which choices were made conditionally based on the presenting discriminative/cue stimulus-conditional discrimination choice task. Adult humans performed conditional discriminative choices under differing outcome delivery procedures while event-related functional magnetic resonance imaging (fMRI) data were collected. Over the memory delay, retrospective processing of the just-perceived cue stimulus may be more resource demanding. Making the transition from retrospective processing to prospective processing of the anticipated choice and/or expected choice outcome taps into different neural systems and may thus help to reduce cognitive load. Interestingly, the functional neuroimaging data indicated that delay-period prospective processing of an anticipated choice response relies more on the multiple-demand brain network, whereas prospection of an expected cue-unique choice outcome relies more on the default brain network. These results have implications for the interpretation of short-term activation and processing of information, and its relation (or not) to the explicit direction of attention.

The effect of word semantic transparency on Chinese lexical unification: A window into lexical learning and organisation
Leh Woon Mok James Cook University, Australia

Word semantic transparency (ST) refers to the extent that word constituents are semantically transparent (T) or opaque (O) to whole-word meaning. Bimorphic compound words (compounds) may be fully opaque (OO), partially opaque (TO or OT), or fully transparent (TT). The word-superiority effect (WSE) describes the superior recognition of word constituents in a word, as opposed to a non-word, context. Chinese compounds comprise two written characters with a natural space between compound constituents. It has been shown that Chinese compounds with at least an opaque constituent patterned together and displayed a larger WSE (more word-like) than TT compounds. This corroborated with results obtained with English compounds when a space was artificially inserted between compound constituents. The present study further examined the modulatory effect of ST on the Chinese WSE by transposing the order of constituent characters; the familiar form of the canonical compound was disrupted, delaying word recognition until at least the initial constituent (now second character) was processed. Expectedly, OO items appeared more word-like than TT items. However, partially opaque items were not as word-like as OO items, especially when the T constituent was the final constituent (now first character). Taken together with previous results, the effect of ST on Chinese whole-word lexical unification appears graded but with a bias toward unification whenever there is an opaque element. These results provided a window into how lexical learning and representation is sensitive to language-specific, script-related variations.

Working memory: Is it associated with socio-economic status?
Azra Mooiwa Wits, South Africa; Kate Cockcroft

It is well known that crystallised intelligence measures are highly susceptible to educational, resource, language and socio-economic influences, and that the implications of using these kinds of measures are manifold affecting school and univer-
sity entrance as well as employment opportunities. In South Africa, wherein tests are regarded with suspicion as a consequence of test misuse during the Apartheid era, there is an urgent need for the development of measures which are resilient to these influences. In answer to this, working memory measures have been identified as possible measures which minimise these biases. Consequently the following study investigated whether working memory tests were less susceptible to socioeconomic influences than the more traditional measures of vocabulary in a volunteer sample of 60 grade one learners from a high and low socioeconomic school. The results from a MANOVA, several ANOVA’s as well as Fisher’s z tests, depicted that working memory measures were consistently less affected by socio-economic status as compared to the vocabulary measures. However socioeconomic status and language were found to be so intricately intertwined that it is not clear whether test performance in the vocabulary measures, was related to one or both of these variables. In light of the fact that this study was correlation in nature, it is recommended that future studies focus on limiting the impact of extraneous variables to better understand the impact of socioeconomic status on test performance. Furthermore future studies should perhaps make efforts toward testing children in their home language to avoid contamination effects.

Is intelligence different from cognition, and if so to what extent?

Cittoor Girija Navaneedhan Sree Sastha College Of Education, India

Intelligence determines the ability an individual possesses to understand complex ideas and to adapt him/herself to the present environment. On the other hand, cognition is the ability to deal with acts of thinking that are associated with judgment and decision-making. Though intelligence and cognition are closely related terms, they can be differentiated. If an individual possesses cognitive abilities, he/she would possess a higher degree of intelligence, whereas a highly intelligent person need not necessarily be cognitive. In order to find the difference between intelligence and cognition, a sample of 100 men and women in the age group 22 to 40 years were chosen for the study. They were given verbal and analytical IQ tests to measure their IQ levels, which determine the subject’s IQ, and a cognitive questionnaire to measure the level of cognition. Results were found to have an inverse relationship between intelligence and cognition.

Cognitive functions in MS patients in comparison to non-patients subject and the relation between severity of illness and cognitive dysfunctions

Ghasem Naziry Islamic Azad University, Islamic Republic of Iran

The purpose of this study was to investigate cognitive functions and its relation with the severity of Multiple Sclerosis (MS) in people suffering from multiple sclerosis in comparison with the healthy ones. In this research 100 samples from men and women afflicted with suffering from MS and 100 samples from healthy people were chosen through available sampling. Different tests such as Persian aphasia Test, Persian naming aphasia Test and Expanded Disability Status Scale (EDSS) were carried out as instruments to evaluate cognitive function in MS patients. Results have shown meaningful differences concerning language functions between healthy people and MS patients in their ability to name objects. There was no significant relation between the disease severity and difficulty in naming objects among MS patients. Also, a significant relation between the disease severity and minor scales in language functions was detected.

Early detection of later dementia: Cognitive, demographic, and biological markers

Lars-Goran Nilsson Stockholm University, Sweden

In most societies, there is an increasing proportion of old and very old in the population. This is a positive development in the sense that it reflects societal and medical accomplishments. However, it also means that a growing number of people will experience age-related problems like cognitive decline and dementia, and thereby a diminished quality of life. Intense research is currently being conducted in many laboratories in the world in order to identify early those persons who later will undergo a cognitive decline or develop dementia. By early detection of these individuals, various treatments might be more efficient than presently, when treatments are given much later at the time of diagnosis of cognitive decline or dementia. The present address will provide a list of early markers that have the potential of discovering those individuals already in middle age, who later will be experiencing these age-related problems. These markers differ in nature; they are cognitive, biological or demographic. A great challenge in contemporary research is to understand how these markers can serve as individual risk factors or as interactive risk factors. Empirical data on early cognitive performance, overweight in middle age, certain genes, beta-amyloid, and metabolites will be presented and discussed as to how they can serve as predictors (each factor separately or in interactions with other factors) for cognitive decline and dementia in late life.

The effect of amplitude on motor programming in aiming movement

Ya-Nan Niu Institute of Psychology, CAS, China; Yue-Jia Luo; Juan Li; Christina Jaeger; Antje Hollaender; Wolfgang Prinz

It still remains unclear whether the programming of upcoming movement is related to movement amplitude, and also whether the programming before movement initiation is related to reaction time (RT, i.e. time interval recorded between stimulus appearance and movement initiation). We aimed to investigate the relationship between RT and movement amplitude, and also the relationship between RT and motor programming, under specific situations. Varying current situations by the instructions emphasizing response speed and accuracy separately, and the experiment set with vision, without vision or of Go/NoGo paradigm, we found that the relationship between RT and movement amplitude varied. It could be that RT was not affected by amplitude, RT increase for small amplitude and RT increase for large amplitude separately. It is concluded that RT interval could ‘float’, that is, different motor programming strategies are applied to optimize the response under specific current situation, allowing more or less motor programming occurring within RT interval. Motor programming strategies seem to be chosen in a way of being economical, which involves several factors being optimised such as speed, accuracy and energy expenditure. Therefore, the amplitude effect, or other effect, on motor programming should be observed carefully under current situations.

Inhibiting effect for false memories by manipulating mutually learning and test strategy for stimulus items

Kenta Naoze Gakushuin University, Japan; Nobuo Ohta

False memories point to either remembering events that never happened, or remembering them quite differently from the way they happened. In this study, the investigation for an inhibiting effect for false memories was conducted by manipulating learning strategies (learning duration and learning time). Furthermore, time limit of recognition task was also added as a second factor. In the experiment, three learning conditions were set. The condition that assigned more learning time (400ms×5 times per a item) was named: distributed learning of condition, the condition that assigned more learning duration (2000ms×1 times per a item) was named massed learning condition, and the condition that above both was insufficient, was named controlled condition. As a result of this study, in these three experimental conditions, distributed learning condition showed highest Hit Rate and FM Rate. On the other hand, massed learning condition showed higher Hit rate and the same degree of FM rate compared with controlled condition. Additionally, Hit rate and FM rate showed the same degree of descent in the case of having a time limit. With all these factors, it showed that distributed learning increases not-true memories but false memories, and massed learning condition was more effective than the other two learning strategies, in increasing true memories with decreasing false memories.

Individual differences in working-memory capacity and their relation to fluid intelligence

Klaus Oberauer University of Zurich, Switzerland

Working memory capacity has been shown to be the closest single correlate of fluid intelligence. It would help us to understand intelligence if we knew what working memory capacity is. We will propose the hypothesis that working memory capacity is the ability to build and maintain temporary bindings between elementary representations, in particular bindings between contents and contexts. Binding of content elements to a common context supports integration of their relations into new structural representations, which form the basis for complex reasoning. Evidence for this hypothesis comes from three sources: (1) Tasks measuring relational integration predictors of reasoning at least as good as tasks measuring storage and processing. (2) Short-term recognition tasks correlate with measures of working-memory capacity to the degree that they require context-context bindings. (3)
Tasks directly measuring binding ability are excellent predictors of measures of working-memory capacity and of reasoning.

**Personalities and self-goal discrepancies predict self-directed cognition and subsequent vitality**

*Emily Oliver, Aberystwyth University, United Kingdom*

Research grounded in self-determination theory (SDT: Deci & Ryan, 2000) has established that self-directed cognition can be meaningfully differentiated into informational and controlling components with affective associations (Oliver, Markland, & Hardy, 2010). Antecedents of individuals' motivational interpretation of their self-talk, however, have received limited empirical attention. The present study explored two potential categories of antecedents: personality dimensions and self-discrepancies. 116 participants (49 males, 67 females, mean age = 25.3, SD = 12.04) completed visual analogue discrepancy scales and measures of the functional significance of self-talk, vitality, conscientiousness, and neuroticism. Personality dimensions predicted the functional significance of self-talk in line with hypotheses; conscientiousness (β = .326; p < .001) and neuroticism (β = -.331; p < .001) predicted the use of informational self-talk, and neuroticism positively predicted both controlling (β = .540; p < .001) and amotivating (β = .481; p < .001) self-talk. Furthermore, increasing ideal-actual and ought-actual self-discrepancies positively predicted controlling and amotivating self-talk. Moderation analyses were nonsignificant; results suggest that individuals' interpretation of their self-speech makes an independent contribution to vitality over and above personality variables. These findings present some challenges to discrepancy-based theories of affect and suggest that the different ways in which individuals interpret their self-talk may be a contributor to well-being.

**Orthographic complexity and reading: An eye tracking study**

*Aparna Pandey University of Mysore, India; Prakash Podakannaya University of Mysore, India*

Eye movement patterns of children with dyslexia while reading vary across the languages depending upon the grain size and transparency of the orthography they employ and also the phonological complexity of linguistic units. For example, studies have shown that while reading German, relatively a transparent orthography with high syllabic complexity, dyslexics make a lesser number of regressions as compared to in English, an opaque orthography, but made longer fixations as compared to reading Italian, a transparent orthography with low syllabic complexity. The present study focuses on eye movement patterns in children with dyslexia while reading Kannada, an alphasyllabary used in South India. Kannada is a very transparent orthography in which the complexity of script layout of orthographic syllables (called akshara) correlates with the phonological complexity of words. There are three levels of orthographic complexity in Kannada: akshara with inherent vowels (basic letters), akshara with consonant and vowel ligature combination, and akshara with consonant clusters and vowel. We made three sets of sentences that varied on the orthographic complexity, but keeping syntactic complexity constant across the sets. We recorded eye movement patterns from 17 children with dyslexia while reading these sets and compared data from two comparison groups viz., reading age (RA) matched and chronological age (CA) matched normal readers. The results revealed that dyslexics made a greater number of fixations, more regressions, longer fixation duration, and took greater reading time as compared to both comparison groups, suggesting some inherent deficiency associated with dyslexia.

**The effects of non-conscious encoding and retrieval processes in memory formation**

*Sowon Park Seoul National University, Republic of Korea; Jongho Shin; You-kyung Lee; Myung-Seop Kim*

The purpose of this study was to examine the effects of non-conscious encoding and retrieval processes in memory formation. Based on the scientific research that memory formation and retention often occurs without conscious intent, we hypothesized that memory can be strengthened with non-conscious encoding, subliminal repetition of information, or non-conscious retrieval, subliminal repetition of partial information of associations.

There were three groups in this experiment: the non-conscious encoding, the non-conscious retrieval, and the control. First, all the participants were asked to memorize twenty pairs of faces with written professions. And then, participants were exposed to subliminal stimuli. The non-conscious encoding group was subliminally exposed to the ten faces with professions and the non-conscious retrieval group was subliminally exposed to the ten faces only, selected from initial encoding session. The control group was subliminally exposed to a new face which was not included in the initial encoding session. Finally, Participants took a true or false test after 15 minutes. The result proved that the participants in the non-conscious encoding group showed higher percentages of correct answers in the ten subliminally presented faces than the other ten faces. The non-conscious retrieval and control groups showed no differences. This result means that the subjects experienced non-conscious encoding processes, and these processes had some influence on memory formation. These findings suggest that non-conscious encoding, not retrieval, can affect memory strength like conscious encoding phase. This research contributes to broaden the understanding of memory in non-consciousness research.

Chimpanzees (Pan troglodytes) know what they know

*Bonnie Perdue Georgia State University, United States of America; Michael Beran*

Metacognition refers to the knowledge of one's own cognitive state. Information-seeking tasks are one way to investigate metacognition in animals, and previous studies showed that chimpanzees knew when they had or had not seen where food items were hidden. We tested three language-trained chimpanzees that could name food items using lexigram symbols by using a variation of this information-seeking task in which the identity of the food item, rather than the location, was the critical piece of information needed to obtain the food. An experimenter entered the test area carrying an opaque bucket with one food item inside, and either showed or did not show the chimpanzee the content of the bucket. The bucket was then placed near an adjacent enclosure in such a way that the chimpanzee had to move into that enclosure and then could either name the item immediately or determine the item’s identity by looking at it in the bucket before naming it (this was costly in terms of the time required, and the distance travelled). This is the first use of this task with a potentially costly move through space and the first to require monitoring of object identity rather than location. All three chimpanzees succeeded on the task and were significantly more likely to visit the bucket first on trials in which they did not know its contents than on trials where they had seen the contents. This also occurred on the very earliest trials, indicating spontaneous and efficient information-seeking behaviour.

**Confronting perspectives: Brain imaging and development**

*Josef Perner University of Salzburg, Austria; Isaac Prilleltensky*

Is knowledge structured in parcels of independent domains, or also along conceptual strands? For an answer we looked at the development of two concepts, belief and identity (e.g., whether the key for the green box is the same as the key for the yellow box) and the cerebral processes involved. These seemingly unrelated concepts share a critical feature. Identity statements can only be informative when one distinguishes different perspectives (Fregé’s modes of presentation: ‘key for the green box’, ‘key for the yellow box’) from the actual object (referent). These distinctions are also required for understanding mental concepts such as belief, e.g., the location of an object has to be distinguished from how this location is (mis)represented by a mistaken agent and by oneself. Accordingly we could show that children become able to use identity information between three and five years as their understanding of false beliefs develops. Moreover, this development relates to a host of other tasks that require children to confront the existence of perspectives and not just switch to different perspectives. A meta-analysis of brain imaging studies shows reliable involvement of the left temporoparietal junction (TPJ) and inferior parietal lobe (IPL) in a variety of perspective tasks: false belief (theory of mind), mental rotation, episodic memory, prospection, visual perspective, and as our data show - identity statements. In sum, developmental synchrony as well as sharing of brain resources is organized along conceptual commonalities cutting across different knowledge domains.

**Ownership, attention and object processing: An ERP investigation of items encoded in relation to self**

*Collard Philip University of Aberdeen, United Kingdom; Olav Krigolson; Todd Hardy; Philip Collard; David Turk*

Information encoded in relation to self through temporal ownership, benefits from an elevated memorial status. The predominant understanding of the mechanisms by which this memory advantage operates, is that self-relevant items are processed in a
structure supported by autobiographical knowledge and the representations are therefore rich and elaborate. Here we report on a body of work that has investigated the mechanisms of this encoding advantage in the milliseconds after ownership is established. We recorded event-related potentials (ERPs) as participants viewed common grocery items in an “ownership” paradigm. The presentation of each item was accompanied by a cue indicating whether the object nominally belonged either to the participant (self) or the experimenter (other). In Experiment 1, we found that ownership cues relating to self, elicited increases in the P300 component: indicating heightened attentional processing upon establishment of temporary ownership. Further, at the visual-perceptual level, spatial attention becomes narrowly focused on self-owned objects, as measured via the lateral-occipital P1 component to distractor stimuli presented alongside the objects. In Experiment 2, we investigated whether these attentional effects also impact on perceptual processing of items. We presented the cue first, followed by the object: allowing a comparison of the early visual evoked-responses to self and other items. As with Experiment 1, ownership cues elicited differences in ERPs associated with attentional biases. Little difference was observed in the object-locked ERPs: indicating that the electrophysiological components of elaborate encoding induced by self-relevance is largely driven by attentional mechanisms rather than differences in early object processing.

100 years of IQ gains: A meta-analysis
Jakob Pietschnig University of Vienna, Austria; Martin Voracek

Generational IQ gains of the general population have come to be known as the Flynn effect, named after the first researcher to systematically describe this phenomenon in the 1980s, and due to their importance, have even found entrance in the American Psychological Association’s Ethical Principles of Psychologists and Code of Conduct. Subsequent research showed differential patterns of IQ gains in different countries and on different intelligence domains (crystallised vs fluid intelligence). These inconsistent findings led the influential psychologist Joseph Rodgers as early as 1998 in a narrative review on this topic to call for a formal meta-analysis in order to facilitate an adequate understanding of the Flynn effect. To meet this demand, in the present systematic meta-analysis we provide evidence for IQ gains over a period of more than 100 years (1909–2010) in more than 240 samples (n = 2,300,000+; age range: 0.5 to 74 years) from 27 countries. Our results show an overall IQ gain of about two standard deviations over the examined period, thus amounting to about 3 IQ points per decade and yielding more pronounced gains on measures of fluid than crystallized intelligence. Influences of moderating variables (children vs adults, country, healthy vs patient sample) were assessed by means of multiple weighted meta-regression. In all, our findings demonstrate robust and ongoing worldwide IQ gains over the examined period.

Expert systems in cognitive assessment
Maretha Prinsloo Magellan Consulting Pty Ltd, South Africa

Traditional psychometrics which relies on IQ tests, structured interviews and assessments centres to measure cognitive functioning is critically evaluated and an alternative methodology proposed which involves the use of expert systems. In psychology which is a descriptive science, theory should dictate the accumulation and interpretation of data. For purposes of cognitive assessment, a self-contained theoretical model was developed consisting of six processing functions. The construct validity of these processing categories was investigated by means of a multithread-multivariate design and structural equation modelling. These processes were operationalised at increasingly detailed levels to enable the externalisation and computerised tracking of cognitive capability and preferences by means of the Cognitive Process Profile (CPP) and Learning Orientation Index (LOI) assessment tools. Results are calculated algorithmically by means of an expert system and represented in a personal report indicating the following constructs: a person’s stylistic preferences, cognitive processing capabilities and preferences; a most suitable work environment; developmental guidelines and learning potential. Numerous studies conducted on the concurrent and predictive validity of the tool are reviewed. Concurrent validity was determined using IQ tests, Structured interviews, Personality results, EQ test results and Value measurements. The predictive validity results primarily range between .4 and .6 – depending on contextual factors. The practical application of the CPP and LOI results for purposes of selection, placement, succession, career guidance and personal and/or team development are discussed. The future of assessment practice is also addressed.

The evolution of consciousness
Maretha Prinsloo Magellan Consulting Pty Ltd, South Africa

A theoretical description of Wilber’s All Quadrants All Levels (AQAL) model of consciousness development is linked to various models on the mind-brain relationship. The AQAL model is also integrated with a number of other developmental and consciousness theories as well as spiritual taxonomies. Ken Wilber’s AQAL model of consciousness maps steps in the evolution of consciousness. The AQAL model will also be linked to the physical, psychological and spiritual aspects of consciousness development. The physical aspects need to be addressed from both a scientific as well as a philosophical perspective. The intricacies of neuro-lological functioning go beyond the scope of this paper. However, philosophical positions on the mind-brain dichotomy, including identity, dualism, interactionism, materialism, physicalism, and mentalism theories are briefly discussed. The emphasis is on Pribram’s holonomic theory of the interrelationship between the mind and brain. His model of structural monism transcends the theoretical duality of most of the existing perspectives and provides a basis for the integration of physical and metaphysical aspects in consciousness development. The model will also be applied to concepts such as information, entropy and energy. Psychological, sociological and spiritual perspectives on consciousness development that reflect the structure of Wilber’s AQAL model are addressed in terms of the theoretical contributions of Gebser, Graves, May, Kolhberg, Loevinger, Kegan, Myss and Perry.

Is the male advantage in mental-rotation performance task independent?
Claudia Quaiser-Pohl University of Koblenz-Landau, Germany; Petra Jansen

Mental-rotation gender difference is one of the largest cognitive differences between the genders (Halpern, 1989). In adults, it is reliably found in psychometric paper-pencil tests, but the results of chronometric studies (Voyer, Voyer & Bryden, 1995), and the findings on the influence of stimulus type with regard to gender differences, are inconsistent (Jansen-Osmann & Heil, 2007). Studies have shown that the features which influence mental-rotation performance especially in children (Courbois, 2000; Rüsseler, Scholz, Jordan, Quaiser-Pohl, 2005). However, the influence of method and stimulus type on gender difference has not yet been systematically investigated with this age group. In this paper the data of 862 second, and fourth graders, collected in two previous studies were reanalysed to examine the influence of method and stimulus type on gender difference in mental-rotation accuracy. The children had to solve mental-rotation tasks with animal pictures, letters, or cube figures either in a chronometric condition (computer test) or in a psychometric condition (paper-and-pencil test). Results show a significant male advantage in mental-rotation accuracy in fourth graders, but not in second graders. Neither method (chronometric/psychometric) nor stimulus type (animals/letters/cube figures) influenced this gender effect. The emergence of a stimulus and method-independent gender difference in mental rotation, in pre-adolescence, is discussed with regard to the interaction between hormonal changes, experiential differences and the role of gender stereotypes at this age.

Human episodic memory is modulated by trial-specific non-contingent reinforcements at the encoding stage
Adam Rickart Durham University, United Kingdom; Alexandre Schefer

While memory has been shown to be modulated by reward, with enhanced recall for rewarded stimuli, research looking at how negative reinforcement might affect memory has been more limited. In addition, most available research on the effects of reward on memory has used reinforcement signals contingent to performance outcomes, which can cause confounds between the effects of reinforcement delivery per se and other factors such as learning effects and the implementation of controlled strategies. The current study aimed to investigate the effects of both positive and negative non-contingent reinforcement on episodic memory encoding. 23 participants took part in an incidental word encoding task in which each word was preceded by a rapid chance decision task linked to random financial gains and losses unrelated to performance. Memory was tested using a surprise free recall test following a distractor task. Contrary to previous research using contingent reinforcement, we found that recall performance was better for stimuli preceded by negative rather than positive reinforcements. In addition, a memory enhancement was seen for words preceded by high magnitude compared to low magnitude reinforcements, but only when there was a long latency between reinforcement delivery and word stimulus onset. These results are compatible with theoretical
views suggesting that aversive stimuli can enhance attentional systems, thereby enhancing the efficiency of encoding processes.

The role of learning styles in the relationship between cognitive ability and academic performance
Claire Robertson University of Pretoria, South Africa; Dawn Blasko
Cognitive ability has a strong and important relationship with academic performance. Numerous factors, however, affect a student’s performance, including among others, learning style, or the way in which students typically receive and process information, and learning strategies, or the level at which students approach learning and studying. Current studies are divided in their findings about the mediatory role of learning styles and strategies. The study sought to investigate the role of students’ learning styles and strategies in the relationship between cognitive ability and academic performance, in order to advance an understanding of the role that they play in this relationship. The study was conducted using a correlational research design within a cognitive psychology framework. Using convenience sampling, a total of 172 university students completed cognitive tests (Raven’s Progressive Matrices and the Letter-N-Back) and a learning style and strategy survey. Structural equation modelling, specifically path analysis, in combination with confirmatory factor analysis (CFA), was then used to test the relationship between constructs. Results from the first model suggest that higher cognitive abilities and the use of rehearsal each play a unique role in predicting academic performance ($c^2 (67) = 145.31, p < .001$). It, in addition, seems as if various components of learning style and strategy do not predict academic performance at all. A refined model of the relationships between constructs will be discussed.

Can priming the brain influence facial recognition?  
Kristan Russell Penn State, United States of America; Erin McCready; Dawn Blasko
The study examined if it is possible to improve or impair facial recognition accuracy by priming the brain’s left or right hemisphere. Priming the right hemisphere with a global task should improve accuracy and priming the left hemisphere with a local task should decrease accuracy in comparison to a control. Participants first viewed a photo array, and then were randomly assigned to complete a task that would either prime the left or right hemisphere (Navon Letters task, Hierarchical Figures). Participants were then asked to view a set of randomly presented photos and decide if they were present in the original set. They also rated their confidence in their decision. The results showed that local processing significantly impaired the ability to recognize a face compared to both control and global conditions. However, priming the brain to global lateralization was not found to significantly enhance recognition.

Dynamic control of representations in visual working memory
Jun Saiki Kyoto University, Japan
We see the world as stable and coherent even through radical changes of our retinal image caused by eye and head movements, blinks, and locomotion. In addition to limited compensation provided by sensory mechanisms, visual working memory (VWM) also contributes to our stable representation of the world. Suppose you are working at your desk, and pick up a phone behind you. After a few seconds you hang up the phone, and VWM helps you return quickly to work. As the capacity of VWM is limited to only a few objects, it is not obvious how and to what extent it facilitates efficient engagement with the world. We investigated three relevant properties of VWM: (1) selective maintenance of important features, (2) updating of VWM representations after a stimulus change, and (3) attentional selection of VWM representations.

Biases, reasoning and personality in finance  
Richard Sartori Verona University, Italy; Andrea Ceschi
The aim of this study is to detect the presence of relations between bias phenomena and general individual differences of performance in financial asset management. Given the recent developments in behavioral finance, owed to some authors like Benartzi and Thaler (1995), Shefrin (2000), Gene- sove and Mayer (2001), it is possible to assume that heuristics and biases have an influence on the management of financial assets. At first the research needs to compare such individual differences as personality traits and reasoning abilities with cognitive biases. In addition, the research aspires to analyse these phenomena in individual and in group levels. The research will therefore be composed of three studies: One dedicated to the influence of individual differences in the resolution of problems designed to detect the inclination to incur in biases, another dedicated to a study focused on group dynamics and the relationship with financial performance, and finally one dedicated to the study of the relationship between problem solving skills of individuals and teams in order to detect the influence of group dynamics on the disposition of the members to incur cognitive errors. To test the influence of these mechanisms we are proceeding by detecting (in a sample of about 1000 individuals) the frequency of incurring such biases through the resolution of some problems structured in a survey. The instrument consists of multiple problems or items taken from previous studies, in particular the experiments carried out by Kahneman and Tversky (1974), She- frin (2000), Gadarowski (2002), Barber and Odean (2008), in order to find the specific biases being researched.

Does attention mediate the emotional enhancement of memory for aversive stimuli?  
Alexandre Schaefer University of Durham, United Kingdom
The emotional enhancement of memory (EEM) is defined by an improved memory performance for emotional, compared to neutral items (Pottage & Schaefer, 2012). A common explanation for this effect is based on attention: emotional information would mobilise greater attentional resources, which would result in more efficient encoding. This model was recently contradicted by evidence showing that a significant EEM for negative stimuli can be observed under divided attention conditions. However, divided attention techniques often do not fully block the utilisation of attentional resources, therefore the observation of an EEM under divided attention could still rely on residual attentional resources. A possible way to tackle this problem is to combine a divided attention paradigm with formal mediation analyses testing the involvement of attention in the EEM. This poster will detail a series of studies examining the involvement of attention in the EEM effect for neg-
Ambivalent effects of goal-setting for strategic decision making under risk
Johannes Schiebener University of Duisburg-Essen, Germany; Elisa Wegmann; Mirko Pawlikowski; Matthias Brand

In the face of achieving goals it is important to decide advantageously among different alternatives. In risky decision situations, when the rules for gains and losses are explicit, decision-makers who deliberate strategically can make more advantageous choices. It is assumed that goals can motivate cognitive effort and monitoring strategies, however, influences of goals on decisions have rarely been investigated. In two experiments (N=98, 2 groups in each experiment) we examined effects of self-set goals for performance in two versions of a risky decision task, the Game of Dice Task (GDT), which varied with regard to the amount of strategic controllability (number of trials: 18 in experiment 1; freely selectable by subjects in experiment 2). Results show ambivalent effects: Self-set goals did not affect decision-making performance in the original GDT (experiment 1) but improved performance in the more strategic task version (experiment 2, t(46)=2.07, p<.05). Here choice behaviour patterns over the tasks’ duration show that goals improved decision-making right from the beginning. In contrast to this positive effect, higher self-set goals were related to more disadvantageous choices. These results indicate that in strategic decision situations the deliberate process of goal-setting (rather than goal monitoring) seems to improve decision-making performance. Nevertheless, the accuracy of goals’ heights is closely related to deciding advantageously. These results are in line with theories on goals and decision making and extend the knowledge of how cognitive processes influence strategic decision making.

The impact of aircraft noise exposure on learners’ reading comprehension: The mediating effect of language acquisition
Joseph Seabi University of the Witwatersrand, South Africa; Kate Cockcroft; Paul Goldschein

Although a body of research exists regarding the association between exposure to aircraft noise and mental health in adults, there is limited research conducted on children especially within the African context. Given that the cognitive capacity to cope with environmental stressors is not yet well-developed in childhood, it is beneficial to investigate the effects of chronic noise exposure on learners’ reading comprehension. The sample comprised 313 primary learners exposed to high levels of aircraft noise (experimental) and 380 learners residing in a quieter area (control). Of these, 151 learners in the experimental group spoke English as a first language (EFL) and 162 spoke English as an additional language (EAL). In the control groups, the numbers were similarly divided (EFL=191; EAL=156). A univariate GLM was used to investigate the effects of noise exposure and language on reading comprehension while observing for the possible impact of intellectual ability, gender and socio-economic status on the results. Intellectual ability was controlled for as a covariate and no significant differences were observed for either gender (F=1.814; df1=, p=.179) or level of socio-economic status (F=2.096; df=3, p=.100) on reading comprehension (n=0.05). Significant differences emerged between the experimental and control groups on reading comprehension, in favour of the control group (F=8.416; df=1, p=.004). A significant difference was also observed between EAL and EFL learners in favour of the latter (F=21.212; df=1, p=.000).

Body laterality affects the advantage of external attention of focus in reaction time task
Mohen Shafizadeh Islamic Republic of Iran; Baharak Mohammad; Azadeh Boujmeherani; Geoff Platt; Andrea Romanelli

The aim of the present investigation was to examine the effect of attention of focus on the speed of decision-making in a choice reaction time (CRT) task. The study consisted of two experiments. In the first experiment 22 undergraduate students were recruited voluntarily and performed 50 key-pressing (J and F computer keys) tasks in response to internal and external cues in a within-subject design. They were instructed to pay attention to their right and left fingers (internal focus) or to the “J” and “F” keys (external focus) in a random order series. The results of repeated measure analysis of variance (ANOVA) showed that participants had a faster reaction time in the internal condition compared to the external condition (F=6.17, p<.05). In the second experiment 21 university students were selected voluntarily and took part in the same experiment. The second experiment was similar to the first experiment but in the external condition the layout of the keys was changed from right-left into up-down to eliminate the association between body laterality and keys. The results of a repeated measure ANOVA showed that participants had faster reaction time in the external condition relative to the internal condition (F=6.33, p<.05). In conclusion, these experiments showed that the benefits of external focus cues for speed of decision making is apparent if it is not related to the laterality of the body.

Does enhancing sense of control improve cognitive performance and motivational structure?
Zohreh Shamloo Islamic Republic of Iran; Miles Cox

Motivational structure (MS; Cox & Küng, 2011) affects the way people approach various situations they encounter in their lives. We hypothesized that improving people’s sense of control will improve their cognitive performance, which, in turn, improves goal planning and achievement. The current study (N = 146; 48% males) tested the effects of experimental manipulations of sense of control on cognitive performance and MS. The experimental manipulation used anagrams and a modified, computerized version of Hiroto and Seligman’s (1975) Concept-Training Cards. The manipulation techniques included enhancement information (i.e., choice, knowledge, feedback) and goal setting. Measures were task-specific versions of the Shapiro Control and Personal Concerns Inventory, and computerized verbal puzzles and memory quizzes to test the participants’ accuracy and speed of cognitive performance. Participants were randomly assigned to three groups: No-Interference (NI); Low-Sense-of-Control; or High-Sense-of-Control. The post-experimental results showed that low and high levels of sense of control were successfully induced in the target experimental groups. The LSC Group showed the poorest performance on the cognitive tasks. The HSC groups showed the highest improvement on cognitive tests and on their task-specific motivation. We conclude that the relationship between sense of control and cognitive performance is reciprocal. Negative experiences that cause a low sense of control adversely affect individuals’ cognitive performance, which, in turn, further reduces their sense of control.

Exploring everyday musical imagery: An experience-sampling study
Branwyn Sherriff University of the Witwatersrand, South Africa; Michael Pitman

Musical imagery (MI) is most simply defined as hearing music in the mind’s ear. Relative to other mental imagery modalities, MI is an understudied phenomenon, particularly via non-experimental methods. Examining the intrinsic dimensions of MI is expected to illuminate novel aspects of everyday consciousness and auditory imagery processes. Consequently, this study investigated four dimensions of everyday MI: namely its content, nature, constancy, and corporeal manifestations (for example, foot-tapping). Initially, data collection involved a cross-sectional survey (n = 87), and participants provided retrospective self-reports concerning MI, demographic information, and details concerning their musical history. Subsequently, iterative experience-sampling was utilised to capture the dimensions of MI during participants’ daily activities. These participants (n = 16; 8 musicians; 8 non-musicians) were selected based on specific inclusion criteria, and were invited to complete 21 experience-sampling questionnaires over seven days, receiving three SMS prompts per day. Overall, MI was consistently experienced by participants, regardless of their musical background. There was a statistically significant association between MI and musical training/experience (χ² = 6.33; d.f. = 1, p = .012) which indicates that musical knowledge could have predisposed participants to MI. Daily exposure to music was also a noteworthy factor underpinning participants’ everyday MI occurrences; especially since the majority of experienced-sampled MI episodes were described as involuntary, familiar, and recently heard. Accordingly, experience-sampling proved to be a robust and invaluable methodology for exploring the multifaceted phenomenon of MI.

Attractor neural networks as models of categorisation task and word reading
Asakawa Shin-Ichi Tokyo Woman’s Christian University, Japan

The attractor neural networks, originally developed by Hinton & Shallice (1991), can be applicable to a cognitive task and word reading.
variety of neuropsychological data. It can account for delays in reaction times of brain damaged patients. When the network suffers damages, the iteration numbers between the output and the cleanup layers would increase. In addition, it can also account for performances of the categorisation tasks of category specific disorders, as well as reading performance of dyslectic patients. We applied the attractor network to the data of Tyler et. al (2000) for categorisation task, and the data of Plaut & Schatell (1993) for a word reading task. In spite of variations in data, the attractor network showed good performances. When the network was partially damaged, increases of the iteration numbers could be interpreted as the delays of reaction times. The triangle model for the word reading task was attempted to mimic human data by this attractor neural network model.

The effect of visual imagery training on creative problem solving
Tushar Singh; Banaras Hindu University, India; Namita Pandey
The paper reports two studies aimed at exploring the effect of imagery training on creative problem solving and to understand the basis on which people consider visual imagery to be useful in creative problem solving. In study one, 50 undergraduate students (age range 18 to 22) were randomly divided into two groups, experimental (instructed to use imagery while solving problems) and control. They were required to solve a creative problem solving test consisting of eight problems of increasing difficulty levels and to respond to 20 statements about the relationship between imagery and creative problem solving. In the second experiment 40 students were randomly divided into two groups. An imagery training module was developed and the experimental group was trained using that module. Both experimental and control groups were administered a problem-solving test at time one and another similar test at time two with a time gap of 20 days. Results of this study show that compared to the control group, participants in the experimental group performed better on creative problem solving while no effect of time was seen in their performance. The results also showed that participants trained in using imagery not only performed better but also considered its usefulness at all three levels of creative problem solving while the control group participants considered imagery to be useful only in generating solutions for problem-solution.

Episodic autobiographical and public events memory is selectively impaired by electroconvulsive therapy
Hedvig Soderlund; Department of Psychology, Uppsala Uni, Sweden; Wayne Khu; Brian Levine; Morris Moscovitch; Namita Kumar; Alastair Flint; Nathan Herrmann
Electroconvulsive therapy (ECT) is sometimes used to treat otherwise treatment-resistant depression. Despite beneficial effects on mood, reports of memory impairment are common. However, when patients sometimes report large and persistent retrograde impairment, physicians and researchers report some impairment only of recent memories that recovers with time. This divergence may be due to insensitivity of tests to different resilience of episodic and semantic memory to treatment. As episodic memory is more vulnerable to damage, impairment may have been underestimated. Here we used the Autobiographical Interview (Levine et al., 2002), which separates episodic and semantic components of autobiographical memories. Memories from the last 2 weeks, 1 month, 1 year, and 10 years were assessed in 20 healthy controls and 24 depressed patients prescribed ECT. We also assessed memory for public events in a similar fashion, as they, too, have both episodic and semantic components. ECT severely impaired episodic components of autobiographical memory from all time periods, and bilateral treatment more so than unilateral. Semantic components of memory were slightly impaired by bilateral but not unilateral treatment. Three months after treatment the episodic impairment persisted. Memory for public events was impaired by ECT in a similar fashion as autobiographical memory, although impairment was smaller. In summary we observed impaired memory for autobiographical and public events, with a particular and persistent impairment of episodic, as compared to semantic, components of memory. This demonstrates the importance of disentangling episodic and contributions to memory, and is informative of long-term memory processes and potential side-effects of ECT.

The impacts of absolute pitch and transposed patterns on melodic pitch memory
Lijun Sun; Nanjing Normal University, China; Bin Ling
Prior research has suggested that absolute pitch (AP) listeners could clearly tell a note of particular pitch in the absence of a reference note. The present study was designed to test whether AP could enhance melody recognition under various types of transposed melody (close-relationship transposed melody, dis-relationship transposed melody and non-transposed melody). In the experiment, participants were assigned to different pitch groups (absolute, partial absolute, and non-absolute pitch group) respectively. With a presentation of a standard melody and a comparison melody order, the participants were all asked to determine whether the comparison melody was exactly the same as the standard melody in terms of pitch. In fact, the results found that the main effect of absolute pitch possession on melody recognition was not significant, but the interaction between absolute pitch and melody was significant. Specifically, 1) absolute pitch did not affect the accuracy of melody recognition, suggesting that AP processors were able to use the relative pitch coding strategy, which was used by non-absolute pitch subjects in cases of recognizing transposed melodies; 2) Participants in the partial absolute pitch group recognized significantly better than others did when remembering the distant-relationship transposed melodies, suggesting that they can use both absolute pitch strategy and relative pitch strategy because of their partial absolute pitch and their not so excellent relative pitch.

The relationship between background music and cognitive performance: Promoting or inhibiting
Lijun Sun; Nanjing Normal University, China; Bin Ling
Over the past two decades, the relationship between background music and cognitive performance (reading, memory, attention and so on) has been extensively investigated. The focus of these studies considered the impact of the background music on cognitive performance, positive or negative, which remains controversial. Some studies suggest that background music could promote the completion of cognitive tasks; however, other studies showed that background music could inhibit individual cognitive performance. Based on existing research, the author reviewed the trends in the field of background music and its relationship with cognitive performance. It is hypothesised that the relationship between background music and cognitive performance might depend on the specific conditions, for example, the characteristics of the background music itself; types, forms, rhythm, emotional content; personality, music preference and task characteristics etc. Under different conditions, the relationship between background music and cognitive performance became different. In addition, the paper also analyses the theoretical framework with a conclusion that the two paths by which background music affected cognitive performance contained the mood-arousal and distraction role, which led to different levels of cognitive performance. Finally, the paper also discussed the limits of the existing research and the future research prospects.

The cause of description-experience gap: Sampling error or judgment error
Liu Tenfei; China Central Normal University, China; Hongyu Ma; Fuming Xu
Recently, a striking finding called the ‘description-experience gap’ has emerged in behavioural decision making research. It describes the fact that rare events are overweighted in decisions based on description, but are underweighted in decisions based on experience. This study examines whether this gap exists even when sampling error disappears, and whether this gap disappears when the judgment probability is precise. We conducted four experiments. In the first experiment, we found the description-experience gap. In the descriptive group, people made choices as if they overweighted the probability of rare events when the pay distribution was in the form of a description. While in the experiential group, people made choices as if they underweighted the probability of rare events and tended to rely on relatively small samples from payoff distributions when the pay distribution was obtained from repetition and feedback. The second experiment found that the gap was not eliminated but weakened when sampling error disappeared. The third experiment indicated that the judgment probability was precise. The last experiment showed that the need for cognitive closure was an influential factor on the gap. In contrast to the individuals with lower need for cognitive closure, those with higher need for cognitive closure tended to rely on relatively small samples of information. We end by identifying some important unresolved questions that necessitate future research.

A solution of aperture problem and collision prediction by binocular apparent optical flows
Mori Terunori; Tamagawa University, Japan; Makoto Mizuno; Terunori Mori; Fumihiko Mori; Naotoshi Sugano

Contrasting the theories of perceptual load and perceptual dilution

Yehoshua Tsal
Tel Aviv University, Israel

The load theory of attention stipulates that distinct attentional mechanisms underlie the effects of perceptual load, cognitive load, and sensory degradation on search performance. Such distinctions mainly rely on the finding that increasing perceptual load reduces distractor interference whereas increasing sensory degradation or cognitive load magnifies distractor interference. We propose instead that all three manipulations simply highlight different aspects of task difficulty. We claim that the different patterns of results are due to the fact that increasing perceptual load has typically entailed the addition of neutral items capable of diluting distractor interference (Tsal & Benoni, 2010; Benoni & Tsal, 2010), whereas increasing sensory load and cognitive load has not. In the present series of experiments we jointly manipulated dilution with each type of load. Similar results were obtained for the three types of load: When dilution was controlled, increasing task difficulty increased interference, but the addition of potential diluters eliminated all types of distractor interference. The theoretical implications of load and dilution will be discussed.

Retinal origins of contrast induced perceptual discomfort

Gert Van Tonder
Kyoto Institute of Technology, Japan

The 1980s Pokémon incident is a well known case where televised display of high contrast black and white line patterns and flash stimuli caused widespread epileptic seizures among young and susceptible viewers. While critical stimulus triggers in this case have been intensively researched, the origin of perceived dynamic contrast patterns in line stimuli - already observed as early as Purkinje (1827) - are not yet fully understood. Here, I will present simulations of retinal cone dynamics that provides unprecedented insight into the possible origin of one of the candidate triggers for display-induced nausea and seizures. The computational model reveals how, where and why the retina encodes line displays as if the stimuli were fraud with scintillating high contrast patterns. This insight reveals that the perceived dynamic contrast patterns constitute ribbons of flowing high contrast that are not congruent with the spatial structure of lines in the actual stimulus line pattern, hence disrupting normal perceptual grouping and moreover, eliciting travelling wavefronts of neural activity in retinotopically organised regions in the visual system that can trigger potential disruptions to processing stages further along the visual pathway, notably, along the temporal cortex.

Role of thought control strategies and meta-cognitive beliefs in mental health of Islamic Azad Ardabil University students

Mehdi Vazifeh Zinabad
Islamic Republic of Iran

In the present study, we used recognition paradigm to compare action memory across ages and cultures. The effects of action complexity and familiarity on recognition of action means-change and end-change were investigated. Thirty-two tool-use action video clips of different complexity and familiarity were selected from German and Chinese cultures. For each action, we prepared both means-changed version and end-changed version. All 32 action videos were presented in the learning phase. In the test phase, the original action or the means-changed version or the end-change version was presented for each action for subjects to recognise. Sixty-four preschoolers and 64 young adults (half Chinese and half German) participated in this study. Preschoolers’ recognition performance was mainly influenced by action complexity, while young adults’ performance was influenced more by action familiarity. Both children and adults recognised action end change better than action means change. The recognition patterns of the two cultures were the same, which indicates that action ends are more salient in action recognition memory and this mode is uninfluenced by cultures.

A survey of and reflections on the creativity of ethnic minority university students in China

Hongli Wang
Guizhou Normal University, China

The University Students’ Creativity scale (Wang&Wei, 2000) was found to have good validity and reliability, and it was used to investigate the creativity of university students in South-west China. The ultimate objective of the study is to propose effective measures to enhance students’ creative capacities, particularly at ethnic-minority universities. Using random sampling, the survey on creativity of university students was carried out in the Guizhou, Yunnan and Sichuan provinces of China where ethnic minority college students constitute a significant proportion of the student population. A total of 124 subjects participated in this study, including 84 male students, accounting for 41.94%, and 116 female subjects, accounting for 58.06%. The results of the study indicate that: (1) As a whole, the levels of creativity among ethnic minority college students was normal. (2) Com- pared with students in other colleges, the creativity of students in ethnic minority universities was strong. (3) By comparison with students majoring in liberal arts, the creativity of students in science and engineering was much better. Furthermore, based on these results, some reflections on promoting the cultivation of creativity of university students are as follows: (1) The training of reflective thought should be paid greater attention. (2) The support of teachers should be increased. (3) The distinctive culture of ethnic minorities should be enhanced so as to enhance ethnic-monitory students’ creativity and creative practice.

Action recognition specificity across ages and cultures: A study of tool-use actions for German and Chinese children and adults

Lamei Wang
Chinese Academy of Sciences, China

In the present study, we used recognition paradigm to compare action memory across ages and cultures. The effects of action complexity and familiarity on recognition of action means-change and end-change were investigated. Thirty-two tool-use action video clips of different complexity and familiarity were selected from German and Chinese cultures. For each action, we prepared both means-changed version and end-changed version. All 32 action videos were presented in the learning phase. In the test phase, the original action or the means-changed version or the end-change version was presented for each action for subjects to recognise. Sixty-four preschoolers and 64 young adults (half Chinese and half German) participated in this study. Preschoolers’ recognition performance was mainly influenced by action complexity, while young adults’ performance was influenced more by action familiarity. Both children and adults recognised action end change better than action means change. The recognition patterns of the two cultures were the same, which indicates that action ends are more salient in action recognition memory and this mode is uninfluenced by cultures.

Research on the attributions to prospective memory failure in daily life situations

Liu Wei
Shanghai Normal University, China

Based on the 6 attributions (poor memory, careless- ness, reluctant, temporary emergency, no attention and force major) to prospective memory failure in daily life which were concluded from an open question, we developed a 12-scenario questionnaire to confirm the influence of the events’ importance (importance, unimportance), relationship (parent-child relationship, friendship, stranger relationship) and failure (self, others), so the influence of the events’ importance, relationship and prospective memory failure were investigated in a $2 \times 3 \times 2$ design to explore how attributions to prospective memory failure were affected by these three factors. 124 college students were asked to attribute prospective memory failures in the 12 scenarios. It was found that (1) the most prospective memory failures were attributed to carelessness, and the fewest were attributed to reluctance, (2) the former 6 attributions can be summarised in terms of three factors (unintentional, deliberate and objective) according to the results of EFA, (3) the three
The cognitive distinction of having information by typing and handwriting

He Wenchui Central China Normal University, China; Yang Wu Central China Normal University, China; Guo Ai Central China Normal University, China; Hong Chang; Bin Zuo Central China Normal University, China

The advent of the internet has made accessing information as easy as lifting a finger. There are more and more people recording information by typing instead of handwriting. In this study, we focus on how people who type and who stick to handwriting differ in information accessing and its cognitive impacts. Ninety undergraduate students (42 male, 48 female) learned one hundred words from The Postgraduate Entrance Exam. We grouped the subjects based on their English levels. And then, we used 2 + 2 design to examine the speed and accuracy of the subjects’ memory performance: different methods for accessing information (type, handwritten) × the type of long-term memory(LLM) retrieval (recognition, recall). The result revealed that methods of accessing information and the way of LLM retrieval all have significant main effects. Meanwhile, there is a significant interaction effect. Subjects who handwrote recall and recognize memory items faster and more accurate, compared to those who memorized items by typing. In other words, although we could access information faster by typing, the impression left on our memory is deeper in handwriting.

Automatic micro-expression analysis

Qi Wu Institute of Psychology CAS, China; Xiaolan Fu; Xunbing Shen

In situations in which individuals are motivated to conceal or repress their true emotions, their facial expressions may leak despite their efforts to conceal them. These leakages can be very useful for expressions may leak despite their efforts to conceal or repress their true emotions, their facial expressions. In situations in which individuals are motivated to recognize memory(LLM) retrieval (recognition, recall), the system could be more accurate than the trained human subjects in controlled conditions. A more thorough understanding of the human face perception process is necessary for developing a practical system which is robust across all situations.

Exploring a new dimension of the hedonic fluency model: Impacts of different cognitive activities on evaluative judgment

Di Yang Southwest University, China, China; Tang Yalong

The hedonic fluency model puts forward process fluency for the explanation of the mere-exposure effect. According to this theory, the size of mere-exposure effects is expected to be larger when the duration of the stimulus is longer. However, contradictory findings showed the size of mere-exposure effects obtained under subliminal conditions was larger than that obtained under supraliminal conditions. To explain the contradic- tion, we propose that cognitive activity type should be another important dimension of the hedonic fluency model. In 2 studies, participants watched a series of neutral pictures and novelty of the stimuli for evaluation, while processing fluency was manipulated by clarity (Study 1) and color (Study 2) of the presented stimuli, respectively. In both studies, learning based on constructing new representations resulted in more favorable evaluations than recognition based on retrieval, when the fluency levels are similarly high. This findings suggest a close link between cognitive activity type and preference judgments and may highlight a possible interaction among cognitive difficulty, one’s ability, and emotion.

Dissociation of the distance effect and size effect in one-digit Arabic and Chinese numbers

Guiyong Yang Guizhou Normal University, China; Yun Pan; Huiling Song; Weixing Lin

In the present study, Verguts’s experimental paradigm was used to investigate the dissociation between the number distance effect and size effect in one-digit numbers. The stimuli were Arabic numbers (1, 2, 8, 9) and numbers typed in traditional Chinese (one, two, seven, eight, nine). The subjects’ task was to identify whether the presented numbers were the same. The results showed that both kinds of stimulus material (Arabic numbers and numbers typed in traditional Chinese) caused a distance effect in one-digit stimuli (e.g. 1-2, 2-8), as well as a size effect in the same trials (e.g. 1-one, 2-two). On the other hand, when Arabic numbers (1, 2, 7, 8) and numbers typed in traditional Chinese (one, two, seven, eight) became the stimulus material, there was a distance effect in different trials, and no size effect in the same trials. The results indicate that a mental number line does not completely result in both distance and size effects.

Relationship of cognitive reappraisal and attentional deployment: A combination study of ERP and eye-tracking

Lin Yuan Beijing Normal University, China; Shun Wang; Renlai Zhou Beijing Normal University, China; Chang Liu

Cognitive reappraisal involves reinterpreting emotion-eliciting event to have downstream impacts on the upcoming emotion responses. Attentional deployment includes directing attention away from emotionally evocative stimuli to fulfill regulation goals. Inconsistent results were found on their relationship. Van Reekum et al. (2007) found participants spent less time fixating unpleasant pictures when reappraised. Therefore they concluded reappraisal modulated emotion relying on attentional deployment. Contrarily, Urry (2010) and Bekbo et al (2011) figured reappraisal and attentional deployment were distinct strategies. In the present study, regulation effect of reappraisal and its relationship with attentional deployment are investigated in a combination study of event-related potential and eye-tracking, with subjective ratings of feelings observed to access emotional responding. Participants included 32 undergraduate students. They were instructed to view 80 pictures depicting unpleasant scenes and 40 pictures depicting neutral scenes from International Affective Picture System for 4 seconds. Pictures were preceded with a brief auditory description of the upcoming picture played through sound box and aimed to influence appraisals of the images. Two versions of description for negative stimulus were presented. One version interpreted negative pictures with negative descriptions (control condition). The other interpreted negative pictures with neutral descriptions (reappraisal condition). For the neutral pictures, there were only neutral descriptions for them. Results indicated that self-report of emotion and amplitude of late positive potential were significantly decreased in reappraisal condition. Besides, images were fixated on more and for longer when reappraised. Consequently, cognitive reappraisal modulates emotion relying on reframing the content of unhappy stimuli, but not distracting attention away.

Segmentation in event perception and memory

Jeffrey Zacks Washington University, United States of America

The inputs to our senses are dynamic, complex, and continuous, yet the subjective stream of experience often seems to consist of discrete events that follow one upon another. In this talk I will describe a theory of why and how this happens. I will argue that the segmentation of ongoing activity into discrete events is a fundamental mechanism of cognitive control and memory updating, and that segmentation results from monitoring errors in prediction during perception and comprehension. This updating mechanism has consequences for episodic memory as well as on-line perception and comprehension. I will describe evidence testing this account by looking at how people understand and remember digital video and narrative texts. These studies combine behavioral assays with functional neuroimaging to measure correlates of event segmentation online. The evidence suggests that event segmentation is a basic component of ongoing comprehension: It is reliable across...
observers, it is associated with transient changes in brain activity, and disruptions of event segmentation are related to disruptions of subsequent episodic memory. Event segmentation changes during healthy aging and changes further in early Alzheimer’s disease, as well as in other neurological and psychiatric disorders. These alterations in event segmentation may be related to experiences of disorientation in everyday comprehension and memory. Therefore, methods for assessing and altering event segmentation may prove useful in diagnosing and treating disturbances of everyday cognition.

Spatial attention affects face-voice integration: An event-related potentials study

Liang Zhang Chinese Academy of Sciences, China; Kan Zhang; Brigitte Roeder

Regardless of the fact that non-verbal communication is usually multimodal, the nature of the multimodal integration has scarcely been investigated. The present study aimed to investigate whether the integration of faces and voices is modulated by attention. Event-related potentials (ERPs) were recorded from seventeen participants while dynamic faces and voices stimuli were presented at left or right side of the body midline. Participants were required to attend either left or right side and to detect target stimuli as soon as possible. Results showed that spatial attention modulated both early (160–180ms) and late (>400 ms) stages of the integrated ERPs (difference waves). The results provide evidence for the spatial attention modulation at early processing stages of the face-voice integration.

The crowded words can be processed semantically: Evidence from an ERP study

Ming Zhang Northeast Normal University, China; Chunhua Peng

Crowding is impairment of peripheral object identification by nearby objects. In this study the event-related potentials (ERPs) were used to investigate the semantic processing of crowded multi-feature targets with the combination of a crowding task and semantic-priming paradigm. The results found that the N400 component, as an index of semantic processing, was elicited both by crowded and uncrowded targets, and the N400 amplitudes was smaller for crowded trials than for uncrowded trials. These results indicate that the multi-feature targets can be processed semantically and can be perceived as a correct object regardless of whether they are crowded or not.

Influence of separation experience on adolescents’ self-representation

Jiyuan Zhang Southwest University, China; Chongzeng Bu

Socialization experiences in children’s interaction with caregivers will influence the content and valence of adolescents’ self-representation. In recent years, millions of Chinese farmers migrated to cities in search of better economic opportunity; they often left their children behind in the rural areas. Those children, who are cared by grandparents or other relatives, are called “left behind children” (LBC). The separation experience made LBC also with their parents and more connection with their caregivers. The aim of this study is to explore the influences of separation experience on LBC’s self-representation by using self-reference effect paradigm. 32 LBC and 34 nonLBC took part in the experiment. The results show that LBC can recall as many as words with reference to themselves, mothers and their caregivers, however, nonLBC only show mother-reference effect. Analyses also find that LBC have different self-representation in valence from nonLBC, the LBC recalled less positive words and more negative words with reference to caregiver while the nonLBC show self-reference and mother-reference effect in positive words. Those results give a light on explaining the dependent self-representation of the LBC and their relationship between their parents and caregivers.

Effect of masking on perceptual learning

Fengjuan Zhang Central China Normal University, China; Chuang GAO

Perceptual learning (PL) refers to improvements in perception as a result of training or experience. Texture discrimination task (TDT) which has been widely used in perceptual learning research is typical of patterned masking. The visibility of the target is reduced to different extents with the shortening of stimulus-to-mask onset asynchrony (SOA), but it remains unclear what role masking plays in perceptual learning. In the present study, an 8×5 within-group design was employed, including eight conditions (210ms, 170ms, 130ms, 90ms, 70ms, 50ms, 40ms, 30ms) and days of training (one to five days). 8 undergraduates participated in this experiment. The results show that masking affected the manifestation of perceptual learning; the effect of masking decreased with training. These findings should be considered in future research of perceptual learning with masking tasks.

The mechanism of depth perception of Wheatstone-Panum’s limiting case

Qi Zhang China

Panum’s limiting case generally refers to the phenomenon that two features presented to one eye and a single feature presented to the other are combined and then perceived as two features at different depths. It is still not clear why experimental results derived from the Panum-type stimulus configurations support double fusion viewpoint, but for the Wheatstone-type stimulus configurations, some experimental results support double fusion viewpoint while others are against this view under small disparity. Under a small disparity, it was found that, when the vertical gradients of the disparity of dichoptic feature pairs in previous Wheatstone-type configurations were increased or decreased, the evidence which were considered to be very convincing in previous studies, either supporting or against the double fusion viewpoint, would be shaken, and even turn to support their opposite. Moreover, it was discovered that the change in the combination mode of features in configurations would alter the experiment results. Together these results indicate that double fusion is the common basis for all kinds of Panum effects. But for the Wheatstone-type configurations, double fusion is also constrained by the vertical gradient of disparity of the configurations apart from disparity and influenced by the degree of similarity/conflict between binocular cues and monocular cues resulting from different combination modes of features.

The configuration of fold line plane: A new approach to explore the correspondence problem in the case of asymmetric feature-number

Qizhong China; Huayan Li; Chuang Gao

Images projected onto the retinas from the three-dimensional (3D) world would be asymmetrical in location, number and horizontal size of features. How to recover a single stable 3D image from two slightly different 2D retinal images is a basic task for the human vision system, which is often referred to as the correspondence problem. In the case where there are different numbers of features in the images on the retinas, how the corresponding features fuse is an important aspect of the correspondence problem. Because of the dilemma of method, it still remains unsolved, even for the simplest Wheatstone-Panum limiting case. By replacing the straight lines in traditional stimulus configurations with fold lines that have characteristics of both line and plane, a kind of fold-line Wheatstone-Panum configuration of large horizontal scale is created and slant effect can therefore be used as the index of dichoptic fusion. The results brought about by the change show that double fusion always occurs simultaneously with depth perception, which provides new and solid evidence for solving the correspondence problem under the condition of asymmetrical feature number of the eyes of the human vision system by means of double fusion, and serves as reference to the research on relevant stereoscopic vision phenomena such as Vinci stereo vision. The method is also useful for informing research on addressing the correspondence problem in other asymmetrical cases.

The perceived depth of Da Vinci stereopsis and Wheatstone-Panum’s limiting case both originating from double fusion

Qi Zhong China; Huayun Li

Da Vinci stereopsis and Wheatstone-Panum limiting case are phenomena in which dichoptic features are asymmetric and where there is a depth between perceived features. For the Wheatstone-Panum limiting case, it has been convincingly proved to be the result of double fusion. For Da Vinci stereopsis, the perceived depth of the monocular element is not from matching. By changing the texture and shape of monocular elements, the background and texture of dichoptic elements, we build a new stereogram to compare the depth of monocular elements in all conditions. As the result shows, whether the background is with features or not, in the Panum’s fusion area, if the physical characteristics of local features in different positions of monocular and binocular elements are symmetrical, the accuracy of its perceived depth will be equal to that of the conventional stereopsis but not definitely be the same as the depth of the background. Only by the process of double fusion can this be explained, which is similar to the Wheatstone-Panum limiting case. By changing the symmetry of the physical characteristics of monocular and binocular elements, the result shows that the perceived depth of monocular element is the result of double fusion.
All these results demonstrate that Da Vinci stereopsis may be one kind of Wheatstone-Panum limiting case, which is based upon double fusion, but the accuracy of its matching is constrained by the symmetry of features' physical characteristics.

Session Type: Posters

The role of verbatim memory in conscious deliberation  
Marlene Abodie University of Toulouse, France; Patrice Terrier; Laurent Waroquier

According to Unconscious Thought Theory (UTT), complex decisions are best made outside conscious awareness. It has recently been demonstrated that conscious deliberation can actually deteriorate judgement that has been formed on-line during information acquisition. In the present study, we replicated, and extended, this finding. The standard UTT decision task was modified in order to either promote or preclude on-line judgement. Participants were instructed that they would endorse the role of a real estate agent in choosing the best apartment for a client. In a first condition, to favour on-line judgements, the client request was displayed before the apartments’ attributes. In a second condition, to avoid on-line judgements, the client request was presented after the apartments’ attributes. Participants were then either allowed to deliberate about the apartments, either distracted, or asked to make an immediate choice. Results revealed that precluding on-line judgement led participants who had deliberated about their decision, to make a better choice, whereas there was no difference between decision modes when on-line judgements were favoured. Furthermore, in a subsequent memory test, participants showed more verbatim memory, i.e. precise mental representation of the choice alternatives, when on-line judgement had not been formed. These findings suggest that conscious deliberation can also enhance decision quality but only when participants have precise verbatim memory.

Left Hemisphere lateralisation of categorical colour perception among Roman and Arabic script readers  
Abdulrahman Al-Rasheed ISU, Saudi Arabia; Anna Franklin; Ian Davies

The Left Hemisphere (LH) bias in colour Categorical Perception (CP) has until now been related to the linguistic nature of the LH and converging evidence to support this hypothesis has been presented in several studies. To date, no evidence of lateralised CP has been shown on right-to-left readers in support of this theory. The influence of reading habits to perception has however been shown in various studies. This study aimed to investigate the possible effect of habitual scanning on lateralisation of colour CP, by comparing participants from two language groups who vary in their reading direction: right-to-left in Arabic and left-to-right in English. Lateralisation of CP was then tested in the two groups, namely Arabic and English. The Arabic group consisted of 35 undergraduate students at King Saud University. The English group consisted of 29 native English-speakers who were undergraduate students of Surrey University. Their ages ranged from 18 to 30 years. Two tasks were used to test this hypothesis: a visual search task with a reaction time measure and a target detection task with eye-movement measure. Both samples performed similarly and the pattern of lateralisation has been replicated, but with the finding that this time it has also been shown that the effect is independent of habitual reading direction. It appears that reading direction has no effect on how colour CP is lateralised.

Acoustic parameters to characterise speech rhythm of non-native Japanese learners  
Shigeaki Amano Aichi Shukutoku University, Japan; Mariko Kondo; Kimiko Yamakawa

Spoken Japanese by non-native Japanese learners often gives an unnatural rhythmic impression to Japanese natives, but it is not clear which acoustic parameters contribute such an impression. Ramus et al. (1999) reported that two acoustic parameters could effectively differentiate the prosodic features of native speakers of different languages. The two acoustic parameters were the ratio of the vowel segments to the total duration of an utterance and also the standard deviation of the non-vowel segments. In our current study we tested whether these two acoustic parameters can effectively discriminate the speech rhythm of native and non-native Japanese speakers. We conducted a speech production experiment in which four Japanese natives and four non-natives (Taiwanese) pronounced 343 Japanese words in a carrier sentence. Their utterances were digitally recorded, and the durations of vowel and non-vowel-segments in the utterances were analysed. Discriminant analysis of the segment durations revealed that the speeches by the Japanese natives and those by the non-natives could not be discriminated by the parameters proposed by Ramus et al. (1999). However, the speeches were successfully discriminated, with only a very small error, by a combination of the standard deviation and coefficient of variation of a phoneme segment’s duration. The result strongly suggests that these two acoustic parameters contribute to the unnatural rhythmic impression of a non-native’s Japanese speech.

The relation between contingencies and the effect of ego-involvement in causal reasoning  
Yoshiko Arai Osaka City University, Japan

In the study of human causal thinking, the method of inferring causality from covariation had been developed on the basis of the power PC theory (Cheng, 1997): we judge whether one thing causes another using the contingencies of cause and effect. The causal model theory (Sloman, 2005) suggests intervention as a method to distinguish causation from covariation: we can judge the causal relation of two events by manipulating the cause of one and noting the change in effect. This study investigates the effect of contingencies and ego-involvement as a mechanism of intervention. In an experiment, two different tasks are employed: with and without ego-involvement. Subjects were randomly assigned to four conditions: medium contingency without ego-involvement, medium contingency with ego-involvement, high contingency without ego-involvement, and high contingency with ego-involvement. They were all asked to rate the strength of the causality of two events. The result showed that the effect of ego-involvement was obvious only when the contingency was high: when ego-involvement was present, the causal relationship was judged stronger than when it was absent. This result is unlike that of an experiment in which contingency was considered as a within-subject variable. Such an effect of ego-involvement was clear when the contingency was medium. It is possible that the effect of ego-involvement varies with the level of contingency.

Nonverbal fluency performance, sleep quality and sleepiness in younger and older adults  
Deniz Atalay Ata Istanbul University, Turkey

Poor sleep quality may be related to performances in some cognitive domains in older adults (Nebes et al., 2009; Tworoger et al., 2006). The object of this study is to examine the relationship between nonverbal fluency performance and sleep quality and sleepiness. Besides this, it aimed at comparing nonverbal fluency performance in younger and older adults. Participants were 100 younger adults aged 18–25 and 60 older adults aged 55–75. Ruff Figural Fluency Test (Ruff, 1996), Pittsburgh Sleep Quality Index (Buysse et al., 1989; Agargun et al., 1996) and Epworth Sleepiness Scale (Johns, 1991; Agargun et al., 1999) were administered to the participants. As data collection is in progress, results will be discussed in the presentation.

Computational modelling of intelligent agents considering cognitive and behaviour al theories  
Felipe Bigesca AEV/FAESA, Brazil

Intelligent Systems that attempt to reproduce aspects inherent to the human race such as cognition, in certain way; are real. This paper considers the subject of Intelligent Agents, used by the author in his first college course a bachelor’s degree in Computer Science, and the prototype created for this. It deals with the cybernetic view of cognition that, according to (KONAR, 2000), “consists of a set of five mental states (...) sensation, (...) acquisition, (...) perception, (...) planning, (...) action (...).”. It also considers Cognitive Psychology, which for (Gazzaniga, 2005) “is based on the position that the mind holds mental representations of information.” In developing the study through a literature review, we discuss not only the computational modelling of intelligent agents using some assumptions of Cognitive Psychology, Psychoanalysis and Behaviourism, but it goes beyond considering Bryson (2001), when he says the agent technology “[...] is itself a major innovation of the project that leverages the innate human capacity to reason about the society of actors.” Speaking about Intelligent Agent, Wooldridge (2002) says that it “is situated in some environment, and it is capable of taking autonomous action in this environment, [...].” So, there is a question: “Can the Intelligent Agents resemble people in some psychological aspect, considering the related theories? What kind of benefits could there be? ” We conclude, without claiming to exhaust the subject, on a possible new vision of man himself that can arise through the collaboration of these two areas.
Auditory background rhythms have both positive and negative effects on visual recognition

Renaud Brochard
Université de Dijon, IUF, France; Maxime Tassin; Daniel Zagar
Université de Dijon, IUF, France

It has recently been reported that background auditory rhythms could enhance visual performance. For example, observers were faster at discriminating pictures when they occurred in synchrony with a strong metric position (on-beat) compared to when they were displayed out-of-synchrony with the implied pulse (off-beat). In the research presented here, we wanted to investigate if similar cross-modal effects of musical rhythm could be observed with written verbal stimuli. Participants were asked to perform a lexical decision task in which bisyllabic words (and pseudo-words) were shortly displayed on screen in two successive parts separated by a blank screen. Simultaneously, we played a binary sound sequence designed to induce a 4-beat metric structure (800 msec between two beats). Our results showed that performance was facilitated if the first syllable of a word (e.g. "pan" in "panda") was displayed on beat. Moreover, if the segmentation did not respect the syllable boundary (e.g. "pa" in "panda"), recognition was expected to be impaired. However, we observed that such processing cost was significantly aggravated when the misleading information appeared on-beat (since it would have received more covert attention than if it had been presented off-beat). To conclude, we confirmed, with verbal material, that auditory rhythmic attention can influence processing within the visual modality. Here we go further since the presentation, yet on-beat, of a piece of information can be either advantageous or detrimental whether it is appropriate for further processing or not.

Different effects of cost in a task switching variant

Noguera Carmen University of Almeria, Spain; Vanessa Plaza-Ayllón; Laura Parra; Dolores Alvarez; Encarna Carmona; Carmen Noguera

The task-switching paradigm is often used to study cognitive flexibility (executive system). We employed a task-switching similar to that used by Reimers and Maylor (2005), but with different stimuli. In our experiment participants had to categorise a face depending on emotion (“happy” or “sad”) or gender (“male” or “female”). Two different patterns of results were observed: a group of participants showed the classic pattern, that is, responses were higher on the ‘switch-trials’ than on ‘repetition-trials’. On the contrary, another group was slower on the repetition trials than on switch trials. We explain these data according to the predictability of events sequence (predictable vs. unpredictable).

Automatic and controlled semantic activation though a forced choice task variant

Noguera Carmen University of Almeria, Spain; Sara Fenoy; Encarna Carmona; Dolores Alvarez; Laura Parra

The aim of this study was to explore the automatic and controlled processes that occur within semantic networks though a forced-choice task variant in a sample of four groups spanning 4 to 12 years of age. Children had to choose between two pictures, which were related to the prime picture. The main factors manipulated were prime-target delay with two levels (250 ms-SoA; 700 ms-SoA) and prime-target semantic relation: direct (black-white), indirect (black [white]-chalk) or unrelated. Automatic semantic activation is more likely to occur at shorter SOAs while controlled expectancy-based processes typically occur at longer SOAs. So, we expect to find a differential pattern of direct and indirect priming according to the SOA level and group of age. We suggest that the time course of activation of distant associations may spread more rapidly with shorter SOAs in younger children than in older children and younger adults. Data are discussed within the spread of activation in the semantic network models.

Evaluating the sources of interference in the stroop colour-word task

James Cheesman University of Saskatchewan, Canada; Eric Lorenz

The Stroop colour-word task is used to assess the extent to which automatic reading can influence other ongoing cognitive tasks. In its simplest form, the task requires participants to respond to the ink colour of a word and at the same time ignore the meaning of the word (e.g., the word BLUE printed in the colour red, correct response = red). Traditional accounts of the substantial interference observed in this task rely mainly on response output mechanisms whereby the code for the irrelevant word slows down the selection of the correct code for the colour. We report a series of studies involving colour naming, manual responding and colour matching that evaluate interference as a function of differing relationships between the distractor word and target colour. Word types included colour words (e.g., RED), colour associates (e.g., FIRE), first-letter controls (e.g., RIM), unrelated controls (e.g., FAR), and cognate controls (e.g., ROD). The pattern of results across all studies supports three major conclusions. First, previous claims that naming and manual responding reflect the operation of different mechanisms are rejected. Second, the results require a model of the task that stimulates two distinct sources of interference, a response output mechanism and a semantic interaction mechanism. Third, direct lexical activation of the distractor word is responsible for a significant portion of the interference.

Does retrieval induced forgetting impair visual short-term memory of two sudden onsets?

Haung Chi-Hsiung Chung Shan Medical University, Taiwan, R.O.C.; Ming-Chou Ho

Previous studies have shown that one sudden onset can capture attention and store in visual short-term memory (vSTM). But our previous study using the two-alternative-forced choice (2AFC) task reported that two sudden onsets did not improve vSTM. In two experiments, we examined the hypothesis that disappearance of vSTM improvement is because of retrieval induced forgetting (RIF). In Experiment 1, we examined whether this null result was because of the sensitivity of the task we used. Therefore, we adopted a more sensitive same-different task to test whether two sudden onsets can be stored in vSTM. We predicted that the same-different task is more sensitive to the content in vSTM than the 2AFC task. Further, in Experiment 2, we examined whether this sensitivity difference was because of more serious RIF in 2AFC task because it required multiple retrievals, but not the same-different task. In this experiment, we directly manipulated the number of retrieval to test whether RIF influenced the same-different task performance. We predicted that when two sudden onsets were retrieved in a row, the retrieval of the second onset would be interfered by the retrieval of the first onset. In sum, we suggested that two sudden onsets may be stored in vSTM, but retrieval of one item could deteriorate retrieval of the other, thereby leading to null result in 2AFC task.

Visual illusion using augmented reality: Perceptual distortions and subjective experiences

Giselle Christoffersen Health Science and Technology, Denmark; Laura Petrini; Lars Arendt-Nielsen

Seeing oneself through mirrors that distort body size can create strong illusions which can modulate perceptual modalities such as tactile acuity and pain and body representations. However, these illusions do not occur with everyone. The aims of this study are: (a) to investigate how people subjectively relate to their bodies through a visual illusion of an in-
creased/decreased hand size; (b) to understand whether tactile acuity and inner representations of the hands can be modulated by mirror illusions, which were induced using an Augmented Reality (AR) setting designed to act as a mirror image of the right hand. 33 healthy right-handed volunteers participated in the study all of which were subjected to four sessions: a) Illusion of a decreased size of the left hand; b) increased size of the left hand; c) right and left hands were normal sized; d) in the control session without no AR settings. Results indicate, that the degree of ownership, and the sense of control of movements to the hands, in the increased hand size session can modulate inner representation of the hands and tactile acuity. These findings indicate that the way people subjectively relate to the limbs they observe through distorted mirror images will have an impact on whether perceptual modalities can be modulated. This could have an important impact on how to utilise augmented reality and mirror illusion in therapy.

Motor action reduces temporal asynchrony between perceived visual changes

Yann Coello University Lille Nord de France, France; Xavier Cavellyon; Ioan Lopez-Moliner

When perceiving a single visual object, the binding of its different physical properties (e.g. colour, motion), must take into account the differential processing delays within the visual system. Consequently, temporal order judgments of changes of object dimensions often give rise to the perception of asynchrony, even when the changes occur synchronously. We analysed the effect of performing a motor action on the perceived relative timing between changes of position and colour of a visual target by using a TOJ. Results showed that in the perceptual condition (no action), change of colour must precede (-3.7ms) change of position, in order to perceive a synchronous change of both target's visual attributes. This physical asynchrony almost vanished when the same changes took place near the end of a manual reaching action executed towards the visual target (-3.3ms). This reduction of asynchrony was, however, not observed when participants performed TOJ of visual attributes change in the presence of concomitant tactile information (-36 ms), but with no action. The perceptual relative timing between visual changes was also unaffected when the timing was obtained by comparing each visual change to tactile information resulting from motor action (-33.5ms) or external stimulation (-27.8ms). Altogether, these results suggest that signals associated with the organisation of a motor action, but not sensory information itself, contribute to reduce the differential delays when processing visual attributes of a single object. Furthermore, the effect of action was not observed when judging relative timing of object-related (visual) versus object-unrelated (tactile) sensory information.

Newborns’ preference for goal-directed actions

Laila Craighero University of Ferrara, Italy; Francesca Simion; Carlo Umlita; Irene Leo

The central role of sensory-motor representations in cognitive functions is almost universally accepted. However, determining the link between motor execution and its sensory counterpart and when, during ontogenesis, this link originates is still under investigation. The aim of the present study is to investigate whether at birth this link is already present and 2-day-old newborns are able to discriminate between visual cues indicating goal-directed or non-goal-directed actions. Here, with a preferential looking technique, a hand grasping a ball was the observed movement and we orthogonally manipulated the three factors necessary to successfully reach the goal: (a) presence of the ball, (b) direction of the arm movement, and (c) hand shaping. Results indicated that newborns orient more frequently and look longer at a hand shape for whole hand prehension, but only when the movement is directed away from the body and toward the external world. In addition, newborns prefer the away from the body movement only when the object is present. We argue that newborns prefer a movement directed toward the external world only when it may develop into a purposeful movement because of the presence of the to-be-grasped object. Overall, our results support the existence of primitive sensory-motor associations since the first days after birth.

Healthcare decisions are context-dependent: Violation of regularity principle

Florence Dumas Aix-Marseille University, France; Michel Gonzalez; Christophe Pascual; Vittorio Gior- to; Vincenzo Crupi; Jean-Francois Botton

Facing a decision problem, the ideal decision-maker would assess the costs and benefits of each feasible option, then select the option that, on average, best fulfills her goals. The choice would be independent from the alternatives that happen to occur in the decision context. However, individuals, and also experts, sometimes violate this regularity principle (Redelmeier & Shafir, 1995). When a given option is presented along with two alternatives, similar to each other, they choose it more often than when it is presented with just one of the alternatives. Despite the theoretical and practical importance of such paradoxical choices in medical decision-making, this effect and its boundary conditions have not been extensively tested. The objective of the three present studies is to generalize the effect with healthcare professionals by using realistic scenarios that involve two alternatives displaying various degrees of similarity. In our studies, 155 psychiatrists, 149 gynecologists and 89 nurse managers had to indicate the treatment they would recommend in clinical scenarios containing one of three options, or just two of them. The results showed that professionals chose the focal option more often when both alternatives were available. The paradoxical effect occurred for all scenarios. In conclusion, the context of available options affects professionals’ choices when the alternatives are similar, but also when they present diverging features. Professionals need to be aware of such a source of practice variability, and encouraged to consider each option per se, before they compare the available options.

Characterisation of change as a cognitive novelty in the solution of a physical-mathematical problem of proportionality

Hugo Escobar Universidad Javeriana, Colombia

The study has the goal of describing and explaining that cognitive development has change as a cognitive novelty at its core. The study captures the process of cognitive novelty through the employment of diverse procedures in solving a problem that involves displacing an object by means of the manipulation of time (event duration) and speed with regards to a specific distance. This problem is presented in an interactive software possessing a complex data repertoire enabling it to follow the subject’s activity. A logical-mathematical model was created to show whether participants assign data to variables in an orderly fashion, the control of variables involved in the procedure, and the presence of a plan translating into the use of multiplicative operations with both variables with regards to the distance needed to be traveled in order for the object to get to the goal successfully. Participants were 90 students. The problem allowed for the capturing of the dynamic process of psychological development, understood as change, transformation, novelty and equilibrium, where participants go from no orderly assignment of data to the variables, to partial control of variables, to a real problem solving plan involving multiplicative operations. The question for change as a cognitive novelty in a conception of development as a dynamic process is answered by this perspective in a significant way, enabling descriptions and explications coherent with the possibility of behavioural variability.

Enhancing spatial working memory in children through differential outcomes

Laura Esteban Garcia Universidad de Almería, Spain; Ginesa Lopez-Crespo; Angeles F. Estévez; Ana B. Vivas

It has been demonstrated that delayed face recognition memory is improved in old adults, and in patients with alcohol induced amnesia and AD, when specific outcomes (e.g. reinforcers) are associated with each face-to-be-remembered (Hochhalter, Sweeney, Babke, Holub, & Overmier, 2000; Lopez-Crespo, Plaza, Fuentes, & Estévez, 2009; Plaza, Lopez-Crespo, Antínez, Fuentes, & Estévez, submitted). In the present study we assessed whether the DOP might also improve spatial working memory in five and seven-year-old children. Three spatial delayed recognition tasks were used. In the differential outcomes condition each position was paired with its own outcome. In the non-differential outcomes condition reinforcers were provided in a random manner. Participants showed a significantly better delayed spatial recognition when differential outcomes were arranged. The analyses also revealed that when the task was very easy participants did not benefit from the differential outcomes training. These findings demonstrate, to our knowledge, for the first time, that spatial working memory in children is improved when differential outcomes are employed, and draw attention to the potential of this training as a therapeutic technique to facilitate working memory performance in humans.

Studying deception in anonymous social interactions: The speed-dating paradigm

Marcel Falkiewicz Nencki Institute, Poland; Justyna Sarzynska; Dagmara Bartczak; Anna Grabowska; Ivona Szatkowska; Tais Carmo

Contemporary models of deception point to several cognitive processes necessary to generate deceptive behaviours. These processes include inhibition of automatic response, attention switching and capacity of working memory. When a person generates a deceptive response, these processes are claimed to
be responsible for longer reaction times compared to telling the truth. We developed a speed-dating paradigm to study deception in a social context. Participants responded to questions belonging to different categories, asked by different dates. After each response, they received feedback informing whether the current date enjoyed the answer or not (happy or sad face). The same questions were asked twice in the context of different dates, which had opposite expectations about the answer. The task subject was to respond in a way that might lead to successful dating. After the experiment subjects completed a questionnaire in which they indicated their true attitude towards specific questions used in the experiment. We found no significant effect of response type (true/deceptive) on reaction times. This result might suggest that the subjects, after the first few questions, were able to build up a cognitive model of date preferences, and that his/her responses to the next questions were adjusted to that model without reference to own preferences. As conditions in the speed-dating paradigm are fairly similar to anonymous social interactions (e.g., chat rooms on the Internet), our results suggest that deception during fully anonymous interactions, might involve different cognitive processes than those involved in deception during non-anonymous, direct conversations.

An ERP research on ambiguity decision under different ambiguity conditions
Zhong Fenghua Jiangxi Normal University, China; Jing Hu
We applied the ERP technique to explore the neural mechanisms of ambiguity decisions under different ambiguity degrees. We adopted the experiment paradigm of a variant of Ellsberg’s paradox. The ambiguity degrees included three: 0–100%, 20–80%, 40–60%, represented by telling subjects the probability intervals to draw the red ball. For example, the probability intervals to draw the red ball between 0 and 100% was completely ambiguous. The probability intervals to draw the red ball was 50% in the risky decision. Subjects made the choice between the ambiguity decision and the risky decision. The results showed: 1) there was no difference in the ERPs when subjects processing the ambiguity decision of different degree; 2) the ERPs between the ambiguity decision and the risky decision existed difference between the 40–60% and 50–80% conditions. We can draw the following conclusions: ambiguity decisions seemed to be specially risky from the perspective of probability processing. When the difference between ambiguity decisions and risky decisions was large, decision-making was easy, when the difference between them was small, it produces a decision-making conflict, so decision-making was difficult.

Aging and self-initiation of encoding strategies: Role of executive functions
Charlotte Froger University of Tours, France
This experiment examined the contribution of executive functioning and processing speed in the explanation of age-related variance of memory performance loss, when the task difficulty, the environmental support and the study time were manipulated. The task difficulty was manipulated by varying the strength of association (weak vs. strong). In the condition without environmental support, 20 younger and 20 older adults were simply instructed to study the word pairs when study time was limited and self-paced. In the condition with environmental support, 21 younger and 20 older adults were provided mnemonic strategies to study word pairs when study time was limited and self-paced. Results showed that age-related differences on memory were greater without environmental support, and that older adults performed less well on neuropsychological tests. Stepwise regression analyses revealed that the processing speed was a better candidate than the executive functioning to account for the age-related variance of the memory performance loss when no environmental support was provided whatever the study time condition and the task difficulty. However, when environmental support was provided, the executive functioning was a better candidate than the processing speed to account for the age-related variance of memory performance loss whatever the study time condition and the task difficulty. These findings suggest that when no strategy was provided, the age-related decrease in memory performance was mediated by speed of processing. However, when strategies were provided the age-related decrease in memory performance was mediated by executive functioning.

Retrieval-induced forgetting of past and future emotional experiences
Elvira Garcia-Bojas University of the Basque Country, Spain; Malen Migueles
Although the impact of selective retrieval practice and inhibitory processes has been studied with past autobiographical experiences, nothing is known today about inhibitory processes for future or prospective life experiences. This study examines retrieval-induced forgetting (RIF) for autobiographical retrospective or prospective life experiences. In the study phase participants were given hints to produce autobiographical experiences of their past or to think on experiences that may occur in their future. In both conditions, to obtain the emotional life experiences, half of the hints were positive and half negative. In the retrieval practice phase participants retrieved half of the positive or negative experiences using cued recall or they retrieved capsules of the world (control groups). In the final phase the participants tried to recall all the experiences. Although there was a tendency to remember more positive than negative experiences, there were no significant differences in the recall of both types of experiences. In addition, there were no differences between remembering past or future events. Retrieval practice produced two main effects: facilitation for practised experiences and inhibition for non-practised experiences when compared to the control groups which performed no retrieval practice. An interesting aspect that may have practical implications is that selective retrieval practice caused greater inhibition of negative than positive experiences.

The effects of attention and working memory on causal judgement
Iiko Hattori Ritsumeikan University, Japan; Masasi Hattori
This study investigated the effects of attention and working memory (WM) on causal judgement. People often tend to neglect instances when the target causal event does not happen. Some participants reported that they regarded them as unrelated (Hattori, 2008). Experiment1 examined the influence of attention. Participants were assigned to either instruction condition, where they were instructed to carefully observe the non-causal instances as well as others, or control condition. Participants were given both small and large samples of either UE stimuli (two candidate dates were different in causal strength but the same in reliability) or UUs (different in both in opposite directions). Instruction had a weak positive influence. Experiment2 examined the effect of WM on causal induction, using stimuli identical to Experiment1. Participants were allocated to either WM condition or control. The WM group was asked to tap on a table at a steady pace while observing the stimuli. They tended to ignore the non-causal instances more than the control group did. These results imply that the capacity of WM and attention affected significantly the processing of the "unrelated" information during causal induction. It may be an evidence for the dual process theory of human thinking that people tend to regard those instances as "unrelated" and postpone taking them into account for the time being.

The sense of verisimilitude in multimodal displays and contents
Jiro Gyoba Tohoku University, Japan; Nobuko Asai; Sota Hidaka; Akio Honda; Hiroshi Shibata; Wataru Teramoto
Realisation of high-quality multimodal displays has been required for advanced communication technologies. As an index for evaluating such display systems, the sense of presence (or immersion) has been well-investigated and found to be significantly based on background information contained in a scene. In contrast, the beneficial effects of foreground components in multimodal contents have not been investigated in detail. Therefore, we focused on the sense of verisimilitude as an index for foreground information quality. Using audio–visual contents, such as a Japanese garden scene and a clip of western orchestral music, we conducted subjective-rating experiments on how the sense of verisimilitude, and the sense of presence were affected by spatio-temporal properties of foreground audio–visual stimulation. Consequently, the sense of verisimilitude was found to be more sensitive to audiovisual synchronicity than display size, while the sense of presence showed greater sensitivity to display size and sound intensity than the temporal property. Hence, the sense of verisimilitude can be another useful index for quality evaluation of multimodal displays and contents, in addition to the sense of presence.

Effects of unrecognised hints and metacognitive control in insight problem solving
Masasi Hattori Ritsumeikan University, Japan
Unconscious cognition plays an important role in solving insight problems. Metacognition is also known to be effective in enhancing creative thinking. Little is known, however, about how unconscious thought and metacognition interact. The current study first examined whether a hint that could not be consciously perceived has an effect on facilitating problem solving, Experiment 1: 102 participants tried to solve the nine-dot problem, half of them after exposure to a subliminal hint. The hint doubled the solution rate. Experiment 2 examined how this effect interacted with metacognitive
instructions. 146 participants solved the same problem under one of four conditions defined by crossing exposure or non-exposure to a subliminal hint with metacognitive control instructions present or absent. The hint raised the solution rate and so did metacognition, but the effect almost disappeared when both were introduced. The results suggest that metacognitive control sometimes operates without monitoring.

Attention: Capacities and limits

Laura Nathalie Hiller University of Innsbruck, Austria; Marco Futter; Pierre Sachse; Markus Martini

Inattention-blindness, regarding the failure to observe visual stimuli, as a perceptual phenomenon is relatively well-explored (Mack & Rock, 2000). There are only a few studies that show a possible analogous phenomenon to ignore auditory stimuli. In one experiment, the effect of salient auditory stimuli on attention was explored. Here, the participants had to read a text, and to remember as much as possible of its content. The auditory stimuli were not to be considered, and were therefore, irrelevant to the task, however, the volume was impossible to ignore. The extent to which these auditory stimuli were perceived by the participants, how they were distracted by them, and how the amount of distraction influenced their attention to the text and their eye movements were explored. Finally, it was explored whether a more difficult and distracted task increases the concentration level. The sample (N = 96) was divided into three groups with varying degrees of distraction. The results show that the distracted participants reproduced significantly less information from the read text, and that the fading out of auditory stimuli decreased recall capacity. The distracted participants rarely watched the visual stimuli and when they did, for shorter periods. Interestingly, the most distracted subjects scored the best results in the subsequent d2-Test of Attention that was performed under the same conditions. It was shown that a high degree of distraction can lead to improved concentration and thus lead to an increase of performance. Practical consequences are discussed.

Trust and confidence in probabilistic forecasting that have the same value but calculated on different grounds

Sunmir Hirota Tokyo City University, Japan

Research has revealed that people make biased decisions under uncertainty. However, in risk communication in the real world, probabilities in risk messages are usually calculated on a number of grounds, for example, frequency probabilities based on vital statistics and epistemic probabilities based on the degree of belief that experts have. Therefore, the purpose of this study was to reveal how these probabilities are perceived and trusted. Seven probabilistic weather forecasts having the same values, but calculated on different grounds, including objective and epistemic probabilities, were presented in questionnaires to 213 university students. The subjects rated them on the following: (1) degree of trust (7 point scale), (2) degree of confidence (percentage values), and (3) degree of desirability of such a forecast (7 point scale). Results showed that ratings of most probabilistic forecasting calculated on different grounds were significantly different.

Objective probabilities were more trusted than epistemic probabilities and the amount of data and number of experts also affected the degree of trust. However, these tendencies were not conclusive. Though they were epistemic probabilities, the values that were based on discussions by multiple experts were more trusted. These results indicated that people judged not only the values generated by probabilistic forecasting but also what grounds these values were generated on. The necessity of showing the grounds along with the probabilistic information in risk communication has also been discussed.

The effects of the increment asymmetry in payoff, and risk cost on the centipede game

Ruye-Yun Horng National Chiao Tung University, Taiwan, R.O.C.; Shih-Pao Chou

The purpose of this study was to examine the effects of the increment asymmetry in payoff and risk cost on decision-making in the centipede game. Seventy-six college students were randomly assigned to three risk cost conditions (20%, 50%, and 90%) to play 51 centipede games. Out of 51 games, 32 games were composed of 2 increment asymmetry in payoff (symmetric vs. asymmetric in payoff increment) × 2 roles (A or B) × 2 amounts of money (large or small) × 4 trials. Result shows that high risk cost (90% decrement) would decrease player’s decision to cooperate, but it only occurred when a large sum of money was involved. Asymmetry in payoff increment would lead to early abortion of the game for both players, but the effect was greater for B. In fact, the role x amount of money interaction showed that B, who was the more disadvantageous player in the games, tended to terminate the game earlier than A regardless of the amount of money involved. In contrast, A only terminated the game earlier when a large sum of money was involved. It seems that A, who was the winner of the game, was afraid of being betrayed by B when the situation was most favorable to A. These findings suggest that people are highly sensitive to the structure of the payoff in the game and would cooperate less when there is a large asymmetry in player’s utility.

Character as the processing unit in Chinese text comprehension

Ruye-Yun Horng National Chiao Tung University, Taiwan, R.O.C.; Sheng-Ping Fang; Yung-Chang Huang

It is believed that the processing unit in Chinese is multi-character words. However, this would create multi-character words. Huang (Taiwan, R.O.C.; Ruey-Yun Horng National Chiao Tung University, Taiwan, R.O.C.; Shih-Pao Chou)

It is believed that the processing unit in Chinese is multi-character words. However, this would create multi-character words. Huang (Taiwan, R.O.C.; Ruey-Yun Horng National Chiao Tung University, Taiwan, R.O.C.; Shih-Pao Chou) character will be activated automatically upon reading the characters of a sentence are processed individually. Typical color-naming and addiction Stroop tasks were used to examine (1) general attentional control ability and (2) attentional bias toward activity-related cues. Previous studies usually emphasised the role of dependence, but largely ignored the importance of activity type. Moreover, very few studies examined internet users’ attentional control abilities and showed inconsistent results. People engaged in Counter Strike (CS) and Facebook (FB) were sampled to represent two different activity types. Typical color-naming and addiction Stroop tasks were used to examine (1) general attentional control ability and (2) attentional bias toward activity-related cues. In addition Stroop task were there three blocks that were counterbalanced: CS block, FB block, and Nature block. Results of color-naming Stroop showed that the high-dependence group had longer color-naming latencies than the low-dependence group, indicating the worse attentional control abilities. In addition Stroop task, we reported a critical role of activity type.

Activity type and dependence level modulate attentional control ability and attentional bias toward activity-related cues

Wan-Ru Huang Chung-Shan Medical University, Taiwan, R.O.C.; Ming-Chou Ho

People with internet addiction disorder (IAD) have impairment in familial, social, and academic function. It remains unclear how activity type and dependence level interact to influence the users’ attentional control ability and attentional bias toward activity-related cues. Previous studies usually emphasised the role of dependence, but largely ignored the importance of activity type. Moreover, very few studies examined internet users’ attentional control abilities and showed inconsistent results. People engaged in Counter Strike (CS) and Facebook (FB) were sampled to represent two different activity types. Typical color-naming and addiction Stroop tasks were used to examine (1) general attentional control ability and (2) attentional bias toward activity-related cues. In addition Stroop task were there three blocks that were counterbalanced: CS block, FB block, and Nature block. Results of color-naming Stroop showed that the high-dependence group had longer color-naming latencies than the low-dependence group, indicating the worse attentional control abilities. In addition Stroop task, we reported a critical role of activity type.
High-dependence CS players showed longer color-naming latencies than low-dependence CS players to CS-related pictures. Alternatively, high-dependence FB users showed longer naming time than low-dependence FB users to both CS- and FB-related pictures. We suggest that both activity type and dependence level are important for development of IAD.

A new look at framing effect

Gang Huangfu Beihang University, Beijing, CN; Liqiu Zhu

Framing-effect plays an important role in behaviour economics and decision-making theory. Due to the inconsistent results of previous studies on framing effect, the paper improved the traditional study paradigm, by adopting a face to face individual lab manipulation, presenting materials and tasks by computers, measuring the time duration of participants’ decision-making, to further investigate whether time constraint influence the occurrence of framing effect. The study also explored to find out the reason of the inconsistency of previous studies, especially the preference shift phenomenon. Results showed that: 1. There was no framing effect under the condition of group test, participants showed risk preference under both positive and negative framing; 2. There was a significant framing effect under the condition of fast decision-making and time constraint; 3. Frames influence the way of information processing. Participants made decision faster under positive condition than under negative condition; 4. Participants’ risk-taking preference influenced the occurrence of framing effect. Frames made no difference to high risk-taking participants, they tended to seek risk under both frames. Frames made a big difference to low risk-taking participants. They chose to avoid risk under the positive framing, but chose to seek risk under negative framing.

Expository text comprehension: Prior knowledge and working memory

Natalia Irrazabal CONICET, Argentina

This paper examines the comprehension of general and disciplinary expository texts as a function of previous domain-specific knowledge, and working memory capacity. Novices or experts in psychology topics read a general expository text and a disciplinary expository text. Two measures of comprehension were collected: the production of a summary, and the response to multiple-choice questions. Working memory capacity was measured with the Reading Span Task. Results indicated better performance from experts on the disciplinary text. No differences were found on the general text, or as a function of working memory, except for expert readers in disciplinary texts. These results support the hypothesis that previous domain-specific knowledge is a key factor in differences in text comprehension, in comparison with the working memory capacity hypothesis.

Is the testing effect dependent on an overt testing procedure?

Fredrik Jonsson Stockholm University, Sweden; Veit Kubik

The testing effect refers to the combination of study and memory testing trials during learning, being more beneficial for final recall performance than repeated study only. Previous research has almost exclusively demonstrated the testing effect with an overt testing procedure. The present two experiments compared the relative efficacy of two different types of testing during learning on retention over time. In Experiment 1, two groups of 20 participants studied 40 paired associates three times, and tested memory either overtly (overt testing group) or covertly (covert testing group) three times. The overt testing group entered their response on the keyboard, whereas the covert testing group was instructed to covertly retrieve each item. Final cued recall tests were given 15 minutes, and one week, later. As measured in terms of the rate of forgetting between the first and the second final recall test, the overt group forgot significantly less information over a week. In Experiment 2, the overt and covert conditions were manipulated within subjects and a main effect of condition was found, where the overtly tested items were remembered slightly, but significantly better than the covertly tested items both 15 minutes and one week. This demonstrates that the overt testing procedure may lead to better learning, although the effect is relatively modest.

Anagram task-solving in the condition of increasing emotional tension

Maria Kapitsa Moscow State Lomonosov Univer, Russian Federation; Irina Blinikova; Anna Leonova

We tested whether the time, errors and strategies of anagram task-solving depend on level of emotional tension. In each of two experiments, the subjects (n=40) tackled two series of 10 randomly produced 4-letter anagrams, with the letters presented one by one. Subjects had to assemble meaningful words retaining, and rearranging, the letters in working memory. Results obtained in conditions of soft test anxiety, showed that high stress-resistant subjects spent a significantly longer time solving the problems (8.9 s) compared to subjects with low stress-resistance (5.4 s). With the increase of emotional tension in the second experiment, the reaction time of subjects with a high stress resistance reduced significantly (5.3 s), while the reaction time of subjects with low stress-resistance increased slightly (6.2 s). The correct implementation rating was significantly higher in subjects with high stress resistance than in the subjects with the low one, in both experiments. These results may be explained by the fact that the subjects of the two groups use different strategies. Subjects with high stress-resistance, used a strategy of deliberately organised sequential sorting of options, and subjects with low stress resistance, relied on the strategy of pop-out solutions with a parallel search. An increase in emotional tension forced subjects to change strategies.

Embodied features in pictography of abstract and concrete concepts

Yanina Ledovaya St.Petersburg State University, Russian Federation

39 teenagers (22 females, 17 males, 14–18 years old, M=15.4) were presented an abstract and a concrete concept (IDEA and later DESSERT, in Russian) with the task of depicting 1) the first image that comes to mind when seeing the word, and then 2) an object that represents the most essential features of this concept, for one minute. We expected differences in the way an abstract and a concrete concept could be “described” within individual mental lexicons. The categorisation of the images showed that among the first sketches there were commonly shared “visual prototypes” like “shining bulbs”, “suns”, and “smiles” for IDEA, and various but stereotyped “cakes” for DESSERT. We received about 30% of “embodied” associations for an abstract concept like “humans” or “smiles”, and about 5% for a concrete one. But among the pictograms that represented core and essential characteristics of the concepts, we received more categories, which show growing individual differences in the way the subjects represent deeper semantic structures. Moreover, comparing the categories for an abstract IDEA and a concrete DESSERT, we discovered that the “embodied” associations prevailed when the subjects pictured the objects conveying the core features of an abstract concept. There were the images of humans or stories happening to humans, actions or energy consuming processes (about 50% of all pictograms for IDEA), whereas there emerged about 25% of “embodied” associations for a concrete concept DESSERT.

The interaction between pitch and duration processing in music notation reading

Hong-Yih Lee Taiwan, R.O.C.

The aim of the present study was to study the relationship between pitch and duration processing in reading musical notation. This paper used a Stroop-like task to demonstrate the effect. A probe display was presented before each target note. The participants were required to process the tonal and metrical information of the probe, and then make a match or mismatch decision between probe and target. The correct implementation rate of participants, which dimension (pitch or duration) need be analysed, the congruity of the irrelevant dimension of the target was manipulated to examine the effect on the relevant dimension. 20 university students, non-musicians, participated in the experiment and demonstrated the obvious interference effect of the irrelevant dimension on the relevant dimension for error-counts results. These results supported that pitch and duration processed interdependently.

The effects of acute post-learning stress on memory, and individual differences in depression

Mingming Lin The University of Tokyo, Japan; Yoshihiko Tanno

This study aimed to examine the individual differences in the effects of acute post-learning stress on the memory of words. Previous researchers have reported that acute post-learning stress can enhance memory performance. In this study, participants were subjected to an acute stress task after a memory task; subsequently, we compared memory responses between low-depression and high-depression groups. Twenty-eight undergraduate students who answered the depression scale were randomly assigned to stress and control conditions. They were instructed to perform a 30-word memory task, which consisted of 10 positive, 10 negative, and 10 neutral words, followed by an im-
Recall of the funnies: A memory experiment

Anum Malik
Foran Christian College, Pakistan

Recall of the funnies, a memory experiment, hypothesised that the participants would have better recall of humorous statements than non-humorous statements. A list of statements was developed in which there were 9 humorous statements and 9 others that were non-humorous. Using convenience sampling, the humorous statements were pilot-tested on a group of ten teenagers in order to ensure that they elicited a reaction of either a smile or a laugh. The results of the pilot study showed that the non-humorous statements were considered to be boring, especially when compared to the humorous statements. Once again using the method of convenience sampling, 20 psychology students from Forman Christian College, Lahore, Pakistan were asked to participate in this within-subjects design experiment. 12 of the participants were women and 8 were men. A paired t-test was run to test the hypothesis and investigate if there was a difference in the means of recall in the two conditions: humorous and non-humorous statements. The results for the one-tailed t-test showed that the mean for humorous statements was indeed higher, 2.55 compared to 1.80 for non-humorous statements. The standard deviation was 1.32 for humorous statements and 1.20 for non-humorous statements: t (19) = 1.86, p = .04. The experimenter, Anum M. Malik, conducted this cognitive experiment and found that the result was statistically significant. The mean recall of humorous statements was higher than that of non-humorous statements.

Autobiographical memory of positive and negative experiences

Malen Migueles
University of the Basque Country, Spain; Elvira Garcia-Bajos

We examined the autobiographical memory of pleasant and unpleasant experiences. One hundred and twenty-four university students were asked to produce positive or negative events occurring during their lifetimes, say when they occurred and assess their emotional content. Then selected one event to relate in detail. The produced and related events were categorized, analysed in terms of time distribution, and the emotional level was evaluated. The factors used to evaluate the accounts were: structure (length, sentences, relevance and coherence), contents (actions, people, sensory details, temporal and spatial details, expressions of emotion and physical condition), and processes (mental, metamemory, mental or verbal rehearsal, planning, justifications and personal assessments). The most common positive categories were: school/academic success, partner relationships, trips/outings/holidays, parties/celebrations, and relationships with mates or friends. The most representative negative categories were: family problems, problems with mates or friends, school/academic failure, death of family members or friends, and problems with partner relationships. There were very few positive and negative memories from early childhood (0–5 years), and percentages increased until the 16–20 years-old age bracket. The distribution in time was similar except for the 11–15 year period, which accounted for more negative experiences. Only the 16–20 year period showed differences in emotion, with greater emotional levels in positive memories. The accounts of positive and negative memories shared the same structure, contents and processes. However, there were more emotional details, references to cognitive processes, mental rehearsal and justifications in negative memories.

Age differences in hypermnesia: When does hypermnesia stop occurring?

Hayashi Mitsuko
Hokkaido University of Education, Japan

Hymenemia is a phenomenon of memory improvement across repeated tests without a re-learning phase. Some researchers (ex, Widner, Otani, & Smith, 2000; Hayashi, 2007) confirmed that it would be difficult for over 65 years old that hypermnesia occurs, but no body conducts an experiment on people from 22 years old to 65 years old systematically to confirm in which ages hypermnesia is interrupted or stop occurring. For example, it may happen that hypermnesia occur in 20’s, 30’s and 50’s but not in 40’s. To ensure it, 60 participants who were from 20 years old to 67 years old were gathered in this study. There is a drawing condition in that participants were instructed to draw a picture what each word in the study book indicates in every 15sec. 60 usual everyday words such as a violin, a shirt, a grasshopper were used in the study book. After the study phase, a distracter task was given in 5min., then the 3min. free recall tests were repeated 3 times. Neither re-learning phase nor rest time was conducted between these tests. Data was analyzed according to the age every 10 years such as 20’s, 30’s, 40’s, 50’s and 60’s. In this study hypermnesia occurs in each age. It is suggested difficulty of hypermnesia is after 60’s.

The analysis of selected cognitive functions and intelligence in children with type 1 diabetes

Ewa Majz
Poznan University of Medical Sciences, Poland; Wlodzimierz Samborski; Elzbieta Skorupskas

Type 1 diabetes in children and adolescents is one of the most common metabolic diseases of complex origin. Manifestations of this disease and its chronic course are the most essential factors affecting the child’s development, including cognition. The objective of this study was to define some characteristics of cognitive functioning in children suffering from type 1 diabetes. The cohort included 59 children, ages 7–16, diagnosed with type 1 diabetes. Neuropsychological methods to test cognitive functions and the Wechsler intelligence test were applied. The level of intellectual functioning of all children studied was at or above standard values for their age group. Yet, our data showed a decrease in cognitive functions that mirrors the disease duration time, blood sugar level-related disorders, and an increase in 3 types of Wechsler Intelligence Scale for Children (WISC-R) subtests: similarities, digit span, and coding. The largest decrease was observed in the group of arithmetic tests and picture completion. This suggests improvement in abstracting capabilities, direct memory function, and learning efficiency capabilities. From the findings, we believe that intellectual deficits in diabetic children are specific and affect only selected cognitive functions. The question as to why there is not a decrease in the WISC-R subtests needs yet to be explored.

Cognitive activity as predictor of cognitive functioning among young and oldest old

Maria De Los Angeles Molina
Autonomous University of Madrid, Spain; Rocio Schettini
Autonomous University of Madrid, Spain; Maria Zamarron; Maria Santacreu; Rocio Fernandez-Bollesteros

Longitudinal studies are the best designs to study people functioning over time. Also, longitudinal, cross-sectional, and intervention studies show how lifestyles affect cognitive functioning. The aim of our study is to establish how two types of variables: 1) educational status and 2) level of activity, predict cognitive functioning in two longitudinal studies (ELEAEand 90+). Two samples, first of 211 older adults (OA) between 54–79 years (59.5% women) and second of 67 elderly adults (VOA) older than 90 years (70.1% women), were involved in a longitudinal study between 2006 and 2011 or 2008 respectively. The assessment protocol was the European Survey on Ageing Protocol. Independent variables selected are the following: educational level, years studied, and level of activities measured as the frequency of social, productive and intellectual activities. Cognitive functioning is measured by the average of three tests: Mini Mental State Status, Digit Span and Digit symbol. For both samples, our results are: 1) cognitive functioning over the time is significantly associated with years of education (OA: r = .384; VOA: r = .410) and educational activities (OA: r = .289; VOA: r = .304), 2) educational level and intellectual activities predict cognitive functioning over time (OA: $t = 4.225 p < .000$; $t = 2.877 p = .004$, VOA: $r = 3.372 p = .001$; $t = 2.250 p = .028$ respectively); and 3) the effect of intellectual activity on cognitive functioning over the time is independent of the educational level (OA: $F = 2.40, p = .007$; VOA: $F = 4.02, p = .000$). From the results, it can be emphasised how important intellectual activity is to preserve cognitive functioning.

Differences within semantic associations during speech production

Juliane Muehlhaus
RWTH Aachen University, Germany; Stefan Heim; Katharina Sass; Ute Habel

The impact of associative relations on speech production varies from facilitation to interference depending on the length of utterance. It is unknown whether the effect of conceptual facilitation or lexical interference might be explained by the fact of different associative types of relation, e.g., part-whole or functional. For this reason, the present study had the aim to examine the influence of both types of associations on single word and sentence production. Two groups of healthy subjects were recruited. For single word production, a
classical picture-word task, and for sentence produc-
tion, an adapted version of the picture-word task was
used. In both experiments, the associative relation
between target and distractor was either functional
or part-whole. The naming latencies were faster for
both types of relations during single word production,
i.e. facilitation occurs. Additionally, latencies were
faster for part-whole than for functional associations.
During sentence production, the effect of facilitation
shifted to interference and the difference between both
relations disappeared. The findings of conceptual fa-
cilitation and lexical interference for semantic associa-
tions highlight the flexibility of the spread of activa-
tion that is sensitive to the context. The different
facilitation effects during single word production
might be explained by different classification and
organisation within our mental lexicon, i.e. better
connected links for part-whole. In contrast, during
sentence production the influence of semantic context
at the lexical level seems to be more important than
types of semantic associations at the conceptual level.

Comparative study of cognitive functions of
patients with bipolar disorder, unaffected
relatives and controls
Ritu Nehra PGIMER Chandigarh, India
The aim of this study is to compare the neurocog-
itive functions of patients with Bipolar disorder
(currently in remission) with their first degree rela-
tives and healthy controls. A total of 60 subjects
participated: 20 patients with bipolar disorder
(mean age = 35.15 years, SD = 7.13) and their 20
unaffected first degree relatives, age and education
matched with 20 healthy controls recruited from the
Department of Psychiatry of a tertiary care hospital
in India. Cognitive functions such as verbal learn-
ing (Hopkins Verbal learning test), visuospatial
memory (Brief Visuospatial Memory Test – Re-
vised), visuomotor coordination (Digit Symbol
Substitution Test) and executive functions (Wiscon-
sin Card Sorting Test) were assessed. The patient
group was also assessed on Mini Mental State
Examination, Hamilton Depression Rating Scale
and Young Mania Rating Scale. There were signifi-
cant differences between the 3 groups, (bipolar
disorder, unaffected first degree relatives, and
healthy controls) on tests of verbal learning (F=20.92,
p<.000), visuospatial memory (F=6.66,
p=.003), visuomotor coordination (F=8.44,
p=.001), and executive function (F=10.64,
p=.000). Comparison of unaffected first degree rela-
tives with healthy controls revealed significant dif-
cferences on the test of verbal learning only (Post-
hoc (scheffe’s)’ p=0.03). Reduction of cognitive
morbidity in patients with bipolar disorder and their
first degree relatives needs to be addressed in a
timely and active manner.

The impact of sleep loss on moral cognition
Olav Kjellevold Olsen Royal Norwegian Naval Acad-
emy, Norway; Jarle Eid; Stale Pallesen
The impact of sleep-deprivation on moral judg-
ments - Olav Kjellevold Olsen, PhD; Stale Pallesen,
PhD; Jarle Eid, PhD. Two studies investigated the
impact of sleep-deprivation on moral cognition. In
study 1, 71 naval cadets judged five justice dilem-
mas on the Defining Issues Test - 2 in rested and
sleep-deprived condition in a counter-balanced de-
sign. In study 2, they anticipated moral and tactical
problems at the start of a simulator combat opera-
tion in the two conditions. The results from study 1
showed that ability to conduct mature and princi-
ially oriented moral reasoning was severely im-
paired during partial sleep deprivation.Conversely,
a substantially more rules-oriented moral reasoning
was found, while no change in self-oriented moral
reasoning was found. Interaction effects showed
that the cadets who displayed high levels of mature
moral reasoning (n = 24) in the rested condition
lost much of this capacity during sleep deprivation
in favour of a strong increase in rules-orientation.
Conversely, cadets at low levels of mature moral
reasoning in rested condition (n= 23) were unaf-
fected by sleep deprivation. Study 2 displayed a
medium to strong impairment in the ability to
anticipate both moral and tactical issues during
sleep-loss, with equally strong impairment within
the tactical and the moral domain. The studies
showed that long-term partial sleep deprivation has
a strong impact on the ability to make moral justice
judgments and the ability to prepare cognitively for
moral and tactical challenges in an operational context.

State’s language: Comprehension of pro-
blems in study process
Veronika Pivkina Al-Farabi Kazakh National Univer-
sity, Kazakhstan; Nora Ferhat; Angelina Khan; Alla
Kim; Taisiya Maslova
In 1991, after the Kazakh language had become a
state language in 1989, Kazakhstan was declared
as an independent country. However, at present,
more than half of the population is still using the
Russian language in professional and everyday life,
in spite of the measures taken to introduce the
native language. In our opinion, it was necessary
to study the psychological impact on the factors that
complicate the study of the language. The aim of
our analysis consisted of researching the subjective
causes of comprehending difficulties in the lan-
guage acquisition process for 2 generations: young
students and their parents. We used the self-report
method to estimate the subjective image of under-
standing language learning difficulties experienced
by these two generations. The survey, in the form of
a questionnaire, was completed by 100 participants.
The conclusion was that low motivation is predom-
inant among the youth. Perfectionism is the primary
reason for low motivation in the older generation:
they are afraid of the failure. At the same time, both
generations of Russian-speaking people don’t re-
value a negative attitude towards the Kazakh language
and culture. It is recommended that more attention
be paid to working with young people to form the
intrinsic motivation, and personal responsibility in
learning. Regarding the older generation, the train-
ing should encourage the need for achievement,
which will counter the need for avoidance and
perfectionism. It is also important for them to over-
come the impression of the youth’s bad language
capability.

Is consciousness a continuous or dichoto-
mous phenomenon: A Levels of Conscious-
ness framework?
Henk Pretorius University of Cape Town, South Africa
Whether conscious visual perception is an “all-or-
none” or continuous phenomenon, is an area of
inquiry that has attracted considerable interest re-
cently. Findings from behavioural and neurophysi-
ological studies have been equivocal, and reveal
that the debate is still unresolved. In this investi-
gation it is argued that a reliance on a unitary and
invariable view of consciousness might have con-
strained the forms of consciousness that can be
observed. Instead of formulating consciousness as
consisting of a single level, which may be dichot-
omous or continuous, several recent proposals sug-
gest the existence of multiple dissociable levels of
consciousness. Further, evidence suggests that the
form of conscious access may be dynamic, and that
different visual phenomena and stimuli may elicit
different forms of consciousness. Recasting the
debate into a dynamic levels of consciousness
view, exposes unexamined possibilities that have
not been fully addressed by the extant literature on
the debate.

Application of analogy transduction to con-
ditional reasoning
Qin Qiu Jiangxi Normal University, China; Zhijing
Hu; Xianglin Shi
Wason selection task embodies a conditional rea-
soning process based on hypothesis testing. The
subject’s solution for the Wason selection task can
be improved by using analogical reasoning, which
is a kind of analogical reasoning about inference
process. When the analogical relation structure of
the source problem and the target problem are non-
isomorphic, it is required to adjust the conditional
reasoning process to solve the target problem which
refers to the reasoning process transduction.

An exploration of thinking strategies applied
by students in a higher education learning
environment
Amone Roos North-West University, South Africa
Popular belief about creativity focuses on the end
result in fields like arts, science and everyday activ-
ities. Creativity is also regarded as a process of
innovative problem-solving and the utilisation of
opportunities, by applying convergent (outcome fo-
cus) and/or divergent, thinking strategies (explore,
think independently and original). Cognitive theories
about creativity appreciate these processes, as well as
the person involved in them. The purpose of this
presentation is to describe how the cognitive process-
es underlying creativity were revealed by students
who were involved in qualitative research. Twenty
Can a specific fluency affect only episodic memory: The effect of self-motion fluency in paths recognition?
Stephane Rousseau; LPNC - Grenoble University / CNRS, France; Melanie Cerles; Alice Gomez LPNC - Grenoble University /CNRS, France

Fluency is the relative ease and speed with which stimulus information is processed. It leads to an increase of recognition for items processed more fluently. Previous experiments using the Remember-Know paradigm have shown an impact of perceptual fluency only on familiarity and not on recollection. Recent episodic memory models have postulated a strong link between episodic memory and spatial processes (Burgess, 2008, Nadel & Moscovitch, 2001), especially with navigation and self-motion (Ratcliff, 2009). The present experiment was conducted to determine whether self-motion fluency affects recognition performance, and particularly has an impact on “Remem-ber” responses. Thirty participants learned a four-minute path movie as if they were really doing the track, and then had to recognise among short paths if they were part of the learned path, followed by a Remem-ber-Know procedure for recognised items. Self-motion fluency was manipulated with the presence of nimbble acceleration applied on a small part of the video recognition paths. Results show that the presence of a self-motion fluency significantly increases the proportion of remember responses on learned paths only. This study spotlights, for the first time, a specific fluency effect on recollection and indicates an implication of self-motion in episodic memory retrieval.

The validity of measuring the intelligence of autistic children: What’s new?
Carole Senechal; University of Ottawa, Canada; Larivée Serge; Roge Bernodette

This goal of this study is to better understand the restrictions brought on by the use of intelligence tests in the evaluation of children with autism, and to better understand the reasons for their poor performance. This study tries to show that the content of these intelligence tests affects autistic student performance and that flexible passing conditions facilities their performance. An experimental group of autistic children and a control group of children without any exceptionality were established. All of the participants were evaluated with the 4th version of Wechsler’s Intelligence Scales (WISC IV). Half of the participants from each group underwent this evaluation in adaptive conditions. These conditions included longer completion times, breaks for games and free time, as well as reinforcements in the form of verbal encouragement and tangible rewards during the test. This study also attempts to show that the low results of autistic children on certain intelligence tests are not necessarily due to competency difficulty, but could be linked to the content or form of the test. The results of this study show that the sample group of autistic children did not benefit from the adaptations put in place. The children evaluated in adaptive conditions did not outperform those evaluated in standard conditions on the WISC IV test. However, children without exceptionalities seemed to have benefited from the adaptation because the results of those evaluated in adaptive conditions were better than those who were tested under standard conditions. This goal of this study is to better understand the restrictions brought on by the use of intelligence tests in the evaluation of children with autism and to better understand the reasons for their poor performance. This study tries to show that the content of these intelligence tests affect autistic student performance and that flexible passing conditions facilities their performance. An experimental group of autistic children and a control group of children without any exceptionality were established. All of the participants were evaluated with the 4th version of Wechsler’s intelligence scales (WISC IV). Half of the participants from each group underwent this evaluation in adaptive conditions. These conditions included longer completion times, breaks for games and free time, as well as reinforcements in the form of verbal encouragement and tangible rewards during the test. This study also attempts to show that the low results of autistic children on certain intelligence tests are not necessarily due to competency difficulty, but could be linked to the content or form of the test. The results of this study show that the sample group of autistic children did not benefit from the adaptations put in place. However, children without exceptionalities seemed to have benefited from the adaptation because the results of those evaluated in adaptive conditions were better than those who were tested under standard conditions.

How does mental imagery navigate our thinking and comprehension?
Olga Scherbakova; St. Petersburg University, Russian Federation

This study was aimed at describing how various components of mental imagery provide the process of text comprehension. Our respondents (N = 37, male and female, aged 17 – 32) were presented with 7 verbal jokes (jokes are a special type of intellectual task, “user-friendly”) graded according to their difficulty. During the following introspective in-depth interview about the concrete techniques of understanding each joke, we asked our respondents to visualise all the imagery they had been experiencing during the thinking process. Using the technique of qualitative expert evaluation of the depictions (we considered them as the objectifications of the inner mental representations), we revealed the following types of encoding of the meaning through imagery components of thinking: labelling the text’s key ideas and characters with isolated imagery fragments, relevant to the text’s verbal content; incorporating relevant imagery fragments into non-relevant imagery scenes; composing generalised mental spaces containing imagery labels for the key ideas of the text; purposeful collapsing of inadequate mental spaces and its replacement with others; involuntary blending of two separate mental spaces in case the latter replacement is difficult to perform due to of the subject’s metacognitive skills and recording the intermediate ideas which help to understand the entire text by using artificial imagery components (such components do not refer to the main idea of the text but play the supportive role for its emerging). These imagery operations are of varying degrees of complexity and should be analysed qualitatively.

Does doodling effect performance: Comparison across retrieval strategy?
Tulika Singh; Indian Institute of Technology, India; Naveen Kashyap

Day dreaming and mind wandering is very common phenomenon, and can be distracting, as much of mental energy is used by these processes. A common strategy employed against these is doodling (simple unfocused drawing while a person’s attention is otherwise occupied). Doodling has been previously shown to improve performance on a learning task by managing distractions (Andrade, 2009). In the present study, we tested whether doodling differentially benefits performance across two retrieval strategies. The present study tries to evaluate whether doodling differentially benefits performance across recognition and recall. Two groups (recall and recognition) of participants (N=32) with mean age (19 ± 1) were involved in a doodling task while a boring story was played in the background. On completion of the task the participants were engaged into another intervening task for 15–20 minutes. This was followed by retrieval tests. The hypothesis is that there will be significant differences between the performance of recall and the recognition group on the learning task. One way ANOVA was used to analyse the data (retrieval strategies – independent variable; performance scores – dependent variable). The value of F (1, 32) = 0.07, p < 0.5 obtained suggests no significant difference between the performance of recall and recognition groups. The possible reasons for our result may be nature of task used in the study or interval between doodling/learning and retrieval.

Aging and organisation in episodic memory: Executive functions and working memory
Laurence Taconnat; University of Tours and CNRS, France

Organising the material in manageable units is an efficient way to improve performances in recall. Use of such strategies in experimental settings can
be quantified by indexes of clustering reflecting semantic (categorical: abstract, natural kind, artifact) of the ontological category (subjective organisation) and in particular in older adults. Cognitive processes underlying the subjective organisation have not been examined. Working memory, a cognitive resource impaired in aging and implicated in associative memory, could explain the subjective organisation, based on the capacity to form new associations in episodic memory. This study aimed to confirm that the age-related difference in semantic organisation is due to decline in executive functioning, and to show that the age-related impairment in subjective organisation is based on the alteration of working memory. 63 younger adults and 60 older adults had to learn two 20-word lists (related and unrelated items) in order to recall them. Organisational indexes were computed (ARC; related items list and PF: unrelated items list). They also took cognitive tests measuring processing speed, working memory, executive functions and episodic memory (independent of the main memory tasks). Results showed effects of aging on recall, semantic and subjective organisational indexes, and on cognitive tests. Processing speed and organisational indexes explained the variance in the number of words recalled, executive functions explained the variance in semantic organisation, and working memory explained the variance in subjective organisation index. These data indicate that both semantic organisation and subjective organisation might be impaired in old age, but suggest that they are sustained by different cognitive processes.

Ontological category and originality in conceptual combination
Ching-Wen Wang National Chung Hsing University, Taiwan; Mei-Rong Chen; Ruyun-Hong Hwang

Conceptual combination refers to the creation of a meaning that links two, or more than two concepts together. According to Campbell's random variation and selective retention hypothesis, conceptual combination is the basic cognitive mechanism that leads to new ideas. However, ideas emerged from conceptual combination may not be original. The purpose of this study was to investigate a variable that may be related to the emergence of original ideas from conceptual combination, namely, the ontological category (abstract, natural kind, artifact) of the concepts involved. The experimental materials were 18 noun-noun pairs composed of 3 ontological categories of the first noun, 10 x 3, ontological categories of the second noun, x 2, trials. The originality scores of 302 participants' responses on nine types of noun-noun pairs were analysed by two-way analysis of variance with repeated measures. Results showed that combination of two concrete concepts of the same ontological category (artifact-artifact or natural-natural) produced significantly lower originality in the emerged concepts. Results of stepwise regression analysis further showed that the remaining 7 types of noun-noun pairs accounted for 88% of the total variance in originality scores. Among them, 3 noun-noun pairs with abstract second nouns accounted for 53% of the total variances in the originality of the emerged concepts. Thus, joining of concepts across ontological categories and joining of concrete and abstract ideas appear to be important factors for creativity in conceptual combination.

Sound intonation perception of the autism spectrum disorder: An event related study
Kiyoshi Yaguchi Bunkyo University, Japan; Akane Morohashi; Masao Yukie; Daichihiro Nakahara

It is well-known that children with autism spectrum disorder (ASD) show little interest in speech sounds in early childhood, and almost all of them have delays in speech development, with little intonation or accent. We hypothesise that ASD children have little sensitivity to vowel pitch shift because they find it hard to detect affective messages in speech. We recorded the event-related potential (ERP) to vowel sounds with pitch shift, for school age children with high function autism (HFA), and typically developed children (TDC) who were of the same age and IQ, in order to clarify the pitch shift perception ability of HFA subjects in two situations. One was passive and the other active. In the passive condition, participants were required to detect rare stimuli in an oddball paradigm by pressing buttons in the active condition. In the passive condition, the peak latency of the component resembling P1 in the HFA group was significantly delayed in slight pitch shift, as compared to clear pitch shift. In the active condition, the HFA group showed significantly shorter latency of the N1-like component to clear pitch shift stimuli than to subtle pitch shift. On the other hand, TDC group had no such difference between stimuli. These results suggest that the HFA group might have difficulty detecting subtle pitch shifts of speech sounds. These facts should be discussed in relation to emotion perception ability in HFA children.

Discriminant variables for Japanese single and geminate stops in spoken newspaper articles
Kimiko Yamakawa Aichi Shukutoku University, Japan; Yukari Hirata; Shigeki Amano

To examine a relationship between speech perception and production, Amano & Hirata (2010, 2011) analysed acoustic variables for perception and production of single and geminate stops in Japanese. They found that a combination of two variables, the duration of stop closure and the duration of a disyllable, is a discriminant cue both for perception and production of single and geminate stops. However, this finding was derived from limited speech materials. It was not yet clear to what extent their findings were applicable to various speech materials. With this background, we conducted a discriminant analysis between single and geminate stops on 177 speakers' 563 utterances extracted from the spoken Japanese database of newspaper articles. The materials included 25 words that contained single stops, and 26 words that contained geminate stops. The discriminant analysis revealed that the combination of the two variables as in Amano & Hirata's (2010, 2011) earlier findings generalize to a wide variety of speech materials. Accumulating evidence including the present result suggests that speech perception and production are strongly connected on the principal acoustic variables.

Developing a working memory test
Yutaka Yamamura Teikyo University, Japan; Ikko Takahasi; Takashi Kanda

The purpose of this study is to develop the working memory test simply using a test paper. Participants were 18 to 28 year old undergraduate students (N=85 males, 19, and females 66) The new simple and easy working memory test (following new working memory test: new edition trial making test / high-middle-low task / high-middle-low-left-right task / conceptual N back task / mental rotation / maze task / color choice task) and the conventional working memory test (mild attentional disorders test / operation span test / reading span test / N back task) was carried out. The results of the factor analysis for new working memory test, showed three functions, “Switching attention function,” “division and selective attention function,” and “control function.” Subsequently, the comparison of the score between the new working memory test and the conventional working memory test indicated positive, quite high correlation, as a result of analysis by the structural equation modelling. From these, it was suggested that the new working memory test was simple, easy and usable in substitution for the conventional working memory test.

Retrieval-induced forgetting and the digit span task on self reported adult ADHD participants
Masako Yamashita Tokyo Ariake University, Japan; Katsuya Tandoh; Kazumi Hanyu; Yoji Kodama; Kazue Igarashi

Some studies have shown retrieval-induced forgetting (RIF) is not usually observed in ADHD patients, but other studies have not supported this finding. This study primarily examined middle-aged adults complaining of living difficulties similar to ADHD. Two groups, 27 participants who strongly suspected they had ADHD (average age: 36.2, SD: 9.4) and 22 participants who did not suspect that they had ADHD and assumed they were normal (average age: 39.2, SD: 8.3), were tested in relation to RIF using category-plus-one-letter-stem cues and the WAIS III. As a result, there were no differences in the manifestation of RIF between the ADHD group and the normal group. Rather, there was a tendency of RIF to be observed in the ADHD group. When we examined how RIF manifests itself in the above two groups, we confirmed RIF in the Digit Span (by WAIS III) high group (scaled score of 10 points or more, average FIQ 109) but could not observe RIF in the Digit Span low group (scaled score of 9 points or less, average FIQ 100). This suggests that low short-term memory function rather than an awareness of living difficulties like ADHD could cause difficulties in the manifestation of RIF.

The effects of different attention capacity and structure position of target stimulus on implicit learning
Xiaojing Zeng Jiangxi Normal University, China; Mei-Rong Chen

The study is to examine the effect of different attention capacities and positions of target stimuli...
The influence of emotional context during encoding on memory for neutral words
Qin Zhang Chna; Xuan Liu

The present study was carried out to investigate the influence of five different emotional background pictures on the encoding and retrieving of neutral words. By adopting the classic study-test paradigm, sixteen college students were tested for their memory of 250 neutral words with five kinds of emotional background pictures as the encoding context. Their reaction time to each word was recorded as the behavioural measures. Meanwhile, their ERP correlates of the word-picture pairs for encoding sessions and words for retrieval sessions were recorded. The behavioural data revealed that, compared with neutral and low arousing positive context, high arousing negative context significantly impaired recognition rate of neutral words. And ERP results showed, in encoding phase (lasting from 150 to 200 ms), the ERPs were more positive-going for high arousing context as compared with neutral and low arousing context. This effect presumably reflected that high arousing context captured attention more, and interfered with neutral item encoding. In retrieval phase (lasting from 300 to 400 ms), the encoding context effect was salient. The ERPs were more negative-going for words encoded in high arousing negative context as compared with words encoded in positive context, which might reflect that words encoded in high arousing negative context were less familiar to subjects as compared with words encoded in positive context. In sum, the present study indicated that, compared to neutral and low-arousal-positive context conditions, subjects’ encoding of neutral words was substantially interfered in the high-arousal-negative context condition.

Small samples and linear integration: Cognitive constraints on human judgment
Peter Juslin Department of Psychology, Uppsala, Sweden

In the wake of Herbert Simon’s work, the idea that humans have limited time, limited knowledge, and computational ability has been enormously influential in judgment and decision-making research. Yet, the idea of such cognitive limitations is often discussed in a rather vague and almost metaphorical way, where they serve as a general motivation for the use of various, and allegedly simple, heuristic cognitive processes. In this presentation, I will argue and illustrate that taking the specific nature of these cognitive constraints more carefully into account can inform judgment and decision research in various ways. I will concentrate, first, on the fact that much judgment is constrained by the small samples of observations that can be activated within the capacity constraints of working memory, and, second, on the inclination for linear additive integration of information by our processes of controlled and deliberate thought. I will review re-
search illustrating how the reliance on small samples as the basis of judgments and decisions, and the default use of linear additive information integration, have nontrivial consequences for judgments and decisions, including in regard to overconfidence, reasoning about probability, and risky decision-making. Finally, I discuss how the fact that people often have to rely on small samples can affect our understanding of rationality and our ability to explain the apparent flaws people show in this regard.

Eye movements during reading: Contributions of cross-language comparisons

Reinhold Kliegl University of Potsdam, Germany

Reading bridges, basic and applied, as well as experimental, correlational, and computational streams of psychological research. In this context, eye movements in reading reflect a large number of oculomotor, visual, sublexical, lexical, and sentence-level effects, as well as effects relating to differences between languages (writing scripts) and differences between readers in developmental status, basic skills, and reading strategies. The presentation pushes the argument that theory must guide the necessarily multivariate and multilevel analyses of eye movements during reading. The theoretical core of this presentation is distributed processing in the perceptual span, dynamically modulated by local processing demands. Statistical inferences are based on linear mixed models. The theoretical issues and the data-analytic framework are illustrated with results from reading Chinese, English, German, and Spanish. Results are based on experimental manipulations of target words (e.g., boundary paradigm) and analyses of large corpora of eye movements. Implications for computational models and various applied issues will be discussed.

Manufacturing memories

Elizabeth Loftus University of California, United States of America

In my research programme, we have been manufacturing "memories" in unsuspecting minds. Sometimes this involves changing details of events that were actually experienced. Other times it involves planting entire memories; events that never happened - "rich false memories". Rich false memories can be planted even when the experiences would have been implausible or impossible. Moreover, once planted, they have consequences for people, affecting later thoughts, intentions, and behaviours. Once planted, they look very much like true memories, in terms of behavioural characteristics, emotionality and neural signatures. And they can persist for long periods of time, as long as their true counterparts do.

Sleep and cognition: A field with broad implications for psychology

Manuel Schabus University of Salzburg, Austria

The suggested functions of sleep are manifold, including adaptation, strategic, physical recovery and more recently offline information reprocessing. A growing body of evidence is supporting the beneficial role of sleep for attention and memory consolidation. I will review this literature and present brand-new data specifically addressing the significance of light sleep spindles - oscillatory EEG events in the 12–15Hz range which are prevailing during light human non-REM sleep - for periods of undisturbed offline processing and cognition. In addition, brand-new data focuses on the possible modification of these typical light sleep patterns by instrumental conditioning (or neurofeedback), in order to increase sleep quality and cognitive performance. Last but not least, we will focus on patients suffering from clinical disorders of consciousness (e.g., vegetative state or minimally conscious state patients). It is well known that abnormalities of sleep are extremely common in these patients suffering from severe brain injuries. Preliminary results now indicate that specific sleep patterns and the complexity of sleep architecture in general are allowing a window into the residual neuronal connectivity of the brain and thereby might support the difficult diagnosis (and prognosis) of these two fascinating clinical entities.

Auditory scene analysis: A competition between auditory proto-objects?

Claude Alain Baycrest Centre, Canada; Sue Denham

Many sound sources can only be recognized from the pattern of sounds they emit, and not from the individual sound events that make up their emission sequences. We propose a new model of auditory scene analysis, at the core of which is a process that seeks to discover predictable patterns in the ongoing sound sequence. Representations of predictable fragments are created on the fly, and are maintained, strengthened or weakened on the basis of their predictive success. Auditory perceptual organization emerges from the competition between these representations (auditory proto-objects). Rather than positing a global interaction between all currently active proto-objects, competition is local and occurs between proto-objects that predict the same event at the same time. The model has been evaluated using the auditory streaming paradigm, and provides an intuitive account for many important phenomena including the emergence of, and switching between, alternative organizations, the influence of stimulus parameters on perceptual dominance, switching rate and perceptual phase durations, and the build-up of auditory streaming.

Neural architecture underlying perceptual organisation of speech sounds

Claude Alain Baycrest Centre, Canada

Over the past decade there has been an explosion in research activity related to the psychological and neurophysiological bases of auditory scene analysis. This increase in scientific interest has been motivated in part by changes in current models of auditory perception that recognise that hearing is more than signal detection; hearing also involves organising the sounds that surround us in meaningful ways. In this symposium, we will review prior research on auditory scene analysis and discuss new research avenues. Several research themes will be covered including the role of attention in the development of auditory scene analysis, and the role of context, knowledge and memory in object/stream perception. Different approaches will also be presented including studies on auditory stream segregation, continuity illusion and concurrent sound segmentation. Together these studies show that understanding an auditory scene requires complex interactions between data-driven and higher level schema-driven processes that reflect listeners’ knowledge and experiences with the auditory environment. Such interactions are at the forefront of hearing and determine our perceptual experience.

Cortical networks for perception of real-world action sounds

Claude Alain Baycrest Centre, Canada

In contrast to visual perception, relatively little is known about how the human brain processes the everyday sounds we encounter, transforming complex acoustic signals into representations of meaningful actions and "auditory objects". Embodied cognition models posit that perception of an action event, such as hearing hoofsteps of a Cape buffalo approaching, involves some degree of sensory and motor simulation related to characteristic sound-producing actions the observer has experienced and/or produced (to at least some extent) in the past. We propose that representations of acoustic knowledge in the brain are organised around different categories of sound-sources that relate to how (or if) one physically interacts with those sources. Beyond tonotopically organised cortices, we and others have observed pathways that appear to be specialised for processing vocalisation signals while others are engaged by non-vocal action sounds. This includes our recent fMRI reports revealing different networks that are sensitive to each of four conceptually distinct categories of action sounds, two of which depict "living" things (human, animal) and two of which depict "non-living" sound sources (mechanical, environmental). Additionally, we have identified partially overlapping cortical regions that are parametrically modulated by various signal attributes and/or perceptual dimensions (e.g. concreteness, effectiveness, spatial scale, object-like spectral structure features), which may contribute to the network-level encoding of acoustic knowledge and representations of different conceptual categories of sound.

Stimulus and perceived duration on electrophysiological correlates of auditory attention

Claude Alain Baycrest Centre, Canada; Michael Schutz; Ben Dyson

Models of temporal estimation focus on an accumulator model whereby attention can facilitate or inhibit the collection of time samples, leading to intervals perceived as subjectively longer or shorter than they actually are. Such experiments usually rely on the use of flat tones (like a touch-tone phone), which provide no information regarding stimulus length until after off-set. This contrasts with percussive tones (like two glasses clinking), whose attack and decay envelope provide predictive temporal information during presentation. Participants were played
3 standard sounds of a fixed length (750, 1000, 1250 ms) followed by a target sound either 25 ms longer or shorter than the standards, and asked to respond whether the target was longer or shorter. Within each trial, stimuli were either all percussive or all flat. ERP data were organised according to stimulus type (flat, percussive) and subjective duration (longer, shorter). Targets judged as subjectively longer were generally characterised by larger negativity (larger N1, smaller P2, larger contingent negativity varia-
tion [CNV]) than targets judged as subjectively shorter. The results also showed temporal and topo-
graphical interactions between stimulus type and subjective duration. Percussive sounds produced effects of subjective duration during early and later stages of stimulus presentation and at more frontal electrode sites, while flat sound produced effects later in the epoch and at more parietal electrode sites.

The data highlight the importance of stimulus selec-
tion in assessing temporal estimation and how the results derived from more ecologically valid stimuli might be different from those produced by laborato-
ry stimuli.

Sound predictability facilitates auditory scene analysis

Alexander Bendixen University of Leipzig, Germany

Many sound sources in a natural environment emit signals in a predictable manner over time, such as a train passing by that is characterised by a foresee-
able sound signature on a likewise foreseeable tra-
jectory. The auditory system is particularly suited

Genetic and environmental influences on execu-
tive functions: Spatial planning and spa-
tial working memory
Victoria Ismatullina Psychological Institute of RAE,
Russian Federation; Sergey Malych; Yulia Kovas;
Ivan Voronin

Genetic influences on executive functions have been
of increasing interest to psychologists in a wide
range of domains (Friedman et al., 2011; Gau &
Shang, 2010; O’Connor et al., 2009). Spe-
cific cognitive abilities such as processing speed,
working memory, spatial ability and verbal ability
have shown heritabilities that range from 30% to
60% in both young and elderly subjects (Singer et
al., 2005). We aimed our study at assessing the
executive functioning of interest – we used a compu-
ter version of the battery of neuropsychological tests
CANTAB "Eclipse", the “Stockings of Cambridge" (SOC) test. The sample included 61 pairs of monzygotic twins and 57 dizygotic same-sex twin pairs, aged from 11 to
17 years old (mean age 13.2). Model-ﬁ tting was
used to estimate the contributions of genetic and
environmental inﬂ uences; all analyses were con-
ducted in “OpenMX” software. The individual dif-
f erences in “Initial thinking” parameter were
explained by “shared environmental” (19%) and
“nonshared environmental” (81%) effects. “Addi-
tive genetic” (24%), “shared environmental”
(16%) and “nonshared environmental” (60%)
effects contributed to “Mean subsequent thinking
time” parameter. For the “Mean moves” parameter
21% was explained by “additive genetic”, 13% by
“shared environmental”, and 66% by “nonshared
environmental” effects.

Symposium title: Eye-tracking studies on reading different languages

Convenor: Prakash Padakkannaya

Multivariate analyses of fixation durations in reading with linear mixed and additive mixed models

Reinhard Kliegl University of Potsdam, Germany; Hannes Matuschek; Matthias Holschneider

Linear mixed models (LMMs) and generalized ad-
ditive mixed models (GAMMs) allow the simulta-
neous assessment of experimental effects and asso-
ciated individual differences. The presentation
illustrates how LMMs and GAMMs uncover dis-
tributed processing across fixations durations dur-
ing reading, that is spillover effects (i.e., processing
of an earlier word during fixations on subsequent
words) and paravelocal-on-foveal effects (i.e., pro-
cessing of upcoming words during fixations on
earlier words). The analyses focus on word-predict-
ability effects from prior sentence context and
word-frequency effects associated with the fixated
word as well as the words to the left and to the right of
the fixated word (word triplets); word lengths,
launch sites, fixation position in word, saccade
amplitudes and skipping status of the word to the
left and the word to the right are also taken into
account. Benefit and cost associated with LMMs
and GAMMs in comparison to traditional multivar-
iate statistical analyses will be discussed.

Eye-tracking studies on reading different languages

Prakash Padakkannaya University of Mysore, India; Prakash Prakash

While the vast majority of data on eye-tracking comes from English, such studies are increasingly
reported from other language milieus too. The
proposed symposium is an attempt at providing
a comprehensive view of reading research through
eye trackers in different languages such as En-
glish, Chinese, German, Thai, and Indian. There
will be four presentations in the symposium. Prof.
Keith Rayner, University of California at San
Diego, USA and Prof. Reinhold Kliegl, University
of Potsdam, Germany, who are among the most

Symposium title: Behavioral genetics: Looking back and looking forward

Convenor: Sergey Malych

The nature of fluid intelligence in Russian-
speaking adolescent twins
Philipp Barsky Tomsk State University, Russian Fed-
eration; Sabirova Elena; Davydova Yulia; Lobaska-
va Marina

The genetic bases of human intelligence have been
extensively studied in the frameworks of individ-
ual differences (Deary, Penke & Johnson, 2009),
behavioural genetics (Plomin et al., 2008) and
cognitive neuroscience since more than a century
ago. The aim of our study was to investigate
gene-environmental contributions to individual
differences in fluid intelligence in Russian-
speaking adolescents. The measure was Raven’s
Standard Progressive Matrices test. The sample
included 524 pairs of 10–17 year old male and
female monozygotic and dizygotic twins (mean age
= 13) from cities of Izhevsk, Tver, Moscow,
Saint-Petersburg and Bishkek. The statistical
genetic analyses were conducted using model-fitting
in OpenMX software. The results of model-fitting
generate particular environmental risk factors
in adolescence in Russian-speaking male and
female children.

Symposium title: Cultural/linguistic spec-
fications of cognitive functions for com-
munication

Speech perception by face and voice in speakers of Japanese and English

Kaoru Sekiyama Kumamoto University, Japan; Aki-
hiro Tanaka

One of well-known aspects of multisensory com-
unication is auditory and visual integration in face-to-face speech perception as demonstrated in
the McGurk effect in which heard speech is altered
by mismatching visual mouth movements. The sus-
ceptibility to the McGurk effect varies depending
on various factors including the intelligibility of
auditory speech. Here I focus on the language
background of perceivers as an influencing factor
on the degree of use of visual speech. When the
auditory speech is highly intelligible, native Japa-
nese speakers tend to depend on auditory speech,
showing less visual influence compared with native
English speakers. Such interlanguage differences
are not apparent at 6 years of age, but are developed
by 8 years due to increasing visual influence
in native English speakers. It seems that native En-
glish speakers developmentally acquire vigorous
lipreading ability such that adult English speakers
can lipread monosyllables faster than they can hear
them, while such visual precedence is not observed
in native Japanese speakers. This kind of interlan-
guage difference is being confirmed by event-relat-
ed potentials and functional magnetic resonance
imaging.
prominent researchers in the field, will be the lead speakers on the theme followed by Dr. Heather Winskel, Southern Cross University, Australia, and Dr. Prakash Padakannaya, University of Mysore, India. The specific titles and abstracts by the four participants are provided to the organisers separately.

**Reading Akshara through eye-tracker: Some beginnings**
Prakash Padakannaya University of Mysore, India
Eye tracking studies in Indian languages are still nascent. There are no eye-tracking studies available that focus on the orthographic features of Indian alphasyllabary. The grain size of akshara, grapheme in Indian writing system, stands for an open syllable, which can be processed either phonemically or syllabically. Aksharas are very shallow and also differ from alphabetic systems by being nonlinear with a complex visual-spatial layout. We present here some of our observations on akshara processing as understood by eye-tracking studies. We have attempted to estimate the perceptual span and basic eye movement measures like mean fixation duration, mean saccadic length, for aksharas and also have tried to probe some of the issues such as the information load in characters, akshara transposition effect, grammatical anomaly and semantic anomaly in text comprehension and unique markers that dyslexics display in reading. We highlight how Indian orthographic features influence reading measures and how such observations could be explained from a cross-linguistic perspective.

**Eye movements during reading Chinese and English**
Keith Rayner United States of America; Simon Liversedge
While the vast majority of data that exists on eye movements during reading comes from studies of English, it is also obvious that many readers throughout the world read languages other than English. There is now also a lot of data from other alphabetic writing systems (German, French, Finnish, Spanish). However, in many ways the most interesting comparison with English is Chinese. In this talk, I will review research on eye movements during Chinese reading and compare the results to those obtained with readers of English. Comments will also be made concerning other writing systems besides Chinese and English.

**Symposium title: Indigenous science and science education: Does culture matter?**
Convener: Douglas Medin

Indigenous science and science education: Does culture matter?
Douglas Medin Northwestern University, United States of America
Does the nature of (psychological) science and science education depend on who is doing it, or is science objective and value-neutral? Do scientists shed their cultures at the door in favour of a "culture of science"? If we concede that one’s culture affects how science gets done, then what makes science distinctive and different from pseudosciences? Is there a "unity of science" and one set of truths waiting to be discovered? This symposium focuses on these questions and their implications for science and science education practices. The symposium speakers come from three different continents and they bring a wide range of perspectives and experiences to these questions. Nonetheless there are some emergent and converging themes across these research programs that have clear implications for both the practices of science and science education. One conclusion, for example, is that common views of science in general and psychological science in particular embody misleading stereotypes. These stereotypes create barriers for both the learning of science and engagement with science as a profession. More specifically, the field of psychology is hampered by the fact that researchers and the researched have come predominantly from Western, industrially-saturated, middle-class, white cultures. The speakers place their work into this historical context and provide suggestions for addressing the consequences of this imbalance.

**The role of egocentric-updating in episodic memory**
Alice Gomez INSERM U562 Université de Neuroimag, France; Stephane Roussé
The relation between episodic memory and spatial function is generally conceptualised through a link between spatial and episodic memory.

**Symposium title: Remembering where you have been helps remembering what you have done: The shared neuro-cognitive basis between spatial and episodic memory**
Convener: Albert Postma

The shared neuro-cognitive basis between spatial and episodic memory
Albert Postma Utrecht University, Netherlands
Episodic memory concerns our ability to remember personal events, such as yesterday’s dinner or last week’s visit to the movies. It involves declarative, conscious memories of past activities and incidents, embedded within a spatiotemporal context. Interestingly, it appears to recruit partly the same brain structures as spatial memory. As such we may speculate that spatial memory has formed the evolutionary stepping stone from which the human episodic memory system originated. However, the link between spatial memory and episodic memory has only sparsely been examined yet, and how spatial learning and information contribute to recollection of one’s personal past is far from clear. The present symposium gives an overview of recent neurocognitive studies on the relation between spatial processing and episodic memory.

**From spatially tuned neurons to human memory systems**
Albert Postma Utrecht University, Netherlands; Christian Doeller

There has been considerable progress in identifying the specific characteristics of neuronal coding of space in rodents. However the exact contribution of spatially localised cellular activity to memory remains unknown. In my talk I will present results of experiments in which we combine functional neuro-imaging with virtual reality techniques in humans. We find evidence for spatial representations in human entorhinal cortex consistent with the firing of grid cells in rodents. Grid-cell like representations further support object-location memory and are found in a circuit of regions which markedly overlaps the network for episodic memory. In sum, our approach might contribute to a more coherent understanding of brain function from neural representations to systems-level involvement in behaviour.

**E cof effects of focal basalolateral amygdala damage on short-term and long-term episodic emotional memory**
Jack Van Honk University of Cape Town, South Africa; David Terburg

Many studies have shown that emotionally charged events are remembered with more clarity and detail
than neutral ones. The brain region most strongly implicated in emotional memory is the amygdala. The release of adrenal stress hormones is thought to facilitate memory consolidation, and the effect in particular depend on central actions of stress hormones in the basolateral complex of the amygdala. Dysfunction of the basolateral amygdala may thus induce selective forgetting of particular emotional information, but in humans there is scarce evidence for this hypothesis. Furthermore, it is still unclear whether these emotional memory effects are estab-
lished instantaneously or in the long-term. Here we present data of a group of five subjects with rare mis-mutation of the ECM gene, which results in selective bilateral calcification of the amygdala. We tested these subjects against a group of matched controls on short-term and long-term memory using standardized stories with emotional content. Our preliminary data show significant selective impairments of short-term emotional but not long-term emotional episodic memory in the basolateral amygdala-damaged subjects. This suggests that hormonal effects in the basolateral amygdala on episodic emotional memory set off to facilitate emo-
tional memory immediately. New data will also be presented on emotional spatial memory in these patients that might give further insights into the role of the basolateral amygdala in episodic emo-
tional memory.

Symposium title: Spatial mental models through the lifespan
Convenor: Valerie Gyselinck

Spatial mental models throughout the life-
span
Valerie Gyselinck Paris Descartes University, France
Spatial representations of physical surroundings may be built by viewing, hearing, touching, or moving around objects in the environment. How-
ever, they need not be built exclusively by a direct exploration of the environment, since humans have the capacity to construct abstract spatial represen-
tations through the use of symbolic supports such as language and maps. Both of these situations correspond to common real-life experiences, such as when we travel with maps or have to under-
stand or produce the verbal description of an itinerary. Spatial models may emerge from various sources and in various modalities (verbal, visual, navigation), and the comparison of these sources is a way to grasp some of basic common and di-
verging characteristics of spatial representations. It has been suggested that spatial models derived from one source (e.g. language) may be flexible enough to allow for the computation of representa-
tions that are equivalent to those elicited from other sources (e.g. a map). Positing the functional equivalence of spatial representations across input/ output and patients with imply that these represen-
tations are formed with the same ease. The cog-
nitive and linguistic capacities of the learner cer-
tainly determine his/her ability to construct an accurate spatial representation and to use it effi-
ciently, but to date little is known about this question. Some experimental studies show that the limitations of our working memory, verbal and visuo-spatial, may be of particular importance in this respect. Although much research has been
devoted to spatial representations in young adults, the nature of these spatial models and the ways in which they evolve throughout life from childhood (developing cognitive systems) to old age (declin-
ing cognitive systems) are far from being under-
stood. In addition, we do not know much about how children construct spatial models of itineraries and how these models change with increasing cognitive and linguistic development. We also do not know much concerning aging adults, who generally show a simultaneous decline in memory and spatial abilities, both of which are involved in the representations of itineraries. Gathering some well-known researchers of the domain, the objec-
tive of this symposium is to shed light on these questions.

Using virtual reality to assess multifaceted episodic memory: Studies in normal and pathological aging
Pascale Piolino Paris Descartes University, France
Within the multiple components of memory that together form a complete episodic memory, the spatial context is thought to be one of the most important. Episodic memory impairment is the hall-
mark of early clinical manifestations of aging. However, most neuropsychological assessments bear little similarity to the events that patients ac-
tually experience as memories in daily life. We used a virtual environment to characterise multifaceted episodic memory profiles in healthy young and older adults, patients with amnestic mild cognitive impairment and patients with early to moderate Alzheimer’s disease. The participants were success-
ively immersed as the driver of a virtual car (active exploration) and as the passenger of that car (pass-

eive exploration). Subjects were instructed to en-
code all elements of the environment as well as the associated spatio-temporal contexts. Following each immersion, we assessed the patient’s recall and recognition of the elements of the environment, temporal and egocentric and allocentric spatial in-
formation. We found that the patients’ performances were inferior to that of the healthy aged groups. Spatial allocentric memory assessments were found to be particularly useful for distinguishing patients with amnestic mild cognitive impairment from healthy older adults. Active exploration yielded enhanced recall of central and allocentric spatial information. Finally, the patients’ daily memory complaints were more highly correlated with their performances on the virtual test than with their performances on the classical memory test. Taken together, these results may provide additional in-
sight into the diagnosis and rehabilitation of patho-
logical aging.

Olfactory-visual interaction in infancy: Do (un)familiar odors influence how 4-month-
old infants look at familiar and novel faces?
Karine Durand University of Bourgogne, France
Benoist Schaal
We conducted two experiments to explore whether and how familiar and novel odors affect 4-month old infants’ responses to their mother’s or a stran-
ger’s faces. In experiment 1, we tested the effects of a familiar odor (the odor carried on a T-shirt worn by the mother) on face preferences. Infants were presented with their mother’s face paired with a stranger female’s faces while either exposed to their mother’s odor or not. Although, overall, infants looked longer at the stranger’s face regardless of the odor condition, they looked less at the stranger’s face in the presence of the mother’s odor than in its absence. In experiment 2, infants were presented the same visual stimuli as in Experiment 1 while exposed to the odor carried on a T-shirt worn by another mother, and a control T-shirt in counter-
balanced order. Results indicate that, in presence of any of the odor stimuli, infants looked less at the stranger’s face. In sum, our study showed that odors influence infant visual attention and modu-
late infant responsiveness to social visual stimula-
tion. These findings raise new questions about the heretofore largely unexplored role of olfaction in the development of multisensory perception and integration.

Visual exploration patterns of 8-month-old infants’ discrimination of facial expressions of emotion
Baudouin Jean-Yves University of Burgundy, France
The purpose of the study was to explore visual scanning behaviour of expressive faces in 8-
month-old infants. Thirty infants were familiarised with the neutral photograph of a female face, and then presented with expressive photographs of happy, angry, disgusted, fearful and sad of the same fe-

male face. Eye-movements were recorded and transformed to match a prototypical face, so as to allow seeing which facial parts were focused according to trials and facial expressions. The results indicated that 8-month-old infants paid at-
tention to different facial parts according to the emotions expressed by the faces, the features asso-

Symposium title: The acquisition of expertise in face processing
Convenor: Baudouin Jean-Yves

Plastic changes during development
Adelaide De Heering McMaster University, Canada
Plastic changes can be tracked during develop-
ment, aging, learning, or in clinical disorders. My work to date, on the development of face processing/recognition abilities and the role of experience in shaping these abilities, has used this

appproach. I have been testing newborns with very
little experience with faces and further investigat-
ed typically developing children’s processing of upright faces they experience everyday. I also conducted experiments with individuals having accumuluted visual experience with other-race faces (adopted children) or children faces (pre-
schooler teachers) and compared their results to those of age-matched controls with no such expe-
rience. I have been pursuing this line of research by contrasting children and preschoolers’ perfor-
mance when recognising upright (experienced cat-
egory) and inverted faces (non experienced categ-
ory). Overall, these results highlights the plasticity of the mechanisms underlying normal individuals’ abilities to process and recognise faces both in childhood and adulthood and empha-
sises the importance of everyday visual experience with upright faces.

Holistic processing as the key to human face perception expertise: Evidence from eye-gaze contingent stimulus presentation

Goedele Van Belle Université de Louvain, Belgium

Two views traditionally dominated face perception research. Analytical processing on the one hand, suggesting that faces are processed in terms of their individual components, and holistic processing on the other hand, suggesting that facial features are simultaneously perceived and integrated into a single representation, implying that a perceptual field covering the whole face. To test this, we gaze-contingently restricted the observers visual field in a face-matching task. In addition to a full view condition, faces were visible either through a gaze-contingent window, limiting the visual field to only the momentarily fixated feature, therefore forcing an analytical processing strategy (one feature at a time), or with a gaze contingent mask, continuously covering the centre of gaze, containing the most detailed, high-resolution information and therefore interfering with analytical processing. The task was used to study the influence of holistic vs. analytical processing for both the inversion effect and the face-processing deficit in three neurological patients suffering from a selective impairment in face recognition (acquired prosopagnosia). Forcing feature-by-feature analysis (window condition) decreased performance for normal observers, but not for the prosopagnosic patients, nor for inverted faces in normal observers. Forcing observers to rely on the whole of the face (mask condition), however, barely affected normal observers performance, while all three patients were massively impaired, and the inversion effect for normal observers increased. These observations indicate that face recognition expertise does not rely on the ability to process features analytically, supporting the view that the expert mind represents individual faces holistically.

The cognition of language: Comprehension and memory

Murray Singer University of Manitoba, Canada

There is extensive evidence that language comprehension is achieved by the application of fundamental cognitive processes to spoken and written messages. As a result, the understanding constructs multiple levels of representation of language form and meaning. This symposium presents contemporary analyses of the interplay of these processes and representations. The effective and ineffective application of attentional processes to comprehension are examined by Long. People’s ability to assess message coherence and detect anomalies at the syntactic, semantic, and pragmatic levels are addressed both by Singer and by Forstl. The abstract and sensorimotor bases of the representation of time and goal situations derived from messages is considered by Tapiero. Graesser describes a computer facility designed to analyze the multilevel representation of discourse, with emphasis on message cohesion. These studies converge in their fruitful application of behavioral, neural, and computational methodologies to these issues.

Validating explicit and implicit text statements

Murray Singer University of Manitoba, Canada

Monitoring the accuracy and consistency of sentence ideas is an essential aspect of comprehension. In keeping with the memory-based text-processing framework (e.g., O’Brien, Lorch, & Myers, Discourse Processes, 1998), it is proposed that these functions depend on message elements continuously providing memory cues for prior text ideas and relevant world knowledge. Suppose one has read, “It was very hot and Ken gobbled some apples.” Upon later encountering “The coach assumed that it was oranges that Ken ate,” the current sentence constituents are posited to cue the retrieval of the relevant, conflicting concept, “apples.” This enables the detection of a text discrepancy. Experiments confirmed that sentence reading times reflect these hypothesized verification processes in the form of interactions among variables of sentence syntax and discourse truth and pragmatics. The cognitive operations contributing to these tacit verification processes are argued to resemble those underlying intentional verification. Complementary electrophysiological (ERP) data that support this analysis are presented.

Symposium title: Visual perception: From experiments to modelling

Convenor: Galina Paramei

Dynamics of oculomotor direction discrimination

Doris Braun Giessen University, Germany; Karl Geiger-Fürnther

Primates use smooth pursuit and saccadic eye movements to track moving objects. Continuous foveation requires good estimates of target speed and direction. The pursuit system typically reaches an asymptotic direction precision similar to that for perception. We explored the dynamics of directional precision during pursuit initiation and initial saccades. We used a step ramp paradigm to obtain pure pursuit initiation, and a ramp paradigm to elicit an initial saccade. Instantaneous direction of eye motion at different points in time after pursuit onset were compared to the eye direction obtained for a purely horizontal stimulus. Oculometric functions for direction discrimination were constructed at each point in time. For the ramp paradigm we also calculated oculometric performance based on the endpoint of the initial saccades. In the step-ramp paradigm, it took about 400 ms after stimulus motion onset for pursuit to reach its minimum threshold of about 2 deg. In the ramp paradigm, initial saccades occurred at about 190 ms. The saccadic endpoint stimulated stimulus direction with a precision of 3.3 deg. At this time, about 100 ms after pursuit onset, pursuit oculometric thresholds for the step-ramp paradigm were still larger than 20 deg and took at least 100 ms longer to reach this value. We conclude that the saccade system reaches more precise estimates of target direction, presumably through the use of positional information that is not available for the pursuit system. Post-saccadic enhancement of eye movement precision might be caused by saccade-pursuit synergy.

Motor action affects memory, not perception

Bruce Bridgeman University of California, SC, United States of America

Embodied cognition posits that, since the function of perception is to control motor activity, that activity should also modify perception. There is evidence that success in a motor task changes the perception of the elements involved in the task, such as size of a baseball or a golf hole. But since the sizes in these cases are measured after completion of the activity, the effect may be on memory rather than perception. To address this issue, we had participants throw a ball into various sized holes in a panel in the frontal plane. They reported, in a haptic (experiment 1) or verbal manner (experiment 2), how large the hole appeared to be. For the haptic measure, participants indicated the size of the hole with their unseen fingers, recorded with video. The verbal measure was a forced choice from an array of hole sizes. Participants gave this report under one of three conditions: 1) concurrent with their throw of the ball; 2)
immediately after the throw, while the hole is still visible; and 3) immediately after the throw, while the hole is not visible. The results were divided into successful and unsuccessful trials. Size estimates were altered only in Condition 3 for both experiments, indicating that the effect of performance on perception occurs only after the act of throwing, in a style similar to memory.

Where we look determines what we see: Effects of fixation position on lightness perception

Karl Gegenfurtner, Giessen University, Germany; Matteo Valsecchi; Matteo Toscani

Humans are remarkably good at judging the lightness of objects even though variations in illumination, scene geometry, and surface texture can lead to massive variations of the light intensities reaching the eye. Low level factors such as lateral inhibition contribute to this ability, but a big influence of mid- and high-level factors depending on the interpretation of the scene has been shown as well. We show that the way we sample a scene with eye movements can have massive effects on perceived lightness. When observers matched the color of natural objects they based their lightness judgments on the brightest parts of the objects. These were also the most frequently fixated object regions, as observers tended to fixate points with above-average luminance. To investigate a possible causal link between fixations and lightness matches, we forced participants to fixate a specific point on the object using a gaze-contingent display setup. The matched lightness was higher when observers fixated a bright region of the object than when they fixated a dark region. We conclude that the way we perceive objects is driven by the way we look at them. More specifically, objects appear lighter when we look at their brighter side. We show that this is an efficient and simple heuristic for the visual system to arrive at accurate and invariant judgments of lightness.

Perception of 3D visual illusions

Galina Moshnikova, Lomonosov MSU, Russian Federation

We investigated the role of disparity cues in perception of visual illusions. For images transformed from 2D to 3D, illusory effect was reported as decreased or unchanged. According to scene-based theory (e.g., Gillam, 1978), decrease of illusion strength is due to the conflict between the depth cues and plane drawings. We hypothesised that adding disparity cues would resolve the conflict and increase the illusory effect. For visualising 3D scenes, we used virtual reality (VR) technique. Eighty observers (32 males, aged 17–30 y.o.) were tested. Geometrical, lightness and brightness illusions were presented as stereopairs and perceived as 2D (zero disparity) or 3D (three disparity values) configurations. Method of paired comparisons was used to estimate the strength of illusion: on each trial observers chose one of two stimuli, a longer one (geometrical illusions) or lighter/brighter (lightness/brightness illusions). For geometrical illusions, we found no difference for 2D vs. 3D configurations. For lightness illusions, the outcome depended on the test patches - background spatial arrangement. The illusion strength did not change when the test patches were coplanar but decreased when they were located at different angles to the background. The strength of brightness illusions increased for 3D compared to 2D configurations. Interpretation of the results in the framework of the multilevel model of illusion perception (Coren & Gircus, 1978), in combination with scene-based theory and anchoring theory of lightness perception (Gilchrist et al., 1999) suggests sensory and cognitive processing mechanisms, with the cognitive mechanisms playing an essential role in perception of 3D visual illusions.

Chromatic discrimination across the lifespan

Galina Parmal, Liverpool Hope University, United Kingdom

Ageing effects of chromatic discrimination were assessed using the Cambridge Colour Test (CCT) in normal trichromats of six life decades, 20–79 years of age. In each age group (20+, ..., 70+), equal number of subjects of both genders were tested. The CCT Trivector test estimated discrimination thresholds along the Protan (P), Deutan (D) and Tritan (T) confusion lines; the Ellipse test estimated parameters of MacAdam ellipses (major axis, major-to-minor axis ratio, angle of the major axis). For each life decade, we found no gender differences in the CCT outcomes. The Trivector test revealed significant increase of all three vectors after 60 y.o.; notably, Tritan discrimination loss underwent greater acceleration and, after 70 y.o., additional increase. The Ellipse test showed stretching of the major axes that reflect incremental elevation of thresholds. Also in the 60+ decade, significant major axis elongation was revealed and, in the 70+ decade, increase of the major-to-minor axis ratio but not any systematic changes of the Ellipse angle. The findings are consistent with the notion of generalised decline in chromatic sensitivity with advancing age and of greater vulnerability of the Tritan system (Werner et al., 1990; Knoblauch et al., 2001). Our earlier findings for a 20-59 y.o. cohort (Parmal, 2012) indicated that onset of noticeable deterioration of chromatic discrimination falls onto the 40+ decade. Results of the present, extended, study point out to the 60+ decade as manifesting significant loss of discrimination in the Protan, Deutan and Tritan systems, with the prevailing Tritan senescence effect.
mathematics and related cognitive and motivational traits. The cross-cultural comparison provides important new insights into the development of mathematical ability.

Representation of colour concepts in bicultural bilinguals  
Panos Athanasopoulos United States of America  
Previous studies demonstrate that lexical coding of colour influences categorical perception of colour, such that participants are more likely to judge two colours to be more similar if they belong to the same linguistic category (Roberson et al., 2000, 2005). Recent work shows changes in Greek–English bilinguals’ perception of within and cross-category stimulus pairs as a function of the availability of the relevant colour terms in semantic memory (Athanasopoulos, 2009) and the length of cultural immersion in the L2-speaking country (Athanasopoulos et al., 2010). The present paper extends previous investigations by looking at cognitive processing of colour in Japanese–English bicultural bilinguals. Like Greek, Japanese contrast blue and blue-green in that it has an additional monolexemic term for ‘light blue’ (mizuiro). The aim of the paper is to examine to what degree linguistic and extralinguistic variables modulate Japanese–English bicultural bilinguals’ sensitivity to the blue/light blue distinction. Results showed that those bilinguals who used English more frequently distinguished blue and light blue stimulus pairs less well than those who used Japanese more frequently. These results suggest that bilingual cognition may be dynamic and flexible, as the degree to which it resembles that of either monolingual norm is, in this case, fundamentally a matter of frequency of language use.

**Cultural differences in sensitivity to emotional cues**  
Keiko Ishii United States of America  
In the past two decades, research in cultural psychology has suggested that different practices across cultures encourage divergent modes of attention and perception. Whereas North Americans tend to attend more analytically to a focal object while ignoring its contextualisation, East Asians including Japanese tend to attend more holistically to both a focal object and its context (for review, see Nisbett, Peng, Choi, & Norenzayan, 2001). Recent studies focusing cultural variation in cognition have thus shed some light on idea, called New Look, that perception is significantly affected by endogenous factors such as expectations, values, and needs (Bruner & Goodman, 1947). In line with these studies on culture and cognition, we have investigated whether and to what extent culturally specific practices (e.g., high- vs. low-context communication practices) and values (e.g., personal control to influence events vs. adjusting to expectations to influence events) influence individual’s sensitivity to emotional cues and found that compared with North Americans, Japanese are more sensitive to vocal tone and more vigilant to the disappearance of smiles. Implications for future work on culture and the process of emotional cues are discussed.

**Cultural differences in emotion perception by face and voice**  
Akihiro Tanaka Tokyo Woman’s Christian University, Japan  
Nonverbal information from facial and vocal expressions plays an important role in social communication. Previous studies have shown that there are cultural differences in how multiple sources of information are combined within the same modality (e.g., Ishii et al., 2003; Yuki et al., 2007). Recent studies have shown crossmodal interaction between facial and vocal signals in emotion perception. Thus the very process of integrating emotional cues from different modalities may also be culture sensitive. Here I introduce our recent studies on the cultural differences in the multisensory perception of emotion by face and voice. A pair of dynamic face and voice, which expresses either congruent or incongruent emotions, was presented in the experiments. Participants were instructed to judge the emotion expressed in one of the two sources (face and voice) and to ignore the other. The result indicates that Japanese participants are more tuned to vocal processing than Dutch participants in the multisensory perception of emotion. Our findings provided the evidence that culture modulates the manner of the multisensory integration of affective information. The results are in line with the finding that the McGurk effect is weaker in Japanese than English speakers (Sekiyama & Tohkura, 1991).

Guilt in the brain: A multifaceted construct that guides moral behaviour  
Melike Fourie University of Cape Town, South Africa; Kevin Thomas; Ernesta Meintjes; George Ellis  
Guilt has been described as a quintessential moral emotion with an important regulatory function for the individual and society. Moral emotions are, however, difficult to study with neuroimaging methods, because their elicitation is more intricate than that of the basic emotions. To study real-time guilt with fMRI, we devised a social prejudice paradigm using a modified version of the Implicit Association Test. The paradigm employed preprogrammed feedback indicating implicit prejudice against Black and disabled people to elicit guilt in 22 low-prejudice individuals. Real-time guilt was associated with increased BOLD responses in areas implicated in mentalising, as well as in anterior paralimbic structures associated with increased emotional arousal. Prominent conflict-related activity in the supragenual ACC furthermore provided support for the association between acute guilt and behavioural inhibition. A noteworthy finding was the significant negative association between self-reports of guilt and the degree of activation in the pregenual ACC. These findings may reflect either decreased emotional reactivity, given that guilt was associated with increased heart rate, or individual differences in the modulation of affective pain. The latter interpretation is consistent with the hypothesis that medial prefrontal dysfunction contributes to the inability to suppress bad thoughts and memories in patients with affective disorders (Shin et al., 2004). Taken together, our results give credence to the notion that guilt is a multifaceted construct, including self-reflection, mentalising, the interruption of ongoing behaviour, and affect regulation, which together may serve to guide and direct moral behaviour.

**Symposium title: Expression and micro-expression: Studies and applications**  
**Convenor: Xiaolan Fu**

Duration of micro-expression: An event-related potential study  
Xunbing Shen Institute of Psychology, CAS, China; Xiaolan Fu; Qi Wu  
Micro-expression is a fleeting facial expression which is discordant with the expressed emotion and usually suppressed within 1/25 to 1/5 of a second. There is much inconsistency about the duration. To explore the neural evidence of the duration of micro-expression, we employed EEG measures and tried to identify brain regions involved in micro-expression processing using standard low resolution brain electromagnetic tomography (sLORETA). We set up four levels of durations. It can be said that the depth of the processing is an increasing function of the duration and there is a turn point after which it should be leveling off. Thus, we chose N400 as dependent variable, which can indicate the level of processing. Event-related potentials (ERPs) were computed for each combination of level of durations and congruent condition. The data showed that there were significant differences between pairs of 40ms and 300ms, 40ms and 200ms, 120ms and 300ms, which implies that, preliminarily, the proper duration of a so-called micro-expression should be 200ms or so. The sLORETA results indicated that the activation was highest in the occipital lobe at 290ms post-stimulus and also the highest activation in the frontal areas at 570ms after stimulus onset in the pairs of durations with significant differences. In a word, the results suggested that the appropriate duration in the definition of micro-expression should be less than 200ms, and the occipital lobe and the frontal areas were responsible for the significant difference successively.

Automatic micro-expression analysis  
Qi Wu Institute of Psychology CAS, China; Xiaolan Fu; Xunbing Shen  
In situations in which individuals are motivated to conceal or repress their true emotions, their facial expressions may leak despite their efforts to conceal them. These leakages can be very useful for deception detection and many of these leakages are manifested in the form of micro-expressions. However, it is difficult for humans to detect micro-expressions. Due to this incompetence, researchers have to manually inspect large amounts of videos in a frame by frame manner. This has become an impediment for micro-expression studies. The combination of computer science and psychology research fields can provide the technical adjuncts to assist researchers and practitioners in micro-expression analysis. In this paper, a novel approach for micro-expression recognition is presented. The system is based on the existing algorithms developed by the computer vision community. Some improvements were made to improve the performance of existing algorithms for facial expression recognition. Results showed that the efficiency of the training, classification, and feature selection process of
the algorithms were promoted. In order to accommodate the problem of micro-expression recognition, further modifications were included. The final system is fully automatic, and analyses videos frame by frame. As for micro-expression recognition, results showed that the system could be more accurate than trained human subjects in controlled conditions. A more thorough understanding of the human face perception process is necessary for developing a practical system which is robust across all situations.

Computer vision research for expression and micro-expression recognition
Guoying Zhao University of Oulu, Finland; Xiaobai Li; Matti Pietikainen; Xiaohua Huang; Tomas Pfister
Computer vision methods are used to analyse expressions and microexpressions. Video sequences are studied rather than the static images because the dynamic information they carry is proved to be effective for expression recognition. Spatiotemporal local texture features are utilised to describe the appearance and motion. A generic classification cascade was built to divide the facial expression recognition problem into subtasks including the following three key parts: 1) General expression recognition, including seven expressions: happiness, sadness, surprise, anger, disgust, contempt, and fear, are usually in the interests. Facial features are extracted in three facial components: mouth, cheeks and eyes of each face image. The effectiveness of each component is studied for specific expression. Partial occlusion is addressed by a sparse representation and feature fusion. 2) Microexpression recognition. Humans are good at recognising full facial expressions which present a rich source of affective information. However, psychological studies have shown that affect also manifests itself as micro-expressions. They are very rapid involuntary facial expressions which give a brief glimpse to feelings that people undergo but try not to express. A temporal interpolation model together with the spontaneous microexpression corpus enables to accurately recognise the very short expressions. 3) Differentiating spontaneous from posed facial expressions: Facial expressions can be broadly classified as either spontaneous (genuine) or posed (faked). A new spatiotemporal local texture descriptor outperforms other descriptors. Temporal interpolation and visual/near-infrared fusion methods are demonstrated to improve the performance.

Symposium title: Hemispheric asymmetry and cognition
Convenor: Pavel Ermakov
Participation of the hemispheres in detection of 1st- and 2nd-order visual stimuli
Vitaly Babenko Southern Federal University, Russian Federation; Denis Yavna Southern Federal University, Russia
Spatial variations of brightness are described by the first-order visual mechanisms. These are striate simple cells, realising linear filtering. The spatial variations of contrast, orientation or spatial frequency are detected by second-order visual mechanisms. However, the brain localisation of the latter is uncertain. We set a task to study the issue focusing on the role of the hemispheres in perception of the 1st- and 2nd-order visual stimuli. We applied an independent component analysis and that made it possible to localize parallel acting generators of the evoked brain activity. The visual evoked potentials (VEPs) were recorded in response to presentations of the unmodulated textures (the 1st-order stimulus) and the contrast, orientation or spatial frequency modulated textures (the 2nd-order stimuli). The observers determined the modulation dimension (the modulating parameter of texture) and absence of the modulation. 20 subjects took part in the experiment. It was found that the dipole sources are predominantly localised in the dorsal visual pathway of both hemispheres. The results suggest that the distribution of the evoked activity generators is similar in course of the processing of both the 1st- and the 2nd-order stimuli. However, responses to the presentations of the spatial frequency modulation were an exception. In this case the right-side laterization significantly increased as long as VEP is formed. The results show that contribution of the right hemisphere is greater in the case where the spatial frequency modulation is analysed. This fact may be related with that the spatial frequency modulation contains 3D information.

Interhemispheric interaction in participants solving verbal and nonverbal professional creative tasks
Liudmila Dikaya Southern Federal University, Russian Federation; Pavel Ermakov
The objective of our research is to investigate the differences in interhemispheric functional organisation of brain cortex in subjects solving verbal and nonverbal professional creative tasks. The study included 104 right-handed students and graduates of university at the age of 18–29 (42 males and 62 females). They were asked to perform professional verbal (to compose a poem, to formulate a scientific hypothesis) and nonverbal (to draw the original picture, to compose music) creative problems. EEG signals were recorded at three stages of creative problem solving: (1) At a preparation stage, (2) at insight stage, and (3) at the stage of checking from 21 scalp electrodes according to the International 10–20 System. EEG coherence in 6 frequency bands (from 4 to 35 Hz) was statistically analysed by ANOVA and post hoc analysis. The specific for each stage of verbal and nonverbal creative process intra- and interhemispheric links were revealed. Significantly higher coherence is revealed at high frequency bands in central and parietal regions at preparation and checking stages of nonverbal task solving as compared to verbal ones (p<0.05). Higher coherence is revealed at beta-2 band in right temporal area at the insight stage of verbal tasks solving as compared to nonverbal ones (p<0.05). We obtained significant increase of EEG interhemispheric synchronisation during insight at low frequency bands and parallel functioning of brain hemispheres at beta-2 band at the insight stage in participants independent of problem type.

Interhemispheric distribution of components of event-related potentials during false responses
Igor Dikya Southern Federal University, Russian Federation; Pavel Ermakov
The polygraph traditionally has involved measures of peripheral physiological manifestations thought to be involved in deception and lie, or to relate to guilty knowledge. And though people sometimes call a polygraph a lie detector it does not detect lies, but only physiological activity that is assumed to accompany telling a lie. Moreover the state of the checked person, his intellectual and character features, interhemispheric asymmetry and mode of thinking can influence reliability of results at revealing of the hidden information by means of a polygraph. So more recently attempts have been made to investigate alternative or additional measures of deception detection, for example, brain function with the help of such method as Event-related potentials (ERP). "Deception is a successful or unsuccessful deliberate attempt, without forewarning, to create in another a belief which the communicator considers to be untrue" [Vrij A., 2008, p. 15]. The purpose of our research is to study the dynamics of interhemispheric distribution of ERP components in different areas of brain cortex during realisation of false responses in experimental participants with different modes of thinking depending on interhemispheric asymmetry.
72 healthy right-handed student-volunteers (34 males and 38 females, mean 22.1 years old) took part in the experiment. The ERP-based in the oddball paradigm Guilty Knowledge Test was used in the present research. The aim of the Guilty Knowledge Test is to examine whether examinees possess knowledge about a particular crime that they do not want to reveal. We modeled a situation in which students had internal motivation to deceive. They were asked to make truthful or deceptive responses concerning whether they used the crib at passing an examination. Bioelectric brain activity was recorded using 21 argentiums chloride electrodes according to the international 10–20 standard. Mode of thinking (left-hand, right-hand, mixed and combined modes) depending on interhemispheric asymmetry was tested by means of a technique "A Choice of the side" by E.P. Torrens. We used statistical post hoc analysis to compare the ERP amplitude and latency in various areas of brain cortex and hemispheres in participants making false and truthful responses with different modes of thinking. ERP effects were found in different brain areas and in different temporal intervals (p<0.05). It has allowed us to create the neurocognitive model of deception which includes the following components: (1) Regulatory components (fronto-parietal attention network), (2) perception of relevant stimulus (higher level of P300 wave amplitude in left frontal brain cortical region), (3) processing of the perceived information (higher level of N400 wave amplitude in the region of Anterior Cingulate Cortex, a brain area that plays a vital role in cognitive control) and (4) decision-making on realisation of the false answer (occurrence of the expressed late P650 wave in parietal cortical region). Also N400 wave latency during realisation of false responses in the left and central frontal areas in participants with right-hand mode of thinking was significantly less, than in subjects with left-hand mode. P300 wave amplitude in the left frontal area in participants with left-hand and combined modes of thinking was significantly more in comparison with other participants of research (p<0.05). Studies measuring ERPs in the cognitive paradigm help to increase our understanding of the interrelations between brain aspects of deception. The positive-negative-positive complex reflecting distinctions of ERP waves am-
Hemispheric asymmetry of the evoked activity during search of the relevant visual information

Pavel Ermakov Southern Federal University, Russian Federation; Vitaly Babenko

Independent component analysis (ICA) makes it possible to find more objective information on the brain localisation of the ERP dipole sources. We used ICA to determine a contribution of hemispheres into the search of the relevant visual signals. 20 observers took part in the experiments. We recorded EEG during visual search. The subjects were looking for the modulated patch textures among the unmodulated. These second-order stimuli are detected by the mechanisms whose nature isn’t quite clear. We compared the results of two experiments: (1) The subjects knew the target in advance (it was the contrast-modulated texture) and (2) the subjects didn’t know the parameter (contrast, orientation or spatial frequency) was going to be modulated in the next presentation (the targets were alternated randomly). In both of the experiments the aim of observer was to detect a stimulus different from the others. The mean age was 18.6 years. The degree of expressiveness at examinees of asymmetry of touch and motor and mental functions (a profile of lateral organisation) makes an authentic impact on estimations of spectral power biopotentials at performance of arithmetic operations of mainly the right hemisphere (right occipital and parietal electrodes).

Motor influence of definite versus demonstrative determiner use in French language

Yann Coello University Lille Nord de France, France; Isabelle Bonnotte

Determiners preceding object-words play a crucial role in estimating the location of the object the words refer to. Recently, the use of linguistic descriptors, such as "this" and "that" in English, has been found to depend on visuomotor representation of space. However, definite determiners differ from demonstrative determiners in that they have no explicit spatial content. In the present study, we studied in the French language whether the use of a definite versus demonstrative determiner depends on how we categorise personal space in relation to action. The use of the definite "la" ("donne moi la tasse" - give me the cup) suggests that the object is at a known location or somewhere in the proximal space. In contrast, the use of the demonstrative "cette" ("donne moi cette tasse" - give me this/that cup) suggests that the object is at an unknown location in the distal space. We tested this assumption by asking adult participants to perform a lexical decision task about whether a determiner ("la" vs. "cette") followed by an object-word (e.g. "tasse" - cup) was correctly spelled or not. When correctly spelled, the participants had to perform a reachability judgment task of the primed objects presented in a virtual scene at different distances. The results show faster reachable judgments when primed by "la", and faster unreachable judgments when primed by "cette". Furthermore, the boundary of reachable space receded in space when the reachability decision was primed by "la". These results are discussed in relation to the embodied theory of language.

The role of the motor system in decoding speech

Alessandro D’Ausilio Italian Institute of Technology, Italy; Luciano Fadiga

Classical models of language consider an anteroposterior distinction between perceptive and productive functions. This dichotomy has been weakened because of empirical evidence suggesting a more integrated view. Passive listening to phonemes and syllables activates motor and premotor areas. These activations were somatotopically organised according to the effector recruited in the production of these phonemes. However, a feature of action-perception-theories is that motor areas are considered necessary for perception. In fact, it has been argued that in absence of a stringent determination of a causal role played by motor areas in speech perception, no final conclusion can be drawn in support of motor theories of speech perception. The mere activation of motor areas during listening to speech might be caused by a corollary cortico-cortical connection that has nothing to do with the process of comprehension itself. A possible solution might come from the selective alteration of neural activity in speech motor centres and the evaluation of effects on perception. Therefore, we designed a series of TMS experiments to tackle the causal contribution of motor areas to speech perception. We demonstrated that activity in the motor system is causally related to the discrimination of speech sounds and might be more critical under adverse listening conditions or when coping with inter-speaker variability. Interestingly, this functional association is somatotopically organized according to an effector-sound motor map. Listening to reproducible speech sounds might activate the same motor gestures necessary for production and thus help sensory classification and decision.

Impact of linguistic context on action, function information activation during object identification

Solene Kalenine URECA, France; Charlene Lee; Erica Middleton; Daniel Mirman; Laurel Buxbaum

A large body of evidence suggests that manipulable artifact concepts importantly rely on action and function knowledge. However, how and to what extent this information participates in object semantic processing is still an open question. This issue is particularly challenging when considering the many distinct action and function-related features a single object may have. We hypothesise a flexible, context-dependent involvement of those features in conceptual processing, and assume that semantic activation is sensitive to both context and feature type. In several recent experiments at MRRI (Philadelphia), we used eye-tracking in the Visual World Paradigm to assess linguistic context influence on incidental activation of various types of action and function-related information during object identification. In this paradigm, participants hear a target word and point to its referent among four object pictures. Gaze fixation time course on non-target objects signals the temporal dynamics of activation of the features shared between targets and non-targets. This paradigm is well suited to assess linguistic context influence on incidental semantic activation temporal dynamics. Target words can be embedded in contextual sentences that described different action goals. Using this methodology, we tested the effect of linguistic context on activation of distinct object action-related features (structural gestures, functional gestures) and several types of object use knowledge (thematic, specific functions, general functions). Subtle differences in semantic activation time...
course were detected as a function of feature type and linguistic context. These findings highlight the dynamic interaction between language and visuo-motor processes in semantic processing of manipulable artifacts.

The role of motor activation in building situation models from language
Rolf Zwaan Erasmus University Rotterdam, Netherlands
Language comprehension is commonly viewed as the construction of a mental model of the described situation, a situation model (Zwaan & Radvansky, 1998). To what extent does the brain’s motor system play a role in building situation models from discourse about actions? Most studies to date have focused on motor activation associated with individual words. Though useful, this does not tell us much about language comprehension. I will argue that a fuller understanding of the role of the motor system in language comprehension requires consideration of more complex and extended linguistic constructions. I will review recent neuroimaging (fMRI, EEG) and behavioural studies from my lab that have examined the role of the motor system in language comprehension. Specifically, I will focus on the role of motor activation in understanding intended actions, actions in the narrative past, figurative language, and extended discourse.

Cross-linguistic comparison of reading skills among Nyanja-English bilinguals in Zambia
Bestern Kaani Texas A&M University, United States of America
Zambian languages, like most African languages, exhibit high levels of orthographic transparency, and thus educational authorities have adopted seven widely spoken languages for school instruction at the first grade level before switching to English, the country’s official language, from the second grade onwards. This study compared reading performances among learners receiving initial literacy instruction in Nyanja, their mother tongue, and English, an orthographically opaque writing system. We expected performances to be significantly better in Nyanja compared to English. In this study, 109 participants (Grades 5–7) from a Nyanja-speaking region of Zambia received pseudo and real words, reading fluency passages and spelling word measures in both languages. Participants performed significantly better in fluency and single-real-world and decoding tasks in Nyanja than in English. Nyanja reading speeds were quite slow and laboured but more accurate while spelling skills were significantly better in English. Results on all of the assessments except fluency tasks provide support for Ziegler and Goswami’s (2005) findings. However, while Nyanja reading was significantly more accurate, it was less fluent. This could be because manipulations of letter-sounds take up more time than lexical skills. The results are not only for the applicability of the Psycholinguistic Grain Size theory in more transparent orthographies, but also for the importance of reading instruction in familiar language. Their failure to excel in Nyanja spelling could be attributed to greater exposure to English reading materials.

Cortical reading pathways in children learning to read two scripts
Nandini Singh National Brain Research Centre, India
The human brain though not inherently “wired” for reading, is known to develop a distributed network to master reading during the learning period. Earlier studies on how the developing brain learns to read have focused on reading networks in monolingual children; little is known about how a developing brain simultaneously accommodates networks for reading multiple scripts. The current study uses functional neuroimaging (fMRI) to uncover cortical pathways for reading in children learning to read Hindi, written in Devanagari and English, written in the Roman script. Cortical activations were obtained while 20 right-handed children in the age range 8–10 years performed an fMRI reading task in English and Hindi. There were blocks of word reading where subjects read 80 high frequency words in English and Hindi alternating with rest, during which the subjects fixated on a string of symbols. Behavioural measures consisted of vocal reaction times for word reading in the two languages. The reading networks for English and Hindi in young readers were found to share a basic pattern with bilateral activations in superior temporal gyrus, middle temporal gyrus and fusiform area. Word reading in English showed extensive superior temporal activation and was more left dominant than word reading in Hindi which activations were more bilateral. Extensive bilateral motor and cerebellar activations were also seen while reading both languages.

Cognitive and linguistic impact of early language brokering experience: Spanish-English speakers in Texas
Jytosna Vaid United States of America
Three experiments were conducted to examine the impact of early childhood informal translation experience (so-called “language brokering”) on proficient Spanish-English bilinguals’ subsequent meta-linguistic awareness and conceptual organization in young adulthood. In two of the three tasks examined (accessing literal vs. figurative meanings of phrases and sound segmentation of cross-language homophones) bilinguals with prior brokering experience performed faster and with more sophistication than bilinguals with no brokering experience. No group differences were obtained on a measure of conceptual organization (category exemplar generation). The findings are discussed in the context of their significance in shifting the focus away from bilingual/monolingual comparisons to intra-bilingual differences in mental functioning arising from early language experience in language brokering, a phenomenon that is particularly common in immigrant families.

Symposium title: Multifaceted autobiographical memory and the brain
Convenor: Pascale Piolino

Neural substrates of self memory system: New insights from a meta-analysis
Spedutti Marco France
The self has been the topic of philosophical inquiries for centuries. In line with neuropsychological data the declarative self can be fractionated in three functionally independent systems processing personal information at several levels of abstraction going from episodic memories of one’s own life (EAM), semantic knowledge of facts about one’s own life (SAM), to semantic summary representations of one’s personal identity (CS). Even if the self and memory systems interconnection has been well established, works on the neural correlates of the self have concerned mainly the more abstract level, while the more concrete levels have been quite exclusively considered in the scope of memory research. Our proposal here was to present a comprehensive description of neural networks underpinning self-representation. With this aim we performed three for EAM, SAM and CS. We expected a shift from posterior to anterior structures associated with the gradual abstraction level of self-representation. The key finding was that EAM predominantly activated posterior and limbic regions including hippocampus. SAM was associated with anterior activations, and also posterior and limbic activations in a lesser degree compared with EAM. CS mainly recruited medial prefrontal structures. Interestingly, medial prefrontal cortex was activated irrespective of the level of abstraction but a more caudal part was recruited during CS while SAM and EAM activated more rostral portions. To conclude, in line with previous proposals, our results corroborate the idea that the declarative self is not a monolithic but rather a multidimensional construct.
Comprehension in normal aging? Neuro-functional process underlying autobiographical deterioration

Pascale Piolino Paris Descartes University, France

Two levels of representation can be distinguished within autobiographical memory (AM): episodic AM (EAM) and semantic (SAM). Several studies have shown a selective deterioration of EAM in normal aging, but the underlying neuro-functional process is still controversial. Two hypotheses emerge from the literature: The compensation hypothesis (CH) postulates the over recruitment of different brain circuits in older people while the dedifferentiation hypothesis (DH) states that older people would fail to activate a specific circuit for different kind of memories. We registered, using fMRI, the brain activity of 20 young and 17 older volunteers while they were engaged in the recuperation of episodic or semantic autobiographical memories. An imaginative task was used as a control condition. In both groups, AM conditions recruited several areas previously reported in the literature comprising: The medial prefrontal cortex, the precuneus and medial temporal lobe structures. EAM, compared with SAM, in young subjects recruited to a greater extent the anterior cingulate cortex (ACC) and right hippocampus. These differences were not reported for older subjects. Interestingly ACC was the only region showing an interaction between group and memory condition. This area was in fact specifically activated in young subjects for EAM condition. Our results seem to support more the CH than the DH. In fact, we did not find any regions showing increased activity in older compared with young subjects. Moreover, specific activity for EAM in the ACC reported in young subjects was not found in older people.

Perceptual richness of autobiographical and laboratory episodic memory and the hippocampus

Marie St-Laurent Rotman Research Institute, Canada

Perceptual richness, the reliving of multi-modal sensory details that accompany recollection, is a defining feature of memory for personal life episodes. The medial temporal lobe (MTL) is essential to episodic memory retrieval, although the features that determine its engagement are not well characterised. We assessed whether perceptual richness mediates MTL involvement during episodic memory retrieval. Participants encoded laboratory episodes with rich (film clips) and impoverished (written narratives) perceptual content that were matched for other characteristics such as relevance, emotionality and story content. Participants also recalled autobiographical memories (AMs) in a comparator condition. They had a few seconds to retrieve an AM or a laboratory memory, and they described its content and perceptual features in their own words. We compared performance between controls and patients with medial temporal lobe epilepsy (mTLE), a condition that affects the integrity of the MTL. Controls retrieved a greater number of perceptual details in the film condition than in the narrative condition, but this difference was greatly reduced for patients. Perceptual details were also reduced for AM in patients. In a parallel fMRI study, we identified brain regions whose activation was greater during AM and film clip retrieval than during narrative retrieval, indicating a sensitivity to perceptual richness. Such regions included the anterior portion of the right hippocampus. In patients with right mTLE, activation was reduced across those regions. Together, our findings indicate that the right medial temporal lobe is central to the neural circuitry supporting the integration of perceptual details into complex episodic memories.

The shielding function of task sets

Gesine Dreisbach University of Regensburg, Germany

In a dynamically changing environment, cognitive control refers to the ability to direct attention towards relevant information and shield against irrelevant information. In my talk, I will present results from different studies, showing that task sets (i.e., simple binary categorisation rules) modulate the control of attention and action: Categorisation rules (for example: Round objects - left reaction, angular objects - right reaction) as compared to simple stimulus-response rules (e.g. circle - left reaction, ellipse - left reaction, square - right reaction etc.) help to direct attention towards task-related information, thereby reducing the influence of task-unrelated information. These results are taken as evidence for the shielding function of task sets. Furthermore, I will show that this shielding mechanism is temporarily relaxed in the course of task switching. The results supporting the assumed shielding function of task sets will then be discussed with respect to its underlying processes. I will argue that task shielding follows from the enhanced processing of task set related information thereby reducing the influence of unrelated information. Such a mechanism would be highly adaptive because at least outside the lab - task related information more often than not is also task relevant information. Moreover, a shielding mechanism, based on enhanced processing of task related information might also circumvent the selection problem between relevant and irrelevant information by processing just any information that matches the currently active task set.

Measuring task-sets by using the instruction-based task-rule congruency effect

Baptist Liefooghe United States of America; Jan De Houwer

Multiple-goal management as investigated in task-switching procedures is often assumed to be based on a task-set, which is a representation of the control settings for processes such as stimulus identification, response selection and response execution. Although task-sets play an important role in many theories of task switching, their functional characteristics remain rather vague. In the present talk a novel approach will be introduced in which it is believed that the formation and characteristics of task-sets can be investigated, and this while avoiding the traditional pitfalls of task-switching research. More precisely, we investigated task-sets that were never applied before and that were only formed on the basis of instructions in the context of a prospective-memory task. We tested if such task-sets could elicit a task-rule congruency effect, which consists of the automatic activation of responses in the context of another task. We will first demonstrate that task-sets, which are solely formed on the basis of instructions, can elicit such effects offering a marker for further investigating the nature of task-sets. Second, we will demonstrate that the size of this effect depends on the level of task-set activation. Third, manipulations will be shown indicating how our procedure can be used to obtain a more fine grained view on task-sets. Implications for research on task-set formation and for research on multiple-goal management in general are then considered.

Multiple goal and task management

Julia Vogt Ghent University, Belgium

In everyday life, individuals pursue multiple goals and tasks, such as having to finish and switch between various tasks at work, or combining work and private life. Because time and resources are limited, multiple goal and task management often requires giving priority to one task and consequently “shielding” this task from interference by other goals and tasks. However, functional goal management also needs flexible shifts between different tasks when goal priorities change. Several approaches from different psychological disciplines have examined multiple goal and task management. The aim of this interdisciplinary sym-
positual model in a virtual environment. Young adults were presented routes in a virtual town and had to perform a series of tasks at the end of the learning phase. Concurrently, participants had to perform a spatial tapping task, an articulatory task or no task. Various tasks were used to assess the spatial representation built. The results showing interference effects indicate that spatial working memory is involved in the memorisation of information tackled by all the tasks except the visual recognition of landmarks. Interestingly, the results suggest that verbal working memory is involved in certain types of information (choice of directions and location of landmarks), but not in visual recognition of landmarks, nor in the drawing of the path on a map. Thus, even when both the learning material and the tests used to assess performance are only visual, a verbal recoding of some information seems necessary. Moreover, the results indicate that individual differences modulate the involvement of working memory. Individuals with higher visuo-spatial capacities use more spatial working memory than individuals with lower spatial capacities, confirming previous results obtained with spatial verbal descriptions.

The impact of instant feedback on ability test performance

Andreas Lohff | Cut-e Group, Germany; Maike Wehrmaker; Katharina Locher; Achim Preuss

Performance on ability tests is not only a function of ability, but also of other factors, like test takers’ own perception of their performance (Tonidandel, Qiñones & Adams, 2002). This perception can be influenced by instant feedback given during the test administration. N = 602 participants in our study were divided into two groups that both worked on different adaptive ability tests: One group received instant feedback after each item processed, the other group did not receive feedback during the test administration. We found that the feedback changed participants’ processing style: Poor performers increased in speed with instant feedback. Furthermore, reliability and face validity was higher for the administration with feedback compared to the administration without feedback. Thus, instant feedback during test administration seems to have a significant impact on test performance and on test quality criteria, an important finding because modern technology allows for instant feedback during test administration. The impact of further determinants of performance in intercultural online assessment is discussed based on various international online assessment samples.

**Symposium title: Spatial mental models through the lifespan**

**Convenor: Valerie Gyselink**

Verbal recoding in the construction of a spatial model in a virtual environment

Valerie Gyselink | Paris Descartes University, France; Doriane Gras

In two experiments, the construction of a spatial model from a visual input (a virtual environment) was considered, and the implications for working memory components studied via a dual-task paradigm. Spatial knowledge can be acquired from navigation and from other different sources. In particular, human beings have the capacity to construct abstract spatial representations through the use of symbolic supports such as language. We will examine the role played by spatial ability, visuo-spatial working memory, cognitive styles, and strategies in spatial text processing and navigation. Data will be presented in support of a model of spatial learning where personal characteristics, sources of learning and tasks interact in affecting memory for spatial texts and navigation. The outcomes will be discussed at the light of theories of spatial learning. Moreover, we will provide suggestions for the implementation of navigation devices suited on the cognitive and strategic characteristics of their users.

Spatial abilities in the elderly

Jansen Petra | Institute of Sport Science, Germany

In two studies it has been demonstrated that the spatial mental model of the elderly did not degrade completely with increasing age. The performance of mental rotation in regard to visual-spatial ability (study 1) and spatial learning and the acquisition of spatial knowledge (study 2) were investigated in young (20-30 years), middle-aged (40-50 years), and old adults (60-70 years). For the first study mental rotation performance was tested with a psychometric and a chronometric mental rotation test in a total of 150 adults (Jansen & Heil, 2010). In both tests the performance decreased with age. The second study was conducted with 60 adults in a virtual environment. Participants had four tasks to learn a route through a virtual maze (spatial learning), to find the previously learned route correct route without landmarks (route knowledge), to recall landmarks that were present in the maze (landmark knowledge), and to draw an overview of the maze (configurational learning). The results showed a general decline with age in spatial learning and in configurational knowledge. There was no age dependent difference in landmark knowledge between the middle-aged and older adults, and no age dependent difference in the retrieval of route knowledge between all three age groups (Jansen, Schmelter, & Heil, 2010). The roles of general learning and memory processes need to be discussed as contributing factors to the degradation of spatial mental models in the elderly.

**Symposium title: The cognition of language: Comprehension and memory**

**Convenor: Murray Singer**

Semantic integration in text comprehension: Evidence from fMRI and TMS

Evelyn Forstl | Freiburg University, Germany

Neuropsychological and neuroimaging studies of text comprehension have added to our knowledge of communication in context. In this talk, I will give an overview of neuroscience studies on inference processes, semantic coherence, and linguistic cohesion. The first experiment used fMRI to delineate the role of gender stereotype information and implicit verb causality bias for pronoun resolution. The results showed increased activations in a wide network of brain regions when a pronoun required reassignment of the expected gender to a noun phrase (e.g., car mechanics are stereotypically male).
This network, involved in the processing of semantic inconsistencies, included the precuneus and the right prefrontal cortex, but also posterior temporal and parietal areas. In the second experiment, transcranial magnetic stimulation (TMS) was applied to posterior temporal regions bilaterally to disrupt the semantic integration of words into the sentential context. The results showed increases in reaction times for a plausibility judgment after left- but not after right-sided stimulation. However, this finding obtained only for successful integration, but not when an anomalous word had to be rejected. Taken together, these results confirm the importance of the left posterior temporal lobe for text comprehension and sentence integration.

The relation between comprehension and computerised metrics of text complexity

Arthur Graesser University of Memphis, United States of America

Discourse psychologists have identified multiple levels of language and discourse in theoretical analyses of printed and oral discourse. Multilevel theoretical frameworks have analyzed meaning by differentiating the levels of words, syntax, the explicit textbase, the conceptual situation model, genre and rhetorical structure, and pragmatic communication. We have developed a computer facility called Coh-Metrix that automatically analyzes text on measures associated with all of these levels, except for pragmatic communication. When a principal components analysis was conducted on nearly 40,000 texts, 8 factors were closely aligned with the theoretical levels, accounting for 67.3% of the variance on differences among texts. Three of the components captured narrativity (a dimension of genre), syntactic simplicity, and word concreteness, whereas the other five captured different aspects of text cohesion. This presentation discusses the extent to which these principal components can predict reading times, text memory, engagement, and other measures of text comprehension. The presentation also discusses how Coh-Metrix components predict psychological measures of oral discourse of political leaders, tutorial dialogues, and multiparty interactions in chat rooms.

Comprehension as a dynamic process: How intentions and duration of events are represented

Murray Simpson University of Manitoba, Canada

Embodied cognition addresses the processes of discourse comprehension, and particularly how intentions and duration of events are represented in memory. This view posits that the representation of language and therefore, its comprehension, is related to an internal motor simulator. In line with this view, neuronal structures involved in the execution of actions should be also involved in understanding the same actions displayed in a linguistic form. This framework is supported by the discovery of the mirror neurons with the macaque (Gallese, 96; Rizzolatti, 96). In people, these neurons underlie both the production and comprehension of the same action (Buxbaum, 2005) and that they would not only code the motor act but also what in a specific context should occur, leading to facilitate the prediction of subsequent events (Fogassi, 2005). Consequently, predicting actions and the corresponding intentions could be supported by the same mechanism of internal motor simulation. In my paper, I assume that this simulation mechanism could be extended to several dimensions of readers’ mental representation, such as intentional-ity and temporality. In that vein, understanding others’ intentions and the duration of observed events that are described in short texts or stories should arise from simulating them. To test our assumptions we will present several experiments that will support our hypothesis. We will extend our results by focusing on the deficits of this simulation mechanism for patients who showed numerous difficulties of social cognition, such as schizophrenia or autism.

Symposium title: The role of human basolateral amygdala in cognition, emotion and social behavior
Convenor: Jack Van Honk

Effects of focal basolateral amygdala damage on short-term and long-term episodic emotional memory in humans
Jack Van Honk University of Cape Town, South Africa; David Terburg; Barak Morgan

Many studies have shown that emotionally charged events are remembered with more clarity and detail than neutral ones. The brain region most strongly implicated in emotional memory is the amygdala. The release of adrenal stress hormones is thought to facilitate memory consolidation, and the effect in particular depend on central actions of stress hormones in the basolateral complex of the amygdala. Dysfunction of the basolateral amygdala may thus induce selective forgetting of particular emotional information, but in humans there is scarce evidence for this hypothesis. Furthermore, it is still unclear whether these emotional memory effects are established instantaneously or in the long-term. Here we present data of a group of five subjects with rare mismutation of the ECM gene, which results in selective bilateral calcification of the amygdala. We tested these subjects against a group of matched controls on short-term and long-term memory using standardised stories with emotional content. Our preliminary data show significant selective impairments of short-term emotional but not long-term emotional episodic memory in the basolateral amygdala-damaged subjects. This suggests that hormonal effects in the basolateral amygdala on episodic emotional memory set of to facilitate emotional memory immediately. New data will also be presented on emotional spatial memory in these patients that might give further insights into the role of the basolateral amygdala in episodic emotional memory.

Symposium title: Time perception: Contemporary perspectives on psychological time
Convenor: Simon Grandin

Temporal event-coding of schizophrenic patients
Anne Giersch INSERM, France

Results observed in patients with schizophrenia question the mechanisms underlying temporal event-coding. At a clinical level these patients display a disturbed sense or continuity. Experimentally, they are impaired in duration judgments, but also in discriminating between simultaneous and asynchronous events. However, recent studies showed that ‘simultaneous’ responses are not associated with a fusion of events in time. During the tasks, subjects decided whether two squares were displayed simultaneously or asynchronously, and gave their response by hitting a left or right response key. We repeatedly showed that when stimuli are asynchronous and displayed on opposite sides, manual responses are biased to the side of either the first or second stimulus. Such a bias allows to explore the implicit processing of asynchronies when those are not explicitly detected by subjects. Results have been replicated in four studies and show that patients distinguish events in time at an implicit level even when explicitly judging such events to be synchronous. In addition, their implicit responses differ qualitatively from those observed in controls, for asynchronies as short as 8–17 ms. There is a clear dissociation between results at short and large asynchronies, that question the mechanisms underlying the implicit coding of events in time, not only in patients, but also in controls. We will review arguments for a selective and implicit coding of time-event structure.

Time perception: Summary of the symposium

Simon Grandin Université Laval, Canada

Adaptation to everyday life is made up of all sorts of temporal requirements. In this symposium, some of the numerous research avenues emerging from these requirements are reviewed. We will review how to code events in time - simultaneous vs. asynchronous - and how studying patients with schizophrenia inform about the mechanisms involved in this temporal coding. We will also try to understand what determines the subjective experience of time. It will be shown that saccadic eye-movements as well as emotional experiences exert influence on our assessment of duration. We will see if psychological time is rooted in spatial representations, and if time perception obeys a law that is a classical one in the field of sensation and perception.

Weber’s law for time: The meaning of failure
Simon Grandin Université Laval, Canada

The scalar expectancy theory is one of the most influential contemporary theories of time perception. According to this theory, the variability to time ratio, or Weber fraction, should be constant over a wide range of durations. In other words, the Weber’s law for time should hold. However, there is quite a bit of evidence in the timing and time perception literature that this fraction is not constant. This presentation proposes a close look at the Weber fraction for very brief intervals (less than 2 seconds), and this look indicates that, in many different experimental conditions involving human participants, this fraction is not constant. Implications of this violation of Weber’s law are discussed.

How emotions influence our perception of time
Annett Schirmer National University of Singapore, Singapore

Everyday experience tells us that our sense of time is not fixed. The same event may seem longer or
shorter depending on how we feel about the event itself and other events that are going on concurrently. That feelings or emotions influence our sense of time has also been demonstrated in the laboratory and different theories have been proposed. To decide between these theories, we conducted a series of experiments that used new approaches to study the relationship between emotions and time. For example, we employed a S1/S2 discrimination paradigm in which a picture of emotional or neutral valence appeared between the criterion (S1) and the probe stimulus (S2). Furthermore, we tested the relationship between emotions, eye-movements, and timing and examined the subjective duration of emotional and neutral events that occur separately and concurrently. The results of this work indicate that none of the current emotion theories sufficiently explain the data. Therefore, a hybrid model is proposed that refers to stimulus-specific and sentential representations as mediators for the relationship between emotions and time.

The mental time-line during linguistic information processing

Rolf Ulrich
Universität Tübingen, Germany

The idea that thinking about time is rooted in spatial representations has long been an inquiry in philosophy, linguistics, and psychology. Consistent with this view, several studies support the psychological reality of a mental time-line that runs from the left to the right. Our experimental research addresses the question whether this time-line is also involved in the processing of linguistic information as strong theories of embodied cognition would suggest.

Symposium title: Treating cognitive disorders: Challenges and advances (British Psychological Society session)
Convenor: Susan Gathercole

Working memory training: Does it work?
Susan Gathercole
MRC Cognition and Brain Science, United Kingdom

There have been reports of substantial and sustained benefits in working memory following intensive training in a variety of populations in recent years. As working memory deficits are closely associated with poor academic progress in key areas such as reading and mathematics, this has raised considerable interest in the potential of these training programmes to prevent and overcome learning difficulties. Findings regarding the critical ingredients of training programmes and the extent of their transfer to educationally-relevant abilities in different populations will be reviewed. Current evidence indicates that in some populations such as children with ADHD and those with low working memory but no recognised learning difficulties, adaptively-based training delivered at sufficient intensity does lead to generalised improvements in memory performance. However, consequent gains in educational progress have yet to be reliably established. In groups whose working memory problems are likely to be caused by processing difficulties rather than in the executive control of memory, the gains are likely to be more restricted. Ways of promoting transfer of training benefits to working memory needs in a broad range of classroom activities will be discussed.

Facilitating generalisation in cognitive rehabilitation

Tom Manley
United Kingdom

Cognitive rehabilitation sometimes involves people developing skills on a training task. The hope is that this will then be applied beneficially during everyday activity. With the availability of personal computers making long periods engaged in such training increasingly possible, it is important to assess whether such generalisation to everyday life occurs and, where possible, to directly facilitate it. With specific reference to an executive function, I will discuss the evidence that systematic guided practice on problem-solving tasks can produce improvements in function; at least as assessed shortly after the training, often in the same context in which the training occurred. I will discuss the barriers to generalisation such as patients’ difficulty in extracting from the particular to the general and tendency to lose track of their intentions. I will describe our own studies that have used text (SMS) messaging to help export key messages from therapy into participants’ daily lives and argue that goal-setting plus cueing may be an important tool in executive function and other forms of rehabilitation.
Research Area: Community

Session Type: Papers

Social action as community resilience: Implications for violence prevention in post-Apartheid South Africa

Eduardo Almeida; Universidad Iberoamericana Puebl, Mexico

Psychoanalysis’ main scientific claims have usually been related to the unconscious, to the first years of individual life, and to sexual drive. The three aspects are undoubtedly referred to the intrapsychic. However, according to Igor Caruso, psychoanalysis is intersubjective once it becomes conscious, then it deals with the analysis of reciprocal social relations. Following from that lead, the author of this paper argues, based on his long-standing relationship with community experiences, that there is a need to include a stronger intersubjective perspective in order for psychoanalysis to become a more useful approach in dealing with community issues. This implies a decisive commitment through a concrete praxis. Community Psychology will be enriched by the socioanalytical intuitions developed after Freud. The paper includes a conceptual review of the ideas of subject, subjectivity and intersubjectivity, the intersubjective perspective of several psychoanalysts, and two intersubjective community interventions. The purpose of the paper is to stress the importance of the social relational in human life.

Experiences of suicide attempters in Ghana: What role does religion play?

Arlene Benjamin

Community counselors’ experiences of healing in a continuously traumatising community

Ronelle Carolissen

The rate of violence in South Africa is amongst the highest in the world and impacts every life in South Africa. Much of this violence is disproportionately skewed geographically, in that poorer and historically disadvantaged communities tend to bear the brunt of the violence. Hanover Park is one such community and is notorious for its high levels of community violence. CASE (Community Action for a Safe Environ, South Africa) community counselors live and work in this community. Only a few studies have explored the experiences of community volunteers and even fewer studies have explored the experiences of community counselors who work and live in disadvantaged communities that experience high levels of violence. The design is a purposive case study of each counselor which will provide an empirical inquiry investigating the narratives they provide of their lives within its real-life context. Follow-up focus groups held with the counselors were guided by ideas and practices of narrative theory. The perspectives of community counselors provide insight into evidence-based interventions from a community-based level. It provides insight into how healing takes place and the multi-systemic nature of the healing process in the face of an ongoing violent environment. Counselor experiences in this particular geographical and social setting, examine the complex meshing of individual, interpersonal and social aspects of trauma and healing in disadvantaged communities.

Promotion of psychological well-being of caregivers in children’s homes in South Africa

Some South African studies suggest how the hidden curriculum during psychology training discursively constructs professional psychologists and psychology as neutral and disconnected from social and political identities. Few studies have however explored how practicing psychologists experience normative constructions of community and identities in their work environments. This paper focuses on how senior psychologists talk about their everyday experiences of community, their identities and experiences of legitimacies as psychologists in South Africa. Three focus groups were conducted with 17 senior psychologists in the greater Cape Town area who have been practicing for at least 12 years. Discourse analysis was used to analyse focus group transcripts. The results suggest that boundaries of difference in terms of race, gender, training institutions and types of professional activities contribute significantly to how qualified psychologists (as opposed to trainees) are afforded “professional legitimacy.” The implications of these implicit knowledges about professional identities for community psychology and psychology are discussed.

A comparative study of citizen participation

Yongsheng Chen

Citizen participation on the demographic variables to predict citizens’ participation in the demographic variables of age, educational degree, time of residence, number of children and degree of religious beliefs, especially among which the scores of religious citizens on the full scale and the three scales were significantly higher than those of the nonreligious. The differences between genders were not significant; (2) Using a regression analysis, the authors examined the prediction of the six demographic variables to predict citizens’ participation, and found 5 variables to enter into the regression equation; of which the time of residence could best predict citizen participation.

Promotion of psychological well-being of caregivers in children’s homes in South Africa

Narainsami Chetty

This study, which examined the promotion of psychological well-being of caregivers in childcare institutions, was addressed a gap in local community psychology research during the period 2001 to 2006. The investigation was predicated on the mental health promotion model and grounded in Zimmerman’s Empowerment theory (1995). A convenience sample of caregivers from two children’s homes were assigned to an experimental and a control group. A triangulated research design was employed. The Maslach Burnout Inventory (1986) was used to measure the pre and post test well-being outcomes. There was a systematic intervention process with the experimental group. Qualitative techniques complemented the research strategy. The data from these qualitative techniques gave the research greater validity, enriched the study and
were critical especially in the light of the moderately significant results. The findings indicated minimal change in the pre and post test Maslach Burnout Inventory scores of caregivers. However, the descriptive qualitative measures suggested appreciable levels of improved psychological well-being by the experimental group of caregivers which can be attributed to the comprehensive empowerment intervention.

Discontinuities in the social positioning of women informal street traders in post-apartheid South Africa
Tamryn Coats Wits University, South Africa; Jill Bradbury
This paper focuses on continuities and discontinuities in the social positioning of women informal traders in a South African city. The narrated life histories of ten women of varying ages, reveal how they became informal traders, forced to the margins of the city and into peripheral economic activity under Apartheid. The paper explores the shifts in the experiences of these women in relation to the policies and practices of informal trade in the city post-apartheid. While the informal sector is increasingly recognised and regulated by the city of Durban, and "race" is no longer the primary basis for marginalisation, women traders continue to be oppressively positioned by class and gender, trapped in conditions of poverty, and vulnerable to police intimidation and gender-based violence. Although participants acknowledge and even celebrate the considerable political gains of democratisation and developments in the city, several women simultaneously nostalgically reconstruct the past and are highly conscious of current injustices.

Knowledge, attitudes and practices of community workers engaged in substance abuse training
Ps Daniels University of the Western Cape, South Africa; Xena Cupido; Tracey-Anne Adonis University of the Western Cape, South Africa
The extent of the substance abuse problem in the Western Cape requires that health care workers be appropriately trained to recognize and care for substance abuse clients, yet didactic curricular context on the topic remains limited. A need for basic training in substance abuse was identified for community members from disadvantaged communities working in the area of substance abuse. The purpose of this research was to develop a database of organisations and community health workers, and to establish current knowledge attitudes and practices of community workers engaged in substance abuse care, prior to receiving training and assessing subsequent change in their practice. Using a mixed method research, a pre-questionnaire was administered before, and a post-questionnaire after each course: reflective journals and group discussion. Validity concerns were ensured by triangulating the data from the questionnaires with the reflective journals and group discussion. Quantitative data was analyzed using SPSS and qualitative data with Atlas Ti. This provided baseline data of the organisational profiles and community workers’ knowledge and skills; an understanding of the context of substance abuse and impact of training. Participants indicated an increase in knowledge and skills. Participants who did not indicate a significant increase in knowledge found that the course validated their existing knowledge and they were empowered. The group discussion revealed a conceptual link between academic knowledge and experience. The reflective journal proved to be a powerful tool in integrating theory and practice.

Psychology of poverty, or poverty of psychology?
Ng Eddie HKPU, Hong Kong
Poverty is disproportionately under-represented in the disciplines of psychology. In spite of endeavours in past decades, most traditional attempts are still focusing on the individual level. In this paper, critical discursive psychology and community psychology perspective, focusing on the multi-level understanding of the issue, are introduced, and compared with the traditional psychological perspectives. As the way an issue is framed affects how the issue is addressed, and intervened, it is believed that both a critical discursive psychology, and community psychology approach, provide a more comprehensive and holistic understanding of the issue of poverty, with important implications on intervention. The strengths and challenges of the approaches are also discussed.

Invisible oppression: Gender and homelessness
Sonja Ferreira University of Coimbra, Portugal; Dora Redruella
Using the classical approach of Grounded Theory, the first author developed original theory about the process of emergence, maintenance and abandonment of homelessness, entitled "Surviving the streets." This theory emerged from an extensive process of participant observation (n= 300 street interventions) and the conducting of 95 interviews with formerly homeless professionals. We focus this communication on the analysis of singularities and homogeneities in how men and women experience homelessness. For both genders, homelessness is a dynamic and non-linear process, which incorporates various disruptions, that exert their influence simultaneously and continuously, and that has multiple impacts on their well-being: psychologically, emotionally, and physically. Both groups also highlight the loss of rights and fundamental freedoms homelessness implies. However, despite the similarity of trajectories, there are marked differences regarding the importance that both genders attribute to several factors/dimensions for the emergence, maintenance and abandonment of the situation of homelessness. For women, conflicts in their relationship networks both proximally and extend. The existence of dependencies, sometimes by the partner and unemployment, were of importance. For men, unemployment was more important, in that it is related to the accumulation of debt, loss of habitation, and the breaking of ties with the nuclear family. Taking into consideration these differences, we propose guidelines for the development of policies and intervention strategies that actually acknowledge the differences between men and women, which are respectful of their rights and liberties, and promote their well-being and life quality.

Acculturation and parenting stress levels in Mexican parents coping with violence in their community
Claudia Fetter Contra Costa Mental Health Dept, United States of America
Associations were examined between Mexican parents’ exposure to violence and their levels of acculturation, parenting stress, and ways of coping. Several hypotheses involving theses variables were tested with correlational analyses. An exploratory regression analysis was performed to analyse how stress was related to all other measures. This research should form a base line on parents’ coping skills, acculturation and parenting stress levels while experiencing community violence. 297 participants from the Monument Corridor of Contra Costa County of the San Francisco Bay Area participated in this study. Five instruments were applied: Short Acculturation Scale, Ways of Coping, Parenting Stress Index, Exposure to Violence and a Demographic Questionnaire. An association in an unexpected direction predicted was found in the relation between witnessing violence and family, work, and planful problem-solving. The more the participants witnessed violence to strangers or to their families, the more planful problem-solving as positive coping skill was shown. The exploratory regression analysis results suggest that these Mexican parents are applying different coping skills from what we expected. Their resilience forms an important protective role and is different than what the research literature and theories report what we can expect from parents and individuals. This research could feature an integrated initiative to develop future studies of prevention, intervention and treatment strategies. Such an initiative is important to provide a comprehensive care program in order to reduce the severity of violence providing tools to parents to increase their community safety.

Perceived obstacles and empowering factors influencing the wellbeing of residents in small towns and urban areas
Donato Francescato Le Sapienza Rome, Italy; Manuela Tomai; Benedetta Brancadoro; Mauro Benedetti; Minou Ella Mebane
Community psychology underlines how multidimensional environmental factors may hinder or enhance the perceived wellbeing, quality of life and empowerment of citizens. The aim of this research was to identify which components of local communities are perceived more as obstacles or instead as empowering factors by people residing in three different territorial contexts: urban, city centers, suburbs, and small towns. About 2000 people (living in 50 districts in the city center of Rome, in 50 suburbs and in 50 neighboring small towns) participated in this action research, which used a modified version of the community profiling technique developed by Martini and Sequi (1988). Different methods were used to gather data, in particular participants were asked to make a movie script of their community. A first analysis of the movie scripts reveals that in all geographical areas, old people felt lonely and isolated. In the center of Rome immigrants were perceived more negatively than in the other areas. The perception of violence also differed in the three communities: in the suburbs it was more related to criminality and use of drugs, and in small towns to personal issues such as
marriage betrayals and break-ups. Sense of community was stronger in small towns, and in some historical Roman neighborhoods but three settings people wished for more opportunities to bridge generational and ethnic divides and have closer relations with their neighbors.

Exploring the use of appreciative inquiry as a viable evaluation method for education NGOs

Angelo Fynn UNISA, South Africa; Angelo Fynn

The South African education system is in crisis. Low matric pass rates, high dropout rates, teacher strikes, rising pregnancy rates among teenage learners, and assaults by learners on educators, and other learners, prevent the system from coping with the multiple demands placed on it, and a number of Non Governmental Organisations (NGO) are stepping in to aid the system. The NGO context in South Africa is faced with a number of challenges that threaten the existence of the organisations, and that seriously undermine their efforts to improve the lives of South Africans: a key issue faced by these organisations’ effective strategies for monitoring and evaluating their efforts in the community. The Appreciative Inquiry approach is a method for generating change within an organisation by looking at what works in the organisation, and facilitates active participation. This approach is entrenched within the social constructionist paradigm and works on the assumption that co-constructed realities are an effective means for generating buy-in from communities. In this presentation we examine the relevance of this approach to the South African context through a case study of an NGO based in Soweto. The presentation will also focus on the challenges faced by conducting qualitative evaluations and the politics of evaluation in the South African NGO context.

Contemporary features of published work in community psychology

Tanya Graham University of the Witwatersrand, South Africa; Carol Long

Published work in community psychology has historically been implicated in preferring individualist constructs, positivist and acentual methodologies, and deficit-oriented theories, and showing inadequate attention to power differentials in society and socially marginalized groups. This suggests a disjuncture between the stated purpose and values of the field and its representation in academic scholarship. This study provides a comparative and critical analysis of South African and international trends in the characteristics of published work in community psychology over the past decade. The study explores the ways in which knowledge production serves and re-entrenches ideologies of social injustice. This analysis draws on a dataset of 2,000 published articles in community psychology in two South African and four international journals. These articles were analyzed according to article type, authorship characteristics, topics, methods, theory choices and types of group representation. In comparing knowledge production trends within South African and international community psychology, the study holds significance for illuminating the relationships that exist between knowledge production and contextual influences in minority and majority world countries. This provides a platform for critically examining the unique convergence of disciplinary development, the academic enterprise and socio-historical context in understanding the politics of knowledge production in community psychology. The findings have relevance for debates about the direction and future development of the field.

Theoretical and methodological trends guiding community psychology based HIV research and implications for marginalised groups

Tanya Graham University of the Witwatersrand, South Africa; Amy Shirley University of the Witwatersrand, South Africa

This study explores how international and South African community psychology has studied HIV in the past twenty years, emphasising the theoretical and methodological aspects of research being produced. The study situates itself within an empowerment theory framework and has sought to comment upon marginalised groups and their presence in published community psychology-based HIV research. Data comprised selected journal articles from the South African Journal of Psychology, the American Journal of Community Psychology, the Journal of Community Psychology, and the Journal of Community and Applied Social Psychology over the period of 1990–2009 (N=138). Data were analysed using content analysis, using inductive and deductive coding. The study looks at trends in publication type, methodological approach, primary method of data collection, research settings, analysis, theory preferences, research topic and key characteristics of the research participants. Results reflect a dearth of community psychology research concerning HIV and a reliance on positivist methodologies across contexts, as well as a predominant focus on epistemologies relating to risk and prevention. It was found that whilst interest in marginalised groups within community psychology-based HIV research has increased particularly in the last decade, the voices of some of the most vulnerable groups, like those marginalised by disability and migration status, remain relatively silent. Race was the most common marker of marginalisation both locally and internationally. A move away from more traditional health psychology methods and understandings of HIV, to a more critical conceptualisation is imperative for the field of community psychology with regards to this prominent social problem.

Street children in Mafikeng, North-West Province: A qualitative study of social experiences

Erhabor Idemudia NVU (MC), South Africa; Patricia Kolobe; Keitumetse Kgokong

The rapid increase in the number of homeless street children in the cities of Africa particularly in the North-West Province, South Africa is a matter of grave concern. The perception of these children is that they pose serious problems to the society. Besides, they experience all sorts of violence in the public space. The extent of the study of street children is not well documented in South Africa and hardly researched hence there are knowledge gaps. The study addresses the problems of street children through their experiences on the street of Mafikeng. Using a qualitative research approach, data was collected in a focus group of purposefully selected 10 male street children with age ranging from 10–16 years. The FGD data was audio taped, organised, continually compared among participants. Data were coded, themes extracted using consensual qualitative research thereby establishing credibility and trustworthiness. The results of this study revealed three major themes on three sub-themes. The major themes include: Reasons for abandoning home; Life in the streets and the desire to go back home. The subthemes include: risks and challenges encountered; regrets including the desire for rehabilitation; and schooling. Some traumatic experiences have been shared ratifying need for change. Due to the risks and challenges encountered in the streets, the street kids desire rehabilitation and a clean start for a better future. The study recommends for intervention using a psychological programmes that could remove the kids from the streets.

Community cohesion as a component of youth resilience processes

Janice Ikeda RRC, Dalhousie University, Canada; Darlene Wall; Michael Ungar; Linda Liebenberg; Michele Wood RRC, Dalhousie University, Canada

Often, remote and isolated Aboriginal communities have few formal mental health supports available to them and therefore rely upon informal community supports to provide help to individuals during periods of psychological crisis. As part of the Pathways to Resilience research project, a five-country study of well-being among youth in marginalized communities, we used mixed research methods to assess community cohesion of several Aboriginal communities in Canada. After assessing community cohesion, we then assessed the youth’s individual, relational and contextual risk and resilience using quantitative tools. The results show that youth who experience less community cohesion experience more individual, relational and contextual risk. In addition, they show engagement in fewer protective processes associated with resilience than youth who are from communities with greater community cohesion.

Mental health risk factors of the poor in Mexico

Palomar Joaquina Universidad Iberoamericana, Mexico; Victorio Amparo

Living in poverty conditions implies exposure to severe circumstances of social disadvantage, associated with greater propensity to contract illnesses. A negative correlation has consistently been observed between health and poverty. The chronic exposure to stress affects people’s well-being through the development of symptoms of anxiety and depression. The suffering of these symptoms for a long time period may be considered as part of a more general syndrome of emotional disturbance, in detriment to a person’s mental health. The objective of this study is to identify psychological factors that influence emotional disturbance, measured as symptoms of anxiety and depression, in adults living in poverty conditions in Mexico’s central region. A total of 913 adults, 65.2% female, were surveyed. The mean age of the participants was 43.71 (±12.58) years and the mean number of
Impact of stress and burnout interventions for educators in high-risk schools: Preliminary findings
Sharon Johnson, Stellenbosch University, South Africa

This study considers intervening in the plight of teachers in the challenging context of high-risk schools on the Cape Flats, Western Cape, South Africa. Three interventions in psycho-educational workshops for stress and burnout were presented over 10 weeks for 15 hours in total to 50 educators in 4 secondary schools. A control group of 20 teachers also took part in the study. Interventions were grounded in transactional analysis, trauma release exercises and transpersonal psychology practice and can be conceptualised as appealing to three different brain functioning. Transactional analysis interventions engage the neomammalian, rational brain; transpersonal psychology interventions, the paleomammalian, emotional brain and trauma release exercises, the reptilian, survival brain. Qualitative data comprised focus group thematic interpretation as well as narrative analysis of individual high school teachers’ stress, burnout, coping and well-being accounts. This was triangulated with quantitative measures of stress, burnout, coping strategies and well-being, assessed at pre- and post-intervention stages. Preliminary findings suggest that teachers were able to reduce stress and burnout. Different coping tools were gained and well-being affected positively. Themes suggested more cognitive understanding of stress transactions with transactional analysis; emotional healing with transpersonal psychology and improved self-awareness with trauma release exercises. Post-intervention measures will be completed by March 2012. At this stage, preliminary findings suggest that stress and burnout can be mediated and well-being positively affected by multiple intervention approaches in this teacher population. A combined triune brain intervention design could be the most comprehensive approach to dealing with educator stress and burnout in high-risk schools.

Community research: Balancing the tensions on the ground!
Sandy Lazarus, Medical Research Council, South Africa

This symposium focuses on various tensions involved in conducting community research, particularly Community-Based Participatory Research (CBPR), also referred to as Participatory Action Research (PAR) or other similar terms. A panel of people who have experience in this area will engage with questions such as (a) whether the ‘participatory’ aspect of community research is essential, or a choice; (b) the strengths and weaknesses of promoting and using an ‘assets’, strengths-based approach; (c) balancing the research and action goals; (d) addressing tensions between different languages and forms of knowledge (particularly the tendency for academic scientific language and knowledge to dominate); (e) addressing challenges relating to ‘control of phenomena’ and collaboration imperatives; (f) dealing with the messiness of community research (especially political dynamics and the need for flexibility for practical reasons); and (g) addressing all the biases and confounding variables in this kind of research, including the impact of the research approach itself on the research process and findings. It is hoped that this engagement will result in a stimulating conversation, and some practical guidelines for interested participants.

The development of a child-centred community attribute questionnaire for South Africa
Scherianne Kramer, University of the Witwatersrand, South Africa; Karin Pretorius

Community attributes such as community connectedness, social control and solidarity economy have demonstrated their ability in decreasing instances of child-related crime, violence and injury and in increasing peace and safety. It is therefore useful to assess the presence of such attributes in communities as a means to inform the focus of future community-based initiatives. However, the scales currently available fail to address the full range of community attributes and instead focus on singular attributes. There are also few that are child-centred or South African specific. In order to address these scientific oversights, this study involved the development of the Community Attribute Questionnaire (CAQ). This was based on recommendations in the literature and outcomes of earlier community-based programmes in South Africa. Items from other scales that had demonstrated validity and reliability and were deemed appropriate were also included. The final assessment device contained scales for ‘community connectedness’, ‘child-centred social control’, ‘social disorder’ and ‘solidarity economy’ which were reviewed by an expert panel. On completion of assessment development, the CAQ was piloted in a small Western Cape community. Findings concerning the psychometric properties and the suitability and relevance to South African communities are discussed, along with implications for safety and peace promotion.

The impact of displacement on community cohesion in Blikkiesdorp
Shoheed Mahomed, South Africa; Bryony Fell, Chris-tel Menette; Sue Drummond; Weslin Charles; Saa-bierah Towfie; Rashid Ahmed

Communities differ considerably in terms of neighbourhood cohesion and numerous processes affect that cohesion. The forced removals of the Apartheid era that displaced communities, has been replaced by the marginalisation of communities related to the neo-liberal pathway followed in the post-Apartheid era. This study sought to investigate the experiences of one such community. Blikkiesdorp is a displaced community in the Western Cape that has been engaged in ongoing social action with local government. Focus group interviews were conducted with community members to explore their experiences of displacement with the aim of informing social action. The impact on neighbourhood cohesion, the extent of poverty, and the increasing incidence of social problems, such as crime and substance abuse, emerged as some of the dominant themes. Social action emerged in a complex, multi-layered, paradoxical way. Themes of both spontaneous popular action, and a sense of helplessness emerged simultaneously. The study concludes by providing suggestions for responding to the challenges that emerged from the data.

Walking the walk: Students’ talk about community psychology in practice
Michael McInerney, Rhodes University, South Africa; Heinrich de Kock; Mpho Mbewe; Kirsten Friis; Malvern Chiweshe; Trudy Meehan, Rhodes University, South Africa

With community psychology as an ever increasing and vitally important aspect of the training of Clinical and Counselling Psychologists in South Africa, there is a need to examine the role and subjective experiences of students participating in community projects. This paper explores the reflections of 12 Clinical and Counselling Psychology Masters students using a narrative approach to community psychology. Six projects emerged from engagement with a diverse range of Eastern Cape communities, including three schools, a support group for parents of children with special needs, a childcare group and the community of Riebeeck East. Through a series of focus groups run throughout the duration of the projects, the students’ reflections on their experiences were compared and contrasted. Similarities and differences in the process of engagement and the students’ roles emerged from a thematic analysis of written reports and the focus group transcriptions. The analysis prompted a reflection on the importance of context and identity within community collaborations. The students’ experiences provide an opportunity for a critique of the narrative approach to community psychology in South Africa, and have implications for the future training of Clinical and Counselling Psychologists in Community Psychology.

Group dynamics in “stokvels” and its implications for members’ mental health and psychological wellbeing
Thandeka Molai, Independent Practice, South Africa; Humphrey Ngcobo

Stokvels are social groups usually formed randomly by people who share a common bond such as
An exploration of group dynamics in “stokvels” and its implications for members’ mental health

Thandeka Moloi Independent Practice, South Africa; Humphrey Ngobo

Stokvels are social groups usually formed randomly by people who share a common bond such as being relatives, neighbours, colleagues or friends. Its purpose is to financially save together on a monthly basis. This study aimed to explore the group dynamics within stokvels and those dynamics’ implications for the members’ mental health and psychological well-being. In this study, the participants were selected by means of a snowball sampling. The sample consisted of eight middle-aged women (35 to 45) from townships in KwaZulu Natal. The inclusion criteria required that they were stokvel participants for over five years. Data was gathered through the use of semi-structured interviews to elicit the spoken experiences and narratives by individual members. The data collected was then analysed using grounded theory, particularly the Straussian approach. The results of the study suggested that the group dynamics of fight or flight response, trust versus mistrust and dependence versus independence appear to be experienced at polar opposites. The latter further infers the ambivalent behaviour that members engage with a view to succeed within the stokvel environment. The study identified three themes, which revealed the members’ mental health and their psychological well-being as experienced within the stokvel environment; the empowering dimension, a pathological dimension and the resilience demonstration dimension. The findings of the research also highlight and further contribute towards the advancement of the communal concepts of “ubuntu” and “we-ness” inherent in the stokvel name.

A participatory approach to healing and transformation in South Africa

Elize Markei South Africa

Post-apartheid South African society struggles with overwhelming problems related to poverty, illness, violence, sexism, and racism. The disproportionate psychologist-client ratio in the privileged community versus disadvantaged communities reflects the reality of one of the most unequal societies in the world. In those communities where the trauma is most severe, professional resources are scarce. For many years, psychology as a profession has mirrored the oppressive and discriminatory practices associated with race, class and gender divides. Clinical training has remained largely westernized and mainstream. The paper proposes a participatory approach which invites psychologists to respond to the socioeconomic and political challenges and the problems that arise from them, by thinking and acting outside the constraints of their consultation rooms and of traditional therapeutic conversations, into active participation in ways that might support healing and social transformation. This approach is informed by Narrative Therapy which is positioned within post-structuralist and social constructionist ideas embedded in a postmodern world view. The paper identifies and describes ten characteristics of a participatory approach: the personal is the professional and political; participation with the other; participation with people; participation with awareness; participation in voicing; participation with our bodies; participation together with others; participation in social transformation; participation in interrelatedness and participation in restitution. The application of the characteristics will be illustrated by referring to examples from the South African context.

Learning about life: Reflections of a young adult about her relationship with an older person

Sade Namubes North-West University, South Africa; Vera Roos

Research conducted on intergenerational relationships between older and younger persons often emphasises the relationship between members of familial generations. The theoretical framework explaining intergenerational relations is the theories of solidarity, ambivalence and conflict. The aim of this article is to reflect on the meaning of the relationship between a young adult and an older person who are unrelated. A qualitative, explorative study was used and a case study design was applied. A young adult (27-year old female), agreed to participate in a research project to explore the relationship between members of two generations who are unrelated, in the North West Province of South Africa. The data were gathered by means of a visual projective research gathering instrument, the Mmogo-methodTM, which entailed the construction of a visual image by using clay, straw and beads, portraying the relationship with a person older than 60 years, as well as a group discussion about the visual images. Visual and textual data were obtained and thematically analysed. The findings indicate that in the relationship with the older person, the young adult observed how the older person dealt with conflict and trauma. The young adult regarded the life experiences of the older person as a valuable resource to deal with difficult situations, and applied the insights that she has obtained from the older person to deal with similar issues in her own life. In conclusion intergenerational solidarity can be promoted if members of both generations are open to learn from one another.

Justice and well-being: Contextual psychosocial processes

Isaac Prillertensky University of Miami, United States of America

Research on well-being reveals a series of psychosocial processes that promote thriving and coping at the personal, interpersonal, organisational, community, and national levels. Some of the coping processes include adaptation, social comparisons, and compensatory mechanisms. Missing from this growing body of literature is an explicit elaboration of the role of justice in well-being at various ecological levels. In order to understand the dynamics of justice and well-being in multiple contexts, from micro to macro spheres, this paper aims to fulfill three goals. The first is to demonstrate the inextricable link between well-being and justice. The second is to elucidate psychosocial processes implicated in (a) thriving under optimal conditions of justice and well-being, (b) coping under suboptimal conditions of justice and well-being, and (c) transforming unacceptable conditions of injustice and suffering. The third goal is to illustrate the role of psychosocial processes in justice and well-being at the personal, interpersonal, organisational, and community levels.

Intrapsychological empowerment and cultural adherence in Norwegian and Palestinian adolescents

Torbjorn Rundmo Norwegian University of Science and Technology, Norway; Venke Aarethun; Hroar Klempe; Vilde Aarethun

The core aim of the present study was to compare empowerment and cultural adherence among Norwegian adolescents and Palestinian adolescents living in the Palestinian territories and in Palestinian refugee camps in Beirut, Lebanon. An additional objective was to compare adolescents who received musical training in a music school and those who did not. A total of 305 respondents replied to a self-completion questionnaire. The respondents were between 12 and 18 years of age. 49.8 per cent of the respondents attended a music school. The results showed that country of residence and culture seemed to be important for psychological empowerment. Cultural adherence also varied due to country of residence. Norwegian adolescents reported more empowerment compared to the Palestinians. To attend a music school was also found to be related to cultural adherence as well as psychological empowerment. When cultural adherence was taken into consideration, attending a music school education seemed to be of less importance. The results are discussed in relation to the special Palestinian situation and the need of the population to liberate from the Israeli occupation and oppression.

Subjectivity processes and intersubjective relations in a transnational migratory circuit

Maria Eugenia Sanchez Universidad Iberoamericana Pue, Mexico

This paper studies a Mexico–United States migratory circuit in which the analysis focuses on the way

Community
in which subjectivities and social identities change in Coyula, a peasant population of indigenous origin that has been forming a transnational community with migrants established in The Hamptons, Long Island, New York. This process generates a specific form of articulation between the global and the local which transcends the National State and make it possible to refer to a transnational community built in the context of networks of globalised subordination. The reconfiguration of a structural framework and the construction of a transnational culture becomes a substratum that allows for the emergence of new social subjects such as grandparents, autonomous women, and young people. The US–Mexico border, a cause of physical, emotional, and symbolic rupture, appears as one of the axes of comprehension for transforming the subjectivities and the intersubjective networks. A dialogue is attempted with a sociopsychological and socio-psychosocial sequence, which is vital in these contexts; the psychic dynamics of losses and appropriations, of unresolved ambivalences, interact with the sociostructural and cultural processes.

Evaluation of psychosocial support (PSS) needs of home community based caregivers (HCBC) in South Africa
Geoffrey Setswe Monash South Africa, South Africa; Mapaseka Majaja; Alicia Davids; Geoff Setswe; Leickness Simbayi

As more individuals and households in South Africa become affected by HIV/AIDS, there is a growing need for assistance with care and support. The dire shortage of professional health practitioners in South Africa means that the greater burden of care lies with informal Home Community-based Caregivers (HCBC) working with the SA Red Cross Society (SARCS). A mixed methodology was used to assess the psychosocial support (PSS) needs of HCBC. The qualitative phase of the study comprised of 11 key informant interviews (KIs) with stakeholders in the OVC field and 15 focus group discussions (FGDs) with HCBC. A cross-sectional survey was also conducted with a sample of 290 HCBC in eight provinces of South Africa. More than two-thirds, 78.4% of HCBCs said they were getting help with caring tasks for people with chronic illnesses, while 73% said they were getting instruction or education about the care for people’s medical conditions, care needs, treatment and medication. With regard to support services for people they cared for, 89.6% said they were able to provide personal cleanliness and comfort for the people they cared for, 82.6% said they were able to provide social contact with others apart from their role as carers. Although there were some issues related to transport, stipend and training which needed to be attended to, it could be concluded that in general, the PSS needs of HCBC working for SARCS had been met.

Family connectedness and parenting style among rural and urban Iranian adolescents
Maryam Sharyati Azad University of Birjand, Islamic Republic of Iran

Parenting styles (authoritarian, authoritative, and permissive) and adolescent–family connectedness (emotional, financial, and functional connectedness of adolescents) are crucial constructs in adolescents’ mental disorders. This study investigated family connectedness and parenting styles among rural and urban Iranian adolescents. Two questionnaires, measuring parenting style and adolescent–family connectedness, were administered to 351 Iranian adolescents. Results indicated that in rural communities the authoritarian style is predominant in the parenting of male adolescents, while the authoritative style is predominant in the parenting of female adolescents. In urban communities, on the other hand, the authoritative style is predominant in the parenting of female adolescents. The connectedness of all female adolescents with their family was stronger than that of male adolescents. The connectedness of girls was found to be more emotional and financial in villages and to be more functional in town. Results thus indicate differences in family connectedness and parenting style between rural and urban adolescents in Iran.

Development of a resilience building program for police using a community based participatory research (CBPR) approach
Ian Shochet Queensland University of Tech, Australia; Colette Roos; Cameron Craig; Jane Shakespeare-Finch; Astrid Wurfi

The health and well-being of police officers is vital to the personnel themselves but is also of paramount importance to the community more broadly. It is well known that police officers are at greater risk for mental health problems such as Post Traumatic Stress Disorder (PTSD), depression and for substance misuse. There is an urgent need to develop interventions to promote resilience in police officers and other personnel working in high risk occupations (such as the ambulance service). In this paper the development of the Promoting Resilient Officers (PRO) program, a resilience building training intervention for police recruits, is described. The program aims to prevent mental health problems such as PTSD and depression and promote post-traumatic growth. Construction of the PRO program took place using a Community Based Participatory Research (CBPR) framework between the police service and the researchers. Working as a team to produce a context appropriate (e.g., language, exemplars), program, the PRO program was created. Feedback from participants (n=167) was extremely positive with both quantitative and qualitative data indicating a high level of engagement and of satisfaction with the PRO program. Results support the CBPR approach to creating intervention and psycho-education programs and suggest that in order for such programs to be accepted by participants, context specific content is vital.

Student HIV support groups as vehicles of community mobilisation: Towards a model of health-enabling social contexts
Tammy Styles University of KwaZulu Natal, South Africa

This study aims to explore the role of Higher Educational Institutions’ (HEIs) HIV support group processes in empowering and mobilising students living with HIV within their respective institutional contexts. It further intends to investigate the social context of institutions to explore their enablement or preclusion of health-enabling behaviour. The research is located within the ‘generation’ approach to HIV/AIDS management conceptualised by Campbell and Cornish (2010) in which HIV behaviour change approaches are charted from first generation HIV awareness to second generation peer education to third (current) generation community mobilisation approaches. The theoretical underpinning is Campbell and Cornish’s (2010) position that community mobilisation cannot be successfully achieved unless a fourth generation approach, accounting for the wider social context in which mobilisation efforts are located, is applied. A qualitative, multiple case study method will be employed with a sample of HEIs in KwaZulu Natal and Gauteng. Focus groups will be conducted with the institutions’ HIV support groups to explore internal group processes facilitating or constraining members’ individual and collective empowerment and mobilisation, and their perception of institutional factors precluding or enabling health-related empowerment and mobilisation. Relevant institutional management staff will be interviewed to investigate the symbolic, material and relational contexts of the institutions. Data will be analysed using qualitative content analysis (Attride-Stirling, 2001). The research objective is to yield a model identifying the relationship between elements of health-enabling HEIs and mobilisation of students living with HIV.

Psychological distress in developing countries: Social justice and public health perspectives
Vindhya Undurti Tata Institute of Social Science, India; Darcy Santor; Rachel Calem; John Hunsley

Curriculum, training, and research in the field of mental health in developing countries are by and large dominated by the bio-medical discourse. Broadly, mental health problems are viewed as an individual’s attribute which means that, typically, the way power differences between social classes and other social structures can impact the mental and physical well-being of individuals is overlooked. Second, the responsibility for pathology is placed on the individual, discounting the role of social oppression and injustice in contributing to mental health problems. In contrast to such an apolitical and reductionist understanding of mental health, there are emerging approaches, mostly from non-academic locations, that bring into their work broad and interlinked perspectives of social justice and public health. Impacted by current debates on development, human rights, gender, and disability, this recent body of work emphasises the need to connect mental health with social determinants, shows the etiology of the more widely prevalent common mental disorders to be linked to psychosocial factors, demonstrates the existence of class and gender bias in access to mental health services, and highlights the relationship of risk factors such as domestic violence to the occurrence of depression in women. The social justice and public health perspectives recognise that social structures that foster social injustice and discrimination can lead to adverse mental and physical health outcomes. Drawing from concrete examples from this emerging literature, my presentation will emphasise the need for scholarship and professional action to focus on psychological distress from the perspectives of social justice and public health, and the implications of incorporating these notions for a more responsive discipline of psychology.
Willingness to communicate, communication apprehension and leadership practices in FDAs of Madhya Pradesh, India

Bal Krishna Upadhya IIFM, BHOPAL, India; Parul Rishi IIFM, BHOPAL, India

Communication is one of the important determinants of the success of any scheme. Looking at the important role that communication, leadership preferences and its practices play in forest management, the study intended to explore the communication practices of field staff of Madhya Pradesh Forest Department and community members living in the forest development agency (FDA) area. The study also aimed to understand the leadership preferences of both the forest staff and the community members living in FDA areas. The sample consisted of community members (male villagers N=144; and female villagers N=150) and forest staff (N=25) of selected forest divisions in Madhya Pradesh. To gather information, interview schedules were developed, which included measures of communication apprehension (CA), willingness to communicate (WTC), and leadership style preference. Willingness to communicate in different communication situations. Age was also found to have a significant effect on WTC and CA for villagers as well as the forest staff. On the measure of leadership preference, male villagers were found to prefer an autocratic and participatory style whereas the female villagers preferred a nurturant style. In addition, staff showed their inclination towards a nurturant and participative style. The study has indicated readiness of villagers of certain age group who may be the target population for dissemination of any policy matters and has concluded with a note pertaining to training need meant for both the types of respondents so as to enhance trust and confidence in various communicating situations.

Implementing a change laboratory intervention in a developing context: Challenges, constraints and theoretical insights

Mary Van Der Riet University of KwaZulu-Natal, South Africa; Harry Daniels; Jabu Kheswa; Charlie Alberts; Nkululeko Sandlanda; Tamaryn Nicholson; Dumisa Soffika; Peter Rule

Changing behaviour in response to HIV and AIDS is a significant problem. Previous research in a rural area in South Africa identified a complex set of historical and current processes which mediate sexual activity for youth. For example, the perception of pregnancy rather than HIV as a risk of sexual activity, a lack of condom use despite awareness of the risk of HIV, and sexual activity as a way of achieving gendered identity. In 2010 a team of researchers from the University of KwaZulu-Natal and Fort Hare embarked on a limited form of change laboratory intervention based on activity theory in the same research context. The aim of the project was to initially change practice in response to HIV and AIDS, and then change practices in relation to the activity system of sexual activity. The intervention thus aimed ultimately at reducing HIV risk. This paper reports on the progress of the project to date. It reflects on the challenges of establishing a change laboratory in the context of a developing country and the difficulties of working with an open-ended activity system. It also reflects on using the change laboratory approach/expansive learning with a health-related intervention such as HIV and AIDS. The paper also reflects on the parallels between the change laboratory approach, participatory research and action research.

Container counselling in Diepsloot: Meeting the needs of a peri-urban community

Zane Wilson SADAG, South Africa; Cassey Chambers

Diepsloot, a township halfway between Johannesburg and Pretoria, is home to a rapidly growing population of over 150,000 people. This population is continually exposed to various types of trauma. Despite its six schools, shopping mall, police station and 13 churches, Diepsloot has only two clinics, and the closest psychiatric facility is over 20km away. Diepsloot urgently needed somewhere for residents to go where they could get support, advice and care for mental health issues. The Diepsloot Container Counselling Centre (established by SADAG and Jansen-Cilag) offers free counselling, referral and support to the residents of Diepsloot. SADAG conducted a patient evaluation survey. Counsellors gave patients questionnaires to fill in to monitor helpfulness, user-friendliness and service, accessibility of the Centre. The majority of people who use the Centre are in the 19 to 40 age group. Double the number of females use the centre as males. 95% of respondents indicated the counsellor was very helpful. 100% said the counsellor was able to provide clear and specific solutions and ideas to help them with their issues. Many of the residents of Diepsloot are poor and are continual victims of crime, poverty and an often uncaring, inaccessible health care system. SADAG’s Diepsloot Container Counselling Centre offers free counselling, referral and support to the residents of Diepsloot as well as working with the community as a whole to educate and create awareness around mental health issues. The centre has been hugely successful and residents are using the services increasingly.

Speaking books: Making health care education accessible to all

Zane Wilson SADAG, South Africa; Bronwyn Dworzanski; Xueyu Lu; Zane Wilson; Cassey Chambers

Illiteracy is a potentially life-threatening issue - health is lowest where literacy is poor. The traditional model of patient education is selective in its target - low literacy reduces distributed literature’s effectiveness. The Speaking Book delivers an innovative, interactive alternative to patient learning. Through a hard-covered, 16-page book with a 30-second-per-page audio track, the Speaking Book talks to the reader, in his own language, about critical health issues. Methodology: Bronwyn Dworzanski (UJ) conducted a study “Exploratory reflections on pioneering a ‘Speaking Book’” with 193 Home-Based Caregivers from five rural AIDS care sites in Modimelle, KwaMaru, Mahakdo (Louis Trichardt), Newcastle and Thohoyandou. They attended a SADAG mental health care workshop, received copies of the Speaking Book for their patients, and completed open-ended questionnaires of the Books’ efficacy. Each Book in this study was shown to 39 people — in places like weddings, shebeens, taxi ranks, at the hairdresser, even at football games. Speaking Book dissemination totalled 7530 PLWA. 98.4% of respondents reported the Books easy to comprehend; 93.3% learnt new facts about depression and AIDS; 70% said the Book gave good information; 60% engaged in the Book’s speaking function. The Speaking Book provides access to critical information for people who are often side-lined on the road to health. The Speaking Books uplift communities and individuals, reduce stigma and increase understanding and treatment compliance.

Motivations and barriers to community participation among youths: The role of empowerment and sense of community

Bruna Zani Italy; Elvira Cicognani

Community participation is considered as a key value within community psychology, both as an outcome and as an instrument for social change and improvement of citizens’ well being. The issue of participation is of particular concern among young people, a group that is often depicted as disinterested and uninvolved with social issues. This paper will present some data of a larger research project aimed at investigating factors influencing youths’ civic and political participation. A specific focus is devoted to the role of sense of community, empowerment, motivations and perceived barriers to participation, and conception of citizenship in influencing the different forms of participation. The data are drawn from a sample of over 800 Italian adolescents and young adults (16-26 yrs), male and female. Results indicate generally low levels of participation, with the exception of voting and new ideas such as net participation and consumerism. Age and parent education significantly increase almost all forms of participation. Different predictors of the forms of participation emerged. In particular, empowerment and sense of community (perceived opportunity to make a difference) are important for net participation, civic participation, consumerism and voting. Net participation and consumerism appear to be influenced by motivation for social change whereas the other forms (civic, manifest, attending public meetings) by motivations for personal enhancement. Finally, different conceptions of citizenship are relevant for participation: net participation and civic participation seem to imply and idea of citizen as an active agent; voting is associated with a conception of citizenship as a duty.

Community resilience: Theoretical aspects and comparative analysis of the recent complex emergencies in Haiti and Japan

Giorgia Barbieri University of Padova, Italy; Angela Barbieri

Community resilience is known as a recovery process of a post disaster balance. Considering community resilience theoretical models, we have examined events and reactions to the disasters of Haiti and Japan, respectively the earthquakes of January 12 2010 and March 11 2011. The comparative analysis allows us to ponder the emerging elements of weakness and strength that have to be identified. It is known that to reduce the psychosocial impact of disasters, community vulnerability has to be
decreased and its own resources enhanced. As from objective data, it is evident that Japan had 16 000 victims, Haiti more than 200 000, although the impact of Japan’s earthquake was 900 times stronger than Haiti’s earthquake. From an extensive analysis of the most recent international literature by authors of several disciplines, it’s clear that Japan provides an excellent example of community resilience, thanks to a culture based on organisation and everybody’s cooperation. Its resilience is based on the variables that emerge from the theoretical models: Emergency preparedness, economic and social resources, communication, sense of community and self-efficacy. In Haiti the major factor of resilience are international aids, but aids must be provided in the right measure in order to give to the local community the possibility to aid itself. Haitians can count on adaptability to adverse circumstances and faith but there are many variables that could be strengthened to make the community more resilient. The comparative analysis aims to bring out what should be done to reduce the disastrous impact of natural phenomena.

Type of words older people use when they talk about younger people

Lenate Bodenstein North-West University, South Africa

The purpose of this study is to describe the manner in which older people use language when they talk about members of the younger generation. The conceptual framework that guided this research is that people are constantly creating meaning in their relationships with each other, and that these meanings are expressed through the choice of certain words. Eighteen Afrikaans speaking older people (males and females, with ages ranging from 60-80) were purposively selected to participate in the research. Data from the Mmogo-method™ and focus group discussions were used to gather data and to highlight, through a systematic grounded theory procedure, the use of certain words when older persons talk about members of the younger generation. The findings revealed that the older people use mainly words expressing discontent and dissatisfaction when they talked about the younger generation. The meanings associated with these critical words reflect discontent and dissatisfaction and seems to judge members of the younger generation. One of the implications is that older people are very critical of members of the younger generation. Most likely this critical stance will elicit critique from members of the younger generation and contribute to the conflict that is observed between members of the two generations. It is suggested that members of both generations interact on an individual basis with one another to become aware of the relational qualities that each other have.

Building evaluation capacity through campus-community partnerships in urban Egypt and rural America

Amy Carrillo The American University in Cairo, Egypt; Carie Forden

In recent years there has been an increasing demand from funders that prevention programs demonstrate the effectiveness of their interventions through evaluation. Many community-based organisations have difficulty meeting this demand because they lack the necessary training and resources. This difficulty provides universities with an excellent opportunity to partner with community-based organisations by assisting them in building evaluation capacity. Developing evaluation capacity enhances community-based organisations’ ability to obtain funding and develop more effective programs. This poster describes evaluation capacity-building initiatives that were developed through partnerships between a branch campus and a community collaborative board in a rural area of the United States, and between a research university and urban NGOs in Cairo, Egypt. In general, these initiatives were relatively simple to set up, did not cost a great deal of money, and were successful in increasing the evaluation capacity of community-based organisations while providing faculty and students with research opportunities. The factors which appear to be important to the success of these initiatives are discussed, and cultural and community influences which present unique opportunities and challenges are also examined.

Development of Chinese urban inhabitants

Yongsheng Chen Zhejiang Normal University, Afghanistan; Dongchi Chen; Jiagui Wang

The purpose of this study is to provide a valid measure for citizen participation in Chinese communities. In this study, the operational definition and structure hypothesis is that citizen participation means community members, as citizens, participate in a variety of public obligations relevant to the existence and development of their local community. Citizen participation includes three dimensions: participation in democratic decision-making, mutual participation in their neighborhood, and participation in public service, with a certain internal unity among them. The qualitative software analysis of 60 community members’ interview information, exploratory factor analysis of 268 community members and the confirmatory factor analysis of 1068 community members, verified the rationality of the hypothesis. Following the three dimensions, the Chinese Urban Citizens’ Participation Scale (CUICPS) developed 16 items in total, of which democratic decision-making participation sub-scale covers 6 items, mutual participation in their neighborhood; the sub-scale covers 5, and the public service participation sub-scale covers 5. Furthermore, the results of the reliability and validity test shows that the CUICPS has good psychometric properties. Of these, the internal consistency coefficient of the full scale is .854, and those of three sub-scales range from .672 to .777, the split-half reliability coefficient of the full scale is .879, and those of the three sub-scales range from .714 to .800; and test-retest correlation over a two-week interval is .718. The distribution of the correlation matrix is significant at the level of .562 to .649. Besides, the correlations between sub-scales and the full scale are significant at the level .797 to .865. The conclusion of this study is that the CUICPS is a good scale for measuring citizen participation in Chinese communities.

Community psychology and African epistemology relationship from clinical psychology masters student’s perspective

Candice Combrinck UNISA, South Africa

Community psychology can be differentiated from other fields within the social sciences, as it focuses on the interaction between the individual and the community, as well as on the community characteristics, culture and processes that influence the lives of people. One way in which community psychology defines a community, is as a construction of a way of life. Shared experiences among people contribute to the creation of a way of life. As part of practical training, 11 clinical psychology masters students were placed in a community in the greater Tshwane area. Through many sessions of supervision in the community, the group of students gained a deeper understanding of what community means to them from an African perspective, and how that view impacted their conceptualisation of community and psychology within that community. This poster will explore the reflections of the experiences of 11 diverse clinical psychology masters students, working in this community, and how they utilised the African perspective to integrate themselves in the community. Semi-structured interviews with the students were done, and a thematic content analysis will be used to analyse the findings. It is necessary to obtain a deeper understanding of what community is, and how community psychology is being viewed in South Africa, because of the diversity we face as mental health professionals. This view would impact the way communities are viewed, how their needs are assessed, and how interventions are formulated and implemented.

Group process under a tree in a community

Candice Combrinck UNISA, South Africa

As part of the clinical psychology masters programme at UNISA, the students are placed in a community in the greater Tshwane area for practical experience. For 11 months, group discussions were done under a particular tree in this community, merely for logistical reasons. This poster will explore how this tree became a prominent metaphor in this group’s process and it explores some ways in which meaning is produced, especially with the use of language. Humans attribute meanings to observed behaviours and to felt sensations. Meaning is the judgement and evaluation of an object, word or phenomenon that leads us to see, feel and understand this object, word or phenomenon in a certain way. A metaphor is much more than a play on words; it is a way in which humans understand their relationship to the world, and a basic cognitive process underlying the production of meaning. The aim of the poster will be to demonstrate a connection that was felt within this group with the impact the use of language has on group process and on interpersonal learning. Narrative experiences of the students will be used to collect data. Thematic content analysis will be used to code findings into themes. We, as mental health professionals, are trained to read cues and emotions so as to co-exist more effectively, but we constantly misunderstand them and, consequently, often wrongly restrict or disadvantage others.

The use of an online community to provide support to caregivers with dementia

Dharma Cortes Cambridge Hospital/Harvard Med, United States of America; Marta Pagan Cambridge Hospital/Harvard Med, United States of America; Noelle Rudloff; Sue Levkoff

One of the challenges faced by many family members of Alzheimer patients is lack of accessible information...
about how to take care of the patient and the caregivers themselves. In response to this challenge, in 2008 the development of a Web site (cuidatecuidador.com) designed to create an online community for caregivers of people with Alzheimer’s disease and other dementias began. This website provides information (in written and audio formats) in Spanish and English for caregivers of people with dementia. Its content was developed and later evaluated by caregivers residing in Puerto Rico, Mexico, and the United States. Cuidatecuidador.com allows users to send questions to experts and to connect with other caregivers. It also provides a forum for users to share stories and photos that describe and reflect their roles as caregivers and for professionals who want to share their knowledge and experiences related to dementia. Through the website, caregivers also have access to more information about dementia and ways to take care of themselves. In response to the social media boom, cuidatecuidador.com is also available through Facebook, where more than 2,000 users have registered. The Facebook page registers about 1,400 unique visits per month by users from 36 different countries. This paper will discuss key information about the site’s development and sustainability as well as the benefits of using social media for caregivers.

Exploring issues pertaining to mass evictions
Patricia-Anne Finlay UNISA, South Africa
The residents of the Schubart Park apartments, Pretoria, were evacuated with no prior notice in 2011, owing to the building having become derelict. This led to thousands of residents being displaced and relocated with approximately 350 families becoming my neighbours. They suffered immense loss, not only materially, but also psychologically and socially. The objective is to create an awareness of the issues pertaining thereto, stimulating discussion and debate thereof. To date, a journalistic approach has been adopted, mainly owing to the sense of immediacy, thus paving the way towards participatory action research and needs assessment. Attending certain community representative meetings and establishing focus groups as well as formal questionnaires and qualitative research could triangulate the data. Since I am not an uninvolved observer, my reflections will also be presented. Ethics regarding identification, confidentiality, protection, expectations and the need for individual counselling were also immediately addressed. The principles of community psychology and various models, as well as evaluations and possible interventions will be considered. Since the communities are beset with social ills, it is anticipated that the interventions already adopted will be confirmed as wanting and an intervention strategy will be proposed. Also, the insights gained here could assist communities to cope with such incidents, and also contribute to preventing such occurrences. Such events in South Africa call for interdisciplinary and intersectoral collaboration, a subject for further research. The enormity of this phenomenon presents numerous facets for potential research.

The Baby Mat Project
Katharine Frost Ububele, South Africa; Melanie Esterhuizen
The Ububele Baby Mat Project facilitates a dialogue between psyche and soma in Primary Health Care Clinics in Alexandra Township in Johannes-
burg. In the context of urban poverty and limited public infant mental healthcare, the Ububele Baby Mat Project provides support to mothers and their infants to promote their attachment relationship. The focus of this community-based, mother-infant preventative intervention is ‘the relationship’ between infant and parent, or caregiver - positioned in a systemic context of couple, triad, extended family and culture. Informed by the work of the Anna Freud Centre, and drawn from psychoanalysis, attachment theory, infant development research and systems theory, the extracted principles of parent-infant psychotherapy are used flexibly by the Ububele Baby Mat practitioners to promote the caregivers’ reflective functioning in relation to infant care. Western theory and research, and indigenous South African knowledge systems interact to reinforce the attachment relationships. It is the baby’s affective-bodily communications which lead the mother and practitioner from the soma to the psyche, to include the psychological dimension of the mother-infant relationship. A focus of this model is the position of the baby as a partner and patient in his or her own right. Since its inception in 2007, the Ububele Baby Mat Project has worked with over 1000 dyads.

The Mmogo-method: Exploring unconscious attitudes and feelings in two generations
Maryke Hewett North West University, South Africa
Projective techniques in qualitative research elicit unconscious attitudes and feelings. This presentation aims to explore the attitudes and feelings that unrelated older and younger persons have towards one another by using the Mmogo-method. This method uses projections and free associations to elicit unconscious attitudes and feelings about people’s perceptions of one another. Thirteen older persons from a community centre in North West Province, South Africa (men = 5, women = 8, age 60–85 years) and 18 younger people from North-West University (men = 1, women = 17, age 21 - 33 years), who were unrelated, participated in the construction of visual images, using clay, beads and straws, in response to an unstructured prompt to illustrate how they perceive their relationship with one another. Reflective journals and follow-up interviews with three participants were also used. Visual and textual data were thematically analysed. Both older and younger persons were unaware of certain attitudes and feelings they have towards members of the other generation. The attitudes that emerged from the younger persons confirmed the stereotypical perception of older persons as narrow minded and rigid, and the older persons perceived the younger persons as uninvolved and emotionally unavailable. Both older and younger persons expressed feelings of loss, longing and regret in relation to significant relationships with people from the other generation. Projective techniques can be useful to explore unconscious attitudes towards people of different generations. It can also reveal the feelings that members of both generations have towards significant others.

Ubuntu Education Fund
Kim Howard University of Witwatersrand, South Africa; Fezeka Mzalazala
Ubuntu Education Fund is a grassroots organisation founded in 1999 that has developed a model for raising children in the townships of Port Elizabeth, situated in the Eastern Cape, one of South Africa’s poorest provinces, ravaged by poverty and high incidences of HIV and tuberculosis infection. Over the past 12 years Ubuntu has built an integrated system of medical, health, educational and social interventions to help orphaned or vulnerable children ultimately succeed in the worlds of higher education and employment. Currently Ubuntu has over 2000 children on the pathway out of poverty with 132 students on scholarships at university. Ubuntu Education Fund was founded on the dream of giving township children the same opportunities to succeed, as someone who is born into privilege. The fund, through its highly trained counsellors and staff, does what it takes to educate and keep each child healthy. This includes basic necessities that should be every child’s right: health care, a roof over their heads, someone to talk to, books, stationery and uniforms for school, nutritious food and time to play, imagine and enjoy being a child. The fund recently opened the Ubuntu Centre comprising a clinic and education facilities. The fund has recently partnered with the Bertha Foundation to create an internal leadership development programme rooted in Ubuntu’s holistic philosophy thereby creating an empowering human resources tool and training local people to develop others in their community. Ubuntu is predominantly funded by international donors and funders.

Listening to the voices of resilient community-based organisations
Madri Jansen Van Rensburg Resilience Analysis Consulting, South Africa
In the not-for-profit sector, funding often means survival. Intermediary NGOs source and distribute funding to smaller NGOs and community based organisations. This study involved an intermediary organisation that worked in HIV prevention and mitigation in southern Africa. During 2007 delayed funding disbursements resulted in all the beneficiary organisations having to develop strategies to survive for an extended period. All the partner organisations survived the year without funding. This led to an investigation to determine the factors that enabled this resilience of the organisations and allowed them to be sustainable. A qualitative survey was conducted with 14 partner organisations in seven Southern African countries in 2008. It investigated the coping strategies that partner organisations (non-governmental and community-based organisations) used, and methods they employed, to survive the challenges during 2007 when no funding was available. The survey used an appreciative inquiry approach, where the first (discovery) phase was used to elicit responses in a positive manner. A thematic analysis was done to determine the enablers of the resilience. The information gained provided evidence of the high level of sustainability achieved by the projects. The key strengths and positive factors that emerged from the discussions included (in order of importance): networking and using existing relationships, sourcing additional funding, community involvement, passion and dedication of staff and volunteers, focusing on internal project strengths, transparency and open communication, building on existing structures and resources, using the organisations’ good reputation optimally, advocacy and lobbying and selling services and capitalising on “spin-offs”.

"Once upon a time..." The meaning of older persons' life stories for younger people
Susan Jansen Von Rensburg North West University, South Africa

The aim of this presentation was to explore how young people describe the meaning they attach to the life stories that older persons share with them. The theoretical framework underpinning this study is a narrative inquiry that involves the reconstruction of a person's life story in a relational context. A qualitative analysis and narrative research design were used.

Eighteen students, between the ages of twenty one and thirty, mostly Afrikaans-speaking, took part in this study. The research was undertaken in North West Province, South Africa. The younger generation voluntarily participated in the data by expressing their relational experience with an older person by using four data collection strategies, namely: their own visual projections (the Mnogo method™), focus group discussions, individual interviews as well as personal journal entries. The Mnogo-method™ (Roos, 2008, 2012) consists of visual projection, using clay, beads and straws, concerning the relationship between these two generations emphasised the outcome. The findings that emerged is that the young people found meaning in the wisdom that older people share, which they can apply in their lives, they appreciated the positive outlook of the older persons and the coping of the older persons despite challenging life experiences. The sharing of life stories is a powerful strategy to promote intergenerational solidarity, provided that the stories are applicable and shared in an equal, mutual relational context.

Non-governmental organisations, community development and participation in Kaduna State, Nigeria
Rosemary Kato Kaduna Polytechnic; Nigeria; Eunice Ohidiah; Hafsat Kontagora

As participatory approaches move into the mainstream of development practice, the need to analyse the practice of participatory development has become important. The purpose of this study therefore, was to examine the level of beneficiary involvement in the community development activities of non-governmental organisations (NGOs) in Kaduna State, northern Nigeria. A total sample size of 12 CSOs and 352 of their beneficiaries took part in the study. The beneficiaries were selected from 28 communities in the State. A combination of qualitative and quantitative data collection techniques and tools were used to generate and analyse the data. The data collection tools included semi-structured key informant interviews, focus group discussions and a survey questionnaire. The results from the study suggest that the level of involvement of beneficiaries in NGO community development activities in Kaduna State is highest with respect to initiating and evaluating activities in the interest of sustainability. Provisions, except for a few activities with less (below 60%) community participation, for example, providing land for the school, arrangement of furniture, construction of a boundary wall, maintenance of existing infrastructure, involvement of community members in planning, supervision, establishment of rapport with school authority, taking decisions in financial matters, time schedule, assisting students with their academic work, assistance for organising extra school activities, and encouraging the parents for the enrolment of their children in the school. The study has implications for the government to take necessary steps for improving community participation in all aspects of elementary education. Community participation will be ensured to solve problems faced at school level, which in turn, will help in enrolment, regular attendance, and retention of children in school as well as the academic achievement of children.

A description of an older woman's appreciation of life
Bianca Marx North West University, South Africa

The purpose of this presentation is to describe an older woman's appreciation of life. The theoretical framework underpinning this study is the positive psychology with the focus on happiness and well-being. A case study design was applied on a white Afrikaans-speaking woman (age 67 years), who participated in the research. The study was undertaken at the Potchefstroom Campus of the North West Province. Three data gathering instruments were used, namely: a biographical data gathering method, the Mnogo method™ (Roos, 2008, 2012) which is a method whereby a visual image is constructed with clay, straws and beads. The visual presentation revealed an appreciation for life which is further explored in individual interviews and observations that were conducted afterwards. She applied a sense of humour throughout life to lighten any situation. Humour is regarded as an adaptive coping strategy and it also promotes the development of resilience both in terms of growth and development, which overall promotes the growth of social capital in the community.

Community participation in development of elementary education in India
Parmod Kumar Hari Om Shiv Om College of Education, India; Rajender Yadav

Community participation is of utmost importance in development of elementary education and Improving School Complex, Organising Socio Cultural Activities, Resource Mobilisation for Schools, and Improving Academic Environment and School Management. This research paper is based on a research study conducted on 100 community members selected randomly from Rewari district of Haryana (India) using a Descriptive Survey method. Community Participation Interview Schedule and Percentage method was used for data analysis. The study indicated overall all community participation was high or moderate (with more than 60% community members’ participation) in all five dimensions, except for a few activities with less (below 60%) community participation, for example, providing land for the school, arrangement of furniture, construction of a boundary wall, maintenance of existing infrastructure, involvement of community members in planning, supervision, establishment of rapport with school authority, taking decisions in financial matters, time schedule, assisting students with their academic work, assistance for organising extra school activities, and encouraging the parents for the enrolment of their children in the school. The study has implications for the government to take necessary steps for improving community participation in all aspects of elementary education. Community participation will be ensured to solve problems faced at school level, which in turn, will help in enrolment, regular attendance, and retention of children in school as well as the academic achievement of children.

Exploring awareness of parents of depression symptoms in teenagers
Matheko Masemola UNISA, South Africa

Depression is one of the leading problems troubling teenagers and their families. It is often deemed as important for parents to be aware of symptoms of depression in teenagers, in order to help teenagers in need. The study focused on exploring parents’ awareness of depression symptoms in teenagers. The qualitative method of study was used to select a sample of 12 parent (males: 6, females: 6) in Daveyton, East Rand. The descriptive phenomenological method was used in the study. It was found that factors such as family interaction, parent-child interaction, and parent monitoring are having an effect on awareness that parents have of symptoms of depression in teenagers. It was concluded that this factor needs to be considered in educating parents about depression symptoms in teenagers.

Community-based support groups for mental health-care users in the Tshwane District, South Africa
Leana Meiring University of South Africa, South Africa; Jacques Labuschagne

A number of studies conducted on mental health-care in South Africa suggest that this field is a neglected area. It can benefit greatly from more research. The high lifetime prevalence of psychiatric disorders among the South African population, places increasingly high demands on the country’s already over-exhausted health care system. Community-based support groups have been used in a variety of health-care institutions within and around the Gauteng Province to serve as a source of community-based rehabilitation for mental health-care users. This poster reflects on such an initiative that took place in collaboration with the University of Pretoria and Stanza Bopape Community Health Centre, Mamelodi East. A support group was
formed with eight mental health-care users. They met weekly for the past two years. The group was facilitated by two Psychology Honours students in partnership with the Clinic’s Psychologist. Topics that were discussed during the sessions include: mental health, medication, learning about relationships and social interaction. The research reflects the value of the support group for mental health-care users visiting the clinic on an outpatient basis. The positive outcomes, as highlighted by the participating group members, include: learning about other people and their problems, learning more about mental health, learning about medication. The research findings can serve as a motivation to suggest the implementation of more such community-based support groups for mental health-care users in primary Health-Care Centres around South Africa. Support groups can benefit both the mental health-care users and the practitioners.

A process of empowerment through a self-help group for divorced women
Sibusiso Mhlongo UNISA, South Africa
The best way of understanding empowerment is to focus on its process rather than outcome. As a result, this study was about the exploration of the interaction between empowerment as a process, and the self-help group which forms a structural basis of empowerment. Therefore, the main focus of the research study was to investigate specific processes through which one goes to achieve empowerment, when participating in a self-help group for divorced women. The qualitative research method, which incorporated participant observation, semi-structured interviews and a focus group, formed the basis for the process of data collection and analysis. The sample consisted of 10 divorced women who participated in a self-help group for a contracted period of eight weeks. The findings of the research study suggested that the process of empowerment within a self-help group structure is interactive, rather than linear. The process included discovering the reality of the divorced status, the role of frustration in the process of empowerment, critical reflection as the powerful force behind the process of empowerment, and taking charge of one’s life is a motivational factor that facilitates the self-help group activities and the process of empowerment. The significant finding in this study was how the self-help group can facilitate the process of empowerment for divorced women, which contrasted with other studies in which a sense of community was critical to personal empowerment.

Sense-making of catastrophic experiences using the drawing method
Takumi Miyamoto Osaka University, Japan
Many disasters have burdened the lives of human-kind since ancient times, and we have struggled with them. The 2004 Chuetsu Earthquake destroyed many mountainous villages in Niigata Prefecture, Japan. It accelerated the depopulation and ageing of the communities and raised a critical question: “What does revitalisation mean?” Previous studies on disaster have not discussed long-term revitalisation sufficiently. The authors have conducted longitudinal fieldwork in several villages in the stricken area. The present study attempts to describe and analyse the long-term processes of revitalisation in these communities from the perspective of survivors. Survivors were interviewed and asked to draw their life courses, from the day of the earthquake, as curves on the graph with their characteristic dips, peaks and plateaus. As a result, we obtained various curves and narratives about them. Some curves included the past and the present, while the others contained the past and the future. They indicated that a variety of revitalisation processes depended on the individuals. They also suggested that each survivor had a different perception of time. They were not linear or physical perceptions, but a living time throughout the revitalisation process. From these observations and the interviews, we conceptualised revitalisation process models and discussed it as a collective construction of “living times.”

Variables related to psychosocial needs among people with severe mental illness using community services and their family caregivers
Manuel Munoz Universidad Complutense Madrid, Spain
The main objective is to identify the variables associated with the needs of people with severe mental illness who live in the community, and the needs of their family caregivers. A sample of 95 randomly selected outpatients with severe mental illness was evaluated with the Camberwell Assessment of Needs (CAN), the Global Assessment of Functioning (GAF) and the Short Disability Assessment Schedule (WHO-DAS-II). A total of 53 family caregivers answered the Caregiver Burden Interview (CBI), a Questionnaire of Needs, and the Questionnaire on Coping Styles (COPE). The most frequently-perceived needs by people with mental illness involved psychiatric symptoms, information about illness, companionship and everyday activities. The total number of needs was related to age, educational level, occupational status, living arrangement, global functioning, and disability. Regarding caregivers, their most frequent needs involved individual counselling and support, financial assistance, family associations, and respite care. The total number of needs was associated to coping styles and utilisation of services by the caregiver, as well as level of needs and disability of the relative with mental illness. People with mental illness and their family caregivers have various types of needs, despite the support provided by their formal and informal networks.

Crossing the (Kej) bridge: Reflections of Stellenbosch University Psychology students serving on Phelophepa Health Train
Tony Naidoo Stellenbosch University, South Africa; Lorenza Williams; Sybrand Hagan; Lauren Conchar; Julie McFarlane Stellenbosch University, South Africa
The Phelophepa Health Train in South Africa is a unique primary health initiative that involves collaboration among the private sector, universities and government to provide basic health services to predominantly rural communities. The train is equipped to run a primary health care clinic, pharmacy, dental clinic, an optometry clinic as well as a psychology clinic. The psychology students are also involved in running workshops and other interventions at schools and sites in the adjacent community during their two week placement on the train. The poster provides personal reflections of 4 students who recently completed a stint on the train. In addition to the range of counselling and workshop interventions rendered, the students also reflect on the lessons learnt and insights gained from their experiences with cultural, racial and language differences and poor socio-economic conditions, with rural versus urban contexts being particularly salient. Other reflections pertain to: the role of local translators and relationships between them and the psychology students, the role of psychology in a diverse health context and the observed differences between working in clinical and community settings. Informal discussions helped to bridge the cultural barriers between the students and local translators. These interactions benefited not only the counsellor-translator relationship, but also interpersonal engagement. Students became aware of the challenging role of psychology in rural settings in South Africa and the differences between well-organised, clinical environment and an underresourced and often seemingly unstructured community context. Overall, the team found the experience to be enriching, rewarding and a time of deep personal growth.

Perceptions of younger people about older people in the South African context
Wendy-Lee Naude North West University, South Africa
Interactions between different generations are informed by the perceptions and attitudes that members have of the other generation. According to Relational Theory, relationships between people are informed by the assumptions that people have about another; the expectations they have of the relationship and different relational qualities that are part of the interaction. The goal of this phenomenological study was to explore the perceptions and attitudes of younger people about older people who are unrelated to them. A convenience sample of 47 young adults, 17 females and one male, aged 21-28 years, participated in the Mnogo-methodTM study. This study was used to create visual images about their perceptions of their relationships with older persons, by using clay, beads and straws. The visual images were discussed individually and in a group discussion. The visual and textual data that were obtained were analysed thematically. The findings confirmed the stereotypical perceptions of younger persons about older people and referred to them in terms of their diminishing physical abilities; loss of sight, hearing, mobility and memory. This form of discrimination is regarded as ‘ageism’ and is detrimental for effective inter-generational relationships. It is recommended that the media, both print and social media, be used to portray older persons as active members of society and that their abilities and contributions are highlighted.

The importance of belonging for personal well-being and (active) Dutch citizenship
Imane Oulali University of Amsterdam, Netherlands
Belonging to a particular group is essential for identity development and for acquiring a sense of purpose and meaning in life. Group membership gives shape to our identities based on social relations and interactions rooted in shared beliefs, values, and practices. In short, group membership
Older people’s perceptions about young people from culturally diverse environments in North West Province

Boitumelo Ponela North West University, South Africa

The aim of this presentation is to explore perceptions of older people (60 years and older) about young people (ages 18 and 30) from two different cultural environments in the North West Province (black Setswana and white Afrikaans-speakers).

The theoretical framework that guided this research is that human interaction always takes place within specific relational contexts, embedded in the socio-cultural environment. Qualitative research was used by employing the Mnogo method™, a visual projective technique that uses beads, clay and sticks to make images based on a prompt to visually construct images of their relationship with the younger generation. The first group consisted of 11 older black Setswana speaking people (aged 60-83) and the second group of 13 older white Afrikaans-speaking people (aged 65-85) of both genders. Both groups engaged in informal discussions about their visual representations and their relational experiences with younger people. The visual and textual data obtained were analysed by using visual data analysis methods and thematic analysis. Findings revealed that both of the groups of older people expressed a need to transfer their knowledge and wisdom to the younger generation.

The Setswana-speaking older persons felt betrayed as young people do not use their opportunities, while the Afrikaans-speaking older persons expressed more compassion towards the younger peoples’ challenges. It is recommended that members of the older generation, irrespective of their cultural environment engage with younger people to learn from each other.

In a European Commission Twinning Project, one of the main aims was to develop training manuals for multi-professional teams for the Romanian Mental Health Service, which had been assessed by several international organisations as underdeveloped in terms of its community orientation. One of the main aims of the project was to develop guidelines for improving the management of mental health services and working appropriately with patients. Materials and manuals used outside of Romania were adapted to the Romanian situation and further developed in a three stage process: namely, Basic Training Sessions for multi-professional mental health teams of hospitals and community mental health teams; a Practicing Period back in the specific services and Lastly, Final Sessions, in which feedback was provided and a basis for the final version of the tools was established.

Two types of tools were developed. First, a group of “how to do” tools (instructions), and second, forms and templates were developed for adaptation in local daily use. Altogether a set of 56 such tools were developed and will be presented in the symposium. 13 tools concern management, team work and supervision; 3 relate to continuity of care; 4 serve for securing a day structure; 34 are for working with patients in the fields of occupational therapy, case management, problem solving, social skills, relaxation and activities of daily living; 2 address complex situations. Conclusion: A set of practical tools has been developed which allows the implementation of well organised community mental health care, despite low resources.

Roles that older people apply when communicating life experiences to younger generation

Elmeret Roets North West University, South Africa

This presentation will explore how older people in an intergenerational relationship apply their roles obtained from their life experiences when communicating with members from the younger generation.

The relational theory, proposing the application of a flexible application of roles in intergenerational relations, was applied as theoretical background. In a recent research project conducted in 2012 on intergenerational relations, on how members of two different generations view and experience their relationships with each other, 18 younger people (aged 22 to 30) and 13 older people (aged 60 to 85) participated. A variety of data gathering methods were used as part of this qualitative research effort; including the Mnogo-method (Roos, 2008; 2012), which is regarded as a visual projective data gathering instrument, together with person centred interviews, self reflection journals, observer notes, audio, and video material of both generations. Through visual and textual data thematic analysis the following findings emerged. Older persons tend to apply mainly one role in relation to members of the younger generation based on the life experiences that they have acquired from their careers or topics that interest them. They assumed the role of the educator who taught members of the younger generation, irrespective of the relational context. Being flexible to adopt different roles, depending on the relational context, irrespective of the intergenerational nature of the relationship, hold much more promise for effective intergenerational relations. Future studies about the roles that older persons adopt and portray can contribute to a better understanding of the dynamics of intergenerational relationships.

Exploring connection between emotional intelligence (EI), communication and level of leadership

Saltanat Saduova Kazakh National University, Kazakhstan; Zabira Madalieva; Satybaldy Jakupov; Olessya Fedorovich; Aliya Tolegenova

EI is extremely beneficial in interpersonal experiences. The intelligence to remove emotion from the interpersonal process allows an individual to listen, learn, acknowledge, and understand the individual we are engaged with. People with this aptitude are typically very effective communicators, conflict resolvers, and leaders who can affect people. In this study, the relationship between EI, communicative abilities and level of leadership were examined in a sample of adults (N=60) with the mean age of 31 by using Pearson’s correlation. EI and personal abilities were measured by the following methods: 1. Questionnaire ‘EMIN’ by D.V. Lusin – measures the level of two components of EI: intrapersonal and interpersonal EI. 2. Test «KOS» - gives an opportunity to evaluate the level of communication and organisational abilities of particular person; 3. Test for exploring the level of leadership skills by E. Jarykov and E. Krushelnitskiy. According to empirical research low level of intrapersonal EI was found to be positively associated with low level of communicative abilities. Also the results revealed that the high level of organisational abilities and leadership skills were correlated significantly with high level of interpersonal EI. In the course of this research it was identified that key leadership skills and communicative abilities are related to aspects of emotional intelligence. EI and communication effectiveness are proposed as an important predictor of key organisational abilities.

Prevalence and psychosocial correlates of illicit drug use among school-going adolescents in Thailand

Penprapa Siviroj Chiang Mai University, Thailand; Karl Peltzer; Supa Pengpid

Illicit drug use is a relevant public health issue in Thailand. Assessing the prevalence of illicit drug use among adolescents may guide policies and programmes aimed at reducing illicit drug use among this age group. Using data from the Thailand Global School-Based Student Health Survey (GSHS) 2008, we assessed the prevalence of illicit drug use and the factors associated with it among adolescents (N=2758). Overall the prevalence of lifetime illicit drug use was 6.0% (11.1% males and 1.3% females). Variables positively associated with the outcome in multivariable analysis were male gender (OR=2.71; 95% CI (1.00-7.31), current smoking (OR=4.74, 1.45-15.43), current alcohol use (OR=4.98, 2.31-10.75) and multiple sexual partners (OR=3.15, 1.34-7.42). Results of the bi-variate and multivariable logistic regression analyses are presented. Inbivariate analyses include male gender, poverty, fighting, current smoking, current other tobacco use, current alcohol use, sexual intercourse in the past 12 months, sexual intercourse at the age before 13 years, multiple sexual partners, psychosocial distress, truancy, lack of peer support and parental or guardian supervision, connectedness.
An exploration of relational qualities of an older male in an intergenerational relational project

Bianca Theron North West University, South Africa

Throughout the world, the number of older persons is expanding constantly, and accordingly, intergenerational relations will become important in caring for older persons. This article’s aim is to explore relational qualities that emerged in interactions between members of older and younger generations.

The conceptual framework, that guides this research, is the interactional approach and the Interactional Pattern Analysis (IPA) (Beuks, Roos & Vorster, 2012). In all human relationships relational qualities are present. Subsequently a case study research design was used to study interactions between an older Afrikaans-speaking male (aged 73), and a younger female (aged 21). Data were gathered by applying the Mnogo-method™ (Roos, 2008; Roos, 2012), whereby the older participant was asked to make visual representations of his perceptions of relationships with the younger generation. In depth person-centred interviews were conducted, and used. Textual and visual data were obtained and thematically analysed. In interactions with the younger person, this older participant approached interaction only from his perspective, and interpreted meanings in interactions from his worldview, which he exclusively regarded as the valid perspective. He jumped irregularly between topics during discussion, and, consequently, it was difficult to meaningfully participate. It is anticipated that in an individual who displays the above qualities, intergenerational interactions will be ineffective. Due to the above-mentioned, intergenerational relations might not be a source of care for older persons. It is recommended to create awareness of the impact of relational qualities, through an exchange of thoughts and emotions, to promote intergenerational relationships.

The joys of having grandparents

Helen Venema North-West University, South Africa

The goal of this presentation is to describe the importance of relationships with members of the older generation (people 60 years and older) from the perspective of members of the younger generation (people ranging from 21–30 years). The theoretical framework that informed this study is relational well-being, linked to solidarity, embedded in community psychology and intergenerational theories. A phenomenology approach was used whereby 11 members of the younger aged was purposively selected to participate in the construction of visual images, using the Mnogo-method (}* (Roos, 2008-2012), projecting their relationships with an older person. The group engaged in an informal discussion about their representations afterwards and self-reflections, on both the visual representations and the discussion, obtained were also used as data. The visual and textual data were analysed thematically. Participants portrayed their relationships with their own grandparents and expressed that time they spent with their grandparents is valuable and meaningful. They express feelings of being cared for and loved in these relationships. They value the life skills and life lessons that their grandparents share with them. Grandparents are also portrayed as being important sources of support. Intergenerational relationships informed by these perceptions hold great promise for promoting solidarity. Implications of this research for future intergenerational research could be to explore more relational qualities that can promote and optimally sustain intergenerational solidarity.

An investigation on rural poor girls’ mental health and coping style

Xiaojin Wang Jiangxi Institute of Education, China

This study was to investigate rural poor girls’ mental health and their coping style. 690 girls from rural areas were tested with SCL-90, coping style questionnaire and a questionnaire made by the researcher, among whom 150 girls were paid special attention. Girls from the rural impoverished families have worse mental health compared with girls from the rich families. Junior high female students from the poor families scored higher in aspects of compulsion, depression, hostility, horror, and tendency to mental diseases (P<0.01). Senior high impoverished female students scored higher than junior high’s in all the above aspects, while they show little distinctive difference when compared with girls from rich families. Junior high two-year impoverished girls scored higher than rich girls in terms of illusion and rationalization (P<0.05). Senior high two-year impoverished girls only differ with rich girls in evasion. Impoverished girls tend to use negative coping styles. Significant correlation was found in “self-blaming” and “evasion”. “Self-blaming” had the strongest predicting function for their mental health in that it explains 36.2% variations in SCL-90 total scores. Paying close attention to rural impoverished girls’ mental health and helping them take positive methods to seek help had great significance in improving their overall mental health.

Community psychology state-of-the-science: Theories, methods, communities and ideas

Marliza Montero Central University of Venezuela, Venezuela

An analysis of papers published in international community psychology journals, some national ones, and books published within the field of Community Psychology (CP), covering 2008 to February 2012, was carried out in order to find: 1) what are the main theories and methods in use; 2) what is understood as a community, and 3) what is being practiced as, and generating research about, community psychology. An analysis of innovative ideas being developed during those four years will be presented. International and national journals in English, French, Italian, Portuguese and Spanish are included. Changes and innovations, growing tendencies, main concepts, as well as reinforcement of settled ideas will be presented in tables and graphics.

A study of the characteristics of young, unemployed people who get a job

Matthias Schmidt TU Dresden, Germany

Youth unemployment has recently become a more urgent issue for the European industrial nations. The current field study researches psychological influences that have an impact on the success of re-integration in the labour market. The research question can be expressed thus: In which characteristics do young, unemployed people who succeed in finding a job differ from the ones who don’t find an occupation. A randomised sample of 241 young, unemployed people was examined in a two-wave panel study over a period of 60 months. The measured variables include intra-personal factors like self-efficacy, occupational expectations, locus of control, achievement motivation, and mental health. A logistical regression was performed to identify factors that show a statistically significant relationship to re-employment. The logistical regression identified the variables in which the constantly unemployed participants were different from the ones who managed to get a job. Variables that have been found to have a significant impact were person-centred variables such as self-efficacy, locus of control and mental health.
Session Type: Invited Symposia

Symposium title: Cross-cultural evidence-based health/psychotherapy research among North America, United Kingdom, China, Korea and Japan
Convenor: Akira Tsuda

Introduction of Systematic Treatment Selection: What Dr. Larry Beutler has developed by science
Satoko Kimpara Asian Americans for Community, United States of America

People have diverse ways to cope with stress and problems. Some of methods of coping are ineffective or destructive and are associated with psychopathology. In fact, some of efforts to cope may actually increase the level of distress or lead a person to avoid situations inappropriately. Other methods of coping (e.g., dispositional factors) may serve as indicators for applying either certain interventions or for adapting therapeutic stance that induce and provokes change. Accepting these phenomena and following systematically scientific disciplines, Beutler and his colleagues have been developed evidence-based principles into a process called the Systematic Treatment Selection (STS: Beutler & Clarkin, 1990). This model not only serves as a system of psychotherapy but a method of planning and delivering optimal treatments consistent with established scientific evidence and cross-theoretical approaches. STS posits that clinicians can assess clients dispositional qualities to individually tailor treatment and improve outcome. Moreover, STS provides clinicians with principles and strategies for addressing a wide variety of patient problems that crosscut specific techniques or theoretical orientations. Presently, self-report approach of STS, called the innerlife (Beutler, William, & Norcross, 2008) has been developed and cross-national reliability and validity studies of innerlife among North America, Japan, China, Korea, Taiwan and Argentina have been conducted. The results of moderately high reliability are consistent among these countries and validity studies of matching interventions have shown high statistical significance.

Development of a multiculturally respectful continuum of care for problem gambling in Northern California
Jorge Wong Asian Americans for Community, United States of America

The Problem Gambling Alliance (PG Alliance) is a collaborative developed to meet the needs and provide a continuum of care for individuals, family members and significant others affected by problem gambling (PG). PG Alliance is a unique partnership between local private and public sector collaborators dedicated to the well being and psychological health of the larger multicultural community of San Jose, California. Partners include three nonprofit community organizations and a major public academic research institution who jointly designed this innovative community service delivery model while simultaneously evaluating the efficacy of this model. The PG Alliance provides treatment services, education, outreach, research and evaluation to an ethnoculturally and multilingually diverse population speaking English, Spanish, Vietnamese, Chinese and Tagalog. Finding a therapeutic intervention model that is evidence based and multiculturally respectful was challenging. The adaptation of cognitive behavioral interventions in multiculturally respectful ways has proven to be an effective model. This presentation will highlight successes and challenges encountered from collaborating with community partners that have historically been funding competitors. Insights gained from working with the communities multi-level needs, age cohorts, cultural and linguistic values and practices will be discussed via case presentation. PG Alliance fills a service gap not addressed by the existing Departments of Mental Health, Alcohol and Drug Services, and the Public Health Department.

Symposium title: Situating the psychological subject: Reframing distress through a political economic and cultural lens
Convenor: Serdar Degirmencioglu

Situating the psychological subject: Reframing distress through political, economic and cultural lenses
Serdar Degirmencioglu Ciumhuruyet University, Turkey

The relationship between psychological difficulties and financial strain, poverty and inequality is supported by a growing and robust literature. Rather than contextualise the suffering that has characterised many people’s lives as a result of prevailing political and economic ideologies, psychological well-being has been substantially viewed as an individual issue that requires psychological or pharmacological intervention. In the UK, the solution has been formulated around the need for short term individual modes of therapy that return people to paid employment. However, despite the assumptions of the UK government that increased access to psychological therapies and, specifically CBT, is the universal panacea to the mental health and employment crisis, such an approach has attracted criticism for that very focus on individual solutions to problems that are usually politically, economically and institutionally driven. A growing number of countries share this individualistic mainstream model. For example, in countries as broad as Argentina, Cameroon and India, psychology has been largely modelled on the clinical approach to psychological problems that significantly borrow theories from the West. In the manner in which psychological well-being is constituted and managed, there has been relatively little focus on the everyday relevance of the political, economic and social changes, many of which are part and parcel of globalisation. In the context of psychological problems, different forms of community psychology have been mobilised to resist modernist deficit models that often marginalise indigenous knowledge systems and community processes. These different forms of community psychology include a broad aggregation of approaches that coalesce around the generic principles of social change, participation and empowerment, and could be a worthwhile perspective from which to conceptualise resistance to the above socioeconomic changes that affect the world. For many, the recent global recession has only exacerbated the problematic relationships between constructions of psychological well-being and treatment, and political and economic ideologies. This session will explore global community psychologies as alternative ways to challenge recent global political and economic changes and their associated psychological ideologies. The presenters will focus on the relationship between neoliberalism and the creation of a suicidal cohort in New Zealand, the need to construe the psychological consequences of social conditions in Colombia as medical as political issues, and the way psychology has served the prevailing political and economic order in the UK and Turkey.

Session Type: Symposia

Symposium title: Can psychology serve humanity in postcolonial and globalised contexts?
Convenor: Heather Gridley

Community psychology as a globalised commodity: A South African perspective
Ronelle Carolissen University of Stellenbosch, South Africa

Community psychology is considered to be both a subdiscipline and a paradigm in psychology, a paradigm that shifts over time. However, the concept of globalisation has fundamentally extended the way in which we think about physical geographical communities as bounded space with defined interpersonal relationships. In this paper I will argue that the dynamics of ‘racial neo-liberalism’ has usurped the liberal promise of community psychology in South Africa. Racial neoliberalism refers to the way in which markets are based on and fuel constantly evolving ways of racial patterning in society. Even though the anti-liberatory trajectory of community psychology as disciplinary knowledge was recognised over 20 years ago, insufficient attention to diverting its course to ensure social justice has unwittingly allowed it to contribute to entrenching racial fault lines, as characteristic of racial neoliberalism. I will examine chronologically the critiques (historical-ly) of community psychology to discuss the apparently contradictory convergence of the ideals of neoliberalism and community psychology in terms of transnationalism and the reshaping and intensification of capitalism. I will conclude by raising some dilemmas that the unintentional and perhaps unanticipated co-option of community psychology by neoliberalism poses in terms of reproducing racial and gendered marginalisation and how this may be interrupted.

Symposium title: Community research: Balancing the tensions on the ground
Convenor: Sandy Lazarus

To do or not: Confronting the challenges of community-based participatory research
Charity Akotia University of Ghana, Ghana

Community research, especially community-based participatory research (CBPR), often comes with challenges which have been documented in the literature over the years. However, if researchers and interventionists aim at sustainability in a meaningful way, then there would not even be a debate about
engaged in community research with different groups who have been marginalised or excluded on the basis of dimensions such as race or ethnicity. In this discussion I will draw on research with a community cultural development agency that uses arts practice to promote Aboriginal empowerment and a project exploring how arts-based interventions that facilitate settlement of recently arrived young people of refugee background to consider some deeper tensions and challenges of community research across cultural/social/racial divides. These challenges relate to, for example, issues of translation, knowledge, epistemic power, and authority, privilege and social positioning. I will draw on theorising from critical race theory and decolonising methodologies to reflect on these challenges, and suggest a decolonising standpoint that might move us closer to the emancipatory aspirations and practices of community research.

Using CBPR to mobilise spiritual capacities and religious assets to promote peace
Naiema Taleef MRC-UNISA, South Africa
Community-based participatory research (CBPR) has not only surfaced as an alternative to conventional research, but has also gained popularity. CBPR is more than just a scientific enquiry; it is an emancipatory, empowering methodology that forges a partnership between the researcher and the researched. The SCRATCHMAPS (Spiritual Capacities and Religious Assets for Transforming Community Health by Mobilising Males for Peace and Safety) study is guided by the values and principles of a CBPR approach. The focus of the SCRATCHMAPS study is on the mobilisation of a significant, often marginalised social and community resource to promote safety and peace, particularly in relation to young men in specific communities in South Africa and the USA. Yet, CBPR is not as neat as conventional research but encounters many challenges and barriers. Against this background, this paper will provide an overview of the SCRATCHMAPS study and highlight the tensions involved in conducting such a community-based research.

Complexities and challenges of negotiating CBPR partnership: A relationship among equals
Tony Naidoo Stellenbosch University, South Africa
Sandy, Lorenza, and I are involved in a community-based participatory action research project in Railton, a township in Swellendam. Residents of Railton were displaced forcibly from Swellendam in 1960s through apartheid legislation. We will reflect on our experience of how we have had to weave a dance between action and research in order to be responsive to emerging issues in the process and consistent to the values that undergird a CBPR approach. My input will focus on how we attempted to put the necessary mechanisms in place for a CBPR approach and on the dynamics of partnership in the engagement. Lorenza will speak to the necessity of CBPR and the role of community health by mobilising males for peace and safety. Sandy will focus on the beneﬁts of CBPR and the role of community cultural development agency that uses arts practice to promote Aboriginal empowerment and a project exploring how arts-based interventions that facilitate settlement of recently arrived young people of refugee background to consider some deeper tensions and challenges of community research across cultural/social/racial divides. These challenges relate to, for example, issues of translation, knowledge, epistemic power, and authority, privilege and social positioning. I will draw on theorising from critical race theory and decolonising methodologies to reflect on these challenges, and suggest a decolonising standpoint that might move us closer to the emancipatory aspirations and practices of community research.

Alcohol abuse and risky sexual behaviour: Young low-income Cape Town community
Saharah Adams University of the Western Cape, South Africa; Shazly Savah
Alcohol abuse is recognised as one of the greatest health and social problems in South Africa. It causes an estimated 2.5 million deaths every year, of which a significant proportion occur among the young. Statistics indicate that the age cohort of 18–25 years is most vulnerable to abuse alcohol, and engage in Risky Sexual Behaviour (RSB). Accordingly, the aim of the current study was to explore the relationship between alcohol abuse and RSB among young adults, aged 18–25, in a low income community in Cape Town. Bronfenbrenner’s bio-ecological systems theory was employed as the theoretical position framing the study, emphasising an individual’s own biology as a primary environment which contributes to one’s development. Data was collected using the street-intercept method by employing two instruments namely the Alcohol Use Disorders Identiﬁcation Test (AUDIT) and Self-Report Risky Sexual Behaviours Scale (SRSB). The data was analysed by means of dependence techniques, and more specifically inferential statistics to determine whether: (i) There is a significant relationship between alcohol consumption and risky sexual behaviour (RSB); and (ii) There is a significant difference between males and females with regard to alcohol abuse and RSB. The results indicate that (i) There is a significant relationship between alcohol consumption and RSB among the sample (r= .48; p<.05), and (ii) There were no significant differences between males and females with regard to alcohol consumption and risky sexual behaviour.

Measuring perceived individual and contextual factors associated with adolescent substance use
Maria Florence University of the Western Cape, South Africa; Elron Fouten
This paper will present the procedures undertaken in the development and validation of an instrument that will measure the perceived individual and contextual factors associated with adolescent substance use in low-socio economic status communities in the Cape Metropole. A questionnaire development design was used to develop the instrument and assess its reliability and validity. This design included the identiﬁcation of dimensions for inclusion in the questionnaire, the writing and reﬁnement of items for these dimensions, pretesting for further reduction of items, translation of the questionnaire and a test of their reliability (internal consistency) and validity (using procedures of internal construct validation) for the target population. The dimensions developed were framed by the bio-ecological systems theoretical framework and were developed through a thematic analysis of qualitative data. The process of writing and selecting items included a pretest of the items to see if they are appropriate for the target population, if they (the adolescents) can relate to these items and if they understand the intended meaning of the items. Any culture bias in these items was also highlighted through this process. The instrument was translated into Afrikaans since this is the dominant language in the communities of interest. Reliability (internal consistency) was assessed by calculating Cronbach’s
Substance abuse in the Western Cape: Reflection from a community engagement project
Serena Isaacs University of the Western Cape, South Africa; Charli Davids
The overall purpose of the paper is to share experiences and lessons learned from working within communities, particularly substance abuse interventions in low-income communities. The substance abuse project conducted in the department of psychology for the past two years has identified a need for interventions with the specified communities. The overall aim of the research is two-fold: To conduct interventions within the community as well as to evaluate the effectiveness of those interventions. Participants in the interventions as well as for the evaluation are approximately 44 - 50 people working within organisations in the community both within Cape Town and along the West Coast. Training in basic counselling skills, personal growth and substance abuse (screening, assessment, etc.) were conducted by the psychologists/counselors on the project and took the form of workshops. Participants acquired basic counselling skills as well as participate in activities focused on personal development and substance abuse. The evaluations had a mixed methods goals-based design. Information was gathered in the form of questionnaires (distributed both before and after the interventions) as well as focus groups (which occurred after each of the workshops). Feedback from all participants was very positive, especially in terms of skills learned and a request for more workshops was made. However, the researchers experienced several challenges within this process owing to a variety of aspects such as differing contexts within the different communities. These lessons learned will be discussed as well as suggestions for future research.

The SACENDU project: Monitoring alcohol and drug abuse trends in South Africa
Andreas Pluddenmann Medical Research Council, South Africa
This is an alcohol and other drug (AOD) sentinel surveillance system that monitors trends in AOD use and associated consequences on a six-monthly basis from specialist treatment centres in six regional sites in South Africa. This paper will focus on findings from data collected between January and June 2011 and compare them to findings of previous years. The objective is to identify changes in the nature and extent of AOD abuse in South Africa. Data were collected on admissions for drug abuse treatment from 61 treatment centres, using a one-page form. A total of 8573 forms were collected and data were analysed using SPSS statistical package. Alcohol remains the dominant substance of abuse across all sites. Treatment admissions for cocaine-related problems have generally decreased over the years. Cannabis remained the most common primary drug for persons younger than 20 years across all sites. Heroin admissions remained fairly stable in three sites and increased significantly in one of the sites. Proportions of Black/African patients increased in three sites and proportions of female patients remain low. Treatment admissions for methamphetamine (MA) were low except in Western Cape where MA remained the most common primary drug reported by a third of patients, mostly less than 25 years. An increase in admissions for methamphetamine has been noted in Port Elizabeth. These findings highlighted that SEQ chapter 1a broad range of globally abused substances is present in South Africa and that the burden of illicit substances is increasing. Further research is needed to explore whether stigma affects usage/non-usage of drug treatment by women.

Contextual factors impacting operations of substance abuse treatment centres in Western Cape
Shazly Sovahl University of the Western Cape, South Africa
Operationalising substance abuse treatment centres is a mammoth task no matter where one tries to establish such treatment centres. South Africa, and specifically the Western Cape, has the dubious title of having the highest levels of challenges related to substance abuse. Setting up and operationalising a substance abuse treatment centre within this environment is fraught with many challenges. This paper seeks to examine these challenges by reporting the experiences of persons involved in setting up and operationalising these centres. The Western Cape has three substance abuse treatment centres, fully subsidised by the provincial Government through various funding models. They seek to address the needs of persons with substance dependence. This occurs within the constraints of government funding and capacity in various sectors. Issues pertaining to addressing access, in-patient treatment processes, and discharge issues are universal but have a specific local flavour when one examines the historical and socio-political environment within which the operationalising of treatment centres occurs in South Africa. The local issues include the Dop system (payment to farm workers by giving alcohol), distribution of drugs for specific racial groups during apartheid, and present involvement of high ranking officials in the illicit drug fraternity. This paper will examine and provide a context for examining these factors.

Addressing poverty from a grassroots community alternative in Puerto Rico
Dolores Miranda University of Puerto Rico, Puerto Rico
This paper presents the results of a social community psychology intervention in a poor region of Puerto Rico. The project addresses the role of psychology in the social economic development of the community from a Participatory Action Research perspective. A description of the intervention as well as a critical analysis is provided. Community intervention counters the government’s deceiving manoeuvres with relative success. When working to develop a community enterprise one is faced with overwhelmingly individualistic capitalist ideology embedded within the participants. One of the main challenges faced by the group is to overcome such ideology and affirm a collectivist or associative enterprise. This requires psychological support which leads to self management. Issues of colonisation, poverty, and social inequalities are addressed.

Symposium title: Global psychologies for the enhancement of human development

Difficult relationships between internal and external agents of change: An analysis
Maritza Montero Central University of Venezuela, Venezuela
Community work is a task assumed by a plurality of agents, both within and without the community. Since its beginnings Community Psychology has been focused on the strengthening and mobilisation of stakeholders and other people in communities (internal agents-IA), more or less interested, play an important role in the transformations desired by communities or considered mandatory or useful by public policies or by academic programmes or, NGOs projects. These are
external agents (EA). They should convey to obtain the best results but it seldom is so. An analysis of community interventions both originated within communities or from public policies, academy, or NGOs projects is presented, making a comparison of objectives; methods; ways of establishing contacts between EA and IA; type of participation; commitment and results, plus opinions of IAs and EAs, when that sort of information has been available, is presented. Possible ways to produce respectful and informed relationships are discussed.

Public policies and community psychological interventions: More than givers and receivers
Alicia Rodríguez Facultad de Psicología, Udelar, Uruguay
In this paper the relationships between Community Psychology and Public Policies interventions and work, their methods and ways, their results and problems are analysed and discussed, as they are being carried out in Uruguay. The focus is centred on the links between public officers, people participating in transformational projects within their communities, or being the beneficiaries of those policies, and community psychology agents. Their ways to construct public policies will be described, as well as the political conception underlying the different ways of acting and interpreting what is happening, and also how they understand and produce autonomy, open the way to new possibilities, or restrain them and how this in a positive or negative way affects the different actors involved. The place occupied by the public officers, the current social settings and how they interact with the communities is another important aspect of the research producing these data. It is concluded that there is a need to generate a relationship between external and internal agents, who are supposed to be the subjects and beneficiaries of the policies, allowed to ask questions, and to receive clear answers.

Constructing community psychology in Peru: Scopes and challenges abstract
Tesania Velazquez Universidad Catolica del Peru, Peru
In Peru, Community Psychology is a discipline still under construction. It is in dialogue with, and enrooted and strengthened by, Latin American Community Psychology. Currently, special attention is given to the notion of exclusion and discrimination of a large part of the population that suffered violence as a consequence of the Peruvian internal armed conflict (1980-2000) and to the processes of social disarticulation and corruption that emerged during the years of dictatorship (1992-2000). On the other hand, the impact of natural disasters in the most vulnerable people is also acknowledged, and procedures to tend to this kind of natural disasters are built along with people in the communities. Different narratives and ways of expressing anger and sorrow have been identified, taking on account comprehension of social phenomena and psychosocial characteristics of the participants. A revision of perspectives and criteria is needed, so that the comprehension of problems and vulnerabilities is assured, while considering the cultural diversity. On the basis of this reality, it is important to develop a Community Psychology promoting social strength...ening, participation and citizenship, starting with recognition and knowledge exchange. This paper presents the development of areas of specialisation such as community mental health and community intervention in post-disaster context, within Community Psychology in Peru. The process of strengthening networks and promoting collective action in a post conflict society is analysed, as well as its role in the consolidation of democracy and the promotion of a culture of peace.

Symposium title: Paternal identity and connections: Research findings on unknown, undisclosed, absent fathers. Fatherhood and the importance of connections with fathers
Convenor: Mzikazi Nduna

Narratives of undisclosed paternal identity among young people in Secunda and Upington
Grace Khunou University of the Witwatersrand, South Africa
Both written and spoken narratives play an important role in eliciting how we construct our identity in relation to the world. Therefore, how we talk or avoid talking about certain topics is important in these constructions of self. Although South Africa has seen a proliferation of man’s studies in the past decade many of them focused on conceptualisations of masculinities and fatherhood. Most of these have been aimed at foregrounding and signifying the role of fathers and the significance of social fatherhood where biological fathers are absent. However, these studies have not addressed how young people speak about the absence of their fathers and how this impacts on their concept of self in relation to others. Through a detailed analysis of in-depth interviews with young people in Secunda this paper illustrates the varied and complex ways young people talk about the unknown identity of their fathers. From this examination, the paper concludes that the structures of their narratives coupled with their experiences of secrecy, fear, anger, haphazard disclosure of the identity of their fathers and fear of hurting others all play an important role in how these narratives are shaped and how they in turn shape the narrative builders themselves.

Silence: A strategy used to deal with psychological distress by young people in South Africa
Mzikazi Nduna University of The Witwatersrand, South Africa; Rachel Jewkes
Reported high levels of distress in South African youth are worrying. This paper presents an analysis of expression of distress from narratives of young people in Butterworth, Eastern Cape Province in South Africa. 24 females and 16 males aged 16 to 22 volunteered. Self-reported data was obtained through one-on-one audio-recorded in-depth interviews conducted in isiXhosa, transcribed verbatim and translated into English. Constant comparison analysis discovered underlying meanings for non-expression of distress related to fulfilling distinct but related purposes. Firstly, silence was a strategy for containing a potentially explosive or hurtful situation. Secondly, silence showed gratitude for...
acquired benefits often constructed as parents’ or guardians’ generosity. Thirdly, silence was maintained as a sign of deference, it was not a choice that participants made, but rather they were conforming to standards of respect as set by their society. Lastly, silence was used to protect, in particular, the mother from distress. This study suggests that young people need to be empowered with appropriate and effective ways of handling distress not based on avoidance because silence as a strategy can only delay dealing with distressing issues.

Each interview has a life of its own: Analysis of fieldwork experiences from a study with young men in secunda on paternal connections

Vuyani Pambo Witwatersrand, South Africa

Through an analysis of fieldwork experience for a study with young men in Secunda on Paternal Connections this article aims to discuss how the personal becomes political during an interview. The paper argues that the interviewer’s experiences covertly influence the interview’s direction and consequently affects the nature of the interview. The vicarious experience that the interviewer goes through during and importantly after each interview forces the interviewer to introspect. And because of the interviewer’s experience-listening and relating with the interviewee’s narrative either makes the interviewer shift from observer, to player, to victim and to be the regulator. This shift of roles by the interviewer influences each interview differently and subsequently gives each interview a life of its own with dynamics different to that of previous interviews or those that follow. The nature of the interview-- Inter-view means that there is an interface between the interviewer and the interviewee, both the latter and the former’s experiences are brought to the fore during and after the interview possibly forging a synthesis of experiences. The paper concludes that this is especially true when the questions of the study are of personal interest to the interviewer. This paper dismisses the conventional textbook methods that suggest standardization in qualitative interviews to be the only possibility.

Symposium title: Social justice and mental health: Perspectives from Nigeria, Liberia, Tanzania, United States and Turkey
Convenor: Arpana Inman

Harmful practices: Experiences of women in Nigeria
Anne Calinger Lehigh University, United States of America; Shannon Patterson; Sr. Rosemary Ukata; Linh Luu; Arpana Inman; Asmita Pendse

Nigeria has made tremendous strides over the past decade to protect the rights of its citizens. Chapter 4, sections 33-43 of Nigeria’s constitution, asserts that all people have fundamental human rights. These basic rights, however, have not been upheld for women, who are often treated as inferior. One result of this treatment is that women are still subjected to harmful traditional and cultural practices that can have extreme negative effects on the individual. This paper highlights findings from three individual studies done by, the Center for Women Studies and Intervention, an NGO in Nigeria, which advocates for women’s rights. These studies examine the following harmful practices: “money woman,” widow-hood practices, and female genital mutilation. Specifically, these studies focus on the possible root causes of these practices and how they affect women’s welfare. The studies have revealed that these cultural practices are still very prevalent in Nigeria, and have significant negative effects on the physical, economic, educational, and psychological welfare of women. Given these findings, further social justice research is necessary to examine possible interventions for change, such as, educational programmes that discuss the importance of women’s rights, advocacy visits to government officials, and the implementation and enforcement of new laws. A continued examination of social justice issues in Nigeria is important due to assertions in previous literature that hold that discrimination is associated with psychological distress and negative effects on an individual’s mental health.

Rebuilding motivation for schools following conflict and disaster: Lessons from Liberia and Katrina
Arnold Spokane Lehigh University, United States of America

Schools close following disaster and conflict; sometimes for a few days or weeks, and in war-torn environments for years. In the interim, students, families and teachers experience health and behavioural effects and will adapt in ways that may compromise motivation and concentration for learning and attendance. When disaster and conflict occur, individuals are affected proportionate to their exposure level (Spokane et al., 2011) and their cultural and social vulnerability. Typically, individuals respond in a resilient manner, but when exposure is prolonged or particularly intense, recovery may take longer, and behavioural markers of trauma will be evident for years or even generations. These markers can include mood disorders (educators and students) that affect classroom behaviour, reduced school attendance, compromised family support, and reduced career and educational aspirations. One moderate-term situation (Katrina) and one long-term situation (Liberia) are contrasted. Strategies for addressing mental health concerns that affect students, teachers, and administrator behaviour, as well as specific interventions for training educators to attend to behavioural markers in ways that can improve motivation for learning and classroom performance are discussed.

Symposium title: The space between: The challenges and opportunities of practising community psychology in post-revolutionary Egypt
Convenor: Hana Fahmy

Social capital, collaboration, and housing
Salma El-Sayeh The American University in Cairo, Egypt

With a population growth rate of 2.03%, it is estimated that Greater Cairo has pushed 63% of its population into informal and extralegal areas (Sims, 2010). These informal settlements take the form of what is called “unplanned ‘spontaneous’ urban areas” which suffer from a variety of problems such as poor infrastructure, and the absence of basic services. NGOs and CBOs have taken a leading role in service delivery and social benefit provision. However, adoption of a charity approach and a political environment that limits advocacy has meant that Cairo’s 5000+ NGOs have only had a modest impact on the daily lives of individuals in the informal communities. During the chaos of the revolution, “popular committees” were created in communities across the country where neighborhood members gathered to protect their neighborhoods. These popular committees have now evolved into community-led government “censors” who work to monitor government activities. Due to the revolution, the emergence of such local action groups, and increased civic participation, there is a new opportunity for greater mobilisation and collaboration which can create real solutions to the problems faced by people living in informal settlements. It is essential to understand how collective social capital and collaboration are currently operating in the settlements. This paper will outline a method by which social capital assessments can be utilised to enhance collaboration between community members and institutions, thus creating conditions necessary for meaningful and sustainable development.

Symposium title: Portuguese-speaking adolescent mental health in Europe and South America
Convenor: Marta Goncalves

The qualitative research method from ecological insertion
Julia Bucher-Malusch Universidade de Brasilia, Brazil

The qualitative method we present is based on Bronfenbrenner’s biocological model and was used in the research “Concepts of mental health and perceptions of services related to youth and their families.” This research was conducted in three countries: In Switzerland with multicultural populations, in Portugal, conducting focus groups, and in four states from different regions of Brazil: Porto Alegre, Brasilia, Fortaleza and Belém. The method called ecological insertion was used to obtain qualitative data analysis. The process of ecological engagement began with the training of researchers regarding the decoding of the meanings that emerge in the language, trying to sensitise these meanings to form a penetration in the context to be studied. The emerging symbolic content aimed at achieving meaning or inherent sense in the subject or the group studied. The contexts studied were health care organisations, schools, families and communities. It was determined that this qualitative assessment provided a greater understanding of the quantitative data obtained in view of the training conducted at the level of observation based on the principle of ecological engagement and provided interpretive clarity. The integration of qualitative with quantitative methodology allowed for a more profound study of the results of the conceptions of young people and their caretakers. Qualitative analysis based on Bronfenbrenner’s model has helped to carefully examine the description of the emerging perceptions of the experiences of young people and their caretakers in different systemic levels offered by the model.

Schools close following disaster and conflict; sometimes for a few days or weeks, and in war-torn environments for years. In the interim, students, families and teachers experience health and behavioural effects and will adapt in ways that may compromise motivation and concentration for learning and attendance. When disaster and conflict occur, individuals are affected proportionate to their exposure level (Spokane et al., 2011) and their cultural and social vulnerability. Typically, individuals respond in a resilient manner, but when exposure is prolonged or particularly intense, recovery may take longer, and behavioural markers of trauma will be evident for years or even generations. These markers can include mood disorders (educators and students) that affect classroom behaviour, reduced school attendance, compromised family support, and reduced career and educational aspirations. One moderate-term situation (Katrina) and one long-term situation (Liberia) are contrasted. Strategies for addressing mental health concerns that affect students, teachers, and administrator behaviour, as well as specific interventions for training educators to attend to behavioural markers in ways that can improve motivation for learning and classroom performance are discussed.

Mainstreaming gender in post-2011 Egypt

Farah Shash Egypt

The Egyptian revolution started in January 2011, asking for liberation, social justice and change in the system. Egyptian women had an essential role during the revolution, they participated, organised, and were considered leaders and spokespersons during all phases of the revolution. They were beaten by police, and some lost their lives. This revolution is an opportunity for change of the status of women in Egypt. It should help promote the participation of women in the social, political and economic spheres, and the mainstreaming of gender on all community levels. Unfortunately, post-revolution events have made women’s rights’ activists fearful that women may be sidelined. Already, women have been excluded from, not only the parliament, but also the drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will may be sidelined. Already, women have been excluded from, not only the parliament, but also the drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will guide the nation through a transitional period until a drafting of the constitutional declaration, which will...
students for service delivery on the Transnet-Phelophepa Health Care Train. The overarching theoretical principles of cognitive behavioural therapy are discussed as it is used in providing a foundation for the teaching of Solution-focused Brief Therapy. The discussion expands on how this foundation is then applied to the teaching and practice of the “Single Session Therapy” approach. The unique environment of the Transnet-Phelophepa Health Care Train also presents unique challenges to psychological interventions on the train and in the surrounding communities. The approaches to these are briefly discussed in relation to: Working with clients with limited knowledge or understanding of psychotherapy; and the challenge of brief counselling within the constraints of cultural and language differences.

**Student’s own reflection on the Phelophepa experience**

*Bronwyn Rooi University of the Western Cape, South Africa*

The student reflects on the personal, academic and professional impact the Phelophepa experience had on her as a B Psych student at the University of the Western Cape. She is one of the few students who were placed on the train on two occasions. She reflects on her own shifts from the first placement as a B Psych IV student to the second placement post the completion of the B Psych internship and degree. The exposure to various forms of intervention (individual counselling, psycho-social workshops and psycho-educational presentations in schools, prisons and community organisations) were invaluable in her personal growth. It further enhanced her understanding and capacity to work not only in a curative manner, but also to have strong focus on primary, secondary and tertiary prevention. The following key issues are addressed: Reflection on the quality preparation, training, supervision and debriefing sessions; reflection on benefits from a personal and academic perspective; how interventions impacted on the self, fellow students, and participants; reflection on being a change agent in unserved and under-served areas in rural and semi-urban areas in the country; challenges faced; experiences about living on the train and to work with fellow students and other professionals. An overall reflection is given on how the student was touched by the Phelophepa experience and how it contributed to her professional career development.
Research Area: Consumer/Economic

Session Type: Papers

Enabling entrepreneurship
Werner Barkhuizen Saville Consulting, South Africa

This presentation will provide an overview of the successes achieved by enabling entrepreneurship in South Africa. 25000 individuals applied for a TV Reality Show, and completed psychometric assessments used in the shortlisting of twelve contestants. The winner of the competition won R5 Million. The objective of this presentation is to showcase the predictive validity of the psychometric assessment tools used, as well as the entrepreneurial exercises and simulations utilised during the filming of the show. Thirteen entrepreneurial exercises and simulations were created to measure entrepreneurial potential and contestants’ performance was measured against a pre-defined criterion. Criterion ratings were used to rank order contestants for each task, and determine elimination of poor performing contestants. The psychosocial implications of entrepreneurship are highlighted and societal upliftment, enablement and empowerment are elaborated upon. Through this process the phenomenon of entrepreneurship has been demystified and the lessons learnt will be discussed in-depth.

Development of the survey of impact factors of consumer intention for lottery buyers in China
Wang Bin School of Physical Education, China; Wu Yanping; Shi Wenwen; Wang Nina; Yang Liu

Although an important part of lottery marketing, lottery buyers have been paid less attention in China. This research aims to develop a valid, reliable survey to measure the impact factors of consumer intention for lottery buyers. The impact factors survey was developed in three phases. The items of the survey were collected by the methods of literature and interview, and identified 21 potential impact factors in Phase 1. Exploratory factor analysis (N = 531) was used to generate a 4-factor, 21-item survey in Phase 2. With other data from 930 samples from Beijing, Chongqing, Jiangxi, and Zhejiang in China, the 4-factor model was further verified by confirmatory factors analysis in Phase 3. The structural equation model was used to confirm the impact factor structure and to reduce it to 3 items. The final survey consists of 4 dimensions of impact factors: consumer cognitive, external information function, economic utility and risk appetite. There is a good fitting of the 4-factor model (X2=422.85, DF=98, X2/DF=4.31, NNNFI=0.93, RMSEA=0.06), and the Cronbach's alpha scores for each factor ranged over .735 - .833. Therefore, the survey of impact factors of consumer intention for lottery buyers has a high reliability and validity, provides lottery managers and staff with the research tools that enable them to evaluate lottery buyers’ psychology and behavior, and can be regarded as a key lottery market survey.

Understanding difficult service encounters from customer and employee perspectives: A needs-based approach
Graham Bradley Griffith University, Australia; Janet McColl-Kennedy; Beverley Sparks; Dieter Zapf; Nerina Jimmieson

While most interactions between customers and service providers proceed smoothly, some entail conflict and incivility. The cost of these difficult service encounters to customers, employees, service firms, and the broader economy are considerable. Research is needed to identify factors that can be targeted by organisations to minimise adverse outcomes from such encounters. Most past studies have focused on employee service behaviours (e.g., not listening, misinforming, rudeness) that lead to customer dissatisfaction and complaints. In contrast, the current study examined links between service encounter behaviours performed both by customers and by employees, and the associations between these behaviours and outcomes experienced by both parties. Drawing on Service Encounter Needs Theory (SENT: Bradley, McColl-Kennedy, Sparks, Jimmieson, & Zapf, 2010), behaviours were hypothesised to have their effects via psychosocial need fulfillment/-violation. Questions containing multi-item measures of behaviours, psychosocial needs, own and (perceived) other’s outcomes, demographic and other variables were completed anonymously by 341 customers and 573 service employees. Multi-group (customer, employee) structural equation modelling provided general support for the proposed mediation model. In particular, the effect of several task- and relationship-oriented behaviours on own and other’s satisfaction with the service encounter were mediated by the extent to which the parties’ needs for justice, trust, respect, and pleasing relations were met. By identifying specific behaviours that appear to affect important service encounter outcomes, and by using a needs-based approach to understand the mechanisms by which these effects occur, this study helps pinpoint targets for interventions aimed at improving service outcomes for all.

Too much choice: Is this affecting decisions to volunteer?
Lauren Carroll University of Plymouth, United Kingdom; Sabine Pahl University of Plymouth, United Kingdom

Engaging in volunteer work has been shown to enhance personal well-being as well as providing benefits to society in general. Governments around the world are thus keen to promote greater volunteering activity. However the selection of organisations to volunteer for is extensive. In the UK alone there are over 164,000 potential organisations. Research in consumer decision making for material goods has shown a "too-much-choice" effect whereby the more options people are presented with, the less likely they are to make any choice, preferring instead to postpone or defer making a decision. This paper presents research from a series of studies investigating the extent to which this too-much-choice effect may affect volunteering uptake and recruitment. While virtually all previous research into the too-much-choice effect has considered it in relation to material consumer purchases, the current research thus investigates whether the effect extends to an experiential time-use decision context. We found evidence of the effect in two studies. More options led to greater deferment and this was mediated by feelings of confusion experienced during the decision-making process. In two further studies the effect was not found and we discuss possible reasons in terms of the choice architectures and decision heuristics that may have facilitated the decision-making process and reducing the impact of the effect. Implications for the recruitment and retention of volunteers are discussed alongside the possible benefits of choice architectures to facilitate volunteering decisions.

What influences online unplanned consumer behaviour?
Wenjing Chen Beijing University of Posts and Telecommunications (BUPT), China; Yue Teng

Although the internet has become a new shopping media, there is little research about online unplanned consumer behaviour (ONCB). Our study examines data collected from 700 participants. We found that consumer’s self-efficacy and price are the most powerful factors that could explain peoples’ unplanned purchases online. Impulse characteristics, advertisement and position, interpersonal environmental effect, convenience, price and self-efficacy are correlated with ONCB. These factors combined with internet experiences, convenience and impulse characteristics can be used to forecast the frequency of ONCB. Self-efficacy and impulse characteristics are useful to forecast the amount of ONCB. Only the factor of price can forecast the degree of regret of ONCB. Further research efforts are suggested.

What are the factors influencing Online-Group-Buying?
Wenjing Chen Beijing University of Posts and Telecommunications (BUPT), China; Xinmiao Li

The purpose of this study is to find out the factors that influence Online-Group-Buying (OGB). By literature review, we concluded that there are seven outside stimulation factors: price, graphic display, others’ evaluation, transaction record, remaining time of group buying, the expiration date of the coupons and the reputation of website. Data was collected via an online survey and questionnaire which resulted in 239 valid samples and all subjects had prior experience participating in OGB. The structure equation model and regression analysis were used to analyze the data. The results show that: the prices, graphic display, others’ evaluation, transaction record, remaining time of group buying, the expiration date of the coupons and the reputation of website influenced the emotional reaction of consumers and the intention to engage in OGB. The price, as in the literature, is the most significant factor that influences the emotional reaction and the intention, followed by graphic display, remaining time of group buying, others’ evaluation, and the reputation of the website. According to the conclusions of this study, we propose several marketing suggestions in order to guide the online retailers in their operations. The limitations of this study and future research directions are also discussed.

Impact of the attribution pattern of a company’s statement about brand crisis on brand credibility
Yuanbing Hua GDIFS, China; Lei Lai; Mei Xiao

The impact of the attribution pattern of a company’s statement about brand crisis on brand attitude and brand credibility is studied by this situational simulated
Exploring brand love versus brand liking
Ronel Du Preez Stellenbosch University, South Africa; Marelike Terblanche-Smit

Brand love is a novel construct within the fields of marketing and consumer behavior. This exploratory study aims to investigate the constructs of brand liking and brand love as well as the nature of brand love, as compared to brand liking, amongst three brands, i.e. Apple, BMW and Cadbury. A comprehensive literature review informs the delimitation of the constructs. Brand liking is defined as having positive feelings, such as closeness, connectedness and bonding, towards a brand; whereas brand love refers to the degree of the passionate emotional attachment a satisfied consumer has with a particular brand, and includes positive evaluation, declaration of love, as well as loyalty beyond reason for the brand (Roberts, 2006). A questionnaire (5-point Likert-type scale) comprising of existing measures of brand attachment, brand commitment, brand knowledge, brand love, brand liking and brand loyalty was administered to a sample of 300 respondents. Data were subjected to descriptive analysis, reliability analysis, Pearson correlation and regression analysis. Results indicate that brand knowledge and brand attachment lead to brand commitment and, depending on the level of emotion, leads to a consumer either liking or loving a brand. Cadbury is the only brand regarded as a love brand, while Apple and BMW tend to be perceived as liked brands. This study provides evidence that marketers will benefit from creating brand love by developing an understanding of the needs of consumers and the development of brand knowledge, attachment, commitment and loyalty initiatives.

Factors influencing online compulsive buying disorder
Jiawei Fan BUPT, China

Online Compulsive Buying Disorder (OCBD) characterized by excessive online shopping cognitions and online buying behaviours that lead to distress or impairment. In this study we focus on how online store facilitated OCBD. We mainly discussed four factors that lead to the OCBD, which are self-esteem, self-control ability, depression and obsessive-ness. A questionnaire was designed to measure these factors and online buying features. Regression analysis results indicated that the online shopping’s anonymity, easy access, enhancing merchandise and low price have obvious moderating effects to the process of OCBD. The findings have important implications in psychotherapy, social health, e-commerce and related research.

Buying decisions: The influence of recommendations in comparison to product attributes
Jens Hofmann University of Duisburg-Essen, Germany; Matthias Brand; Raimund Wildner; Claudia Gaspar; Holger Dietrich; Anja Dieckmann; Myriem Hahne

With an increasing amount of product alternatives to choose from, buying decisions become increasingly complex. To reduce complexity, consumers can rely on personal-individual, social recommendations by acquaintances with or without expertise in the specific product category or general recommendations by Internet communities or professional magazines. Due to the Internet, recommendations are increasingly available and instantly accessible. The relevance of these recommendations in comparison to product attributes for buying decisions has not been examined experimentally yet. In the current study, 163 participants (78 male, mean age 26.22, SD=9.03) selected in a choice-based conjoint analysis (CBCA) in 26 trials among three products each the one maximizing their expected utility. The CBCAs were conducted for two product categories - mobile phones and hotel reservations. Each product was represented by four recommendation sources (professional magazine, Internet community, close expert and close layperson) as well as four product attributes. Afterwards, utilities for each recommendation source and product attribute were calculated in a Hierarchical Bayes analysis. The utilities of the recommendation sources and the product attributes differ significantly (F(14, 2268) =115.15, p<.001). Recommendations have higher utilities than product attributes. The close expert is the most relevant source in both product categories. The results indicate that recommendations by experts close to the decision maker are more important for buying decisions than other recommendation sources, for example professional magazines or Internet communities. The importance of recommendations for buying decisions is emphasised by the lower utilities of the product attributes.

Chinese service corporation employees’ emotional intelligence structures
Chen Hui School of Economy and Management, China

This paper focuses on the emotional intelligence (EI) structure. With the Chinese service corporation employees being the subjects, such empirical research methods as interview and questionnaire are adopted to explore the employees’ EI structures. A structural questionnaire is used in this research. The subjects are 167 employees in a chain super-market. Based on the survey, with exploratory factor analysis, six dimensions of service industry employees’ EI structure are proposed: perception of others’ emotion, perception of one’s own emotion, expression emotion, expression control, emotion usage, emotion inspiration. According to the other researches, employees’ job satisfaction, job performance and organizational commitment should be used as criteria to verify the EI structure. The results suggest that all the six dimensions of EI have obvious positive correlation with employees’ job satisfaction, organizational commitment and job performance.

Ethnic identity and consumer buying behaviour among consumers in Ibadan metropolis
Femi Lekanbo Obafemi Awolowo University, Ile-Ife, Nigeria

In recent times, consumer researchers are beginning to realise that aside personality and socio-demographic factors that seem to predict consumer buying behaviour, other variables could be implicated for the decision that consumers reach in relation to their buying intentions. With this rationale, the study investigated the influence of ethnic identity on consumer buying behaviour among consumers in Ibadan metropolis. A descriptive survey design was used for the study. The sample consists of 302 consumers in Ibadan selected using an accidental sampling technique. Data collection was through a self-reported questionnaire that measured demographic factors, ethnic identity and consumer buying behaviour. Results indicate that ethnic identity of consumers have a significant influence on consumer buying behaviour (t(2,300)=-13.307; p<.05). Discussion focuses on the relevance of ethnic identity in predicting consumers behaviour. It was recommended that marketers and advertising firms should henceforth take into cognisance certain socio-cultural indices into consideration in the course of producing and subsequent presentation of goods and services to general public.

Media influence on public opinion and the perceptions of media owners and consumers about its effects
Zeenat Ismail IBA Karachi, Pakistan

The study was designed to examine the way media influences the formation of public opinion and the perceptions of local media owners and youth, about its influence, in Karachi. Major objectives of the study were to investigate whether the media has really fulfilled its duty in protecting the public from political propaganda, to identify the significance of the media’s effect on public opinion, to understand the views of media owners regarding their duty to remain objective, and to determine the perceptions of young consumers in Karachi about the international media. Of the 300 questionnaires distributed, all 300 were correctly completed. The study revealed that the majority of the youth are regularly in touch with the international media. The results clearly showed that only 15.6% of the youth relies on the media completely while the remaining 84.3% do not rely on the media in every case. They believe that media should do their job without any laws or regulations being imposed upon them. Thus, our first hypothesis was proven to be correct. Furthermore, the chi-square results proved our second hypothesis to be true provided that x2=0.4, hence x2=0.05. Therefore, the youth of Karachi have significant differences in their perceptions about
the international media. However, the majority of youth find the media to be highly unreliable and that the media creates unnecessary hype regarding some events.

Exploring the influence of procedural and distributive fairness on cheating behaviour
Joana Katter York University, Canada; Peter Darke; Laurence Ashworth; Andrew Lutzuk
Cheating is a major concern in both the academic sphere and in the business world, highlighted by the prevalence of high profile fraud scandals. Previous work has hypothesized that cheating behaviour occurs below conscious awareness, as individuals balance the need to maximize economic rewards with the need to maintain a positive self-image. Thus individuals engage in cheating behaviour only so long as they remain unaware of the unethical nature of their behaviour and thereby maintain self-perception of honesty. However, this view does not account for the finding that individuals often consciously admit to cheating behaviour. It is hypothesized that fairness motives will increase conscious cheating. The current study examined the influence of experiencing procedural and distributive unfairness in a variant of the ultimatum game on performance of a subsequent marketing task. It is hypothesized that unfair treatment will result in higher amounts of cheating behavior in the marketing task. Results from MANOVA analyses indicate partial support for the hypotheses, with distributive fairness in particular influencing several indices of cheating behavior. Practical and theoretical implications of the findings are discussed within the context of a series of related studies.

Operationalising the role of satisfiers and dissatisfiers in service quality in the hospitality industry in South Africa
Michael Leary University of South Africa, South Africa
A critical measure of organisational success is its ability to deliver service quality on a consistent basis. The hospitality industry is no exception and where business is to be made, competition and new suppliers will be ever present. Customers demand value for their money and are quick to move to another supplier of service, if they perceive that they are not receiving service quality. Customer feedback therefore becomes crucially important and customer satisfaction and service quality measurements should be important management tools in any organisation’s ability to remain in business, and to compete effectively with the competition. While measurement of both service quality and customer satisfaction are important, it is also necessary to determine the role of satisfiers and dissatisfiers in the achievement of service quality. While all service determinants in the customer service encounter are important, certain determinants can be utilised more effectively by management to enhance the level of service provided. This study set out to determine those service variables which tend to be satisfiers and those which are dissatisfiers in particular situations. Two small hotels were used in the study to obtain a guest sample. Results from the study are reported as is the role of satisfiers and dissatisfiers in providing customer satisfaction and service quality.

Do childhood experiences of economic problems affect risk tolerance and stock market participation
Antti Lehtoranta Aalto University, Finland
I estimate direct effects of childhood experience of economic problems on risk tolerance, and market participation, later in life. In particular, I use exogenous father’s unemployment, and five other childhood family level measures of economic problems as treatment variables to explain survey based risk tolerance metric and stock market participation. I use two U.S. individual level surveys: Health and Retirement Study (HRS) and Panel Study of Income Dynamics (PSID) to estimate these effects. The PSID allows for examining intergenerational effects since the start of the survey in 1968. Specifically, PSID allows identifying exogenous job losses (factory closed, employer died), allowing for causal inference of effects of father’s job loss on later behavior of children. The HRS survey was started in 1992. It samples respondents who were born as early as 1890, thus it includes respondents who were children during the great depression. These adults are asked several questions to evaluate if their family experienced economic hardships when they were children. In estimating the risk tolerance effects, I use interval regression controlling for age, wealth, income, education, marital status, aggregate consumer confidence, as well as individual unobserved effects. I use a similar panel logistic regression model to estimate the stock market participation effects. I find no support that the economic problems experienced in childhood have direct effects on risk tolerance and stock market participation later in life. The economic problems experienced do predict differences in education, and thus indirectly affect later economic behavior.

Understanding the island tourism image formation in Taiwan: Via fuzzy preference relations
Fangyi Liu NTUST, Taiwan, Republic of China; Moue-Jane Lee
This study intended to construct a model of tourism destination image formation in Taiwan and to compare the difference between experienced and potential visitors. The population for the study was citizens of Taiwan and there were 430 questionnaire results. Results revealed that most subjects had a positive image of Taiwan and were motivated to acquire intellectual knowledge. Their most important information came from resources such as books, movies and news. Most subjects were “allocentrics” who were inclined to be adventurous and independent. They perceived that the destinations’ culture and history attracted those most, and felt pleasant, aroused and relaxed. Four conclusions were drawn. (1) It is a homogeneous and heterogeneous travel market in Taiwan. (2) Personal interests and commercial profits interweave to become the most important information sources. (3) There is no difference between experienced and potential visitors in terms of their image formation. (4) A model of tourism image formation is modified by using Fuzzy Preference Relations (FPR) that suggests that psychographics is the most critical variable affecting overall image in the model. The finding makes great contribution to the destination image literature. Implications and suggestions to practice and future research have been discussed.

Development the theme park brand equity model of Taiwan
Fangyi Liu NTUST, Taiwan, Republic of China; I-Ling Chien; Mei-Wei Lan; Szu-Min Chien
Theme parks provide consumers different attribute values. Whether the brand equity determinants of theme park would be different from product brand equity, for those theme parks that provide different entertainment experience and services at the same time. The research objects are the consumers of seven theme parks in Taiwan. The purpose is to explore the essences of theme park brand equity. The results indicate that (1) “Awareness”, “Royalty”, “Service Quality”, “Entertainment-Quality”, “Unique” five determinants have significant impact on building brand equity. (2) “Service Quality” is more important than “Entertainment-Quality of quality” for building brand equity (3) Each theme park has its brand equity essences. “Awareness”, “Royalty”, “Organisational Association”, “Brand Characters”, “Service Quality”, “Environment Quality”, “Entertainment-Quality Quality” and “Unique” have different influence to brand equity components.

The research of luxury consumption behaviour and motivation in Chinese market
Liu Liu Yang China
With the rise of the Chinese luxury market, there comes the need for luxury consumption psychology. This is the first research focused on Chinese
high-end luxury consumers, intended to figure out the differences between Chinese rich people, who are highly influenced by the oriental traditional values and Western rich people. The main research model is VMDBI Values-Motivation-Behaviour. The test group is the luxury brands in Beijing. The result of the research confirmed the model, which means that there is a clear linear relation between consuming values, consuming motivations and consuming behaviours. This result can help luxury brands to realise the true psychological needs of their consumers and fulfill their appeals to develop their brands.

Consumer perception about ethics in advertising

Navin Mathur, University of Rajasthan, India

Ethics refer to a system of accepted beliefs based on morals that control behaviour. They provide guidelines for morally appropriate behaviour for businesses. This research was conducted to find out about consumer perception of ethics in advertising. Consumer perception was judged on the basis of six variables (confidence building in product, role of advertising in selecting right product, truthfulness of information, exaggeration of facts, correctness of claims, decency, undue advantage of lack of information/education, impact of dangerous stunts on minors, adverse impact on children, adverse impact on family relations, indecent representation of women, representation of women in tobacco and alcohol advertising, correctness of price information, misinformation through comparative advertising, scientific reasoning of nutritional and health claims, clarity of terms and conditions) based on the code of conduct prescribed by Advertising Standards Council of India. The research is based on primary data collected through a structured questionnaire administered among 500 consumers selected on a convenience basis. A four-point Likert scale was used and weights ranging from 4 to 1 were assigned to assess consumer perception. The hypothesis was tested using the Chi-square test. The research shows consumer perception is high in six (exaggeration of facts, adverse claims, undue advantage of lack of information/education, impact of dangerous stunts on minors, adverse impact on children, adverse impact on family relations) and moderate in the remaining ten variables. It differs according to gender, age, education and the occupation of consumers.

The consumers’ decision-making process in the local food system: An empirical research in Sicily

Laura Milani, Iulm University, Italy; Barbara Ghirghelli; Vincenzo Russo

The Mediterranean diet is an eating pattern characterising a lifestyle and culture reported to contribute to better health and quality of life. (UNESCO, 2010). Strong theoretical and conceptual frameworks, integrating constructs from the different research traditions and disciplines are used. (Douglas et al., 1997)

The objective is to assign to homogeneous groups in the Milan metropolitan population, food education programmes and communication campaigns. The aim of this interdisciplinary research is to examine the applicability of population segmentation based on the adherence to the Mediterranean diet, food lifestyle and the BMI score. Using a cross-sectional survey, the subjects, primary school-aged children (6-11 years) and their parents living in the metropolitan municipality of Milan are studied. The instrument used is a self-administered questionnaire completed by the parents (N=1900), constructed from the consumer psychological and epidemiological literature review (Sahingoz et al., 2011) and consists of 40 items researching the following areas: socio-demographic, food purchase and consumption habits and values, physical activity and anthropometric measures, lifestyle habits and other habitual factors such as nationalities. A cluster analysis is conducted according to a Mediterranean diet score defined a priori on the basis of the literature, considering specific principles sustaining the traditional healthy Mediterranean dietary patterns, although high adherence to the Mediterranean diet and lifestyle score, educational and informing activities on nutrition are needed.

An experimental approach to the optimisation of customer information at the point of sale

Friedrich Mueller, Leuphana University, Germany; Roland Guenther

Do-it-yourself-stores attract, by product ranges, up to 75,000 different articles. As most of the custo-
mers are lay people, the points of sale (POS) must provide clear and understandable information and support in the decisions for the most suitable product. An experimental approach was applied to optimise the presentation of saws. 4 participants each were given suitable material together with one out of 8 different instructions for a predefined action (e.g. produce a picture frame). They were then asked to search for the most suitable tool to meet the task. While searching at the POS participants were cam-
corded and instructed to think aloud. Indicators for effectiveness, efficiency and customer satisfaction were the adequacy of the selected tool, the time spent on the shelf, and the scaled certainty that the right tool was found. Camcorder, voice records and interviews subsequent to the experiments were the basis for fundamental changes in the design of the POS. After redesign the experiments were re-
peated with other participants. At the redesigned POS the effectiveness of search was increased from 50% to 92%. Search time was reduced from 260 to 194 seconds and the certainty having selected the correct saw increased from 50% to 77%. Customer surveys prior to, and after installation of, the revised presentation surfaces validate the experimental findings. In addition, the participating markets report a significant increase in revenues at the new designed POS and the sales engineers report less effort maintain-
ing the optimised shelves.

Food consumption and healthy behaviour: Empirical research in a metropolitan area in Italy

Laura Milani, Iulm University, Italy; Barbara Ghirghelli; Vincenzo Russo

The Mediterranean diet is an eating pattern characterising a lifestyle and culture reported to contribute to better health and quality of life. (UNESCO, 2010). Strong theoretical and conceptual frameworks, integrating constructs from the different research traditions and disciplines are used. (Douglas et al., 1997)

The objective is to assign to homogeneous groups in the Milan metropolitan population, food education programmes and communication campaigns. The aim of this interdisciplinary research is to examine the applicability of population segmentation based on the adherence to the Mediterranean diet, food lifestyle and the BMI score. Using a cross-sectional survey, the subjects, primary school-aged children (6-11 years) and their parents living in the metropolitan municipality of Milan are studied. The instrument used is a self-administered questionnaire completed by the parents (N=1900), constructed from the consumer psychological and epidemiological literature review (Sahingoz et al., 2011) and consists of 40 items researching the following areas: socio-demographic, food purchase and consumption habits and values, physical activity and anthropometric measures, lifestyle habits and other habitual factors such as nationalities. A cluster analysis is conducted according to a Mediterranean diet score defined a priori on the basis of the literature, considering specific principles sustaining the traditional healthy Mediterranean dietary patterns, although high adherence to the Mediterranean diet and lifestyle score, educational and informing activities on nutrition are needed.

An experimental approach to the optimisation of customer information at the point of sale

Friedrich Mueller, Leuphana University, Germany; Roland Guenther

Do-it-yourself-stores attract, by product ranges, up to 75,000 different articles. As most of the consumers are lay people, the points of sale (POS) must provide clear and understandable information and support in the decisions for the most suitable product. An experimental approach was applied to optimise the presentation of saws. 4 participants each were given suitable material together with one out of 8 different instructions for a predefined action (e.g. produce a picture frame). They were then asked to search for the most suitable tool to meet the task. While searching at the POS participants were camcorder and instructed to think aloud. Indicators for effectiveness, efficiency and customer satisfaction were the adequacy of the selected tool, the time spent on the shelf, and the scaled certainty that the right tool was found. Camcorder, voice records and interviews subsequent to the experiments were the basis for fundamental changes in the design of the POS. After redesign the experiments were repeated with other participants. At the redesigned POS the effectiveness of search was increased from 50% to 92%. Search time was reduced from 260 to 194 seconds and the certainty having selected the correct saw increased from 50% to 77%. Customer surveys prior to, and after installation of, the revised presentation surfaces validate the experimental findings. In addition, the participating markets report a significant increase in revenues at the new designed POS and the sales engineers report less effort maintaining the optimised shelves.

Signaling with sustainable innovations

Ernst Noppers, University of Groningen, Netherlands; Jan-Willem Bolderdijk; Linda Steg; Kees Kelzer

Sustainability-related innovations are a hot topic today, and if adopted, a positive development in combating climate change. However, these innovations often come with a cost for consumers. Take for instance the electric car (EV). Compared to "traditional" cars, EVs are expensive, have a limited driving range, and recharging is time-consuming. Besides, stressing environmental benefits, stakeholders typically promote EVs by stressing how consumers can cope with these instrumental drawbacks. However, based on Steg (2005), we argue that cars not only have instrumental, but also affective and symbolic (signaling) functions. We hypothesise that, especially for early adopters, non-instrumental factors, such as self-expression and status concerns, play a key role in the interest in EVs. We also hypothesise that people don’t recognize the impact of these motives on their preferences. A questionnaire study among potential car buyers supported our reasoning, revealing not only the impact of symbolic motives but also how underrated this impact is. When asked how important different attributes of EVs are, respondents rated Instrumental (e.g. range) and environmental attributes as most important. However, the actual interest in EVs was predicted by evaluations of symbolic and environmental attributes of EVs, while instrumental attributes did not play a significant role. Our findings have important implications for marketing EVs. They suggest that persuading early adopters should focus more on the signaling functions of EVs and less on coping with functional drawbacks.

Is employment in a call center sickening and affecting the effectiveness of managing customer needs?

Devina Oodith, University of KwaZulu-Natal, South Africa; Sanjana Brijball Parumasar

This study aims to assess the impact of Sick Building Syndrome (layout, ergonomic design of workstation, lighting/ventilation, health, noise and aesthetics) on the effectiveness of Call Centre agents in managing
customers and their needs. The study was undertaken in the Durban area and was conducted within a Public Sector service environment which comprised of four major call centres employing a total of 240 call centre agents. A sample of 151 call centre agents was drawn across these four centres, using a simple random sampling technique and secured a 65% response rate. These call centre agents were responsible for inbound calls only. Data was collected using a self-developed, precoded questionnaire whose psychometric properties of validity and reliability were statistically determined using Factor Analysis and Cronbach’s Coefficient Alpha respectively. Data was analysed using descriptive and inferential statistics. The results indicate that the dimensions of Sick Building Syndrome have the potential to impact on employee performance. Analyses reflect, in descending level of impact, that noise and aesthetics followed by effects on health, poor ergonomic design, poor workplace layout and poor lighting and ventilation impact negatively on agents’ performance and their effectiveness in managing customer needs. Based on the results of the study, a graphical representation has been designed and presents recommendations that, when implemented in call centre environments, have the potential to enhance agents’ effectiveness in managing customers and their needs.

Being on top of your game at the bottom of the pyramid
Pravina Oodith University of KwaZulu-Natal, South Africa; Sanjana Brijball Paramusur
This study aims to conceptualise competitive business-level strategies that multinational corporations (MNCs) can adopt in order to profitably market products and services to South Africa’s Bottom of the Pyramid (BOP) market. The study adopts a theoretical research study. It reviews statistics and secondary data on the extent of global and domestic poverty. The BOP proposition, as advocated by Prahalad (2005), is examined and the researchers assess how the prevailing strategies need to be altered in order for MNCs to profitably serve the needs of BOP consumers in South Africa as well as establish a competitive advantage. The secondary data indicates that businesses need to radically re-design their business models, focus on lowering their costs through economies of scale without compromising on quality, understand the needs of the BOP market, utilise advanced and emerging technologies in order to innovate smart yet practical products, and redesign their distribution networks. The authors confirm that by redefining business strategies MNCs can offer low-priced, yet good-quality products to BOP consumers in order to secure and grow market share and profits whilst eradicating poverty. They also propose a model of underlying strategies for active participation at the bottom of the pyramid.

The effect of agreeableness on the relation between perceived useful, perceived ease of use and intention to use 3G mobile
Lingsi Qiao Peking University, China; Lei Wang Peking University, China
Mobile phones are ubiquitous and have become a part of everyday lives, while the third generation mobile telecommunications (3G) systems are not widely accepted by customers in China. The purpose of this study is to analyse personality influencing customers’ usage of 3G mobile services. We applied a technology acceptance model (TAM) and proposed that the relationship between perceived useful, perceived ease of use and intention to use 3G mobile depends on customers’ standing on agreeableness. Specifically, we expected that high-agreeableness customers’ intention to use 3G mobile was high even when their perceived useful and perceived ease of use were low. The positive relation between perceived usefulness, perceived ease of use and intention to use 3G mobile was not significant. In contrast, perceived usefulness and perceived ease of use were positively related to intention to use 3G mobile when customers’ agreeableness was low. Results revealed two 2-way interactions in 356 participants who were tested twice within a one week interval and were generally supportive of our predictions. The findings reveal the important effect of personality on 3G mobile use intention and supply a new way to develop the use of 3G mobile.

Short-term modulation of temporal discounting in the view of life-history theory and optimal foraging theory
Li-Lin Rao Chinese Academy of Sciences, China; Xiao-Tian Wang; Shu Li
To understand an organism’s temporal discounting in contrasting or variable environments, foraging, allocation and life history should be integrated. The aim of the present study was to examine the short-term modulation of temporal discounting within a synthetic framework of life-history theory and risk sensitive foraging theory. Studies 1 and 2 demonstrate that a lower daily body-energy budget would lead to steeper future discounting in natural contexts. Studies 3 and 4 test predictions drawn from the life-history perspective. The results revealed that the body-energy budget simultaneously affects the survival and reproduction strategies and that it is domain-specific in the short-term modulation of temporal discounting. From these studies we suggest that primary evolutionary traits underpin modern economic behaviours and financial activities. In general, our results emphasise the importance of considering how resources might be allocated among life-history traits in the field of temporal discounting.

Using multi-method measures in consumer research investigating eye-tracking, electrodermal activity and self report
Beverley Sparks Griffith University, Australia; Helen Perkins; Ying Wang; Jan Mattsson
Applied research is frequently compromised by the limitations associated with using a single source to measure complex dependent variables, such as affective and motivational phenomena. In the field of consumer psychology, customer evaluations are almost universally assessed via self reports. The limitations and biases associated with this data source are well known. This presentation reports on a study that uses a novel triangulation approach to the measurement and analysis of attentional and affective responses to tourism promotional material. The approach comprises two psychophysiological technologies (eye-tracking and electrodermal activity) as complements to more traditional self-report data.

The effect of free, prepaid or shared-benefit advice on decision making in gain and lose situations
Che Tang Beijing Normal University, China; Gonggu Yan
Gino F. (2008) indicated that people tend to accept prepaid advice because of the sunk cost effect. The purpose of this study was to investigate how decision makers were influenced by free, prepaid or shared-benefit advice in gain and lose situations. 193 subjects were randomly assigned to free, prepaid or shared-benefit advice conditions using the Judge-Advisor System (JAS). In each condition, participants first made a decision in a gain situation and then in a lose situation. All of the subjects were paid for decision making with valued-tokens based on performance. It was found, not surprisingly, that (1) when the offered advice was free, people tend to know it, but value it less, however, (2) people tend to buy advice in gain situation rather than in lose situations, but equally accept them, and (3) people asked for shared-benefit advice equally in both gain and lose situations, but they tended to accept the advice more readily in lose situation. The results in prepaid conditions could be explained by prospect theory and sunk cost effect. The results in shared-benefit conditions were more complex. It partially supported Harvey and Fischer’s (1997) hypothesis that people took advice to share responsibility in lose situations. A new two-process model which could explain all the above results better was proposed and discussed in detail.

Overconsumption: Can it be a means of escape from existential fears?
N. Pinar Ugurlar Gediz University, Turkey; Mert Tekozel
Starting from the terror management theory (Greenberg, Pyszczynski and Solomon, 1986), this study investigates how anxiety arising from the ‘awareness of death’ implicitly affects consumers’ decisions. An experiment was conducted to demonstrate the effects of mortality salience, self-threat and product status on two consumption-related measures for a specific product, i.e., willingness to pay and purchase intention. 143 university students were randomly assigned to one of the eight experimental conditions in a 2 (feedback: self-threat vs. control) x 2 (mortality salience: death vs. dental pain) x 2 (product status: low vs. high) between-subjects design. Results demonstrated that subjects

Two short promotional videos were used as stimulus materials in a study seeking to better understand potential consumer responses to such material. Respondents (N = 10) viewed video material presented on an eye-tracking screen while wearing an unobtrusive wrist-band measuring electrodermal activity. On conclusion of the video, respondents completed a self-report questionnaire. The modest associations obtained through these three sources of data are viewed as a positive outcome in that electrodermal activity (arousal), direction of gaze (interest), and self-reports (hedonic tone) are viewed as important and complementary components of consumers’ responses. The presentation explores the use of complementary data to assess attentional and affective responses, as well as the advantages and challenges associated with this triangulated approach.
who were reminded of their mortality have higher purchase intention even for the low-status product. Mortality salience did not lead to any difference on willingness to buy. Instead, willingness to buy was affected by the presence of self-threat. Subjects who were exposed to self-threat were willing to pay more for the high-status product. Overall, the data seems to suggest that existential anxiety boosts the tendency toward overconsumption by increasing consumers’ purchase intention whereas self-threat raises the value of the high-status product by increasing willingness to pay. Importantly, results of this study indicate that there is a clear difference between the factors influencing willingness to buy and purchase intention of consumers although these two measures seem to indicate a very similar consumer attitude towards a product. This study highlights the need in the literature to rigorously explore reasons for this difference between measures.

Consumer vulnerability: A new frontier in consumer research and teaching

Leona Ungerer University of South Africa, South Africa

Human well-being is intricately linked with acquiring, consuming and disposing of goods and services. All consumers may experience vulnerability, characterized by powerlessness and a lack of control during the consumption process. Some consumers, however, may be particularly vulnerable to exploitation because they do not have the necessary marketplace expertise as a result of their age, economic conditions or low level of literacy. Vulnerability analyses include mainly vulnerability defined by demographics, the environments in which people live, the situation in which they find themselves, and people’s community and context. It has, however, been proposed that vulnerability should not be regarded as a property of groups or environments – it should be approached as a dynamic process, and not a static state. Vulnerability is not an acceptable condition and when vulnerability is investigated as a multidimensional process, pathways to building resilience may become evident. Investigating consumers’ experiences of vulnerability and their resilience in dealing with these experiences offers ways to transform consumer research, which aims at improving consumers’ well-being. Investigating the process of vulnerability, especially in developing countries, appears warranted in the light of the high incidence of groups who have been traditionally regarded as at-risk consumers, for instance the poor and people with low levels of literacy. In this presentation, we share how we incorporate consumer vulnerability in two honors research modules in consumer psychology at the University of South Africa.

Mental accounting of time and its influence on intertemporal choice

Pei Wang Peking University, China; Guibin He; Lei Wang Peking University, China

Mental accounting describes the entire process of coding, categorising, budgeting, and evaluating. Previous studies indicated that people create a mental account for time as they do for money. With the aim of extending previous results, this study first examined whether the mental accounting of time is a topical mental account or not by modifying the station tickets paradigm advanced by Leclerc, 1995. However, unlike the previous study, we found that the mental accounting of time was a minimal account which was only influenced by the absolute saving level. Furthermore, we investigated whether the mental accounting of time would affect inter-temporal choice just like the mental accounting of money does. Two consecutive experiments were carried out and it was found that people tended to bear a smaller discount rate when they were in the work account compared with the leisure account, whether it was a money-related intertemporal choice or a time-related one was irrelevant. So, the influence of mental accounting of time is a crucial factor that we should pay attention to in the further study on intertemporal choice.

Self-predictions of future financial risk tolerance

Rebecca White University of Chicago, United States of America; Derek Koehler

Many important life decisions require us to make predictions about our future behaviour. Previous work suggests that when making self-predictions, we often place too much weight on the strength of our intention to carry out a target behaviour at the time of prediction, and fail to account for future situational factors that can affect the reliability with which intentions are translated into action. We examine whether people may systematically mispredict their future risk tolerance, and, in particular, may overestimate the likelihood that their future risk-taking behaviour will coincide with their current intentions at the time of prediction. In three studies, we presented participants with 40 investment decisions presented in either a narrow (one-at-a-time) or broad (four-at-a-time) investment outcome bracket, in which they chose to make either "conservative" (high probability of small gains), or "aggressive" (low probability of large gains) investments. In a manner consistent with myopic loss aversion, those in the narrow bracket condition made fewer aggressive investments than those in the broad bracket condition. Although participants were aware of the frequency with which they would evaluate their investment outcomes, self-predictions made before the simulation were insensitive to this influence, especially in developing countries, appearing warranted in the light of the high incidence of groups who have been traditionally regarded as at-risk consumers, for instance the poor and people with low levels of literacy. In this presentation, we share how we incorporate consumer vulnerability in two honors research modules in consumer psychology at the University of South Africa.

Spending vs. redemption: How cash gifts differ from gift cards

Rebecca White University of Chicago, United States of America; Oleg Urminsky

Gift cards hold great appeal for many gift givers and gift recipients. In order to better understand the underlying psychology of gift cards, we address a novel question: how does purchasing with a gift card differ from purchasing with equivalent cash? Across a series of five studies, we show that the format in which people receive gift funds, as either a cash gift or a gift card, influences how those funds are mentally categorised and spent. First, we demonstrate that the presentation of a gift card rather than an equivalent cash gift leads to significantly greater spending, with intended and actual spending exceeding the amount of the original gift on average. Even when the gift card has unrestricted use and unspent funds are returned as cash (i.e., when the card is therefore economically equivalent to cash), receiving a gift card still led to significantly greater spending than with an equivalent cash gift. Therefore, we conclude that difference in payment mechanisms does not fully explain the spending boost we demonstrated for gift cards. Our evidence suggests that gift cards, while functioning as a currency, are thought about more as objects than currency. We differentiate this unique characteristic of gift cards from other mental accounting phenomena, such as windfall gains or earmarked funds. We further propose that the gift card spending boost results from the object-like properties consumers associate with gift cards (as opposed to currency-like properties) and we examine this mechanism in a series of studies.

Time perspective and investment decision-making

Cai Xing Renmin University of China, China; Wenjun Wang; Jian-min Sun; Jia-jie Cai

Can shifts in time perspective as individuals are approaching an ending influence their decision-making propensity? Based on socioemotional selectivity theory and regulatory focus theory, we hypothesised that unless individuals are approaching an ending, they are motivated more toward maintaining a nonloss status than toward gaining rewards. In contrast, when approaching an ending individuals are motivated more toward gains than toward a nonloss situation. Three experiments were conducted to compare individuals investment decisions at different time stages as they were working through a set of decision tasks. It was predicted that participants would increase their investment toward the end of the tasks. As predicted, participants in Experiment 1 significantly increased their investment as they were approaching the end of the decision tasks. This effect remained significant after controlling for rewards associated with previous investments. Experiment 2 further corroborated this finding and showed that this tendency was unlikely to be caused by factors other than approaching an ending (e.g., fatigue or practice effect). In Experiment 3, participants increased their investment toward the end of the decision session even when they were offered the opportunity to participate again, suggesting that findings reported in the present research were not simply due to anticipated regret of not having the chance to participate again. The present research expanded the existing motivational accounts of decision-making and suggested great research opportunities to integrate factors associated with time perceptions of approaching an ending into existing models of decision-making.

Operators and weight distribution in consumer commodity assessment

Jiaoyuan Yu Nanjing Normal University, China

The purpose of this study was exploring the operators and weight distribution in consumer commodity assessment. Undergraduates’ evaluations on Master Kong beef instant noodles were used as a case in this research. The Likert scale was often
Does satisfaction moderate the relationship between repurchase intention and repurchase behaviour?

Huan Zheng BUPT, China; Wenjing Chen

Reesearchers have demonstrated that satisfaction is one of the most powerful drivers to customer retention, while, how it works and the relationship between the variables are controversial. This research mainly aims at exploring whether customer satisfaction moderates the relationship between repurchase intention and repurchase behaviour when online buying is concerned. The study is conducted in collaboration with “Dipartimento dei Servizi all’Agricoltura P.O. Promozione dell’agroalimentare, Regione Lombardia”. Data has been collected following a mixed methods approach with the usage of typical food. This work has been conducted in a convenience sample of 58 South African students at the University of the Witwatersrand and 1273 questionnaires (972 online and 301 paper). One quantitative instrument, the Smart-Phone Usage Diary, captured the usage pattern of the participants in the form of frequencies. From the findings it was evident that there was a strong, positive and significant relationship between addiction and impulsivity. Females on average had a higher addiction level than males, whilst males were more impulsive than females. The Smart-Phone Usage Diary unveiled that Social Media and Social Networking were most frequently used, as well as impulsive checking of the phone despite it not having vibrated or beeped. This study implicates that smartphone addiction cannot be equated to Internet addiction but that there are different underlying dynamics between the two. Furthermore it is specific features/applications characteristic of smartphones which elicit excessive use.

Consumer loyalty as a factor in consumer choice

Tatiana Folomeeva Moscow State University, Russian Federation

The main object of the research was the consumer’s behaviour of the Moscow’s citizens of both sexes, 18–60 years (4000 mobile and Internet users). Research was done by a method of tracking gauging annually from 1996-2015 (10 points, each of them consisted of focus groups and interviews). To measure attitudes scale of Likert was used, brand loyalty was measured using method of NPS (F. Rainhhold). For the analysis of the quantitative data we used a statistical package SPSS: frequency distribution, correlation analysis (Spearman coefficient) and analysis of variance (ANOVA). The dynamics of the consumer’s attitudes can be characterized by a predominance of rational assessments and by an increase of emotional component, which is stabilized during the period of saturation of the market. We found a significant association between the severity of positive customer attitude and the degree of loyalty to the brand consumed (r = 0.40; p <0.01). Analysis of variance showed that the degree of brand loyalty directly depends on the length of usage of a certain α mobile operator (a = 0,000). Upon reaching a mass market, choice of a particular brand is based on the emotional evaluation of alternatives, and the choice of a specific proposal, to a greater extent, is based on rational factors. We have allocated decision-making levels. Strategic the decision of the manifestation of consumer activity is made. Categorical. Consumer attitudes develop in the entire life course, we want to explore the flow of taste, habits of consumption and attitudes to buy the entire life course, we want to explore the flow of taste, habits of consumption and attitudes to buy.
Word-of-mouth effect of aboriginal cultural products purchase behaviour in Taiwan
Fangyi Liu NTUST, Taiwan, Republic of China; Sue-Ting Chang; Cheng-Hsi Fang; Tom Lin
The effect of word-of-mouth (WOM) does retain better and higher customer loyalty than advertisement broadcasts. In a sense, WOM serves as an efficient money saver in advertising for business entrepreneurs. The purpose of this study was to explore consumer’s purchase behaviour on the impact of WOM when buying aboriginal cultural products. 556 questionnaires in Taiwan were collected, using a statistical tool, and research questions concentrated on the following categories were analysed: (1) The effectiveness of positive WOM, (2) the professionalism of the distributors, and (3) the interactions of WOM between the distributor and the receiver. As the results revealed, aboriginal cultural products did have a higher WOM supported by its purchasers and highly-recognised brand awareness among aboriginal cultural activities. This indicated that the influence of WOM compared with those of media and advertisement promotion, did play a crucial role which matched with the goal of this current research. The research provides an excellent model and reference for aboriginal cultural products distributors to set up future marketing plans. With the help of this study, distributors in Taiwan will benefit from marketing, consumer communications, and consumer psychology discussed in various phases.

Social complexity and agent based modelling in consumer behaviour research: Context limitations and benefits
Ariel Quezada Universidad Adolfo Ibanez, Chile; Ernesto L’Huillier
Today we are witnessing many unsuccessful attempts by companies to understand social phenomena, that do not, necessarily, translate into a better understanding of consumer behaviour. Market research attempts are the daily work of an industry enterprise that hardly manages to rescue critical information for decision-making. This study proposes a related methodology for consumer research and analysis from the complexity perspective. Accordingly, the study aims to demonstrate the benefits and limitations in the implementation of Agent Based Modelling and Simulation (ABMS) as a method to obtain crucial information about social phenomena or Complex Adaptive Systems (Bonabeau, 2002; Miller and Page, 2007). To validate the use of ABMS this study reviews state-of-the-art consumer behaviour modelling, and proposes a new model as an example. This work analyses the contribution of studies regarding about, among others, decay effect (Zhang and Zhang, 2007) and lock-in effect (Janssen and Jager, 1999). Later, contributions are analysed to recognise benefits and limitations in ABMS. Following the compilation of investigations, a new model is proposed to understand the inferences in the telecom industry, specifically, the rate of migration between mobile service providers according to social influence. This work shows the links of complexity science and ABMS with a study of consumers’ behaviour. We expect to find: a) unique contributions of this method through phase transitions and emergent properties detection (Solé, 2011); b) validation as a research market tool (North and Macal, 2007), and, c) recommendations to apply the method according to research aim and contexts.

The influence of advertising in the buying decision-making process among adolescents
Marcillo Silva UFPE, Brazil; Bruno de Souza; Antonio Roazzi
This work refers to Brazilian adolescent consumers’ aspects and motives. It focused on the Brazilian adolescent’s consumer behaviour, since only very few studies have explored this field so far. Its main objective was to find out whether, according to the adolescents’ participants’ opinions, advertising influenced their buying decision. It initially covers aspects related to the Brazilian social context, adolescence and media, especially one of its main promotional tactics: advertising. It critically analyses the possible direct or indirect relationship between advertising and buying decisions. It takes on factors such as the theoretical premise, and the qualitative-quantitative approach to data collection. As instruments for data collection free associations, directed classifications, hypothetical buying situation, Likert’s scale and interviews were applied. Descriptive, variance and multidimensional (SSA) analysis were applied for data analysis. Although the total of participants N = 73 (males/ females) was insufficient to draw more reliable correlational linkages, there emerged 64 different motives for purchasing a product, including advertising. However, there also emerged significant evidence that variables such as price, product quality, and access to money were more important for adolescents’ buying decisions than advertising itself.

Primary attributes and secondary attributes in consumer decision making: Examination of construal level theory
Yuki Tamari Waseda University, Japan; Shozo Abe; Shigetaka Okubo; Tokoashi Ideno; Kazuhisa Takemura
Consumer choices of alternatives are affected by attributes. According to construal level theory (Liberman, & Trope, 1998; Trope, Liberman, & Wakslak, 2007), attributes are classified into two categories: primary and secondary. Construal level theory asserts that if the mental distance between consumers and alternatives is small, then secondary attributes impact consumer choices. If that distance is large, then primary attributes affect consumer choices. Previous studies, however, have not revealed what features and distinctions produce the two categories. Therefore we examined what attributes consumers recognised as primary or secondary. An internet survey was administered in Japan, garnering responses by 1044 participants (516 male, 528 female). Participants were asked to describe primary and secondary attributes of five goods and one service freely: digital cameras, electronic dictionaries, travel accommodation, mobile phones, laptops, and winter outerwear. For each item and category, participants were able to respond with up to six attributes. Nouns, verbs, and adjectives were extracted from responses through morphological analysis. In descending order of frequency, 30 parts of speech were picked up for each of six products. Spearman rhos were calculated among total, primary, and secondary rankings. Results show that both primary and secondary rankings were highly correlated with total rankings, and primary rankings were moderately correlated with secondary rankings. Participants tended to recognise functions of products as primary attributes, and acknowledged design and colour as secondary attributes. Individual differences were also noted.

Session Type: Symposia
Symposium title: Preference and decision making
Convenor: Kazuhisa Takemura
Preferences aggregated for sequences of events
Tommy Garling Sweden; Margareta Friman; Dick Ettema; Haruna Suzuki; Satoshi Fuji; Lars Olsson
An important issue in preference construction is how preferences for sequences of events are aggregated to an overall preference for the sequence. It differs from multi-attribute preference integration in that the part preferences are separated by time. It has been argued that depending on the length of the time separation different memory systems are activated to retrieve information about the events on the basis of which preferences are formed, semantic memory (schemas) for longer time intervals and episodic memory for shorter time intervals. An alternative is that part preferences are formed during the event sequence and remembered. Even if memory for part preferences is accessible, different aggregation rules may be used. One is the peak-end rule implying that the overall preference is the average of the highest preference and the preference for the last event in the sequence. It has been shown that this rule leads to inconsistencies such that a higher average of the part preferences is not preferred to a lower average if the preferences for the peak and end are higher. We tested whether the peak-end rule applies in the context of preferences for work commutes. In a survey of 713 work commuters in three urban areas of Sweden, self-reports of overall preference for the most recent normal commute to and from work were collected by means of a multi-item measure. Self-reports were also made of preferences for the legs of the commutes. Model tests showed that the peak-end rule was outperformed by a duration-weighted averaging rule.

Preference construction by choice
Tsuyoshi Hatori Ehime University, Japan; Kakuzhisa Takemura; Satoshi Fuji
The objective of this study is to examine the effects of prior choice making upon preference construction. According to theories on post-decision processes like differentiation and consolidation theory (Svenson, 1991) and cognitive dissonance theory (Festinger, 1964), preferences are likely to be reconstructed in line with a preceding choice. On the basis of these theories, the present study hypothesizes that preferences are constructed such that aspects which are superior (inferior) on a chosen alternative come to be weighted higher (lower) than before. The hypothesis was tested in a questionnaire survey targeting at 100 university students in Japan. Questionnaires comprised two sessions, each regarding (1) bicycle and (2) commute for
university. In each session, participants were firstly asked to evaluate the desirability of the attributes of alternatives that they previously chose in their real-life contexts. For bicycles, the attributes were (a) price and (b) design. For commute, the attributes were (a) commuting time and (b) comfort. Next, participants were asked to make choices from a pair of alternatives, which varied only in the pre-mentioned attributes. The data on decision tasks were used to estimate the weights of attributes in utility functions of respective participants. The obtained data gave supports to the hypothesis; weights of superior (inferior) attributes of the alternative that was chosen increased (decreased), as time passed since the decision was made. This result implies the validity of the causal relation in which choices shapes preferences, which is reverse to what is generally assumed in decision research.
Level of marital satisfaction among married students in Iran
Ali G. Afroz; PCI IRAN, Islamic Republic of Iran; Sogand Ghasemzadeh; Ali Afroz
Marital satisfaction is an important factor in family solidarity. According to the latest statistical report in Iran, the rate of divorce is much higher among young couples, especially during the first three years of their married life. The purpose of this research was to determine the prevalence of marital dissatisfaction, and the divorce rate among married university students in Iran. An anonymous sample group of married students (N=370) living in university housing, returned a completed questionnaire, Afroz Marital Satisfaction Scale (AMSS). Results from all students indicated that about 21% of married students were experiencing dissatisfaction in their first three years of marriage. A lack of communication skills among married couples was also indicated. The results showed that there is a great need for intensive psychological and marital enrichment intervention to increase marital psycho-sexual attraction among young married students.

Understanding and addressing clients’ transpersonal and spiritual experiences: Implications for spiritually sensitive counseling practice
Shaima Ahammed UAE University, India
In recent years, scholars and mental-health practitioners have been quite mindful of the transpersonal experiences and spiritual concerns that clients bring to counseling/psychotherapy context. However, they continue to be constrained in their capacity to resolve these issues effectively, due to the lack of any clear guidelines or conclusive understandings regarding how to address clients’ transpersonal and spiritual concerns or experiences. Many fundamental factors, historical as well as contemporary, contribute to this predicament. Among these are the parent-discipline, psychology’s avoidance of issues concerning consciousness and transpersonal dimensions of self, conceptual ambiguity and debate over the value and validity of transpersonal experiences, the counselor-client value conflicts and concerns with professional ethics in addressing spiritual and transpersonal experiences etc. Thus, even as we recognize and acknowledge the far reaching implications that these profound transpersonal experiences may hold for the client’s sense of self and wellbeing, we continue to deny or pathologize these experiences, thereby overlooking the healing and transformative potential of these experiences. This paper will highlight the importance of spiritually-sensitive counseling practices by reviewing the effective counseling outcomes of two true-life case studies featuring clients’ transpersonal experiences. This discussion will center around insights drawn from different sources such as scholarly literature lending credibility to the existence of transpersonal and spiritual experiences, recent debates and ensuing inferences on the differential diagnosis of psychopathology and transpersonal experiences, differing philosophical stances and worldview paradigms espoused by counselors and their relative value and merits in the context of effective resolution of transpersonal concerns etc.

Using the My Systems of career influences in a South African township
Anouk Albien Stellenbosch University, South Africa; Tony Naidoo
Career choices have been historically constrained for many South Africans by the Apartheid system, with attendant socio-political and economic factors also prescribing the field of career psychology (Nicholas, Naidoo, & Pretorius, 2006; Watson & Stead, 2002). The Systems Theory Framework of career development (McMahon & Patton, 1995) was used as a framework to inform a career intervention with Kayamandi high school learners. The present research examines the complex interplay of contextual variables that impact Grade 12 learners in making career decisions, aiming to provide a more informed understanding of the perceived occupational structure, enablers and unique contextual constraints (McMahon, 2008; McMahon & Watson, 2007; Savickas, 2005). The present study provides a thick description of the respondents’ career influences, using the My Systems of Career Influences (MSCI) (McMahon, Patton, & Watson, 2005) as an assessment and interactional process to elicit respondents’ descriptions of self-awareness, surrounding environmental resources, influences of significant others in their mesosystems (parents, teachers and peers) as well as effects of past, present and future influences on career exploration. The identified themes that emerged in these learners’ career stories can assist in providing insight that would aid career development and counseling processes to create context-specific interventions (McMahon, Patton, & Watson, 2004) especially where socio-economic factors may circumscribe career options.

The career self-efficacy of a previously disadvantaged man in early adulthood: A post-modern perspective
Dinah Alexander University of the Witwatersrand, South Africa
People in the young adulthood stage specifically seek opportunities for advancement, and to use their special aptitudes and educational background to advance in their studies and the world of work. The acquisition of these age-appropriate requirements seem to be dependent on a variety of factors, such as personal determinants, contextual factors and behaviour, which vicariously and reciprocally impact on each other, as espoused by Social Cognitive Career Theory (SCCT). This study used the SCCT as backdrop, and employed a qualitative, descriptive and intrinsic single case study as a research design. The aim was to explore the self-efficacy for successful completion of a select course of study of a Black, previously disadvantaged, 28 year old man. Data were collected through an in-depth semi-structured interview and a postmodern career assessment instrument, namely the Career-O--Gram. It makes provision for the telling of childhood and current contextual experiences, and the facilitation of these stories to understand its impact on life and career experiences. It is also applicable for utilisation within a postmodern framework such as the SCCT. The data were analysed using thematic content analysis. The results were in line with previous SCCT findings, namely that external and internal barriers impact on the career trajectories of previously disadvantaged people, due to the triadic reciprocity of personal attributes, contextual factors and the individual’s self-efficacy. Postmodern career approaches can be meaningfully employed in assisting individuals with their career development, through facilitating of their life and career stories.

Relationship between emotional intelligence and marital satisfaction in married women and their spouses
Mahnaz Alakbari Dethkordi Payame Noor University, Islamic Republic of Iran
The aim of this research was to study the relationship between emotional intelligence and marital satisfaction in married women and their spouses. For this purpose, 500 married women, with diploma-level education or higher who were employed in Tehran state administrations, organizations and companies as well as their spouses were selected by random stratified sampling (the number of them was reduced to 446). The necessary information was collected by means of the Emotional Intelligence Scale (Petrides & Furnham, 2000) and the Family Assessment (Najarian, 1374) device. These two tests have high reliability and validity. To analyze data statistically, Pearson’s correlation coefficient and multivariate regression were employed. The results showed that there is a significant positive correlation between women’s emotional intelligence and women and their spouses’ marital satisfaction. Also, there is a significant positive correlation between men’s emotional intelligence and the couples’ marital satisfaction. In addition, the emotional intelligence of women and their spouses can explain 35% of women’s marital satisfaction variance and 6% of their spouses’ marital satisfaction variance. In conclusion, in regard to there being significant positive correlation between emotional intelligence and marital satisfaction in married women and their spouses, the quality of emotional intelligence can be considered as an influential and fundamental construct in improving and reinforcing satisfactory marital relationships. Therefore, we can effectively improve interpersonal and marital relationships by increasing emotional intelligence.

Counselling and social justice: Terms of engagement
Nancy Arthur University of Calgary, Canada; Sandra Collins
Social justice has been a key concept in the development of the counselling psychology profession. However, the meaning of the concept of social justice is often taken for granted in the professional literature, as it commonly understood. The lack of conceptual clarity regarding the meaning of social justice in the counselling psychology literature is problematic in terms of setting directions for professional education to prepare professionals for roles that address social justice. The multiple and contrasting meanings suggest different implications and foci for counsellor education and practice. In
Factors contributing to marital stability
Keltoum Belmihoub Algiers University, Algeria; Keltoum Khalfi
This research aims to study the factors contributing to the stability of marriage which means the achievement of a high level of satisfaction in the dimensions of marital life such as sexual, emotional, cognitive, relational, family responsibilities, the ability to resolve the conflict through effective communication, to realise marital expectations, and to feel happy. This research was designed to verify the existence of statistically significant differences (in marital stability), according to different levels of socio-demographic factors and different levels of emotional and behavioural factors. It also tries to answer some other questions. The research sample consisted of 400 married persons, of both sexes. 180 males and 220 females, aged between 18 and 66 years. Five measures were used to measure the marital relationship in all its aspects, (the dyadic adjustment scale, marital satisfaction scale, marital communication inventory, marital expectation scale, and the marital happiness scale). The results of this research demonstrated the existence of three basic groups of factors that contribute to marital stability. All of them are significant at the level of statistical significance 0.01. The first group can be called logistic factors of the relationship, while the second could be called the personal factors, and the third could be renamed the interactive factors between the two parties.

Career-shifters: Key factors in voluntary career change process
Duygu Biricik Koc University, Turkey
Occupational callings are defined as occupations in which an employee desires to pursue, enjoys doing and feels as a central part of their identity (Berg, Grant, Johnson, 2010). People who changed their occupations to answer their callings are called "Career-shifters" (Biricik, in progress). This study consists of two parts. In the first part a qualitative method will be applied to understand the personal and environmental factors that lead career-shifters to change their occupations. In the second part the relations between career salience, self-concept clarity and occupational regret will be tested and modelled via quantitative analysis. Career salience and self-concept clarity scales will be distributed to the participants. In both of the studies Turkish sample will be used who are recruited via online advertisement. The sample size is expected to consist of 50 career-shifters and 50 non-career-shifters. The results will be discussed in terms of developmental, practical and theoretical implications.

Does sexual orientation of couple influence psychologists’ perceptions of intimate partner violence?
Lisa Bendzim Alliant International University, United States of America; Terra Slavin; Deborah Miore; Susan Holt
Domestic violence (DV) and increasingly, intimate partner violence (IPV) has been a focus of law enforcement, courts, and mental health attention. Until the start of the 20th century, in the United States, women were perceived to be the property of men and only with the women’s rights movement and Lenore Walker’s conceptualisation of Battered Women’s Syndrome (BWS) did enforcement of newly developed law serve to protect women’s rights. Misconceptions of, and bias against same-sex coupling has precluded efforts to understand and address the unique challenges that beset these couples in general and when violence of psychological and physical proportions enters the equation. The current survey study of psychologists will use a vignette varied by the gender of the couple, sexual orientation of the couple, and levels of intimate partner violence (emotional and physical), to assess whether depicted IPV is viewed and responded to differentially. A 2 x 2 x 4 ANOVA between-subjects experimental design is expected to show significant differences in the extent to which IPV is detected and responded to (recommendation for prosecution or treatment) depending on the sexual orientation of the couple and the nature of the IPV (overt or covert/emotional or physical). Results are predicted to have significant implications for the training of psychologists who are likely to come into contact with same-sex couples saddled by IPV.

The role of emotional-related aspects of insecure attachment and career indecision
Hedva Braunstein-Bercovitz Academic College of Tel Aviv-Ya, Israel
The main goal of the current study was to examine the role that insecure attachment, anxiety and pessimistic views play in career indecision. It was expected that anxiety and pessimism would mediate the relationship between insecure attachment (manifested by anxious [ANXA] and avoidant [AVDA] attachment) and career-indecision (CINDCN). Participants were 200 first-year behavioral science students. They completed the following questionnaires: (1) Experience in Close Relationships, (2) Life Orientation Test, measuring trait pessimism, (3) the Trait Anxiety Inventory, (4) the Career-Anxiety and Career-Pessimistic Views subscales of the Emotional and Personality Career Difficulties Scale, (6) the Career Indecision Scale. Structural equation modeling analysis was used to test for mediation. The statistical analysis revealed that the relationship between ANXA and CINDCN was both direct (β=-20*) and indirect, with AVDA only indirect: ANXA increased career-anxiety, which in turn increased CINDCN (β=-12**); AVDA increased career-pessimism, which in turn increased CINDCN (β=-10*). Trait-anxiety and trait-pessimism did not play a role in predicting career-indecision. We concluded that indecision, which refers to a temporary-state career decision-making difficulty, is linked to attachment via the mediation of state-emotional symptoms, career-anxiety and career-pessimism, rather than to trait-emotional symptoms. Implications for career counseling are discussed, and potentially useful intervention methods for career counselees characterized by an insecure attachment style are suggested.
Interventions that can be most suitable for this population/context will be discussed.

Using a computer-based exploration tool on children’s career development learning

Ewald Crause; Nelson Mandela Metropolitan University, South Africa; Mary McMahon; Mark Watson

The renewed emphasis on lifelong career development has led to a greater focus on the career developmental stage during childhood. Despite this awareness, it is surprising that little is available in terms of research based career exploration activities that are appropriate for children. This deficit acted as the catalyst for the current research which focuses on the development and trialing of a research-based computerised career exploration tool, Grow-up: Children Building Careers™ (GCCB™), Digital environments, such as the GCCB™, are tools that broaden and extend learning possibilities for children and can be used to assist learners in developing age-appropriate career developmental skills. The research is divided into four stages and includes 100 eight to ten year old students as participants. Stages one and two include the program design and pilot study stages (ensuring content validity and age-appropriate language use), while stages three and four focus on the fieldwork (pre- and post test experimental design) and focus group discussions with a small sample of participants. Involving children in career activities is about choosing careers, rather it is about developing career related skills that will facilitate career development and future career decision-making. The poster will present an overview of the rationale for, and methodology of the study.

Effectiveness of individual life skills training on shyness among adolescents

Lancy D’Souza; Maharaja’s College, University, India

In the present study, an attempt is made to find out the effectiveness of Life Skills Training (LST) in reducing shyness among adolescents. The sample consisted of 64 adolescents who had high levels of shyness. Shyness Assessment Test (SAT) developed by D’Souza (2006) was employed to measure levels of shyness in 3 domains: Cognitive/affective, Physiological and Action oriented. Initially a large number of adolescents were screened for shyness and those who had high shyness scores were selected (64) for the final study. After the selection, LST was given to the experimental group for 60 days (8 sessions). In the intervention program, after the introduction, the researcher explained about the LST programme and evaluated the problem regarding LST (2 sessions), the subjects were trained in some of the life skills such as self awareness, thinking skills, self esteem, social skills, interpersonal and communication skills (3 sessions), and also used Assertiveness training through Role playing and Modeling techniques (3 sessions). At the end of each session, the researcher gave a home assignment to the subjects and investigated the response at the next session. At the end of LST, again, SAT was applied and data were collected on 3 dimensions of shyness. Results revealed that LST is highly effective in reducing the shyness of adolescents in all the domains, cognitive/affective, physiological and action oriented. Maximum reduction was observed in the action oriented domain of shyness among adolescents. There was no differential reduction in shyness score for a particular gender.

A therapeutic model for parents for enhancing internal locus of control in primary school children

Genevieve Da Silva UNISA, South Africa; Hester Roets

Based on masters and doctoral research, this paper presents a therapeutic model for parents to enhance internal locus of control in their primary school children. Research into the antecedents of locus of control revealed that parents play a crucial role in the development of internal locus of control. Thus, I undertook a study to explore this phenomenon. Through an action research model involving 4 case studies it was found that consistent reward and behaviour, modelling internality, nurturance, authoritative parenting style, positive home environment and encouragement of development were factors in enhancing children’s interiority. Further, mother-child and father-child interactions and the responsibility required of children play a role in developing internal control orientation. Therefore, I conducted research as to the practical implications of these findings. Literature was consulted as to the theoretical and practical underpinnings of parent guidance. A therapeutic model for parents was established based on literature research and the aforementioned findings relating to parenting and the development of internal locus of control. Continuing with an action research design, the implementation and results of such a therapeutic model were cyclically evaluated and adjusted. The results indicate a positive impact of such a model on the development of internal locus of control in primary school children.

The effectiveness of person-centered approach applied to patients suffering from deterioration of Algerian self-concept

Zenad Dallala; Algiers University, Algeria; Linda Liebenberg; Alexandra Restrepo; Jackie Sanders; Guoxiu Tian

The aim of this study is to highlight the role of psychotherapy in the prevention and treatment of mental disorders associated with a distorted self-concept, specifically among persons with disabilities. The treatment encourages the development of positive potential, and enables access to the patient’s own self-realisation. We implemented a programme of psychological treatment based on the patient. Ten Algerian patients, suffering from distorted self-concept, as a result of physical disabilities due to road traffic accidents, attended the psychiatric hospital clinic. The treatment was divided into phases: 1 - Diagnostics: Allow the patient to present himself, collect personal data, indentify the experience of disability, which is the basic experience of the patient’s suffering, and clarify the plan to be applied during the treatment. 2 Treatment: All members of the sample benefited from the psychotherapy, based on seven stages, presented weekly, including six healing techniques. 3 Follow-up: re-apply the self-concept tests with an external judge. This paper explains this programme and the steps used to apply it to these patients.

Acculturation and psychodynamic processes: An intercultural psychodynamic counselling model proposition

Sylvia Dantas Federal University of Sao Paulo, Brazil

This paper is based on counselling of immigrants, return migrants, immigrant descendants, and prospective migrants at a university counselling service in Brazil. The service was part of a research project developed by the author at a Brazilian university. Through psychosocial intervention with that population, an intercultural psychodynamic model was developed. The intercultural approach promotes a broad, dynamic and flexible view of the psychosocial phenomena (Lambert, W., 1980) and considers the human development and human manifestations a result of a dialectical relation between the individual and his/her cultural and socio-political context (Berry, J.P., Poorlinga, Y., Segall, M., & Dasen, P. 1992). Categories such as cultural and ethnic identity, gender roles, intergenerational relationships, transnational social networks, psychological acculturation, acculturation stress and prejudice emerged from the analysis of the material, indicating the profound psychological implications of cultural contact. Based on a psychoanalytical brief psychotherapy (Fiorini, 1985) and intercultural approach, a new model of psychosocial intervention was developed. The psychosocial intervention has a primary and secondary preventive attribute. Issues on how countries deal with their own ethnic/racial plurality emerge indicating the need for an intercultural perspective and promotion of culturally effective psychotherapists and health professionals.

Resilience factors in families caring for a family member diagnosed with dementia

Melanie Deist; University of Stellenbosch, South Africa

Dementia is a chronic illness characterised by the progressive deterioration of cognitive functions. Patients diagnosed with dementia are most often cared for by family members. Families caring for dementia patients are faced with tasks that are physically exhausting and psychologically distressing. Nevertheless, some families show resilience and are able to overcome the adversity of the illness. What factors help these families to adapt to their situation and counteract the difficulties that impair family functioning? This study aims to answer this question by exploring the resiliency factors these families utilise to rise above the hardships faced when caring for a demented family member. A mixed methods approach will be followed to collect data from a convenience sample drawn from the Cape Metropolitan area in the Western Cape, South Africa. Participants are spouses and adult children caring for the dementia patient, since the role of caregiver most often falls on these subgroups. The family resilience factors of these subgroups will be explored separately and will be compared with each other. By expanding the current literature regarding family resilience, the body of information collected in this study could be used to help families caring for dementia patients to create a family environment that maximises adjustment and adaptability. The results could also be used in the development and evaluation of intervention programs tailored to the needs of these family subgroups.
Development of a new vocational interest model representative of the current US workforce

Chi-Ping Deng National Changhua University of Edu, Taiwan, R.O.C.; James Rounds

Though Holland’s RIASEC is the most predominant interest model to assess occupational interests and connect individuals to occupations, it cannot represent the current US occupations (Deng, Armstrong, and Rounds, 2007). The study developed a new occupational interest model representative of the current US workforce. We presented this model with a three-dimensional spatial presentation of both occupational interest clusters (OICs) and occupational interest areas (OIAs). The data were from 1175 college students’ preferences for the 337 occupational titles in the Occupational Outlook Handbook, representing approximately 88% of the US workforce (U.S.Bureau of Labor Statistics, 1996, 2004). Cluster analyses grouped the occupations into 31 OICs and 10 broader OIAs. Reliability and validity information was provided to support the use of 31 OICs as basic interest scales for identifying individuals’ vocational interests, including direct linkages to information collected by US government agencies. Multidimensional scaling applied to the relations among the 31 OICs yielded a three-dimensional configuration. The dimensions of the occupational interest model were: People vs. Things, Dynamic vs. Structural, and Prestige. A Sex type dimension was also identified. Furthermore, the results stress the importance of considering prestige and sex type associated with occupations when assisting individuals explore their occupational choices.

The impact of Holland’s four secondary assumptions on college students’ academic satisfaction

Chi-Ping Deng National Changhua Uni of Edu, Taiwan, R.O.C.; Yi-Ling Lai; Alimee Ferreira

We explored the relations between Holland’s four secondary assumptions (congruence, consistency, differentiation, and identity) and academic satisfaction of college students. Congruence is a frequently used concept. Though congruence significantly correlates to career satisfaction, correlation does not exceed .25 (e.g., Tsabari, Tziner, & Meir, 2005). Tracey (2007) suggests that consistency and differentiation moderate this relation. Thus, we also examined whether consistency, differentiation, and identity moderate the relation between congruence and academic satisfaction. 652 college students completed a questionnaire including an interest scale of activities and occupations (four activities and four occupations each Holland type), and an academic satisfaction scale constructed according to the SWLS from Dinner, Emmons, Larson, and Griffen (1985), and the PSS from Cohen, Kamarck, & Mermelstein (1983). The reliability and validity were provided to support the use the study questionnaire. The study results show congruence (r = .25) and differentiation (r = .17) both have significant Pearson’s correlations with academic satisfaction, and consistency and identity moderate the relation between congruence and academic satisfaction. The correlations between congruence and academic satisfaction are higher in the high-level consistency group (r = .53) (the low-level group’s r=.34, and the middle-level group’s r=.25). The results stresses that all Holland secondary assumptions, not just congruence, provide valuable information for career exploration.

Interest congruence, ability congruence, and adjustment styles on academic satisfaction of high school students after curriculum tracking

Chi-Ping Deng National Changhua University of Edu, Taiwan, R.O.C.; Shu-Ling Chen

The congruence of interest and ability is a major consideration when students decide their curriculum track in Taiwan. Theory of Work Adjustment (Daws & Loquisit, 1984) proposed the congruence affected the satisfaction, and when the incongruence occurred, four personal adjustment styles (flexibility, activeness, reactiveness, and perseverance) would impact satisfaction. Thus, we investigated the impact of the congruence of interests and ability and the curriculum track decision, and the important impact of adjustment styles on academic satisfaction after curriculum tracking. 691 high school students completed the Adjustment Style Scale and Academic Satisfaction Scale constructed by the authors based on TWA definitions (Daws, 2005) and SWLS (Diner, Emmons, Larsen, & Griffen, 1985). They also provided their results from a College Entrance Examination Center Interest Survey (Jin, Lin, Chen, Oh, 1995),Multi-aptitude Test (Luo, Lu, Oh, 1997). The reliability and validity of these scales were provided to support legitimacy of the study measures. Chi-square results indicated that interest congruence significantly related to the final decision of their curriculum track, but ability congruence did not. Multiple regression results showed only flexibility and perseverance of the adjustment styles significantly predicted the academic satisfaction with the explained variance of 17.9% (VAF). This study stresses the association between interest congruence and ability congruence, and the curriculum track decision, and the important impact of adjustment styles on academic satisfaction after curriculum tracking.

The Imago profile: Revealing the dynamics of relationship choices

Carol-Ann Dixon South Africa; Michele Naudé

The condition of our romantic and intimate lives impacts our psychological, physical and relational health, as well as the greater social, economic and community environment. With the burgeoning of social network sites and the opportunities they offer for relationship choices (30% of current relationships “met” on the internet), an understanding of how people make partnership choices is critical to future individual, relational and societal well-being. Imago Relationship Therapy (Hendrix, H, 2005) is one framework through which relationship choices can be understood and provides both a theoretical framework and practical application for therapists. It is a process whereby both individuals and couples come to a deeper understanding of themselves and each other and how and why they make the kind of relationship choices they make. The “Imago” is the influence of the unconscious on partner selection. The “Imago Profile” is an experiential process where an understanding of the internal blueprint for relationships is facilitated. The result is an identification of the relationship characteristics that have been internalised during development, and how this internalised blueprint, or “Imago”, serves as a guide or template for future relationship choices. This paper presents an introduction to the formulation and psychotherapeutic use of the “Imago Profile”. It is an interactive and experiential presentation.

Re-employment psychology: The synthesis of cognitive, social, and organisational psychology

Jeremy Dixon University College Dublin, Ireland

Ireland currently stands in a vortex of change experienced at every level of society. Employment and organisational life is no exception, with every category, type, and size of organisation rapidly attempting to evolve and survive in an environment where human resources are now frequently perceived as the life force of an organisation. With a renewed emphasis and calling to understand the nature and potential of personal organisation fit, more research is being placed on job seeker to research and communicate their personal synergy with target organisations. Numerous psychological studies have exposed the varied pathologies related to the effects of unemployment. However, less is known of how psychological theories can be applied to enhance ‘Re-employment’ and organisational entry for the job seekers perspective. Literature reviews indicate very little empirical evidence for the actual validity of job seeking advice available to the general public, particularly in a rapidly changing economy. This paper proposes the necessity to consider re-employment as a separate psychological discipline to the traditional ideographic approach of career guidance counselling. Supporting the argument of Fugate, Kinikki, & Ashforth (2004), that unemployment should be construed as a psycho-social construct. This paper discusses insights and findings from cognitive, social, and organisational psychology to demonstrate what advances to job seeking/assessment techniques can be achieved through the application of psychological research and classical theories. Such techniques promote the ethos of positive psychology, enhance mindfulness, and self efficacy whilst helping organisations forge a determined community of purpose.

Group music therapy for increased resilience of 7th grade students in the Sichuan earthquake stricken areas

Rong Dong East China Normal University, China; Wenziu Geng

It has been 3 years since the ‘5-12’ earthquake in Sichuan Province. However, the resilience of teens in stricken areas is still significantly lower than in ordinary cases. This study seeks to improve their resistance to adversity, help them fulfill their potentials and help them achieve post-trauma growth. Based on previous researches, this study aims to combine traditional group therapy with music therapy and develop a group therapy course for teens in stricken areas. We chose 22 7th grade students with low resilience from schools in earthquake stricken areas, divided them into a control group and an intervention group, both of which contains 11 students (5 males and 6 females). In order to test the effect of group music therapy, CD-RISC, SAS, SDS, Social Support For
Teens, Coping Style Scale for Teens, SES and self-designed interview outlines were used in pre-, post-test and follow-up surveys. Horizontal comparison indicates that after the therapy course, the students in the intervention group showed higher levels of resilience and more positive coping styles than the control group students. Vertical comparison indicates that after the therapy course, the students in the intervention group perform much better in various aspects, including resilience, goal, Social Support, positive coping styles (Problem-solving, Looking for social support and rationalization) and Self-esteem. By contrast, they express lower anxiety and depression and less negative coping styles (eg. escape). The follow up survey reveals that Group music therapy has sustained influence on resilience.

Open marriages and infidelity: Emerging therapeutic trends in India
Chetna Duggal
Tata Institute of Social Sciences, India

Infidelity in marriages is one of the most damaging relationship events. This has never been uncommon, but it is only now in India that more and more couples are seeking therapy for issues around infidelity. Disclosure or discovery of infidelity in one or both partners usually precipitates an emotional crisis that leads couples to seek therapeutic help. This paper will focus on case studies of couples who sought therapy post-disclosure or discovery of infidelity within the marriage and who were not looking at conjugal dissolution or complete repair but wanted to work towards open marriages. Open marriages are understood as arrangements between a married couple to explore sexual and emotional intimacy with another partner outside the marriage. This is a new therapeutic trend in India, driven by changing social and cultural norms and the increasing empowerment of women. This paper will attempt to examine the societal and cultural backdrop for this development, and will focus on identifying key challenges and value conflicts faced by the therapist. Implications for therapeutic intervention in the Indian socio-cultural context will be explored.

Stress and personality factors as predictors of suicidal ideations in college students in Kolkata, India
Sreeparna Dutta
University of Calculutta, India; Sadhan Dasgupta; Urbi Mukherjee

Suicidal ideations are more common than complete suicide, and although most patients with suicidal ideations do not ultimately commit suicide, it may be taken as a tendency towards negative coping, and increased risk, towards self-mutilating behaviour. To find out the prevalence of suicidal ideation among college students and to find the extent to which it is predicted by life stress, sex, emotional intelligence and other personality factors, data was collected from 354 undergraduate college students (263 males & 91 females) aged between 19 and 21. Tools used included the Life Events Scale, Adult Suicidal Ideation Questionnaire (ASIQ), the NEO 5 Factor Inventory and the Emotional Intelligence Scale. Data were collected using the technique of purposive sampling. Statistical analysis revealed suicidal ideations among 14.97% of the sample studied (N=53). Significant differences were found between the levels of suicidal ideation of male and female students (F= 7.815, 0.005). Significant negative correlations were found between ASIQ scores and levels of conscientiousness (r = -0.39, sig: 0.004) and ASIQ scores and level of emotional intelligence (r = -0.63, sig: 0.001). Regression revealed that the following variables were significant predictors of suicidal ideation: emotional intelligence and life stress (R^2 =0.25, 0.0002), levels of neuroticism and extraversion (R = 0.019, 0.013) and sex and emotional intelligence (R = 0.031, sig: 0.002). The results provide insight into the factors that predict suicidal ideation among youths. Several need-based interventions are suggested.

The comparison of ways of coping with stress among hospital staff
Salar Faramarzi
University of Isfahan, Islamic Republic of Iran; Zohreh Kodadad; Shokah Sadeghi

The main aim of the present study was to compare the ways of coping with stress among hospital staff in Isfahan (Iran). The method of this research was a descriptive correlation. For this purpose, 100 staff in a hospital of Isfahan (49 Nurses; 20 Licensed Practical and 31 Paramedical staff) were selected using simple multi-stage sampling. The research instrument was Rogers’ questionnaire. The validity and reliability was confirmed. The data were analysed by variance analysis with SPSS software. The results showed ways of coping with stress in hospital staff (Nurses, Licensed Practical and Paramedical staff) is significantly different (P<0.05).

Meta-analysis of effectiveness of the psychological interventions on marital satisfaction in Iran
Azimeh Alsadat Fatemi University of Isfahan, Islamic Republic of Iran; Amir Ghamarian; Mahnaz Shir-ansabadadi; Ahmad Abedi

In recent years, experts in the field of marital satisfaction were followed to assess and compare the effectiveness of psychological interventions on marital satisfaction. For this, 33 studies which were methodologically acceptable were analysed. The research instrument was meta-analysis checklist. This study includes 68730 subjects and 37 effect sizes. The results of meta-analysis indicated that the rate of the effect size of psychological interventions on marital satisfaction was 0.7 (p=0.00001). This effect size, according to Cohen table, is rather high. It means psychological interventions increase marital satisfaction and has high impact.

Reclaiming life: Developing counselling strategies with but not only for homeless people
Sonia Ferreira
University of Coimbra, Portugal; Sonia Ferreira; Daniela Guerreiro; Lara Figueiredo; Dora Redruello

This research was developed with the goal of understanding homelessness from the perspective of (formerly) homeless people and professionals. Through a multi-method qualitative approach we studied multiple factors that enhance the probability of becoming homeless, being homeless over time and, also, successful re-insertion into society. The data were collected through participant observation in street interventions (6 teams, n>300) and interviews with formerly homeless people and professionals (n=95). The three groups of participants were asked to describe and analyse their life path, identifying in it key moments that explain homelessness, their current expectations, their major concerns/fears and how they manage/solve them. The third group analysed the life trajectories of the homeless and singularities of this group. Through the comparison of their perspectives it was possible to understand how homeless people perceive their life story, and which factors are more/less relevant to develop counselling strategies. Findings suggest that homeless professionals emphasise four main factors: (i) Society problems (e.g., social policies, national and European economy); (ii) Lack of social/interpersonal relations (e.g., lack of fulfilling intimacy relations); (iii) Education, training and work (e.g., school/professional qualifications, precarious jobs); (iv) Personal factors (vague/ambiguous life projects; vocational volatility). However, each group gives different importance to each one of these factors to explain homelessness and social reintegration. These differences are seen as one of the major factors for the resistance this population shows in participating in counselling and also for withdrawal.

The influence of the therapist’s activities on clients’ subject positioning with relation to gender in narrative couples therapy
Kirsten Fris Rhodes University, South Africa; Michael Guilfoyle

Narrative Therapy draws on an understanding of how discourse acts to construct, reproduce and deconstruct power relationships, and it focuses on collaborating with clients to re-author their self-stories by resisting dominant discourses. While there exists a large body of theoretical knowledge on post-structuralism and psychotherapy, few discourse analyses of psychotherapy sessions have been published. This paper aims to further explore these therapeutic processes, focussing specifically on subject positioning with relation to gender in Narrative Couples Therapy, and the influence of the therapist in this process. A video recorded couple’s therapy session conducted by Narrative Therapy’s primary developer, Michael White, will be analysed in detail. Using discourse analysis as a methodological approach, the analysis aims firstly to identify gendered talk and shifts in subject positioning, and then examines the therapist’s activities in relation to these positionings. As the research remains ongoing for the duration of the year, the results of the analysis are not yet available. It is expected, however, that the analysis will show both how the therapist’s attempts to resist dominant discourse and draw out alternate stories within the context of Couple Therapy act to shift subject positioning in relation to gender, and how the individuals within the couple themselves act to negotiate a wider range of subject positions within various discourses.

The role of personal versus intersubjective mental health literacy in seeking professional psychological help
Wenjun Gao; Nankai University, China; Qiang Li; Ling Li; Ping Qin
Extensive studies have been conducted to investigate factors influencing people’s professional help-seeking for psychological distress. Mental health literacy (beliefs about mental disorders and treatment) has been identified as an important factor; however, most research focused on personal rather than intersubjective beliefs, despite the fact that studies using an intersubjective approach have demonstrated that perceived shared beliefs can affect behaviours beyond personal beliefs. To address this lack of knowledge, the present study examined the influence of mental health literacy on professional help-seeking, in both the personal and intersubjective levels. Specifically, the present study aimed to resolve two main issues: (a) The relationships between personal and intersubjective mental health literacy, including beliefs about the aetiology of mental illness, and beliefs about the effectiveness and stigma of receiving professional treatment; (b) the extent to which these beliefs are associated with help-seeking intention and behaviour. To investigate these issues, 557 community residents from 13 different regions of China and 555 undergraduates from three universities were recruited to complete a battery of questionnaires. The results showed that (a) the personal beliefs in question are different from the corresponding intersubjective beliefs; and (b) while controlling for demographic variables and informants’ mental health states, both personal and intersubjective beliefs are significantly associated with help-seeking intention and behaviour. These findings contribute to our deeper understanding of the role of mental health literacy in professional psychological help-seeking, and inform the efforts to facilitate the utilisation of mental health services.

The creation of a pre-group preparation DVD for university clients: From conception to application
Rone Gerber; University of the Western Cape, South Africa; Willem de Jager; Shahieda Jansen
Group therapy is a preferred therapeutic modality at the Centre for Student Support Services, a Student Development and Support service at the University of the Western Cape, South Africa. Pre-group preparation of group therapy clients has been through a semi-structured face to face meeting between a prospective client and the group therapist. A review of the process highlighted inefficiencies. The use of film (DVD), viewed by the client prior to the meeting with the group therapist, was proposed to augment the relational method which will enhance efficiency and standardisation of the contents of the pre-group meeting. After viewing the film, a potentially more informed, empowered and motivated client emerges, and at the meeting might present primed and better prepared to engage the facilitator. During this meeting the facilitator can focus on the relationship based aspects of group preparation such as alliance building, screening and assessment of client fit for group therapy. In this paper the authors present the background and rationale of the shift in strategy from an exclusive relationship based group preparation method, to an approach that creatively blends the complementary use of relationship and media based client preparation methods. They describe the production of the DVD from conceptualisation to implementation and share the educational, experiential and methodological aspects of the film. Qualitative and Quantitative methods will be used to evaluate the impact and value of the new intervention.

Catch 22: The double bind which exists between marriage and psychology masters studies
Claire Hart; University of the Witwatersrand, South Africa; Vinita Jithoo
The profession of Psychology in post-apartheid South Africa has been dominated by women. The transformative trends over the past 50 years have seen women delaying marriage to complete their studies; however, this trend has not always extended to postgraduate studies in psychology in South Africa. The purpose of this study was to provide an in-depth understanding of why students take on the challenge of being married during Masters, as well as the pros and cons of this dual adjustment. The sample comprised of eight married female participants who were enrolled in first- and second-year of Professional Masters programmes in Clinical, Counselling or Educational Psychology. Semi-structured interviews were employed to provide an in-depth analysis examining the intersection and articulation of marriage while being a student. Thematic content analysis was used to interpret the data set with the following results emerging: (i) There was a strong idealisation of marriage and the notion that it would act as a buffer against the stressful year, (ii) the longevity of study simultaneously coincided with the culmination of the dating phase and further delays resulted in relationship insecurity, (iii) postgraduates experienced the blurring of boundaries between the perceived challenges and benefits as the idealised complementarity was not actualised. This study used feminist theory to challenge the Life Cycle theory’s chauvinistic notions of marriage and career development for women. It also directly explored the implications of the “feminisation” of the profession of Psychology on recruitment, training and future practice of female Psychologists.

Self-disclosure and seeking professional help: Cross-cultural differences
Edward Helmes; James Cook University, Australia; Laura Gallou
Cross-cultural research on attitudes toward seeking professional help for mental health problems emphasizes the major role played by traditional, collectivist type cultural values. Self-disclosure by people from non-Western backgrounds is little studied despite the emphasis in modern therapeutic approaches on self-disclosure. The present study examines the cultural aspects of self-disclosure and attitudes toward seeking professional psychological help among first and second-generation Greek Australians in Sydney (n = 106), Anglo-Celtic Australians (n = 35), and Greek Cypriots (n = 189). Participants ranged in age from 18 to over 70. A self-report survey measured individualism-collectivism, attitude toward seeking professional help, actual self-disclosure to a friend, hypothetical self-disclosure to a counsellor, and social desirability. It was hypothesized that participants who were more collectivist would have less positive attitudes toward seeking professional help, and would be less likely to self-disclose. Results showed modest group, gender, age, generational, and educational level differences and also that participants in general were neither strongly individualistic nor strongly collectivist. Results also showed that all three groups did not differ in their attitudes toward seeking professional psychological help, and that in general they did not have positive attitudes toward seeking professional help. There was a modest positive relationship between individualism and attitudes to seeking psychological help that confirms previous literature. As predicted, the Australian group was most likely to self-disclose. The study confirms that cultural factors affect attitudes toward seeking professional psychological health and willingness to self-disclose.

Postpartum mental health: The role of social support and culture for migrant women
Ingrid Hogge; Asian Health Coalition, United States of America
Giving birth and subsequently adjusting to the process of caring for an infant is a significant life transition. Significant stressors, including delivery stress, difficulties with breast feeding, lack of sleep, and relational problems, may accompany the postpartum period. Additionally, mothers who have immigrated to the United States may face unique stressors due to language barriers, financial concerns, loss of social network, and unfamiliarity with social systems. A potential result of these stressors, in conjunction with other biopsychosocial factors, is the risk for development of postpartum depression, estimated to affect 13% of women in the United States. Researchers in the field of psychology increasingly look to systemic factors to explain the occurrence and presentation of mental health issues. One such factor is culture, now often considered integral to the understanding of mental health problems. Similarly, social support has received significant attention and has been shown to moderate risk factors for a range of psychiatric disorders. However, previous attempts to explore the relationships between culture and social support on postpartum depression have resulted in mixed results overall. A recent literature review urged the use of more comprehensive research approaches. In this presentation, we will discuss the preliminary findings of a qualitative study exploring the postpartum experiences of Chinese-born women living in the United States. We believe that discussing the experiences of this population can provide information to assist practitioners and researchers in developing strategies that best attend to the multiple factors associated with postpartum mental health.

Suicide ideation in transitioning university undergraduates
Ronald Holden; Queen’s University, Canada; Talia Trostler
Worldwide, approximately one million individuals die by suicide annually. Life transitions are times of stress often associated with suicide and its precursor, suicide ideation. This study documents the nature of suicide ideation for individuals during...
their transition into university life. Between 2008 and 2011, the Beck Scale for Suicide Ideation (BSS; Beck & Steer, 1993) was administered to 6,113 undergraduates in psychology during their first month of university life to determine the presence, degree and content of suicidal thinking. Nineteen BSS items (scored 0 to 2) assessed suicidal wishes, attitudes toward suicide, and suicide plans. Analyses and comparisons were conducted for the overall sample (N = 6113) and subsamples of individuals with and without previous suicide attempt (n = 5948), single attempters (n = 95), and multiple attempters (n = 70). Overall, 2.7% of students transitioning into university indicated at least one suicide attempt and 1.1% of students reported multiple attempts. For all subsamples, the most frequently endorsed aspect of suicide ideation focused on suicide as a means to escape from problems and on the recognition of the availability and means to die by suicide. Whereas distinctions between suicide attempters and non-attempters emphasized suicide ideation associated with completing attempt preparations, working out a life-ending plan, and taking actions in anticipation of a suicide attempt, differences in suicide ideation between single and multiple attempters focused on reasons for dying outweighing reasons for living, formulation of a suicide note, and the frequency of suicidal thoughts. Implications are discussed.

The association between forgiveness and marital satisfaction
Ashrafalsadat Hosseini University of Melbourne, Australia; Seyed Jalal Younesi; Hooria Seyedselami Ghaheh; Hadis Aryarapur Forgiveness can be defined as a cognitive, emotional, and behavioural response to interpersonal conflict. The aim of this study was to investigate the association between forgiveness and marital satisfaction in the samples of families in Tehran, Iran. It was a descriptive study and family forgiveness scale (FFS), questionnaire of marital satisfaction (EN-RICH), and socio-demographic questionnaires were used as measurement for this study. Findings demonstrate a significant association between forgiveness and marital satisfaction (r = .51). There was a significant association between marital satisfaction and the following five subscales of forgiveness: realisation (r = .32), recognition (r = .46), reparation (r = .35), restitution (r = .49), and resolution (r = .42). Moreover, the results of the study reveal that increase in the level of forgiveness correlates with increase in age, marital duration and levels of education. Along with the findings of this study we can mention that abilities like forgiveness might help psychologists and family professionals to assist families.

Combined usage of psychodynamic, existential and cognitive-behavioural approaches in psychotherapy: A case study
Ferhat Jak Içoz Istanbul Bilgi University, Turkey Psychodynamic, especially psychoanalysis, and cognitive-behavioural psychotherapies have been regarded as rivals for a long time. In addition to these two major forces, existential-humanistic therapeutic approaches emerged as a new front for practicing psychotherapists. However, in recent years practicing psychotherapists, and clinical and counselling psychology researchers have started to come to terms with adopting a relatively holistic, integrative and eclectic stance, in line with the client’s patient’s needs. At the theoretical level, the present study delineates the integrative stance employed in psychotherapy by the author. The present study proposes the usage of different modes of therapeutic action taking the time perspective into account, namely psychodynamic approaches for dealing with the past, existential approaches to remain in the present time, and both cognitive-behavioural and existential approaches in regard to the future. At the practical level, the present study is illustrated by a case in which this integrative approach had been implemented. Different techniques that are applied in the run of sessions are explained thoroughly, with details of interaction between the client and the psychotherapist. The outcomes of the psychotherapy are measured with subjective measurements by the client and by the psychotherapist. A comparison is provided between expected outcomes, case formulation and actual outcomes. In a feedback loop fashion, limitations and possible amendments to the techniques are outlined in the end for further application of the approach.

Counselling the plural self: Challenges and prospects
Cherian Isaac Madinat Zayed HCT, India; Shaima Ahmed The inherent multiplicity of self has long been a matter of serious philosophical reflection right from Psychology’s earlier days. Such a pluralistic conception of self prevailed for a brief period of time since William James’s classical reference to ’selves’, and soon fell into oblivion as the conventional conceptualisation of a ’unitary’ and ’centralised’ selfhood gained prominence and strength. In recent times, however, the multiplicity perspective has reemerged with a lot of strength and renewed sense of purpose, as can be seen from the wave of theoretical perspectives advocating the notion of multiple selves. In the wake of postmodernism, this perspective is a perfect fit and serves well as the need of the hour. However, for counsellors and psychotherapists such a perspective of self may prove to be both a bane and a boon. The implications become quite obvious as we realise that understanding the client’s phenomenal world is at the base of any counselling process or theoretical paradigm. So, what are the challenges and prospects that confront a counsellor assuming a pluralist conceptualisation of self? This paper is an attempt to address this question, as it draws particular attention to Hubert Hermann’s Dialogical Self Theory (2004) which has made great strides in conceptualising ’self’ as multiple and formulating practical implications for psychotherapy and counselling. It is argued that the very notion of ’multiplicity’ in self has equal potential to empower as well as constrain the counselling process and experience.

Counsellors’ and adolescents’ appraisals of psychological counselling effects
Kirill Khlovmov MSUPE, Russian Federation Objective. To compare appraisals of psychological counselling effects made by adolescents and by counsellors. We assumed that adolescents in difficult life situations and psychologists-counsellors evaluate the effectiveness of counselling in different ways, and knowledge about these differences could allow improving the counselling process. We based on the ideas of cultural-historical theory (Vygotsky, 1934), restorative justice (Zeer, 1998), and humanistic psychotherapy approaches (Robine, 2006; Batson, 1980). Methods. 14 semi-structured, focussed interviews with adolescents and 4 with counsellors were performed. Qualitative analysis was used. Interviewed adolescents had been counselled because of behavioural disorders (abuse, vandalism, truancy etc.) about 3–6 months. Work started from the call from school, justice, or police employee. Counsellors’ professional experience was from 1 to 5 years. Results. Effects of counselling are described differently by counsellors and adolescents. An important result for adolescents is satisfaction of mental needs (in acceptance, understanding, respect). They don’t consider the decline of behavioural symptoms, duration and quality of cooperation with a specialist as a result. For counsellors important results are: behavioral symptoms reduction, changes in the social situation of the adolescent, quality of contact, and the duration of cooperation. Discussion. Identification and acknowledgement of adolescent’s pressed psychological needs by counsellor is a factor of their cooperation strengthening. But the differences in appraisals of results by counsellors and adolescents may be a factor of professional burnout, and this topic should get attention and be discussed over supervision support.

A client’s perceptions of the changing dynamics in a longstanding therapeutic relationship
Harriet Knott South Africa; Jean Fielding A qualitative case study was conducted to explore the changing dynamics in a therapeutic relationship between a female client (Pseudonym: Kim; age 46 years) and her therapist (Pseudonym: Janet; age 57 years). Kim was sexually abused as a child and has been in therapy for the past twenty years. Kim and Janet’s therapeutic relationship has evolved through several phases of development. This study explored the alignment of the relationship’s development between Janet and Kim to the separation individuation phases of an infant and her mother, as stated by Margaret Mahler (Mahler, 1969; Mahler, Pine and Bergman, 2000). The goal of the study was to explore how Mahler’s theory of the mother/infant journey applies to this specific client/therapist relationship. Semi structured interviews were transcribed and correlated with Mahler’s theory on separation and individuation to understand how the therapeutic relationship had evolved over a longitudinal cycle. It was crucial to examine how and to what extent the relationship between the therapist and client followed a similar pattern to Mahler’s (1969) theory. The findings indicated parallels that the therapeutic relationship between Janet and Kim essentially progressed from where Kim was in an autistic state, which followed Mahler’s phases (Mahler, et al., 2000) into the emotional object constancy phase. The study presented a novel way of looking at the client/therapist relationship, and in turn offered beneficial insights for therapists about their own therapeutic relationship and developmental changes.
Campus violence: A study of the students of University of Jos in Plateau State and implications for counselling psychologists

Susan Kolawole
University of Jos, Nigeria

This paper investigates the conditions that could incite students to participate in campus violence. The study was guided by two research questions conducted in two faculties in the University of Jos. A 76-item questionnaire was used. A sample of 150 students were selected using stratified random sampling. The raw data gathered from the respondents, was collected, computed and tabulated using simple percentages to answer the research questions. The questionnaire designed by the researcher were validated by two experts in guidance and counseling and Test and Measurement Unit of Educational foundations in the University of Jos. The major findings of the study were as follows: 25% of students showed that the most important conditions that prompted the students to be involved in campus violence are: (1) when they fail tests and examinations; (2) when they are encouraged to join campus violence by friends; and (3) when there is lack of enough staff and provision of facilities. The campus violence most frequently involved in by the students is when the university authorities are unable to meet their demands, and the least, when they are being lured in joining campus violence about girls and money. The paper appeals to all stakeholders to use counselling techniques which have the potential for lasting solutions to promote peace and tranquility in tertiary institutions. Recommendation of counselling psychologists is to be encouraged by all stakeholders, and government should provide funds to the university authorities for necessary provision of amenities and services.

Improving couple communication through the Imago workshop for couples: South African research

Wendy Lawson
South Africa

Couples can improve their communication and relationship by attending a marriage enrichment programme, such as the Imago Getting The Love You Want Workshop for Couples (GTLYW Workshop). This is the psycho-educational application of the theory and principles of Imago Relationship Therapy, developed by Harville Hendrix. Couples learn crucial communication skills by means of a structured communication technique, the Imago Dialogue. Hundreds of couples in Southern Africa attend GTLYW Workshops each year. The GTLYW Workshop was under-researched when compared to other enrichment programmes. This was the first outcomes-based study in South Africa on the impact of the workshop. Based on a philosophy of pragmatism, a mixed methods approach was used, incorporating both quantitative and qualitative data analysis. A longitudinal design incorporated pre-workshop, three- to four-week post-workshop, and three-month follow-up measures. The main objective was to determine whether improvements occurred in a couple’s communication and their relationship after engaging in the GTLYW Workshop, and whether improvements were sustained over a three month period. While there was evidence of short-term improvements in aspects of communication and the relationship, the effects seemed to dissipate over time. This is in-line with international marriage enrichment research, which recognises the value of post-intervention “booster” follow-up programmes. The results of this research offered an opportunity for practitioners and educators to seek ways of better supporting couples to sustain improvements over longer periods of time after they have attended such a workshop.

Establishing an outpatient eating disorder programme in South Africa

Despina Learmonth
University of Cape Town, South Africa

With high mortality rates, frequent co-morbid diagnoses and associated medical complications, eating disorders represent a considerable healthcare burden, even though only a small percentage of cases are believed to actually seek, or receive, treatment. Modes of treatment, and access to treatment facilities, are very limited in South Africa. A recent survey showed that more than 13% of female participants were affected by an eating disorder. This survey was conducted among more than 7,000 women between the ages of 15 and 65 years who earned more than R3000 per month. There are also indications that prevalence is increasing, particularly amongst Black girls and women. It would appear that many Black South African women who used to be proud of their full figures have changed their mindsets as a result of urbanisation and westernisation and now want to be as thin as the models and actresses of the western world. However, the overall prevalence of obesity in South Africa is nevertheless still extremely high, with more than 29% of men and 56% of women being classified as overweight (BMI >25) or obese (BMI >30). This paints a poor picture of health outcomes for much of the population. This paper is an introduction to the development of the first stand-alone private eating disorder outpatient treatment service in South Africa. Its development was based on the Transdiagnostic Model - first developed by Fairburn and Waller. Initial implementation and the successes and difficulties of providing such a service within this particular cultural context are also discussed.

The relationships among beliefs about human nature, self-concealment, and psychological help-seeking behavior

Ling Lee Nankai University, China; Qiang Lee; Wenjun Gao Nankai University, China

Shared implicit theories refer to common beliefs and knowledge people share within certain social groups. Extensive studies have shown that once shared implicit theories have been established in a community as intersubjective reality, people will tune their own judgments and actions in accordance. In this study, we investigate how perceivers’ shared beliefs about human nature influence their self attitude and overt behavior, and apply this model to the field of mental health service. The implicit structure of the social representations of human nature was revealed through a free association test, in which participants were asked to indicate what they freely associate with the term “human nature”. The collected items were categorized by another group of subjects, and then divided into different facets by cluster analysis. Proverbs were selected in accordance with the results of cluster analysis, and the View of Humanity Scale was formulated. Based on the results of factor analysis, the scale contained three dimensions: virtualness, stability, and complexity of humanity. More than 500 undergraduates in Tianjin completed a set of questionnaires, measuring beliefs about human nature and self-concealment, and the intention of psychological help-seeking. Results showed that both shared implicit theories about human nature and self-concealment had a significant effect on psychological help-seeking intentions. Self-concealment is the mediate variable between implicit theories and intentions. These findings indicate that psychological help-seeking has its roots in basic cultural assumptions, and thus explains the different help-seeking patterns between Chinese and Western mental health service users.

The philosopher as counsellor

Dirk Louw
University of Stellenbosch, South Africa

Within the Western philosophical tradition the role of the philosopher as counsellor can be traced back at least as far as Socrates’ (470–399 B.C.) notion of the philosopher as a ‘midwife’ who assists others in giving birth to their own ideas (i.e. in thinking through their predicaments). In recent times the title ‘philosophical counsellor’ (PC) has been used more and more frequently since roughly the early nineteen-eighties and the idea and practice of PC are spreading to a growing number of countries. But what exactly is PC? Current definitions of PC can be summarised in terms of three overlapping sets of opposites: (a) practical versus theoretical definitions; i.e. definitions that include descriptive accounts of PC’s actual practice versus those that do not; (b) monistic versus pluralistic definitions, i.e. definitions of PC that defines it in terms of the work of one specific philosopher or approach in philosophy versus those that draw on the work of a variety of philosophers or approaches; and (c) substantive versus antinomous definitions, i.e. defining PC by saying what it is versus defining PC by saying what it is not. The purpose of my paper is to discuss critically and in detail all these definitions of PC with reference to a variety of examples. It also and specifically includes the discussion of a recent attempt to define PC as practiced in South Africa.

Primary, secondary and rejected pictures: An approach to integration in psychotherapy

Roger Lowe
Queensland University of Technology, Australia

Integration is a major theme in contemporary psychotherapy. However, there is an implicit assumption that therapists can and should be able to switch between seemingly incompatible models, based on an objective appraisal of what is required. In actual practice this may be unrealistic. Firstly, it assumes that therapists can become equally competent in the use of a wide variety of specialized therapeutic approaches. Secondly, it downplays the importance of therapists’ preferred ways of working, the concepts and practices in which they are particularly skilled and interested. In response, this paper examines ways for therapists to selectively ‘borrow’ concepts and skills from different models, while maintaining a commitment to a preferred orientation. The concepts of primary, secondary and rejected pictures (Wile, 1993) are used to address this issue. Primary pictures are our preferred theoretical concepts and practices which we try to adopt in any situation. Secondary pictures are alternative
approaches which we turn to temporarily while searching for a way to return to our primary pictures. Importantly, when switching from primary to secondary pictures, therapists do not necessarily use these secondary concepts and skills in the same way as specialists might. Instead, they may adapt them in ways which are more in accord with their primary pictures. Rejected pictures are concepts from incompatible models that we try to avoid using. This approach allows a practitioner to be an orientationist who integrates rather than a "pure" integrationist. Case examples are presented to illustrate the process.

Developing career supporting courses at Prague university of economics
Martin Lukes Prague University of Economics, Czech Republic; Eva Jarosova; Lenka Malinova
At Czech universities, there is a lack of courses that are directly focused on supporting students to make informed career-related decisions, and to build competences that will help them to make a successful start in the labor market. At the same time, there is a fast-growing number of higher education graduates in the Czech Republic. The labour market entry is thus more complicated for fresh graduates. To improve the situation, Prague University of Economics has started, since September 2011, to offer two courses that aim at developing attitudes and skills that students will utilize when starting their career. The first course is Career Development. It is intended for undergraduate students and covers topics such as labor market for graduates, individual preparation for labor market entry, how to write an appealing CV and cover letter, and how to perform well in selection interviews or assessment centers. The course contains a number of experiential learning methods, such as answering real job ads, practicing mock job interviews, or participation in assessment centers. The second course is Development of Managerial Potential. It is focused on graduate students in the prestigious Honours Academy programme. The topics include understanding own managerial potential, taking responsibility for own career, and taking specific steps towards own goal fulfillment under the coach's guidance. The experience from two semesters of teaching these courses is presented.

Research on physical education students career anchors types in China
Qi Luo Wuhan Institute of Technology, China; Tianbiao Zhang
800 students in Physical Education at five Universities in China were surveyed by questionnaire using college student's career anchor measurement scale. The career anchors of Physical Education major Students in Hubei Province were mostly technical ones, and lack of the awareness of entrepreneurship and the spirit of challenges. The problems of the single type of career anchors and employment difficulties, can be changed via strengthening career planning education, promoting teaching reform and updating the concepts of teaching practice.

The effect of psychodrama on self-esteem and forgiveness of female adolescents with divorced parents
Ladan Mansour Shahid Beheshti University (SBU), Islamic Republic of Iran
The present study investigates the effect of psychodrama on the increase of self-esteem and forgiveness of female adolescents with divorced parents. Twenty-four female adolescents (aged from 14 to 17), all under the support of the Imam Khomeini Committee, were randomly selected and divided into experimental and control groups. This study was conducted based on a pre-test, post-test and follow-up design. At the first stage as pre-test, the Forgiveness Questionnaire and Pope Self-esteem Questionnaire were administrated to both experimental and control groups. For post-test, the experimental group received ten two-hour sessions of psychodrama while the control group did not receive any intervention. After one month, both questionnaires were administered to all individuals as a follow-up study. All the collected data were analyzed using the repeated measures of variance. The results indicated that psychodrama significantly increased the forgiveness and self-esteem scores, in particular the family, social and physical self-esteem scores, of the female adolescents. No effect on educational self-esteem was shown.

'Should I stay or should I go?' South African families' experiences of emigration
Maria Marchetti-Mercer South Africa
An analysis of South African emigration in the past decades suggests that during the apartheid years it took place in waves often linked to specific political events. However, emigration has continued post-1994 and it is often argued that it is directly linked to the increasing occurrence of violent crime, poor service delivery coupled with corruption and affirmative action. Despite the prevalent "Should I stay or should I go?" debate around emigration and the fact that many South Africans have been affected by it, little is known about the psychological impact on the families involved. This paper, based on the findings of a qualitative research project examining the impact of emigration on South African family life, will explore the interactional dynamics around the decision to emigrate in ten South African families where at least one of its members had decided to emigrate. The stories of those leaving as well as those staying will be juxtaposed so as to illustrate how the larger social discourse plays out in the lives of families. A more systemic perspective on South African emigration will also be provided.

Weaving a nest of healing: Reflections on being a therapist working with adolescents in a South African context
Di Terlizzi Marisa St Stithians Girls' College, South Africa; Celeste Wolfensberger
Creating a conducive therapeutic environment is probably one of the most essential foundational aspects used to promote healing (Mulhauer, 2011; Zimring, 1994; Hazler & Barwick, 2001). In general, a negative stigma surrounds therapy, and this is especially amplified with adolescents, who measure themselves against the norms set by their peer group, where the perception exists that you should only see a therapist if you are 'crazy' (Kelly, 2008; Hardy, 2009). To challenge this perception, and through the use of the metaphor of an African Weaver bird, the recently qualified authors reflect on the process of therapy with adolescents in their different South African contexts. The authors believe that, much as the African Weaver weaves a nest using indigenous resources that are located in its specific environment, so too, the therapist needs to tap in to the 'indigenous resources' of the adolescent client in order to create and present a safe space for the adolescent to enter, share and grow. The authors will draw upon the concept of 'Ubuntu', which is embedded in the paradigm of community psychology, and will highlight Ericksonian principles (Rosen, 1982; Zeig, 1994) which can be woven into therapy successfully with adolescents. This theoretical framework for therapy with adolescents will be demonstrated through case studies, depicting the nests of empowerment, growth and self-confidence that therapists can potentially weave with their clients.

Stages and themes in the professional development of Filipino counselors
Nino Jose Mateo De La Salle University, Philippines
The context of professional development of Filipino counselors differs significantly from that of Western countries. Existing models of counselor development in the West therefore may not apply. This study sought to develop a model reflecting the stages and themes of counselor development in the Filipino context. Using a grounded theory approach to research, 29 practising counselors of varying age and years of experience participated in one-on-one interviews and focus group discussions. The model derived from the study consisted of four stages of professional development differentiated in seven dimensions. Four themes of development also emerged from the study. The model revealed Filipino counselors' notion of autonomy, motivation, and personal-professional integration. The model also highlighted the unique journey of Filipino counselors which included (a) the tendency of counselors to practice before receiving training, (b) the greater emphasis given to achieving professional identity than to mastery and (c) the lifetime involvement in the counseling practice. Based on the model that emerged, recommendations were made on how to improve the practice of counseling in the Philippines by focusing on areas for growth and by addressing the conditions conducive for stagnation.

Studying the relationship between schemas and marital satisfaction
Azar Matin Aramesh Counseling Center, Islamic Republic of Iran; G. Ali Afroz; Nafshe Madani; Azar Ziamanesh; Adis Krakian Mujembari
The purpose of this research was to study the relationship between schemas and marital satisfaction. 100 Married people (72 females & 28 males) with at least secondary school education were selected as the sample. Young Schema Questionnaire (YSQ) and Afroz Marital Satisfaction Scale (AMSS) were used as research tools. The results indicated an inverse relationship between marital satisfaction and the schema of emotional deprivation, mistrust/abuse, snags, emotional inhibition, abandonment, defective-shame, dependence/incompetence, vulnerability to harm or illness, self-sacrifice and insufficient self-control/self-discipline. In other words, if the above schema is enabled, marital satisfaction decreases. Also, there is no relationship between the schemas of social isolation/alienation, failure, subjugation, unremitting standards and entitlement and marital satisfaction.
Story telling: Valuing human experience in career counseling
Mary McMahan The University of Queensland, Australia

Story telling is a very human experience. On a daily basis, we tell stories to our children, friends, families and partners. Our lives are composed of many stories and everyone has a story to tell. Stories are constructed to relate, and to make sense of, our daily experiences as we interact with the influences of our family, social and community contexts. Stories can bind families, communities and societies together as a sharing of common experience, shared history and understanding. Story telling and the sharing of stories is a human experience that is part of how people live their lives. No single story is capable of encompassing all of life. The lives of individuals are multi-storied as no story is capable of encompassing all of life. Stories represent an attempt by individuals to make meaning of, and to actively construct, their lives. In career counseling we are privileged to hear the stories of our clients. We work with clients to co-construct future stories that are invested with hope and meaning. This presentation focuses on the story telling approach to career counseling that places importance on the individual in context by applying systemic thinking. The story telling approach offers a non-linear way of viewing clients, contexts and possibilities and of examining, connecting and making meaning of clients’ subjective and objective experiences. The presentation considers the potential of story telling in career counseling to value human experience in respectful and meaningful ways.

Resilience in families with mental illness
Sikhumbuzo Mfusi Walter Sisulu University, South Africa

Mental illness has far-reaching effects, not only on the individual suffering from the illness, but on other family members. While the study of its impact on the family has been reported in specialized mental health literature, it is only recently that it has received much attention from social scientists. The study of families with a mentally ill patient has tended to highlight the strained relationships between family members and the mentally ill person. Recent approaches are less likely to blame family, or specific members, for causing the illness. Instead, the focus is on the family processes, in order to promote the treatment, and rehabilitation, of the patient. Not surprisingly, researchers have begun to look for signs of resilience which might reduce the effects of the burden associated with caring for a family member with mental illness. This paper explores the experiences of families with a mentally ill patient. Five focus groups of mentally ill patients, together with their family members, met to describe their experiences and coping strategies. The results suggest that the resilience approach can help to inoculate families in order to deal with ordinary and exceptional circumstances.

Towards understanding incompatibility as a construct used to explain conflicts within marital relationships
Khumoetsile Modisa University of the Witwatersrand, South Africa; Davydova Yulia; Lobaskova Marina; Sabirova Elena

The field of marriage and relationships research has largely been pre-occupied with relationship breakdown and dissolution. Incompatible patterns within marital sub-systems have been linked to marital dissolution to a great degree. This tendency has therefore somewhat obscured the body of literature that explores the reasons why some marriages are enduring, satisfying and happy, despite the spouses being labelled by self, or others, as “incompatible” in various respects. Drawing on this literature, this paper examines “incompatibility” as a construct especially used to explain disharmony within marital relationships. The following two questions are then worthy of investigation: firstly, is it because of incompatible patterns that some marriages do not last; and secondly, does it mean that those marriages that last are compatible? Case examples have been used to highlight key issues pertinent to addressing these questions. Furthermore, these case studies have been used to highlight the importance of openness to other forms of knowledge and understanding of other related social factors. The paper is not intended to provide a critical analysis of the literature on other causes of marital breakdown, but rather focuses specifically on and explores incompatibility as a commonly ascribed reason. The discussion embraced in this paper bears significance for marital therapy on a broader scale.

The effect of group counselling with a cognitive-behavioral approach on self efficacy beliefs and goal orientation on Afghan girl students in Tehran
Khodayarifard Mohammad University of Tehran, Islamic Republic of Iran; Parvin Mohammad; Shiva Khali

The purpose of this study was to determine the effectiveness of group counseling with a cognitive-behavioral approach on self efficacy and goal orientation in Afghan girl students in Tehran. The design of the research was a quasi-experimental method with pretest, posttest, and group control. At the first stage the students completed Schwartz’s efficacy test questionnaire and Elliott & Mac Gregor’s test questionnaire for goal orientation. Based on the result, 30 Afghan students in the academic year of 2009–2010 who received scores from the tests were assigned to two groups (an experimental group of 15 and a control group of 15). The experimental group participated in the group counseling in 12 sessions of 90 minutes duration while the control group didn’t receive any treatment. The scores of the two groups were compared in post tests. Data was analyzed though analysis of U Man-Whitney. The results indicated that the group counseling with a cognitive-behavioral approach led to an increased self-efficacy in the experimental group. Goal orientation, the second variable of this study after holding group counseling in the experimental group in pretest and posttest were different, but this difference was not significant because of having few samples. The implications for future research and self efficacy learning by holding group counseling with a cognitive-behavioral approach for immigrant high school students was discussed and proposed.

The effect of self and partner on relationship attributions
Parisa Nifhoroooshan Islamic Republic of Iran; Mohammad Abedi; Maryam Fatehizadeh; Ahmad Ahmadi; Vahid Ghasemi

In a dyadic perspective, the aim of this research was to study the self and partner’s effect on couples’ relationship attributions. It was hypothesised that one’s relationship attributions are affected directly by one’s personality and attachment dimensions and indirectly by partner’s personality and attachment dimensions through relationship attributions and emotional reactions. This research was a correlational one. 522 available persons (261 couples) were selected. In this research, the NEO-Five Factor Inventory (NEO-FFI), the Experiences in Close Relationships-Revised Questionnaire (ECR-R), the Relationship Attribution Measure (RAM), and the Geneva Emotion Wheel (GEW) were used for collecting data. Structural equation modeling (SEM) was used to analyse the data. The model was examined for wives and husbands. The couples were considered as the analysis unit to study the both self effect and partner’s effect on relationship attributions. The results revealed that in both husbands and wives, relationship attributions were influenced by person’s attachment and the partner’s relationship attributions. Wives’ attributions were affected by the husbands’ antagonistic and resignation emotional reactions, while the husbands’ attributions were not influenced by wives’ emotional reactions. In general, spouse’s relationship attributions have mutual influence on each other. Relationship attributions are affected not only by personal characteristics but also by partner’s attributions and emotional reactions.

Gender and cultural differences in perception and content of self-disclosure among young South African adults
Sikhumbuzo Mfusi Walter Sisulu University, South Africa; Maga Bekenska

Self-disclosure of feelings, thoughts, experiences, and beliefs is central to our lives as social beings, and has numerous implications for relationships and health. It is usually studied in terms of verbal messages that contain statements such as “I feel” and “I think”, but nonverbal messages such as the clothes that people wear, as well as what they say may be examples of self-disclosure, if the goal is to reveal something about themselves that the other people did not know. Essentially, it is the process that grants access to the inner self and its secrets. Personal relationship researchers believe that self-disclosure plays an important role in initiating, as well as maintaining intimate relationships. However, it is the disclosure of highly personal information that has many consequences for relationship development and maintenance. Also, it is the individual’s perception of self-disclosure that serves as a predictor of whether the process will occur or not. This paper presents the results of a study that was conducted using two hundred male and female young adults of different cultures and race groups. A questionnaire that assessed different dimensions of self-disclosure was administered to the participants. The data collected were analysed qualitatively, using tables, pie charts, and statistics. The results are discussed in the context of the importance and significance of self-disclosure in the development and maintenance of intimate relationships.

Effect of cognitive restructuring on drug abuse among secondary school adolescents in Onithsha Education Zone of Anambra State, Nigeria
Vera Nwadinobi College of Education Nsugbe, Nigeria

The effect of self and partner on relationship attributions
Parisa Nifhoroooshan Islamic Republic of Iran; Mohammad Abedi; Maryam Fatehizadeh; Ahmad Ahmadi; Vahid Ghasemi

In a dyadic perspective, the aim of this research was to study the self and partner’s effect on couples’ relationship attributions. It was hypothesised that one’s relationship attributions are affected directly by one’s personality and attachment dimensions and indirectly by partner’s personality and attachment dimensions through relationship attributions and emotional reactions. This research was a correlational one. 522 available persons (261 couples) were selected. In this research, the NEO-Five Factor Inventory (NEO-FFI), the Experiences in Close Relationships-Revised Questionnaire (ECR-R), the Relationship Attribution Measure (RAM), and the Geneva Emotion Wheel (GEW) were used for collecting data. Structural equation modeling (SEM) was used to analyse the data. The model was examined for wives and husbands. The couples were considered as the analysis unit to study the both self effect and partner’s effect on relationship attributions. The results revealed that in both husbands and wives, relationship attributions were influenced by person’s attachment and the partner’s relationship attributions. Wives’ attributions were affected by the husbands’ antagonistic and resignation emotional reactions, while the husbands’ attributions were not influenced by wives’ emotional reactions. In general, spouse’s relationship attributions have mutual influence on each other. Relationship attributions are affected not only by personal characteristics but also by partner’s attributions and emotional reactions.

Effect of cognitive restructuring on drug abuse among secondary school adolescents in Onithsha Education Zone of Anambra State, Nigeria
Vera Nwadinobi College of Education Nsugbe, Nigeria
This study focused on the effect of cognitive restructuring on drug abuse among secondary school adolescents in Onitsha Education Zone of Anambra State, Nigeria. Two research questions and two hypotheses guided the study. The study was an experimental one and the design adopted was the randomized post test only group design. The population for the study consisted of 256 senior secondary school adolescent drug abusers identified with Drug Users Observation Scale (DUOS). A Purposive Sampling Technique was used to compose 60 students from Onitsha Education Zone of Anambra State. The sampling was based on urban and rural schools while taking cognizance of the gender status. The instrument used in data collection was the modified Drug Abuse Screening Test (DAST) developed by Skinner (1982), and the Drug Users Observation Scale (DUOS) developed by the researcher which was used in identifying the drug abusers. The subjects participated in six sessions of one hour duration per week. The internal consistency reliability estimates using Cronbach alpha were 0.81 for DUOS and 0.70 for DAST respectively. The data collected was analyzed using means, standard deviation, t-test and one way analysis of variance (ANOVA). The results of the study showed that cognitive restructuring was an effective therapy for reducing drug abuse among secondary school adolescents.

Efficacy of self-control and relapse prevention therapy in controlling sexual urges among youths in South East Nigeria
Osochre Obi Michael Okpara University of Agric., Nigeria
Transmission of HIV/AIDS through heterosexual modes accounts for more than 80% of HIV/AIDS infections and related problems among youths in Nigeria. This has been attributed to risky sexual behaviour due to lack of control of sexual urges. This quasi-experimental study employed pretest-posttest-control group design to investigate the efficacy of Self-Control and Relapse Prevention Therapies in controlling sexual urges among youths in South East Nigeria. 1000 volunteer youths (age range 17-28, mean age 24) from the five South Eastern states of Nigeria drawn from rural and urban areas responded to the researcher-made Response Rate to Sexually Arousing Stimuli-Male and Female versions (RRSAS-M&F). 20 volunteer youths from across five selected tertiary institutions with a high rate of response to RRSAS-M&F were selected for the experiment. The treatment group was exposed to behavioural techniques of Self-Control and Relapse Prevention Therapy while the control group was engaged with unrelated matters. Data were analysed using the t-test. Findings reveal significant differences between the treatment group and control group during both posttest and follow-up periods. There was no gender difference in treatment effects. Implications of findings include exposing youths to behavioural techniques to assist them in exercising control over their sexual urges.

Anger control group training to reduce aggression of male prisoners
Mehdi Omidian Payame Noor University, Islamic Republic of Iran; Mahnaz Alakbari Dehkordi
This study evaluated the effectiveness of anger control group training, with rational, behavioural and emotional approaches to reducing aggression of male prisoners in Shahrekord’s Central Jail. The design of this study is quasi experimental, with a pretest-post-test control group. This study was conducted on 40 prisoners who were assigned randomly into experimental and control groups. The Bell Adjustment Inventory was administered before training. The Michael Fire’s protocol of anger control was used for training the experimental group, consisting of a half-hour session for 12 weeks. The results of repeated measures revealed that anger management training significantly reduced maladaptive behaviours of prisoners. A rational behavioural and emotional approach to anger control is effective to improve the adjustment of male prisoners in Shahrekord’s Central Jail.

Returned children: Who to blame? An analysis of the Portuguese adoption system
Dora Redruella Faculty of Law, U Coimbra, Portugal; Sania Ferreira
This communication aims at sharing the results of a pioneer investigation, conducted on the Portuguese mainland and islands, on returned children, during the pre-adoption stage. This exploratory research, based on a qualitative matrix, involved the three key agents implicated in adoption procedures, namely adoption teams (n=13), adoptive families who returned children (n=4) and technical staff of foster homes (n=6), in a geographical and demographical balanced representation. An interview guide was created, attending all stages of the adoption process, and applied to the 23 group interviews conducted. Specific questions were asked of each of the agents (e.g., At the time did you know a family with adopted children? How was the first contact made between candidates and the Social Security?). From the discourse of the participants, pre-conceptions and dynamics were analyzed and triangulated with the aim of better understanding this complex issue. Specific case reports (success and failure) were requested and proved most valuable in revealing the real practices and conceptions about adoption, and particularly on the returning children matter. The main result is that all agents have partial readings on the phenomenon, not anticipating the needs and expectations of the others. We will identify the specifics of the definition of adoption as a life project and the key drivers that may lead adoptive parents returning children to shelters (e.g., the matching between family and the child). We conclude by discussing the impact of these results on developing strategies to reduce the number of returned children and increase successful adoptions.

Tropical depression: Counseling students through life transitions at a Caribbean medical school
David Sacks Ross University School of Medic, Dominica; McMillan Cuffy
There are approximately fifty medical schools in the Caribbean, about half of which are comprised mostly of foreign students. These individuals have the challenge of adjusting not only to medical school, but also to a different culture, climate and environment, all while already navigating the transition to adulthood. This presentation will explore some of the common presenting problems among students in a large Caribbean school. Not surprisingly, homestick-

ness is a frequent presenting issue that is exacerbated by students’ missing not only their friends and family, but also their culture of origin. Another common issue is difficulty adjusting to the rigorous curriculum. Also, during these transitions, students recognize signs of identity foreclosure and begin to explore their personal and career goals. This particular issue is emblematic of a broader phenomenon. That is, having undertaken this experience in a novel and distant setting, students for the first time have the “space” to look at themselves and become introspective. Stigma associated with cultural beliefs about psychotherapy has also prevented many students from seeking help sooner. Especially for those clients seeking services for the first time in medical school, the experience may become a model representing psychological services in general. The therapeutic encounter therefore has great potential impact on these future physicians’ likelihood of referring their patients for psychotherapy. When done well, psychotherapy at Caribbean medical schools facilitates clients’ recognition of the long-held assumptions that they have taken for granted and allows them to achieve a broadened world-view.

Differences between men and women in the perception of their marital problems before entering therapy
Angelas Sanz Universidad Autonoma de Madrid, Spain; Dolores Perez
The objective of the investigation is to assess whether there are differences between sexes in their perception of their marital difficulties or not, and if that were the case, to evaluate them. The sample is 97 heterosexual couples without any emotional or physical problem. All of them went through an hour structured assessment interview (by the same Clinical Psychologist) and through the complete form of the Stuart-Premarital Inventory. Results show that there are some significant differences between sexes in the perceptions of their marital problems in some areas, not in a general way. We explain some reasons that could explain such differences and also we make some suggestions about the implication that these results may have for clinical practice with couples.

Psychotherapy with creative artists
David Seeman Boston University, United States of America
The literature on therapy with creative artists is quite slim. However, there has been a recent trend of expanding the field of sports psychology to include work with creative artists, under the more general concept of performance psychology. This paper will explore some features of working therapeutically with artists. What are the particular developmental struggles of artists as they are in the early process of cultivating their craft and career? And how do the educational methods of their university training interact with these struggles? This presentation will explore these questions from the standpoint of a long-time practitioner of university mental health. I will examine the psychological challenges of creative arts students using both empirical data (derived from a campus-wide survey of student mental health) and clinical vignettes (taken from therapy hours with a variety of international and North American students), in order to shed light
on the unique gifts and hindrances that creative artists must balance in launching and sustaining their careers.

Trauma recovery and clay therapy: Working with grief, loss and anger
Patricia Sherwood Edith Cowan University, Australia
This experiential workshop is based on innovative, repeatable clay therapy sequences developed to assist clients’ work nonverbally to identify, express and transform traumatic experiences associated with grief, loss and anger. These sequences can be facilitated for groups of trauma survivors, thus multiplying the effectiveness and scope of the transformation and healing in affected groups and communities. Community-based mental health workers can be readily trained in these sequences, hence increasing the scope of delivery to traumatized groups who lack sufficient numbers of psychologists. The sequences have been used with efficacy in working with trauma survivors in Rwanda. Developed by Dr Patricia Sherwood these sequences give participants a sample of the power of clay therapy, as documented in her book, 'The Healing Art of Clay Therapy'. Dr Jabu Thwala has trained in clay therapy in Australia.

Use of cognitive behaviour therapy with children in an urban setting
Mamatha Shetty Tata Institute of Social Science, India
In an urban metro city the demands faced by an individual are enormous. Stress seems to be a given when intense competition is looked at as a norm. These demands are affecting families, of which children are the most vulnerable. Additionally the intricate web of support systems for children is slowly disintegrating and the gaps are becoming huge causing early stress in children. This stress is manifested in children mostly through visuo-audio addiction, anxieties, relationship difficulties, academic problems, substance abuse and early sexual exploration. Mental health professionals are increasingly approached for daily challenges along with psychiatric problems. In current practice, the therapist finds herself dealing not only with issues of children, but also with parental anxieties. Using case studies, this paper will illustrate how Cognitive Behaviour Therapy was used with children and adolescents between 4–18 years of age with clinical and sub-clinical problems. CBT was used to empower them with techniques to meet future challenges. This paper will also look at the challenges of working with parents and families in the Indian context and further elucidate the therapist’s reflections on the current emerging scenario.

The experiences of trauma counselling interns in organisations: The case of UNISA
Reet Shirinda-Mthombeni University of South Africa, South Africa
The professional category of Bachelor of Psychology (BPsych) Registered Counsellor was created in 2003 to deliver psychological services at a primary health care level to previously disadvantaged communities. In 2006 the programme was introduced at the University of South Africa’s department of Psychology and the focus was on trauma counselling internships supervision. A total of 800 students were trained and some graduated between 2006 and 2011. In an attempt to explore the impact of the BPsych internship programme (Trauma counselling) and the experiences of these graduates, a survey study was conducted where questionnaires were distributed to some of them. This presentation aims to highlight the impact of the BPsych internship programme (Trauma counselling) in the Department of Psychology. The experiences of the trauma counselling interns during and after their training in different organisations will be highlighted. The presentation will further shed light on whether the BPsych trauma counselling programme is effective in addressing the initial objectives.

Aasha, the surviving line for suicide prevention across continents
Namita Singh India
This article looks into the working of ‘Aasha’, the suicide prevention help-line in a city in North India. It highlights one of the many successful cases in rescuing a highly depressed and suicidal patient through the crisis intervention team. This suicide prevention help-line has been a major source for mitigating the suffering of highly depressed individuals, psychotic cases, substance abusers and students under stress-general anxiety situations. In Indian context, the accelerating suicide rate may be attributed to fast expansion of economy and social systems, increase of substance abuse, very high competition levels, and population pressure. According to Burrows and Laflamme (2006), in contemporary societies variables contributing to a suicide can be political, economic, psychosocial, physical or environmental. The socioeconomic and the pathological factors underlying suicide are somewhat similar across the globe. The cross cultural and societal variables across the two countries of South Africa and India are to a certain extent resonating in spite of geophysical diversity of the two different continents. With the current scenario increasing alcohol and substance abuse, evident socioeconomic upheavals the South African population with a multi racial demographic structure is under a constant change and strain resulting in high level of angst. Thus the necessity of a comprehensive and preventive step in this direction can save major costs on already strained medico-legal systems and the immense emotional trauma for the concerned individuals. The formulation of a similar Suicide Prevention help-line is much needed in South African context.

Good enough: A new relationship paradigm
Sonja Snyman South Africa
The paper is based on my book ‘Good Enough: Relationships that last’ which will be available from January 2012. In an attempt to address the question of why only 40% of couples achieve happy long-lasting relationships, this new paradigm offers a deeper understanding of how long-term relationships in the 21st century function. It explores the emerging nature of the current long-term relationship by looking at (1) its transactional nature, (2) the mix of heart and head, (3) the cycles and losses that relationships go through, (4) the patterns that develop between partners and how redundant patterns drive relationships, and (5) how couples put their relationship on probation. The concept of the ‘good-enough’ relationship evolved from reflecting on numerous long-term relationships I have observed in my practice and social circle over the past 20 years. Good-enough relationship are mindful relationships (1) where both parties take ownership, (2) where opposites are balanced, (3) where the relationship is viewed as a journey, (4) where ambivalence is tolerated, and (5) where a couple has managed to create a sacred space which is special to them and that creates a healthy relationship boundary to hold potential intruders at bay.

The development of career compromise during university stage
Qianni Song Renmin University of China, China; Ping Hu
Focusing on the process of career choice among Chinese university students, this research combined the traditional theory of Gottfredson and Gati and tried to find the pattern of development of career choice during the university stage. The present research had two goals: First, to explore the aspects that university students in China would concern in the process of career choice, and second, to examine the pattern of the career-choice-aspect-change during the university stage by comparison among three grade levels: Low-grade-undergraduates, high-grade-undergraduates, and graduates. To achieve these goals, patterns of intercorrelations among 49 students-concerning aspects from previous researches’ results were analysed, using data collected from 226 university students from China. Factor analyses revealed correlation among five main factors: Suitability, Welfare, Personal Development, Environment, Job Nature. There were significant differences (p<0.05). To conclude, the main factors the study explored differed from that of Gottfredson and Gati’s work, which could be attributed to cultural impact. Also, the result indicated no developmental difference in career choice during university stage, which might have resulted from the unrealistic experimental condition without using specific career choices. Therefore, to reveal a more realistic situation, the current study shall be followed up with additional experiments that are based on specific career choices.

Relationship between future time perspective and depression in college students
Shanggui Song University of Jinan, China
This paper was to investigate the relationship between future time perspective and depression in college students by using the general future time perspective questionnaire and SDS. Results were as follows: (1) There was no significant difference between male and female college students. There was a significant difference between arts students and science students; science students got a higher score in behaviour commitment and purpose awareness than arts students. (2) Behavior commitment, future efficiency and future image in future time perspective were positively related to physical disorder, psychomotor activity disorder, and mental disorder of depression; purpose awareness was positively related to psychotopic-affective symptoms, physical disorder, psychomotor activity disorder and mental disorder of depression. (3) There was a significant difference between the students who
got a high score and the ones who got a low score at the future time perspective in physical disorder, psychosomatic activity disorder, and mental disorder of depression. (4) Purpose awareness and far-reach goal orientation can significantly predict psychotropic-affective symptoms of depression, purpose awareness can significantly predict physical disorder and psychosomatic activity disorder of depression, purpose awareness and future image can significantly predict mental disorder of depression.

Rebuilding motivation for learning following disaster and conflict: Lessons from Liberia and Katrina
Arnold Spokane Lehigh University, United States of America
This paper is part of a symposium chaired by Arpana Inman on Social justice that has already been accepted.

Animal assistant therapy and ‘happy’ hormones
Hendrik Swanepoel South Africa
Although animal assisted therapy is recorded in scientific literature since the 1960s, there are very few - if any - reported clinical evaluations that reflect neurochemical changes. In this pilot study a client, a 14-year-old boy, suffering from cerebral palsy and receiving psychotherapy, was exposed to animal assisted therapy. The animal used was a tame ten-year-old male African elephant. An elephant was used because for its intelligence and the caring nature of their social relationships. Elephants were viewed as an alternative to the well-known dolphin assisted therapy. In this study blood samples were taken before and after client/animal interaction to determine if there was any significant change in the Serotonin, Oxytocin, Prolactin and Cortisol levels of the client because of the interaction. Some significant changes were found in the levels of the above-mentioned hormones. That is, there was an indication that physiological changes occurred in the client because of the interaction with the animal. This physiological change is beneficial to psychotherapy.

Working integratively with humanitarian workers, co-constructing a space between affect regulation and meaning-making
Roslyn Thomas Webster University, Switzerland
Humanitarian workers increasingly find themselves working in complex emergency situations which generate a significant risk of harm, to the point that intentional violence has become the leading cause of death. Counsellors know that to cope with these harsh environments, many humanitarian workers require therapeutic field proofing (subject/object work) keeping somatic body work to the forefront. They also know that those who return to headquarters need symbolic work on their ‘inner life’ and existential questioning (subject/subject). This presentation asks questions about what happens when people work in places that result in them coming up against the edges of their identity. It considers what happens when profound experience results in shifts in the individual psyche to the point that identity is ‘stripped down’ and shorn of its comfort zone. It considers what happens when they return home and have to funnel themselves back into an environment into which they struggle to fit. Using humanitarian worker narratives it considers how individuals organise inner experience, so that they can ‘come home to themselves,’ fold in and organise all they know into an inner experience. It opens up space for a discourse that allows us to make contact with how humanitarian workers address the existential questions brought on by profound experience that ruptures identity in some people through this work.

A culturally-sensitive replication of a programme of mental health research in the African diaspora
Earlise Ward University of Wisconsin-Madison, United States of America
The aims of this paper include, (1) to discuss a programme of mental health research conducted successfully in the US with African Americans, (2) to discuss replication of this programme of research in the US Virgin Islands, and (3) to discuss potential replication in other countries of the African Diaspora. In the US we conducted a programme of descriptive research examining African Americans’ beliefs about mental illness, coping behaviours, and barriers to treatment-seeking. Results showed African American adults believed that mental illness is chronic with negative health outcomes, and praying and counseling were identified as preferred coping strategies. Treatment-seeking barriers included poor access to care, receipt of culturally insensitive care, and stigma. These results were used to develop the Oh Happy Day Class (OHDC), a culturally-specific intervention designed to treat depression in African American adults. The OHDC is a 12-week group-counselling intervention, using a cognitive behavioural approach and Afrocentric principles (Nguzo Saba). The OHDC focuses on increasing knowledge of depression, reducing symptoms of depression, and increasing use of healthier coping behaviours, which were supported in a series of pilot studies. A large scale NIH funded trial examining effectiveness of the OHDC among African American adults is in progress in the US. This programme of research is presently being replicated in the US Virgin Islands. According to the WHO, by 2020 depression is projected to become the leading cause of disability and the second leading contributor to the global burden of disease. Our programme of research can reduce the burden of depression in the African Diaspora.

Comparison of forgiveness interventions with implicit theory interventions for early adolescents after peer transgression
Ting Ting Zhu Nanjing Normal University, China
The aim of the present study was to compare the effectiveness of short-term forgiveness intervention (SFT) and implicit theory intervention (ITI) on the decrease of unforgiveness, and increase of positive emotions in early adolescents after peer transgression. SFT was a short-term explicitly-promoted forgiveness intervention, based on the Enright and REACH model. ITI was an intervention designed to change one’s implicit personality theory more incrementally. 30 early adolescents (aged from 12 to 14), who were recently deeply offended by friends or other peers, were randomly assigned to three groups: one SFT experimental (n=10), one ITI experimental (n=10) and one control (n=10). All subjects were asked to complete the Chinese version of Transgression-Related Interpersonal Motivations Scale-12-Item Form (TRIM-12) and Chinese Positive and Negative Affect Scale for Student as pre- and posttest. One experimental group received eight half-hour sessions of SFT, and the other experimental group received eight half-hour sessions of ITI, while the control group was received no intervention. Data analysis showed SFT and ITI significantly decreased unforgiveness, and ITI significantly increased positive emotions. Results indicated both of the interventions were effective and adolescents less unforgiving and more positive as their implicit theories changed.

A comparison of cognitive behavioural therapy and Reiki in the treatment of depression
Zuleikha Ahmed University of Pretoria, South Africa
Depression is the most prevalent form of major mental illness, and has become a significant public health concern globally (Üstün et al., 2004). The treatment of depression utilises various psychotherapeutic and/or pharmacological interventions (Shannon, 2002). This study takes a quantitative approach to establish the effectiveness of Reiki in treating depression as compared to CBT. Forty-one CBT, and thirty Reiki, male and female participants between the ages of eighteen and sixty were randomly selected. A pre/post quasi experimental design was used. All participants completed the Beck Depression Inventory (2nd edition) (Beck, 1996) as well as the Zung Self Rating Scale for Depression (Zung, 1965). Depression, was diagnosed using the DSM-IV TR criteria for a Major Depressive Episode. All participants received Reiki or CBT with a minimum of six sessions, over a three-month period. Results revealed that Reiki brought about a more significant reduction in depression than did CBT, as measured by the Beck Depression Inventory. On the Zung Self Rating Scale for Depression no significant differences in the reduction of depression were obtained. Explanations for these results were then proffered. This study shows that Reiki can be successful in treating depression. It furthermore contributes to the dearth of research in validating a complementary form of therapy in a scientific manner, thereby paving the way to further investigations involving other types of complementary and alternative medicine.

The relationship between humor style of counselor and burnout: The mediating effects of interpersonal variables
Alnara Aimbakanbetova Kazakh National University, Kazakhstan; Mi Kyung Kim
The purpose of this study were, firstly, to examine the effects of humor, social support, working alliance with clients and working alliance with supervisor on burnout. Secondly, to determine the mediating effect of social support, working alliance with clients, and working alliance with supervisor on the relation between humor and burnout. For these aims of this study, data were collected from 203 counselors working at public counseling institutions and private counseling centers. For the analyses of mediating effects, data were used through correlation analysis and structural equation modelling. The
results of this study were as follows. Firstly, burnout showed a positive correlation with non-conforming humor but did not show a significant correlation with conforming humor. Moreover, burnout showed a negative correlation with social support, working alliance with clients, and working alliance with supervisor. Secondly, conforming humor had a significant positive effect on social support, working alliance with clients and working alliance with supervisor, and non-conforming humor had a significant negative effect on them. Finally, social support and working alliance with clients had a significant negative effect on burnout. These results suggest that the positive or negative tendency of humor has different effects on interpersonal relations, and negative interpersonal relations increase the risk of burnout while positive interpersonal relations lower the risk. On the other hand, working alliance with supervisor did not show a correlation with burnout. Lastly, the implications of the findings, the limitations of this study, and tasks for future research were discussed.

An expatriate wife’s experience of expatriate adjustment
Petrus Bester; Piet Bester; Willem Schurink
A preliminary review of the literature on cultural and expatriate adjustment with regard to the spouse of diplomatic personnel clearly indicated a gap in the existing knowledge scholars have of the adjustment experiences of spouses of expatriate managers. The aim of this study was to explore and describe one South African expatriate’s wife’s authentic experience of expatriate adjustment to India. A qualitative methodological approach with symbolic interactionism as theoretical framework was employed. The case study and in particular a life story was used as research strategy. Purposeful sampling was employed. Plummer’s (2001) critical humanism was included to reflect the flavour of diversity of frameworks available. This yielded a life history with rich descriptive data that were systematically analysed with Strauss and Corbin’s grounded theory approach (1990, 1998). A conceptual framework was compiled and used to substantiate the findings by means of a literature review, the identification of the core category, and finally the development of a substantive theory called: A transitional theory of expatriate expatriate adjustment. Guidelines proposed in the literature were followed to ensure the authenticity, trustworthiness and credibility of the study. The findings provided some understanding of how wives of expatriate managers experience the process of expatriate adjustment. Recommendations were made to improve current practice. The study also made a methodological contribution to the local study of Industrial and Organisational Psychology and in particular International Human Resources Management. Recommendations are made for future research.

Qualitative research in counselling psychology: Acculturative trends?
Kuldhir Bhati The University of Akron, United States of America
Qualitative research is increasingly being incorporated with Counselling Psychology. This phenomenon has been termed a paradigm shift, and a fifth force within the discipline (Ponterotto, 2005). Previous journals have been explicit in stating their openness, and in their solicitation of qualitative research. However, even though the debate over the validity of qualitative research and its existence within the field has toned down over the years, negotiations over its location and form continue. This study examines the pressure on qualitative researchers to acculturate and adapt in order to gain legitimacy, and acceptance, in a field dominated by quantitative research. We conceptualise the entry of qualitative research into a field dominated by a positivistic paradigm as an interaction between diverse research cultures, and use a cultural lens to examine how the minority culture has had to adapt to the dominant majority culture. Additionally, data is presented on the kinds of qualitative research that has been published within Counselling Psychology journals and the trends over time. The concomitant adjustments and accommodations, as well as methodological compromises that have been made, are examined and its impact on the kind of qualitative research that is fostered is examined. Recommendations are made about ways to effectively bring about an authentic integration of qualitative research, so as to enable the desired methodological diversity.

South African depression and anxiety group supports local communities with over 180 support groups
Cassey Chambers SADAG, South Africa; Zane Wilson Access to health care facilities is often severely limited in Africa. Mental health support is often non-existent due to stigma, geographical location, and socio-economics yet 16.5% of South Africans suffer from mental disorders. (South African Depression and Anxiety Group (SADAG), through its facilitation of over 180 Support Groups, has created a replicable nation-wide support network to help patients and loved ones. Support Groups offer a cost-effective sustainable mental health resource even into remote areas. Thematic analysis was used to assess responses which emerged from a reflexive review of the organisation’s experiences, as well as the qualitative results of feedback sessions. Focus groups were conducted with support group leaders country wide, as well as SADAG representatives who are actively involved with maintaining these networks. Results: The findings suggest that Support Groups represent an under-utilised but vital mental health resource. Further, regular, long-term support by family and friends who truly understand from a firsthand perspective is lacking. SG Leaders report patients no longer feel intimidated and alone with their diagnosis. Support Groups challenge the stigma and perceptions of a community and give members a voice. Support Groups provide a cost-effective, sustainable mental health resource. Support Groups are an under-utilised but vital mental health resource. Support Groups are shown to be invaluable in terms of ongoing support and maintenance. They need minimal financial investment, and mobilising this resource, particularly in rural and under-resourced areas, is a key factor in improved national mental health.

The objective of this study is to evaluate the psychometric properties of the Psychological Career Resources Inventory (PCRI) (Coetsee, 2008) as a career counselling tool in culturally diverse contexts. The study is based on four separate studies involving different sampling contexts: (1) Employed adults in the South African services industry (N = 2,997), (2) human resources management field (N = 358), (3) academic and non-academic staff and students at four different tertiary institutions in Nigeria (N = 400), and (4) employed adults from private and government institutions in Kuching, Taiwan (N = 64). Each of the four studies involved a quantitative survey approach collecting primary data. Results of an exploratory factor analysis and confirmatory factor analysis in the South African context are reported. The study also reports the descriptive statistics (means, standard deviations and Cronbach’s Alpha coefficients) and inter-item correlations obtained in each of the four studies. The statistical results obtained in the four different studies confirmed the reliability (inter-consistency reliabilities ranging between 0.71 and 0.90), and the construct, convergent and discriminant validity of the PCRI. The results confirm the relevance of the PCRI in diverse cultural contexts, its usefulness in career decision making and fostering career self-awareness and agency in the contemporary careers context. Recommendation for future research and practical applications for the use of the PCRI in the career counselling context are provided. Examples of individual case profiles are also provided.

Core self-evaluation compared to fluid intelligence and personality traits in decision-making
Annamaria Di Fabio University of Firenze, Italy; Letizia Palazzeschi
A topic of recent interest regarding the decision-making processes is core self-evaluation. This study investigated the role of fluid intelligence, personality traits and core self-evaluation in relation to decision-making (career decision-making difficulties, decisional styles, indecisiveness). The Advanced Progressive Matrices (APM), the Big Five Questionnaire (BFQ), the Core Self-Evaluation Scale (CSES), the Career Decision-making Difficulties Questionnaire (CDDQ), the Melbourne Decision Making Questionnaire (MDMQ), and the Indecisiveness Scale (IS) were administered to 143 Italian high school students. Descriptive statistics, Pearson $r$ correlations and hierarchical regression were performed. The study revealed that core self-evaluation added significant incremental variance beyond the variance accounted for by fluid intelligence and personality traits with respect to decision-making variables. The results highlight the role of core self-evaluation in decision-making offering new research and intervention perspectives.

An integral investigation into the phenomenology and neurophysiology of Christian Trinity meditation
Stephen Edwards University of Zululand, South Africa; David John Edwards
This integral investigation explored phenomenological and neurophysiological, individual and collective dimensions of Christian Trinitarian meditation
Correlates of received empathy experiences:

Stephen Edwards University of Zululand, South Africa; David Edwards

The main objective of this research was to explore the neurophysiologic, phenomenological, cultural, social and spiritual nature of received empathy experiences within the context of Wilber’s Integral approach and Person Centred theory and praxis. A triangulated, within subjects’ post-test design was used with two control conditions, a rest period and a factual information period, and one experimental condition, where participants explored empathy experiences in relation to particular emotivisers and situations. Individual subjective and objective data were complemented with collective inter-subjective and inter-objective perspectives on empathy. A neurophysiologic apparatus recorded basic electroencephalographic (EEG), electromyography (EMG), blood volume pulse (BVP) and respiratory activity respectively in a convenience sample of 13 psychologists. Participants provided individual and collective reports and discussions on their empathy experiences. A consistent pattern emerged from data gathered. Received empathy experiences were associated with an unexpected, statistically significant increase in alpha activity, with some associated increasing trends in theta and beta activity. Expected findings were significant decreases in delta activity accompanied by decreasing trends in gamma wave activity, muscle tension, heart and respiration rate. Individual and collective experiences generally reflected an affective, interpersonal, cultural, social and spiritual state of normal waking consciousness. Participant consensus was that the neurophysiologic, phenomenological, cultural, social and spiritual correlates corresponded truthfully with typical empathetic moments, insights and peak experiences, which are associated with effective therapeutic change in traditional and contemporary healing contexts.
Positive psychology focused couple therapy for married couples

**Sang-Bok Lee** Kangnam University, Republic of Korea

Objective: To examine the efficacy of positive psychology focused couple therapy (PPFCT) by conducting a programmed workshop for Korean American married couples among those who were in marital conflict. This pilot study was designed to examine diverse variables affecting marital relationship and quality. Methods: Ten couples (n=20) finally completed a total of eight 90-minute sessions of marital enrichment programme based on major therapeutic themes of positive psychology: trust, empathy, hope and optimism, intimacy, forgiveness, resilience, happiness, and emotional support. The format was a group workshop including positive couple therapy results. The significant outcomes were that positive emotional variables' rates (life satisfaction, hope, happiness, intimacy) were increased and that negative emotion variables' rates (loneliness, depression, anger) were reduced. The couples' anxious attachment style demonstrated less marital satisfaction and more marital conflict than those couples having a secure attachment style. Conclusion: This study demonstrated the efficacy of positive psychology focused couple therapy.

The parental competence and resilience scale in at-risk psychosocial contexts

**Jaime Leon** University Los Palmas de Gran Canaria, Spain; **Juan Martín**; **Eduardo Cabrera**; **Maria Rodriguez**; **Jaime Leon**

This poster describes the development of a scale to assess parental competence and resilience in psychosocial risk contexts. The research was conducted with 63 professionals from the Gran Canaria social services (Canary Islands, Spain), over 498 cases of at-risk families. The factor structure was obtained by Exploratory Structural Equation Modelling (ESEM) with oblimin rotation and WLSMW estimation method. The mothers scale showed a structure of five factors with 44 items: Personal Development and Resilience, Household Organisation, Seek of Support, Educational Competence, and Community Competence. These factors showed good internal consistency (ordinal alpha ranging from .70 to .97). The fathers scale consisted of four factors with 32 items: Personal Development and Resilience, Educational and Household Organisation Competence, Community Competence, Seek of support. These factors showed good internal consistency with ordinal alpha ranging from .68 to .97. The results suggested that the questionnaire, in its double version for mothers and fathers, captures the specifics of each parental role, and showed sound psychometric properties that make it suitable for the social services field.

Study on the invention effect of the cognitive-behavioural group counseling on college students’ social anxiety

**Nini Li** Jiangxi Normal University, China; **Qing Li**

The study intends to explore whether the cognitive behavioural group counseling can effectively reduce college students’ social anxiety level, so as to improve their social ability. Firstly, use the SCL-90 scale and IAS interaction anxiety scale as a research tool and adopt the methods of psychometry and individual interview to select the college students who have a social anxiety tendency. Next, divide these students into two groups randomly, the Experimental Group and the Control Group. Each group will have 12 students. Then, give the Experimental Group cognitive behavioural group counseling while the Control group receives no counseling. After the invention, evaluate the Experimental Group and the Control Group and conduct the paired test- t test on them. Finally, evaluate the invention effect according to their evaluation and other people’s evaluation. After the invention, the Experimental Group’s scores of such factors as interpersonal sensitivity, somatisation, obsession, depression, terror, anxiety and loneliness, have obviously decreased in the SCL-90 scale (p<.05). The scores in the IAS scale have also decreased significantly (p<.05). The cognitive behavioural group counseling can effectively reduce the level of social anxiety, negative thinking and loneliness.

The intervention effect of peer psychological counseling on college freshmen with maladjustments

**Jie Li** Jiangxi Normal University, China

This paper is to explore the intervention effect of peer psychological counseling on maladjustments of college freshmen, which is a new trial of orientation education for freshmen. 60 college freshmen with maladjustments were respectively divided into experimental group and control group randomly. Subjects were measured by Self-Rating Anxiety Scale and College Student Adaptability Inventory before and after peer psychological counseling. The result showed that the anxiety score of the experimental group deceased significantly; and the scores of the experimental group increased significantly on learning adaptability, interpersonal adaptability, self adaptability, environmental general evaluation and somatisation symptom. There is no significant difference on each dimension to control group. The above result showed that peer psychological counseling could improve the adapted condition of college freshmen with maladjustments.

Exploring university students' views of stress

**Mpho Madzhe** University of Venda, South Africa

Stress is a normal part of living. The experience of feeling stress depends on what events one notices and how one chooses to appraise or interpret them. Things which are stressful for one person may be routine for another. The aim of this study was to explain the views of students towards stress. The study was exploratory in design. Purposive sampling was used to select 10 students. Data was collected through semi-structured interviews. The interviews were conducted in Tshivenda, transcribed and translated in to English. The collected data was analysed using thematic content analysis.

The study revealed that the students experienced various forms of stress.

Exploring the underrepresentation of men in the psychology degree programme

**Pilot Mudhovaiz University of Venda, South Africa; Fatima Peters**

The number of people enrolling for psychology degree programmes is growing, yet men continue to be outnumbered by women. At school, boys and girls take the same subjects in similar numbers. After completing high school education, many boys and girls go to universities to pursue degree programmes of their choice. However, fewer men than women pursue psychology as a career field. The exploratory study sought to investigate the underrepresentation of men in psychology at a Historically Black University. Purposive sampling was used to select participants for the study. Phenomenological exploration was used to analyse the data. The study revealed that gender-stereotypes influence male students to shun psychology. The findings of the study would help the University and Heads of Psychology Department to understand the underrepresentation of men in their psychology degree programmes.

Knowledge of values and abstinence as preferred sexual behaviour among 10–13 year-olds

**Cordelia Oluwatolu Redeemer's High School, Nigeria**

The study examines the relationships between the levels of knowledge and acceptance of abstinence as acceptable sexual behaviour among 10–13 year-olds in two junior schools in Southwestern Nigeria. It was hypothesized that the levels of knowledge of this age group will determine their level of acceptability of abstinence as the most preferred sexual behaviour with less risk of contracting HIV/AIDS in the Nigerian society. A sample of 200 subjects were randomly selected and a survey instrument that measures level of knowledge and acceptance of abstinence was administered. Analysis was carried out with the aid of Pearson Product Moment Correlation Coefficient and some relationships were found between the two variables. The study concludes that low levels of knowledge of societal values by minors in the 10–13 year-old group will determine whether they will accept abstinence as the most preferred behavioural strategy for preventing the contraction of HIV/AIDS. The study recommends that parents, teachers and school counsellors need to do more to update minors in the Nigerian society about societal values which are held in high regard in relation to the subjects’ sexual behaviour. The mode of presentation of the values should also be given critical attention.

Social factors and desire for academic excellence among 10–13 year-olds: Implication for career counseling

**Cordelia Oluwatula Redeemer’s High School, Nigeria**

The study examines the relationship between social factors and desire for academic excellence among 10–13 year-olds in two junior high schools in Southwestern Nigeria. A total of 250 students were randomly selected for the study and Desire for Academic Excellence Questionnaires (DAE) were collected from the participants and a total of 170 students (Mage = 11.82, SD = 0.6) completed the questionnaires. Results revealed that the participants (M = 3.14, SD = 0.8) reported a median desire for academic excellence in the range of ‘medium’ level. The majority of the participants (M = 1.02, SD = 0.57) reported a median of ‘no pressure’ with social factors. The results indicated that among the four social factors of family, friends, peers, and teachers, social support from family was the highest (M = 3.11, SD = 0.85) followed by teachers (M = 3.06, SD = 0.73). The social factors and desire for academic excellence were negatively correlated (r = -0.27, p < 0.05). The results point towards the necessity of focusing on social support in the setting of appropriate career guidance in order to promote academic excellence.
administered on the students to measure the relationships between social factors such as satisfaction with parental career, access to media, peer pressure, and the desire for academic excellence. The scores were statistically analysed with Multiple Regression and the Pearson Product Moment Correlation Coefficient. The results show that some relationships were found between the social factors and the desire for academic excellence and some of the factors predicted desire for academic excellence. The study concludes that the students do have the desire to excel academically except that some social factors predispose them to average performance or failure. The implications of the study for career counselors are also discussed. The study suggests that school counselors should develop counseling programmes aimed at helping them to overcome the challenges of the social factors investigated and other extraneous factors that affect their desire.

An investigation of the emotional intelligence and rate of recreation among female university students
Zeinab Rostami University of Isfahan, Islamic Republic of Iran; Nasim Nafar; Iran Baghban; Mohammad Abedi
The main purpose of this study was to investigate the relationship between emotional intelligence and rate of recreation. The population of the study was all of the University of Isfahan female students. For this purpose 238 of the female students were selected by simple random sampling method and the Petrides and Furnham emotional intelligence Inventory and the rate recreation scale (according to this inventory students must determine their rate of recreation from 0 to 100) was completed. For the analysis the results were used in the statistical program SPSS 15 and correlation and regression analysis (stepwise methods). The results showed that a positive significant relationship exists between emotional intelligence and rate of recreation (R = 0.195, p < 0.001). The results of research indicated that the rate of recreation among female students. According to the research findings it can be concluded that the students who have more emotional intelligence have more attention to their needs to recreation and have more recreation in their lifestyle.

Professional orientation and career direction by university students
Pavla Rymesova Czech University of Life Sciences, Czech Republic
The article focuses on professional orientation and career direction by university students with the view to factors of a subjective character which determine career orientation. For the purpose of research the method of questionnaire was used. The questionnaire surveys the vision of future occupation development and a study of chosen field. The select sample consists of students of Faculty of Economics and Management and Faculty of Agrobiology, Food and Natural Resources of Czech university of Life Science Prague. The result was analysis of factors which influence the vision of future occupation development, recording the degree of influence of family tradition on work achievement and activity involvement with those students filled their eventual time interval between beginning of current study and end of their secondary school. The part of the research was evaluation of possibility of practical usage of survey results in work with study applicants.

Art therapy as an intervention to cope with the psychological concomitants of learning disability in adolescents
Sangita Sarah Santosham SCH, India
Few studies in India have focussed on art therapy with adolescents diagnosed as learning disabled. The goal of the study was to enable the subjects to effect change and growth on a personal level through the use of art materials in a safe and facilitating environment. The study used a pre-post test design to evaluate the effects of art therapy on the psychological well-being of adolescents with learning disabilities. Participants were 23 adolescents with learning disabilities. The adolescents were randomly assigned to the control and experimental group. The art therapy intervention was designed to alleviate frustration and anxiety and bolster self-esteem. The Thematic Apperception Test (TAT) – Indian Adaptation was used as a screening tool. The participants completed the Madras Picture Frustration Study (MP-F), State-Trait Anxiety Inventory (STAI) – Form Y and the Rosenberg Self-esteem Scale to evaluate changes brought about in frustration, anxiety and self-esteem as a result of the intervention. The Independent sample t-test was used to find the significance of difference between the experimental and control group on frustration, anxiety and self-esteem before and after intervention. The paired samples t-test was used to find the significance of difference between the pre-intervention and post intervention scores of the experimental and control group. The results suggest that art therapy is an effective intervention to cope with the psychological problems associated with learning disabilities.

College students adult children of alcoholics: Depression, anxiety, co-dependency and self-esteem
Jose Serra-Taylor University of Puerto Rico, Puerto Rico; Maria Jimenez-Chafey; Wilda Jimenez-Pastora; Angel Villafane-Santiago
The main objective of this study was to explore the prevalence of Adult Children of Alcoholics (ACOA) and associated risk factors in first year students at the University of Puerto Rico, Rio Piedras Campus. The prevalence of psychological risk factors (co-dependence, self-esteem, symptoms of depression and anxiety) was described and compared between ACOA and non-ACOA students. A self-report questionnaire measuring the variables of interest was administered to 2020 students; 64% females. The questionnaire included: the anxiety and depression subscales of the Symptoms Checklist (Derogatis & Cleary, 1977), the Rosenberg Self-Esteem Scale (1965), and the Children of Alcoholics screening scale (Hodgins, Matica-Tyndale, El-Guebaly & West, 1993). Twenty-three percent of the sample reported being ACOA. The general results reveal that there were significant differences between ACOA and non-ACOA in symptoms of depression and anxiety, co-dependence and self-esteem; ACOAAs presented lower self-esteem, higher co-dependence and more symptoms of depression and anxiety. A positive significant relationship was found between being an ACOA and symptoms of depression and anxiety, and co-dependence, as well as a significant negative relationship with self-esteem. These results suggest that first year students might be a population at higher risk of presenting mental health difficulties that can impact on their academic, personal and professional development. Effective early identification and intervention strategies should be developed at university counseling centers to work with this population.

Physical and psychological violence in couples and families among university students
Jose Serra-Taylor University of Puerto Rico, Puerto Rico; Angel Villafane-Santiago; Maria Jimenez-Chafey
Studies suggest that having experienced, or witnessed, violence in the family of origin, increases the risk of becoming a victim, or an aggressor, in a relationship. The aim of this study is to explore the prevalence of violence in couples and families among university students, and to evaluate the relationship between experiences of violence in the family of origin, and in couple relationships. The Experiences of Violence in Couple and Family Relationships in University Students Questionnaire was administered to a convenience sample of 3949 students from the eleven University of Puerto Rico campuses. The instrument has 41 items that explore experiences of physical and psychological violence in 4 subscales: Parent-Child Relationship, Observed between the Parents, Aggressor, and Victim. Twenty-five percent reported moderate experiences of violence. There was a significant correlation between all subscales; the strongest one was between Parent-Child Relationship and Observed between the Parents (r = .637; p = .000). When making comparisons by gender in experiences of violence by context, a significant difference was obtained in the Aggressor subscales (r = 4.588; df = 3882; p = .000) and Parent-Child Relationship (r = -2.128; df = 3924; p = .033); females reported more aggression towards their partners than males, while males reported more experiences of violence in their Parent-Child Relationship. Because of the high prevalence of violence in couple relationships among students, results suggest the need to develop public policy to promote prevention and intervention programmes.

Monotheretic integrated therapy, a new spiritual model of psychotherapy
Mohammad Hussein Sharifinia Research Institute of Hawzah, Islamic Republic of Iran; Mohammad Sharifinia
In recent decades two major evolutions occurred in counselling and psychotherapy: 1) developing eclectic and integrated models; and 2) emphasis on spiritual values and religious issues in counselling and psychotherapy process. Monotheretic integrated therapy is a response to these evolutions. In this comprehensive and multimodal system, I attempted to integrate behavioural, cognitive, analytical, and humanistic concepts and techniques in spiritual matters, especially faith in God and intimate attachment to him. This model is suggested for treatment of mood and anxiety disorders, drug dependence and reducing risky behaviour in prisoners. Monotheretic integrated therapy is based on the following principles: 1) Human beings have four different aspects: biological, mental, social, and
spiritual. These aspects have complex interactions with each other; any change in one will lead to changes in other parts, either directly or indirectly.

2) A human is a responsible, dynamic, and developing being, therefore he/she can change him/herself any time. 3. Behaviour disorders often include multiple biological, psychological, social, and spiritual causes. 4. Faith in an almighty, benevolent God can be considered as an effective and powerful healing factor in treating mental disorders. The author argues that if spiritual teachings of religions, especially an intimate relationship with God, are integrated with different techniques of psychotherapeutic approaches, we can improve efficacy and consistency of psychotherapy and counselling results. As according to Allport (1951) religious beliefs and values are the most influential factor in unification and integration of client’s personality, which is the base of recovery and mental health.

**Relationships between counselling and cultural engagement and native American adolescents’ academic achievement/college-decidedness**

Turner Sherrri University of Minnesota, United States of America; Gale Mason-Chagil; Maria Pabon; Yang-Hyang Kim; Ju-ri Joeng; Shari Dade; Julia Conkel-Ziebell; Robert Magelky

Throughout the world, indigenous persons are seeking to emerge in contexts other than those into which they were born. Many indigenous people desire to maintain their own cultures, while at the same time to obtain employment that would allow them to participate in the economic benefits that inure to people from dominant ethnicities/cultures. To do this, they need to progress educationally, yet, as a group, they face serious challenges to their educational attainment. For example, in the U.S., only 50% earn high school diplomas, and only 3% earn college degrees (Alliance for Excellent Education, 2009). Counselors in schools are charged with providing services designed to increase students’ achievement and help them plan for post-high school endeavors. In this study, we designed a model in which counseling and cultural engagement predicted achievement and college decidedness. The model was based on the American School Counselor Association’s National Model (2005). Our sample was 194 Native American high school students. We tested the model using Structural Equation Modeling. Data were gathered via the Stanford-Achievement-Test-10 and survey methods. Results indicated that counsellor-led individual planning was positively related to achievement and college decidedness. Group planning was positively related to achievement motivation. School climate was also positively related to achievement motivation (partially mediated by cultural engagement). Individual responsive counselling was negatively related both to achievement motivation and achievement. We recommend providing individual and group planning and engaging Native American students culturally as ways to increase their achievement and college decidedness.

**Paths to math for inner-city and suburban adolescents**

Turner Sherrri University of Minnesota, United States of America; Shari Dade; Monica Froman; Marcuetta Williams

Helping adolescents develop math interests and career choice goals can be critical in assisting them to obtain jobs. Fifty percent of people across the world live in cities (CIA Factbook, 2011); 1/3 of these people live in poverty and have little ability to obtain sustainable employment. Yet, the future employment of young people from these families is also important to the economic sufficiency of the world. In this study, we surveyed two groups of 10th – 12th graders in the U.S.: (1) impoverished students from an inner-city high school (n = 152), and (2) higher SES students from two suburban high schools (n = 234). From the data, we then constructed and tested two Structural Equation Models of math career choice, one for each group. Both models were significant, but two distinct paths to math choice emerged. For suburban youth, the path included strong peer and parent support, concerns about society’s expectations concerning women working in a math field, and concerns about the best way to support one’s family. For inner-city youth, the path included a negative relationship between parental role modeling and math interests, and a commitment to take more advanced math classes in order to be able to qualify for a math career. Results suggest that different counseling paradigms should be developed in order to meet the needs of both groups. For inner-city youth, this could include assisting parents to also excel in math, and making more advanced math classes available to them.

**Psychological covariates to high school graduation**

Turner Sherrri University of Minnesota, United States of America; Maria Pabon; Julia Conkel-Ziebell; Ju-ri Joeng; Shari Dade; Gale Chagil; Yang-Hyang Kim; Robert Magelky

In the U.S., finding ways to increase high school graduation rates are a primary focus of counselling, school, and educational psychologists. Only 70% of students from the U.S. are graduating from high school on time (Alliance for Excellent Education, 2007), even though public high school educations are available for all. For U.S. residents, this equates to $329 billion annually in lost lifetime incomes, greater unemployment, and more involvement with social welfare and justice systems (National Center for Education Statistics, 2011). In this study, we conducted a 6-year longitudinal investigation of co-variates to increasing high school graduation rates in 5 school districts (3 metropolitan, 2 rural). Each of these districts had implemented programs designed to increase graduation rates that included counseling and academic interventions. Districts served multi-ethnic populations across the SES spectrum. Three (2 metropolitan and 1 rural) increased graduation rates, and two (1 metropolitan and 1 rural) did not. Through examining student records and surveying students annually, we found that significantly more students from schools in which graduation rates increased reported grade/credit checks and course-selection assistance from counsellors, higher expectations and accessibility from teachers, respect from other students, and from themselves, putting forth their best efforts, employing self-regulated learning strategies, readily engaging in school activities, and having greater enthusiasm to plan for post-high school. Neither grade point average nor attendance covaried with increasing graduation rates, indicating that attending to psychological and support factors along with academic achievement may be key to helping young people graduate from high school.

**Varied predictors of interests in maths/science career clusters among adolescents**

Turner Sherrri University of Minnesota, United States of America; Marcuetta Williams; Monica Froman; Shari Dade

Working in a math/science career could increase the likelihood of attaining financial security and making valuable contributions to the economy. Often research investigates predictors of many types of math/science career interests combined; however, interests can be studied more accurately by clustering careers (Turner & Lapan, 2003). Because of the divergence between men and women in math/science interests, we predicted that both clusters and predictors would differ by gender. In this study, 111 females and 212 males (ages 14–18) identified their math/science career interests by completing Mapping Vocational Challenges-I (Lapan & Turner, 2000). Participants also completed instruments designed to ascertain their supports for, and barriers to entering into math/science careers. We analysed the data using multi-dimensional scaling and multiple regression. For males, there were four clusters (computer-related, essential math/science, applied science, health professions) and one stand-alone career (astronomy). The strongest predictor for each was career efficacy. The next levels of predictors varied across clusters (e.g., parents’ verbal encouragement, math is a male domain). For females, interests clustered around educational requirements instead of occupational characteristics. There were two clusters: 2-year and 4-year college required, and two stand-alone careers (physician, veterinarian). Females had a very different pattern of predictors than males. For example, for 2-year math/science career interests, efficacy was not predictive, but parents’ role modeling was. We suggest that promoting interests in different types of math/science careers among adolescent males and females need different types of interventions.

**An investigation of stress coping mechanisms during Masters dissertation completion in an open-distance learning environment**

Fortunate Silinda UNISA, South Africa

Recent and past research on goal attainment among students emphasises the value of underlying factors impacting on student success. These studies either investigate psychological sub-dimensions or combine these with other factors (i.e. sociological factors such as family, peer pressures previous education background and university setting) to the factors impacting on student success Tinto (1975), Cope (1978), Fraser & Kilten (2003) and Okopi (2011). It is against this background this study seeks to investigate coping and stress mechanisms among post-graduate students at UNISA (University of South Africa). The study population will be students currently enrolled for their Masters degree at UNISA. Student records indicate that there are currently 3000 students who are registered for their Masters degrees at UNISA. An important inclusion criterion will be that the student has to be conducting their dissertation. A two-stage stratified sample design will be used to select a total (of 300 students per
Psychological health is important for lecturers in order to alleviate stress. Using a stratified sampling method, we investigated 252 lecturers from CCNU University by adopting self-made Employment Situation of University lecturers Questionnaire and Mental Health Schedule. Based on data analysis, I drew some conclusions as follows: 1. University lecturers, generally, are under enormous occupa-
tional pressure, and lecturers who are facing serious occupational stress, account for 61.51 percent; lec-
turers who have little stress account for 4.17 per-
cent; lecturers who are facing moderate stress ac-
count for 34.32 percent. 2. Based on the comparison of the difference notability of SCL-90 of different groups, this study drew some conclu-
sions as follows: The psychological health of male lec-
turers is lower than that of female lecturers; there is no remarkable difference in the psychological health of university lecturers of different ages, ace-
nemic qualifications, job titles, subjects, and teach-
ing experience. 3. The factors which hindered the psychological health of university lecturers are oc-
cupational stress, individual factors and specific occupational characteristics. Correlation analysis on occupational stress shows that occupational stress is negatively correlated with psychopathic factors. Occupational stress has a significantly neg-
atively impact on the psychological health of univer-
sity lecturers. The key factors which led to the occupational stress in lecturers are the load of re-
search work, little opportunity to obtain program-
ness and great difficulty in occupational promotion.

Individual factors cover personality, cognitive style, interpersonal relationship, ability, coping strategies and emotion.

The purpose of this study was to examine the use of phototherapy for self-concept development. The study focused specifically on phototherapy to im-
prove the self-image through the creative engage-
ment of the client in a process of reflection, aware-
ness and acceptance. Phototherapy utilises photographs in a therapeutic context to facilitate understanding. Photographs serve as a tool to ex-
press meaning, to clarify feelings and to reveal relationships in a client’s life world. The study used a qualitative research methodology within the nat-
uralistic research paradigm, as this study focused on the understanding of phototherapy. Therefore case studies were selected to study in-depth. The case studies showed that the application of phototherapy leads to a new understanding of others, objects and the self, and to consider change that can lead to a positive self-concept. I came to realise that this technique is an excellent tool for psychologists to use. Four case studies are not a reflection on the population as a whole, and therefore no general-
isations can be made. This has been a study of limited scope and not all aspects of phototherapy could be illustrated, therefore more research is needed. The multicultural aspect of the South Afri-
can context may have an influence in the interpre-
tation of the study. Phototherapy revealed to be a valuable tool as it can be of assistance in reflecting on the self, to improve self-knowledge and thus enhance the self-concept.

Analyzing psycho-emotional challenges in person-centred therapy with older adults

Sofia Von Humboldt (SPA, Portugal); Isabel Leal

This research aims to evaluate psycho-emotional challenges for older adults and the relevance of person-centred therapy (PCT) for older adults. Fy-
ty senior adults, aged above 65 years (M = 71.7; SD = 4.6) were assessed with the the Self-Esteem Scale (SES), the Mini-Mental State Examination (MMSE). Socio-demographic data, including gen-
der (57.5% women), marital status (37.5% married) and education (39.2% mandatory school) were also assessed. Bivariate associations were also per-
formed. Results yielded a set of five descriptive categories that captured the distinct ways older adults perceived psycho-emotional challenges and that reflected the individual’s perceived importance of PCT: time perspective, the aging body, autonomy and control, cognitive endurance as well as loss and reminiscing. Regarding bivariate associations, results indicated that ‘autonomy and control’ was associated with the ‘aging body’ and with ‘time perspective’. This latter was also associated with ‘loss and reminiscing’. This study highlights the importance of PCT for older adults facing psycho-
emotional challenges in old age. Interventions with older adults may benefit from clearly understanding older adults’ specific issues as an important com-
ponent for promoting successful aging and reducing health disparities.

Academic procrastination, overconfidence and parental unrealistic expectations as cor-
relates of academic rebelliousness among undergraduate students in Ogun state, Nigeria

Taiwo Williams Babcock University, Nigeria; Comfort Oyinloye; Ruth Aderanti; Ngozi Uwanna

The study examined the relationship between aca-
demic procrastination, overconfidence and parental unrealistic expectations and the academic rebel-
liousness of undergraduate students in Ogun State, Nigeria. Two hundred and fifty participants were randomly selected from a tertiary institution in Ogun State, Nigeria. Multiple regression analysis was employed to determine the joint and relative contributions of the independent variables to the prediction of the dependent variable. The results showed a relationship between academic procrasti-
nation, overconfidence and academic rebelliousness of the students. The multiple correlation coefficient (R2= 0.82) indicating a joint contribution of the independent variables on the dependent variable was recorded for this study. Further verification using regression analysis of variance (ANOVA) produced F (3, 194) = 5.765; P< 0.05. This study, also conclusively found that overconfidence and academic procrastination relatively contributed to the prediction of academic rebelliousness of the undergraduate students. Implications for adolescent counselling are discussed in the study.

Effect of some dysfunctional behaviours on job performance of University workers in Ogun state, Nigeria

Taiwo Williams Babcock University, Nigeria; Comfort Oyinloye; Ngozi Uwanna; Ruth Aderanti

This paper examined the effect of some dysfunc-
tional behaviours (Smoothing, Biasing and Filter-
ing) on the job performance of University workers in Ogun State, Nigeria. A sample of 250 University workers participated in the study. Multiple regression analysis was employed to determine the correlation among the variables as well as the joint and relative contributions of the independent variables to the prediction of the dependent variable. Findings of the study revealed that the independent variables jointly accounted for variations in the dependent variable, indicating a multiple regression coefficient value $R^2 = 0.70$. The result of the Regression Analysis of Variance (ANOVA) showed $F(3, 219) = 5.518$, while smoothing had the greatest relative effect on the prediction of job performance among the university workers. Implications for counseling are discussed in the study.

**Group cognitive-behavioural psychotherapy in combined treatment of in-patient with depressive disorders**

Alesandra Volkonskaya MSUMD, Russian Federation; Natalia Sirota MSUMD, Russian Federation; Boris Tsygankov; Vladimir Volkonsky MSUMD, Russian Federation

Objective of the study was to assess the outcome of group CBT in combination with pharmacotherapy for in-patients with unipolar depression in comparison with the standard pharmacotherapy. Sample consists of 120 patients (mean age 35.8± 9.0, Male / Female - 49,3%/50,8%) diagnosed with Depressive episode, Dysthymia or Recurrent depressive disorder according the ICD-10 criteria. All patients were randomly divided into two groups. Main group undertook 8 sessions of group CBT each for a 2.5 hour duration on top of the standard pharmacotherapy. The control group received only standard pharmacotherapy. As outcome measures, the Russian versions of Beck Depression and Anxiety Inventory (BDI & BAI), Dysfunctional Attitude Scale, Automatic Thoughts Questionnaire were used. The BDI score at the baseline were 23.8 (± 10.0) in the main group and 20.4 (± 8.1) in the control group. The decrease after treatment composes 59 % and 40%. Post-treatment BDI scores were 9.7 (± 6.1) and 10.6 (± 7.0) for the two groups respectively. The BAI score was significantly higher in the main group, and decreases in both groups after treatment ($p<0.05$), dropping by 54% and 43%, respectively. A similar trend was observed in the level of automatic thoughts with more significance decrease in the main group. Dysfunctional attitude level remains steady over the treatment course for all patients. Group CBT in combination with pharmacotherapy shows to be more effective for treatment of in-patients with depressive disorders than pharmacological treatment alone.

**Session Type: Invited Addresses**

The wild wild west of therapeutic wilderness adventure

Mark Burdick United States of America; Shayne Gallagher

America is a land of expression and of freedom. However, there are unfortunate instances where youth lose sight of innocence and future. The author is a well known psychologist promoting outdoor therapeutic programmes to families in need of healing through indigenous cultural avenues. Troubled youth mysteriously do well temporally distanced from their families, to consider their own need to change. But how? Set amidst the backdrop of the American old west, the echoes of both the cowboy and Native American cultures whisper across the wild desert places. These places are the setting of WinGate Wilderness Therapy in Utah. As in the cowboy days, a rugged lifestyle brings self-confidence, where a sense of a young person’s own capabilities are discovered and re-discovered, around every new bend. An ancient and profound place of healing and hope comes to the spirit of those who have the once-in-a-lifetime opportunity to regain who they really are, and to re-establish relationships with those who love them. The magic of indigenous culture’s healing techniques start here and only get better, to strengthen the individual and the bond between the youth and the family. Shayne Gallagher, co-presenter and Executive Director of Wingate, will do a demonstration of this technique.

NARRATABILITY AND CAREER CONSTRUCTION: EMPIRICAL EVIDENCE OF INTERVENTION EFFECTIVENESS

AnnaMaria Di Fabio University of Firenze, Italy

Rapid and fundamental changes in the world of work demand a contemporary approach to career counselling. Career counsellors should heed these changes and adapt their discipline appropriately and timeously. The theory and practice of the discipline need to be redesigned to enable people to design successful lives and adapt to multiple changes. This keynote maps the way forward, and addresses the question regarding the effectiveness of contemporary interventions in particular. The value of a qualitative approach in combination with a quantitative approach is emphasised. It is proposed that career counselling interventions should move from foundations to innovations, guided by and based on the venerable career construction theory of Savickas, which presupposes a narrative or storied approach to career counselling. After delineating the theoretical and conceptual frameworks of the new approach, the significance of some intervention methods will be examined. The need to establish rigour in qualitative career counselling interventions will be highlighted next and attention will be drawn to the importance of validating narrative interventions aimed at facilitating life designing. The results of recent studies will be highlighted and the effectiveness of life design counselling interventions will be demonstrated. These studies investigated the value of, for instance, the Career Construction Interview, the Career Interests Profile, the Career Future Autobiography and the new Career Genogram and demonstrated the usefulness of group-based life design counselling. Lastly, future research imperatives are proposed.

COUNSELLING IN THE ARAB WORLD: PSYCHOLOGISTS’ ROLE AND CHALLENGES

Adnan Farah University of Bahrain, Jordan

Many countries across the Arab region are currently experiencing rapid and historical changes known as the "Arab Spring" or "Arab Awakening." These changes represent an opportunity to address different challenges not only for politicians and policymakers, but also for many educators, and scientists in many aspects of life. The purpose of this address is to provide an overview of the challenges Arab psychologists are confronted with, that require coming out of their isolation and considering a new role at the academic and professional levels. The address attempts to clarify that the dramatic change that is taking place in some Arab countries, have brought with it a mandatory reform in the field of psychology. In this context, the address proposes a new role for Arab psychologists as agents of change, that makes psychology more relevant to daily life, and to empower people for positive change. The lecture draws attention to possible roles that Arab psychologists need to develop or emphasise in different disciplines such as forensic, and police psychology. Recommendations are made to provide more psychological support to refugees and marginalised disadvantaged populations, as well as victims of traumatic events, torture and violence.Keywords: Arab Spring, Arab Psychologists, Psychologist role.

**Career adaptability in Portugal: From measurement to interventions**

Maria Duarte Portugal; Mark Watson; Jenny Bimrose

Adaptability turned out a key issue in the domain of psychology of life construction. Career adaptability is a psychosocial construct that describes an individual’s readiness and resources for coping with current and anticipated tasks, transitions, traumas in their occupational roles that, to some degree large or small, alter their social integration (Savickas, 1997, 2005). Portugal contributed along with other countries for the development of an international core measure of career adaptability. The Portuguese research version of the Career Adapt-Ability Inventory (CAAI) is turned into Career Adapt-Abilities Scale – P(ortugal) (CAAS - P).This revised form consists of four scales - Concern, Control, Curiosity, and Confidence each with seven items (Cooperation scale was excluded). One national item per scale was added. The Portuguese revised form has been administered to a variety of Portuguese samples. Some of the main psychometric properties and differentials analysis is presented. Implications of the studies at inter- and intra-individual levels are discussed. The presentation and discussion of the results and its importance for career counseling illustrates the importance of an adaptability measure. But, more important, are the implications for practice and intervention on the field of career construction.

**Overview**

Jacobs Maree University of Pretoria, South Africa

This symposium revolves around Career adaptability a multidimensional construct which deals with individual differences in the willingness, competence, and behaviours required to address work transitions (Savickas, 2010). (Career) Adapt-Abilities (which include the scales concern, control, curiosity, and confidence) are psychosocial competences, rather than behaviours that produce adaptation and its outcomes. In this invited symposium, representatives
from four countries participating in the international project will present the results of their ongoing research on the development of this instrument. Firstly, the symposium will provide a brief update on the theory and organisation of career adaptability. Secondly, participants will elaborate on steps taken to contextualise the model of career adaptability in their attempts to address cross-cultural issues. Lastly, the results of studies that empirically investigated the CAAS will subsequently be presented. Outcomes: (1) Appreciate the theory of life designing in relation to career adaptability, (2) distinguish between the four dimensions of career adaptability, namely concern, control, curiosity, and confidence, (3) appreciate the value of these four dimensions as psychosocial resources for managing occupational transitions, developmental tasks and work traumas, (4) examine empirical research on career adaptability, and (5) appreciate cross-cultural differences in career adaptability.

Standardising the South African version of the career-adapt-abilities scale and developing a narrative supplement

Jacobus Maree University of Pretoria, South Africa

Savickas et al. (2009) recently developed the Career-Adapt-Abilities Scale (CAAS) to help people deal with challenges to their working lives and managing occupational transitions, developmental tasks and work traumas (Savickas & Portli, 2012). Career adaptability is a multidimensional construct which deals with individual differences in the willing-ness, competence, and behaviours required to address work transitions (Savickas, 2010). Career Adapt-Abilities include the factors concern, control, curiosity, and confidence, which are psychosocial competences, rather than behaviours that produce adaptation and its outcomes. The aim is to provide a brief update on the theory and organisation of career adaptability and to delineate the steps taken to standardise the CAAS in SA. The model of career adaptability was contextualised to address cross-cultural issues in SA. A cross-sectional survey (N = 464) was then carried out to determine the validity and reliability of the CAAS in SA. I will present the results of our efforts to investigate the CAAS empirically and elaborate on the results of confirmatory factor analysis, item analysis and reliability analysis. Internal consistency estimates for the subscale and total scores ranged from good to excellent. The CAAS-South African Form is identical to the International Form and seems to be an ideal instrument that counsellors can use to assess their clients and help them acquire the skills referred to above.

Career adaptability: A qualitative analysis of the career narratives of older women

Mary McMahon The University of Queensland, Australia; Jenny Bimrose; Mark Watson

Career adaptability is widely regarded as an essential competency for individuals to manage their careers in the 21st century. To date, career adaptability has been conceptualised primarily as a quantitative construct despite calls for it to be understood and applied qualitatively. This presentation reports on the initial phase of an international qualitative study investigating the career transitions and adaptability of older women. The aim of the study was to investigate how 36 older women from Australia, England and South Africa experienced career transitions. A two stage data analysis was conducted. The first stage of inductive data analysis revealed nine themes and 19 subthemes of which one subtheme was career adaptability. The second stage of deductive data analysis was guided by qualitative descriptors of the five dimensions of career adaptability, specifically concern, control, curiosity, confidence, and cooperation, as well as three levels of career adaptability proposed by Savickas (2008). Illustrative examples of the dimensions and elements of adaptability will be presented. The results offer a rich and nuanced understanding of career adaptability and suggest that qualitative assessment of career adaptability may be used to complement quantitative assessment. Subsequently the study has been extended to a further three countries.

Symposium title: Health psychology

Convenor: Vito Tummino

The role of the psychological component in primary care

Giancarlo Marenco HSA, Italy

The project aims to promote increased knowledge and awareness on treatment of psychological distress in the reorganisation of the Territorial Assistance, especially in services that provide the so-called ‘Primary Care’. One patient in four, among family doctors practices complain about many diseases that have a psychological base. CMI (Common Mental Illnesses), namely mild and moderately anxious and depressive states, are more and more frequent in the general population. The consumption of psychotropic drugs is steadily rising. A lot of physical diseases are caused by states of psychological suffering, like chest pain, insomnia, difficulty in breathing, and many types of physical pain (stomach, muscles, head, back, etc.). In addition, many physical pathologies may cause significant states of psychological diseases, like aninia, diabetes, COPD, stroke, chronic diseases. Another problem is the increased presence, in primary care, of MUS (medically unexplained symptoms), responsible for many diseases that provoke many requests of intervention by the health care system, interventions that, most of the time, are of no benefit to the patient, but cause a lot of obstacles and hinder the health services. Consequently our aim is to plan several psychological interventions that fit well to this situation and that can be useful and suitable for this kind of psychological disease, that doesn’t find a correct answer in the secondary care, or in an emergency room, but only in a primary care context.

Culture, illness and healing: Prospects and challenges for integrating indigenous and western healing practices

Tholene Sodi South Africa; Olaniyi Bojuwoye

Culture influences conceptualisations about illness, health and healthcare. In this paper we argue that Western-oriented health care models have limited success when applied to health conditions of people of non-Western cultures and contend that culture is an important factor in health, illness and healing. We present two cultural modes of illness and healing to illustrate that many health conditions are meaningful and can be effectively managed with consideration of the cultural contexts of the communities concerned. We illustrate, by case examples, how these cultural conceptualisations influence the treatment of illness in three different cultural settings. In addition, we identify some of the key challenges to integrating traditional healing into counselling and psychotherapy. Integration of different cultural healthcare models is a best practice in comprehensive context sensitive delivery of healthcare.

From Hippocrates to Chisti: Islamic healing in Pakistan, India and Bangladesh

Humair Yusuf University of Toronto, Canada

This presentation examines the healing practices of pirs, traditional Islamic healers in India, Pakistan and Bangladesh, whose techniques are derived from a range of sources: the Quran as revealed to the Prophet Muhammad; Tabb-e-Unnani, a humoral approach to illness originally conceived by Hippocrates in ancient Greece; and Sufi traditions that evolved from orders such as the Chistiyyah of Central Asia, which were brought to India by Moinuddin Chishti and whose contemporary practices blur the boundaries between spirituality, magic, herbalism and Islam. Interviews with three pirs from the cities of Ladakh, North-west India, five types of healers and “counsellors” can be found: traditional Tibetan medical doctors (amchis), allopathic doctors practicing modern medicine, shamans or “oracles” (lha pa and lhamo) who become the vessels of deities or spirits (lha), monks providing spiritual advice and counselling including the highly regarded abbots of monasteries (rin-poche), and influential astrologers (onspo, tispa) who are engaged in a kind of “primary prevention.” Prospective clients from the local population frequently engage in “healer shopping” and tend to adopt a pragmatic attitude toward the expertise and efficacy of the different types of healers. Based on participant observation, interviews with two lhamo, and a review of the pertinent, predominantly European (e.g., German, French, British) and Indian literature, I outline and compare the functions and approaches of the respective healers and draw parallels to other healing traditions. In this context, I pay special attention to the often dramatic life histories and healing sessions of the shamans. Increasingly, women are called by the spirits to serve as shamanic healers whose activities have indeed intensified in recent years. Although the belief systems of traditional healers in Ladakh and those advocated by modern psychotherapists and counselling psychologists diverge widely from each other they nevertheless serve many of the same therapeutic functions.

Healers and counsellors on the roof of the world: A study of Buddhist Ladakh

Uwe Gielen St. Francis College, United States of America

In the Tibetan-Buddhist culture of Ladakh, North-west India, five types of healers and “counsellors” were called to the patient, but cause a lot of obstacles and hinder the health services. Consequently our aim is to plan several psychological interventions that fit well to this situation and that can be useful and suitable for this kind of psychological disease, that doesn’t find a correct answer in the secondary care, or in an emergency room, but only in a primary care context.

Symposium title: Integrating traditional healing into counselling and psychotherapy

Convenor: Roy Moodley

Healers and counsellors on the roof of the world: A study of Buddhist Ladakh

Uwe Gielen St. Francis College, United States of America

In the Tibetan-Buddhist culture of Ladakh, North-west India, five types of healers and “counsellors”...
Lahore, Multan and Bahawalpur form the basis of an examination into their approaches to healing. Findings indicate that distress is typically attributed to a defective relationship with God or possession by evil spirits known as jinn. Healing entails moving closer to God through prayer, purification, reading the Quran and appealing to saints. If the distress is ascribed to possession, then pirs perform exorcisms that involve ritual cleansing, reciting the Quran to agitate the jinn and dialogue to convert the jinn to Islam. Participants' narratives of treatment by pirs suggest that underlying their experience of relief was the creation of a therapeutic environment in which they were treated with sympathy rather than stigmatised, and could therefore understand and ascribe meaning to their suffering, as well as explore, accept and share their emotions. In this context, links between Western approaches to healing are explored and the implications of integrating Islamic traditional healing into counselling and psychotherapy are discussed.

Symposium title: New challenges for vocational psychology
Convenor: Maria Duarte

Vocational designing and career counseling: Challenges and new horizons
Maria Duarte Portugal; Laura Nota; Mary Heppner; Salvatore Sorese; Punchy Heppner; Lea Ferrari

While studying the issues of Vocational Designing and Career Counseling and trying to help people think about and choose their future and build their professional projects, we have learned to put ourselves in 'other people's shoes' and ask them questions to understand their points of view, their interests, their aspirations, their worries. We have become convinced that by encouraging people to narrate their stories, and tell us about their situations we will find it easier to help them to carefully consider the representations they have of themselves and of their contexts and their predictions about possible futures. But, do the thoughts and worries and hopes of those who deal with Vocational Designing and Career Counseling 'make a difference' in the way they do research and assist people? We think it does and we believe that this should be of interest also to those who decide on social and youth policies, as well as on educational and labour policies. In occasion of the international conference "Vocational Designing and Career Counseling: challenges and new horizons" held in Padova, Italy, on September 2011, participants answered ten questions. The first collection of thoughts, beliefs, worries and hopes focused on new challenges to Vocational Designing and Career Counseling must be ready to face, the second collection on how Vocational Designing and Career Counseling can help the most vulnerable people, the third collection on how Vocational Designing and Career Counseling can increase their adequacy.

Differential effects of specific outcome expectations on career counseling's effectiveness
Maria Duarte Portugal; Marijke Verbruggen; Nicky Dries

Client expectations about counseling have been studied extensively in the past few decades. Expectations have been shown to affect, among others, whether a person chooses to enter counseling, how satisfied clients are with the counseling and how much improvement they make. Yet, surprisingly little research has been directed toward examining clients' expectations of career counseling. In addition, a few studies that examine career clients' expectations measure expectations as a global positive or negative set toward counseling. They can also not look at discrete expectations. However, it is likely that specific expectations will have specific effects. We tested this hypothesis empirically using data from 293 adult career counseling clients. Data were collected at both the start and the end of the counseling. Nine specific outcomes (e.g. increased self-awareness, restored work-life balance, new job), all positive and realistic, were distinguished. At the start of the counseling, clients had to indicate whether they anticipated this outcome from the counseling. At the end of the counseling, they evaluated whether the counseling had actually led to it. We found that specific expectations indeed had specific effects. In addition, we found that expecting an outcome was more important for career counseling to realise it than actually needing it. For instance, we found that clients were less likely to report improved work-life balance as a result of the counseling when they had not expected this outcome, even when they had low work-life balance when they started with counseling.

Psychology of financial cages: Psychology and personal debt
Serdar Degirmencigolu Cumhuriyet University, Turkey

The financial market in Turkey has become part of the global financial game, with globalisation and the European Union accession process, and there has been an increase in levels of personal debt. Banks have been very successful in adopting ways to generate personal debt across the country. Even instant credit/indebtedness has become possible. As poverty and unemployment grew, indebtedness and terms that have to do with debt have become part of daily discourse. Just as with new forms of microorganisms, new forms of debt (credit card, personal credit) are spreading and reproducing quickly. However, it takes years for a given society to develop both social and political ways to resist the waves of debt. Indebtedness and consumerism are facilitated and endorsed by various institutions. There are very few regulatory mechanisms to restrain indebtedness and the debt industry strives continuously to pull people into debt. Psychologists in Turkey have been very reluctant to engage with debt-related social and psychological problems. To the contrary, there are psychologists in various positions who are actively serving the debt industry. This paper examines how psychologists in Turkey have responded to the economic crisis in 2001, to rising levels of poverty, unemployment, and indebtedness, and the ways in which psychologists are serving the debt industry. The discussion focuses on reasons why psychology has served the prevailing political and economic order in Turkey.

Reconsidering the psychological significance of social anomie
Carlos Parales Quenza Universidad Nacional de Colombia, Colombia

The concept of anomie takes on renewed importance as it allows us to research on the psychological consequences of rapid social change and disorganisation. Anomie is a condition of collective disengagement expressed at both social and individual levels. It is a "total social fact". It is also the result of social disintegration and the declining regulatory force of collective beliefs, but then individualism remaining as the single collective representation left in the contemporary world. The world is changing at a pace never seen before. Amidst fading collective beliefs, new representations embedded in novel forms of social relations struggle to emerge, meanwhile forcing people to fill the void in their need to belong through binge drinking and eating, shopping and compulsive sex, the very problems of self-regulation. Communication technologies offer new forms of social contact, they transform the representations of the world and provide people with a renewed sense of belonging to communities, which they desperately look for. Even though anomia is not a mental illness category, it...
does pose significant challenges to the mental health of the population as it is expressed in social isolation, acedia, and the lack of direction and purpose in life. Anomie makes for a silent epidemic, one that combines boredom and desperation. It is the gateway to common mental disorders, i.e., anxiety and depression, and other health problems. I discuss the importance and implications of the concept to understand social psychological problems in contemporary societies.

Session Type: Symposia

Symposium title: Adaptable-Standardising the Career-Adapt-Abilities Scale (CAAS) and developing its narrative supplement
Convenor: Jacobus Maree

Psychometric properties of the Career Interest Profile in an Italian context
Anna Maria Di Fabio University of Firenze, Italy

In the theoretical framework of the new paradigm Life Designing for the XXI century (Savickas et al., 2009), it is important to use qualitative assessment in a perspective that underlines the passage from scores to stories (McMahon & Patton, 2002). This contribution aims to present the Career Interest Profile (CIP, Maree, 2005) a promising modality of qualitative assessment in the narrative career counselling. The CIP allows us to explore the professional interest areas, facilitating career story narratives for constructing life trajectories. The purpose of this study is to examine the Italian version of the CIP in order to verify the psychometric properties of this tool for use in an Italian context. Participants were students of the University of Florence in Italy. Reliability and validity analyses were completed. The carried out analysis indicates that the CIP is a reliable and valid instrument in the Italian context. The CIP is a promising tool for narrative career counselling in a life designing perspective.

Development and validation of the Dutch CAAS: Comparison with Belgium and the Netherlands
Nicky Dries Katholieke Universiteit Leuven, Belgium; Rein De Cooman; Ute-Christine Klehe; Raoul van Esbroek; Annelies van Vianen; Jessie Koen; Roland Pepermans

The Dutch version of the CAAS (Career Adapt-Abilities Scale) consists of four scales, each with six items, which measure concern, control, curiosity, and confidence as psychosocial resources for managing occupational transitions, developmental tasks, and work traumas. We administered the survey to large samples of high school, college, and university students both in Belgium and in the Netherlands. Internal consistency estimates for the subscale and total scores ranged from satisfactory to excellent. The factor structure was identical to that of the CAAS-International, which was computed for combined data from 13 countries, and equivalent across educational levels. The convergent validity of the Dutch CAAS-Netherlands Form was established by relating the CAAS scores to general mental ability; no significant relationship was found between career adaptability and general mental ability. As expected based on cultural and institutional factors, the CAAS-Belgium Form scores were slightly lower than those for most of the other countries participating in the project. CAAS-Belgium scores did not vary with age or educational level; small differences were found between male and female respondents. As will be discussed in the presentation, although the northern part of Belgium and the Netherlands share the same language (Dutch), they are different cultural contexts in terms of career development.

Symposium title: Applications of psychology to human service development in Africa
Convenor: Robert Serpell

Cost effectiveness of psychosocial services for school learners in Botswana
Elias Mpofo University of Sydney-Cumberland, Australia

Psychosocial programmes are likely to be effectively implemented if aligned to existing delivery platforms that both providers and beneficiaries find both credible and accessible. We used cost effectiveness analysis (CEA) to evaluate the relative worth of competing delivery mechanisms for psychosocial services to school learners in Botswana. Participants were 447 psychosocial servicers (PSSS) from a broad spectrum of civic and public service agencies (n=220) and student learner beneficiaries of the services (n=227). Sampling of informants involved both purposive and planned random sampling from identified informant sites (e.g., schools, communities). Survey data on perceived delivery and usage of PSSS were collected. Two complementary CEA methods were used to assess the comparative effectiveness of alternative PSSS delivery mechanisms: (a) A simple cost effectiveness ratio based on prospective increases in number of clients served, accessibility of PSSS and psychosocial needs addressed (or inclusivity of the PSSS option) and (b) from estimates of cost of the current PSSS per prospective customer of beneficiary multiplied by the imputed satisfactoriness rating of each service portfolio. The effectiveness of the current PSSS delivery systems was rated marginal by both officers in education and allied ministries. The service was perceived to be operating at a median 40 to 50% efficiency. Cost effectiveness and efficiency were compromised by lack of planned coordination among these service departments. Efficient PSSS delivery depends on the quality and timeliness of data on which decisions are made. A credible information management system must be in place for efficient PSSS delivery.

This symposium focuses upon the development of children and young people’s pro and anti-social behaviour in four countries: Brazil, China, Chile and the UK. Monks, Ortega, and Etchepare present data examining the nature and extent of peer-victimisation among pre-schoolers in Europe and Chile. Koller discusses the prosocial moral reasoning of adolescents who live on the streets and do not go to school in comparison to lower-class individuals who do go to school and live with their families. Maras, Poterton and McAdams provide a model which shows how social identity and self-concept correlates to behavioural problems and how these affect intentions to attend higher education for young people in mid-adolescence. Zhu and Yu discuss the relationship of pre-school children’s pro behaviour and its relationship with theory of mind.

Symposium title: Integrating traditional healing into counselling and psychotherapy
Convenor: Roy Moodley

Role of traditional healers in counselling and health promotion: Toronto healers project
Roy Moodley University of Toronto, Canada

This presentation offers a brief introduction to the Canadian Social Science and Humanities Research Council (SSHRC) sponsored research on the role of African, Caribbean, and South Asian traditional healers and their healing practices in Toronto. Ethnic minority groups, especially in the large metropolitan cities in North America, have been accessing and practising traditional healing since the days of slavery using healing practices such as Animism, Voodoo, Orisha, Santeria and Espirituismo to support their health and wellbeing. However, the healers and their practices have been excluded from mainstream culture, and are forced underground as a result of the hegemony of Western medical models. In this presentation, I discuss the background, rationale and the context of the Toronto traditional healers project and the results and analysis of the African, Caribbean and the South Asian traditional healers.

Indigenous knowledge and healing among the AbaNguni in KwaZulu-Natal, South Africa
Lorna Ngai University of KwaZulu-Natal, South Africa

Reports on indigenous knowledge and healing systems are, in the main, presented through Western scientific biomedical lens. This paper provides an emic perspective on significant cultural concepts and indigenious healing practices among the AbaNguni in KwaZulu-Natal, South Africa. Data is drawn from the author’s over three decades of clinical experience and a single case study of a seasoned sangoma who is an indigenous AbaNguni healer who practices by means of divination as opposed to the use of traditional medications. The paper aims to capture the intricacies of an indigenous practice that has withstood the onslaught of colonialism. At least 80% of AbaNguni in South Africa use indigenous healing at some time in their lives and adhere to cultural practices based on a communal worldview which is diametrically opposite to the individualistic worldview on which Western psychotherapy is based. Hence, the paper speaks to the need for Western mental health practitioners to become knowledgeable about the cultural contexts in which they work. The
value of both indigenous and Western healthcare practitioners being regarded as equal partners in the delivery of mental healthcare is highlighted. The author is of the opinion that it is possible to generalise principles enunciated in this paper to a global context.

Integration of indigenous healing in mental health care
Suzanne Stewart University of Toronto, Canada
Canada’s indigenous population is a vulnerable group in the mental health care system, with specific counselling and healing needs that are not widely being met. Indigenous peoples face certain historical, cultural-linguistic, socioeconomic, and system barriers to access to mental health care that government, health care organisations, and social service agencies must work to overcome. Current health indicators present a dim and dismal view of Canadian indigenous health status, including mental health. To address some of these inequities in health and health care, some indigenous health organisations have recently developed services to mental health that include traditional cultural approaches to healing. This paper reports on the link between traditional indigenous healing practices and community mental health care delivery in the context of healing from the legacy of colonisation and the need to survive as distinct cultural peoples. The author’s research shows that indigenous-based traditional models of mental health and healing are culturally appropriate because they can contribute to developing forms of health services and promotion that respond effectively to client needs created by the complex history and social context of Canada’s indigenous peoples. 7

New challenges for vocational psychology
Maria Duarte Portugal
Reflections about the theories in the field of career psychology constitute the basis for the discussion and proposition of a new approach and the consequent change of paradigm, which is expected to be innovative. Thus, the main principles underpinning this new paradigm as well as the objectives, the processes, the assumptions, and a comprehensive theoretical frame for interventions are the object of analysis and discussion in this symposium.

A meta-reflection theory of career counselling:
An exciting opportunity for vocational psychology
Jacobus Maree University of Pretoria, South Africa
Many changes have taken place in the world of work recently. Workers have to address increased levels of uncertainty. Many people have either lost their jobs or are forced to change jobs repeatedly. Globally, career counselling theorists have taken on the challenge of revisiting and revising extant career theories to enable them to provide a time-appropriate service to their clients. The theoretical base for a novel career counselling strategy that entails guiding clients to meta-reflect on their own career-related responses is elaborated. I hope the explicated approach will equip counsellors with a strategy to help clients not only choose appropriate careers but also use these careers to design and live successful lives. The results from two research projects dealing with the practical implementation of the meta-reflection theory of career counselling in South Africa will be presented. The first (case) study employed a qualitative research paradigm. The second study (N = 422) used a multi-method (quantitative and qualitative) research paradigm. The meta-reflection theory and practice of career counselling can transcend the weaknesses associated with and/or approaches to career counselling. This paradigm seems suitable for use in the SA context, both conceptually and practically.

The use of the fine art in practice of psychological work
Tatiana Kharitonova The State Hermitage Museum, Russian Federation
Currently the interest to studying of art and its applications not only as art -therapeutic practice - but also as the possibility to set up the problem of the modern person’s lifespan constantly increases. Recognising the importance of using the expressive arts with the aim to awake the creative activity, we attach great importance to research of perception of the fine arts as the process of comprehension and verbalisation of an existential position of the spectator. The experimental researches of perception of the classical fine arts spent by us at the museum expositions have allowed us to draw conclusions on the factors, allowing us to realise experience of art perception as a vital event. Modern art research gives the chance to the spectator to set up the problem of life meaning, the authentic choice conducting to existential growth. The combination of the unique stimulus material and the experimental research that include also psychophysiological parameters, allows us to use the perception and interpretation of the fine arts products to the forming of and developing the entire personality.

Using dreams interpretation for awareness of the exactness of life choices
Elena Lyutikova Psychological Institute RAO, Russian Federation
Dreams of every person are unique and give valuable material for a psychologist providing an insight of a person’s inner world. Dreams were seen as manifestations of unconscious repressed contents and a means of satisfaction of a forbidden desire, collective unconscious and conflicts caused by the process of the ego establishing, as a reflection of inner conflicts and an aspiration to compensate an incapacity, as information on “in-the-world being” or “in-itself being”. The results of some research on dreams and their connection with different factors of human development are presented: Data on contents, structure and determinants of dream, particularities of businessmen’s dreams, which showed that entrepreneurship activity leads to the emergence of a particular type of images in dreams, implying business situations. The “attentiveness to dreams at present” index is positively connected with most indices of the Existence Scale (Langle and Orgler methodic), and with positive evaluation of the person’s own health, absence of sleep disorders, emotional acceptance of dreams and a higher assessment of his own potential. The respondents are ready to accept the connection of dreams to life events, but have difficulties in evaluating

Symposium title: New Challenges for vocational psychology
Convenor: Maria Duarte
Strange bedfellows: Theory, research, practice, training and policy?
Jenny Bimrose University of Warwick, United Kingdom
The principle of social equity nestles at the heart of professional practice, since a key purpose of vocational psychology is to support all individuals to realize their true potential. Yet, the discipline is criticized for its continued ambivalence to the struggles of disadvantaged populations, with increasing loud calls for a social justice approach. However, funding is problematic since those perhaps most likely to benefit from being recipients of such services are least likely to be able to pay. Persuading policy makers to invest public funds in such services requires robust evidence about the positive impact of interventions. Here, vocational psychology faces a critical challenge. Published research predominantly addresses academic and practice agendas, often providing an independent analysis of social issues. Consequently, there is a dearth of relevant evidence that can be used in dialogue with policy makers - who want research on what works, how and why. Should researchers’ invocational psychology respond to the agendas and priorities of funders or governments, or confine themselves to pushing back the frontiers of knowledge? This presentation will explore some of the tensions inherent in the existing dichotomy between ‘blue skies’ and ‘contract’ research for the discipline.

Symposium title: Ontological aspects of lifespan in the practice of psychological counseling
Convenor: Victoria Dmitrieva
Problems of authenticity and moral choice in psychological counselling of businessmen
Victoria Dmitrieva St. Petersburg State University, Russian Federation; Tatiana Vereitnova
The concept of authenticity represents the major integrative characteristic of the person. In individual consultation with businessmen rises the question of authentic existence and it is frequently connected with the ethical problems arising in professional work. The series of research projects on businessmen’s ideas concerning the moral in business, made at our department, let us gather the data about axiological-motivational aspects and moral installations of modern businessmen (Russian, Brazilian, European). We studied the moral elections in the dilemma concerning the enterprise activity, and interrelation of expressiveness of the factors of a moral choice with a cultural accessory, the viability indicator, valuable orientations. The obtained results allow to judge about cultural, mental features of investigated groups, and also about similarity of respondents in orientation, first of all, on internal criterion at realisation of a moral choice. The formalisation of ethical representations and their changes are one of the regulators of vital and professional activity.

Emotional well-being in the context of the lifespan

Veronika Odintsova  I.M. Sechenov First Moscow Stat, Russian Federation; Natalia Gorchakov

Multiplicity of the problem of health, suggests different approaches to its apprehension: the problem of healthy behaviour, adequate functioning, temporary balance and well-timed solving of constantly arising conflicts, development and maturity, psychological well-being, apprehension of genuine inner nature and authenticity. The emotional pressure, the erroneous way of living, the emotions and the reaction to the stressful factor, which makes an active neuroendocrinal and vegetative nervous system, can be one of the factors promoting interruption of psychological well-being. The report will present the data of research carried out with different groups: patients with bowel diseases and patients with alimentary addictions, a comparison with healthy people of the same age group. We studied biographical data, features of emotional sphere at different stages of life, alexithymia level, defence mechanisms (Kellerman-Pluchik method), coping strategies (Amirkhan method), subjective assessment of emotional experiences frequency, unconscious component of personality (projective methods). We made an attempt to describe, integratively, the behaviour, breaking psychological well-being (defence mechanisms, relations with microsociety, coping, features of emotional sphere) through the biopsychosocial model. The data about features of living of the emotions of healthy people and patients of different profiles were obtained.

The optimal experiences of solving the diagnostic problems

Natalia Rozhdestvenskaja  Moscow State Univ. for Human, Russian Federation

The emotional sphere of a person is an important regulator of a reality situation of a person. The ability to manage the emotional state is one of conditions of successful activity and that is especially important: well-being of the person in whole. The report will contain the results of the research of "optimum experiences" in the process of solving the diagnostic problems. The diagnostic problems are included into the structure of various kinds of activity. The diagnostics role, as a kind of knowledge, obviously increases in conditions of uncertainty and in crisis situations of any character that makes the studying theme of "optimal experiences" and individually-psychological features of the individual while solving the diagnostic problems especially actual. The conducted research allowed to allocate links between individually-psychological features of the diagnostician and the success of decision the diagnostic problems, and also, to designate the role of "optimal experiences" in the process of solving the diagnostic problems. Thus, the optimal experiences are represented and as consequence and as a condition of successful diagnostic activity. The check of hypotheses about influence of "the individual scenario" on success of diagnostic activity and a role of intuition in the diagnostic process is of some interest.

Symposium title: Satisfaction, retention, and career development of college students in the U.S.: A longitudinal study

Convenor: Hung-Bin Sheu

Examining the career development of college students in a longitudinal study

Shiqin Chong United States of America

Using the aforementioned longitudinal data, this presentation will focus on the findings regarding college students’ career development. We explored how variables collected in the first semester – Week 1 gender, work status, and personality traits, Week 5 academic and social supports, and Week 10 career exploratory behavior (CEB), career decision-making self-efficacy (CDMSE), and certainty about college majors – might be related to one another. We also examined how these data gathered in the first semester might predict how long it took for students to declare their majors in the following two years. Participants were 38% racial minorities and 62% Caucasians. Results of hierarchical regression analyses indicated that gender, work status, personality, Week 5 academic and social support, and Week 10 CEB explained 45% and 40% of the variances of Week 10 CDMSE for racial minority and Caucasian students, respectively. Academic support and CEB were significant predictors of CDMSE for both groups. In predicting Week 10 certainty about major, the above predictors, plus Week 10 CDMSE, explained 50% of the variance for racial minority students with CDMSE as a significant predictor, and 40% of the variance for Caucasian students with extraversion, social support, CEB, and CDMSE as significant predictors. Lastly, these variables (Fall 2009) explained 11% and 9% of the variances in the number of semesters to declare a major for racial minority and Caucasian students over a two-year period. Practical implications for improving students’ career development will be discussed.

Enhancing student success and career exploration at a large American university

Mary Dowes None, United States of America

This presentation will describe a program designed to enhance student success and improve retention at a public university in the United States. Retention continues to be a major focus in the U.S. with college persistence from first year to the second below 80%, and institutional graduation rates below 60% nationally. Loss of student potential and revenue is substantial. This university set ambitious goals for first-year persistence of 90 percent and a graduation rate of 70% by 2012. A program was instituted to enhance the transition of exploratory (no major selected) first-year students with two required, five-week, one-credit courses in their first semester at the university. The first is a college success course designed to teach skills and practices of successful college students, and connect students to the university. The second is a career exploration course that guides students through self-exploration of interests, values, and personality, researching majors and career options, and choosing majors. Features of the program will be described. A longitudinal research program was launched in Fall 2009 to assess adjustment and career development of 807 first-year students across the two-course intervention (10 weeks in total), and surveys were administered across this period. Data analysed for this symposium came from Weeks 1, 5, and 10. Follow-up data on retention, academic performance, and choice of major were gathered in the subsequent two years. The next two presentations will introduce the results from this longitudinal dataset.

Satisfaction, retention, and career development of college students in the U.S.: A longitudinal study

Hung-Bin Sheu University at Albany, SUNY, United States of America

The symposium will highlight the current status of college student retention in the U.S. and introduce the results of two longitudinal studies conducted at a large American university. In their transition into college, most students experience the challenges of adjusting to a new environment and exploring their future careers. The first presentation will provide a review on college student retention and its consequences, describe the two five-week courses taken by students in the first semester to facilitate their transition to the university. This presentation will also introduce a longitudinal research program based on Bandura’s (1977, 1986) social cognitive theory. The second presentation will outline findings of a longitudinal study on college students’ adjustment to the aforementioned university and how initial adjustment predicted their retention and academic performance two years later. Using the same longitudinal data, the third presentation will emphasise the career development aspect of students’ transition. Specifically, this study explored the predictors of career decision-making self-efficacy and certainty about choosing college majors during the first semester, and tested how these variables predicted how much time participants took to declare their majors in the next two years. The audience of this symposium will acquire knowledge about how the undergraduate courses could help students successfully deal with the challenges they faced at a new environment. They will also gain understanding of variables that are hypothesised to predict students’ well-being, retention, career decision-making, and choices of majors longitudinally. Practical implications for mental health and student affairs professionals will be discussed in the symposium.

Longitudinal prediction of satisfaction, retention and academic performance of American college students

Hung-Bin Sheu University at Albany, SUNY, United States of America

This presentation will highlight the findings of a longitudinal investigation on students’ satisfaction, retention, and grade point average (GPA) at university. The sample consisted of 807 participants (45% male, 55% female; 38% racial minority, 62% Caucasian; mean age = 18.24 years). Data analyses were based on variables from Week 1 (personality, academic and social supports, academic and social self-efficacy, academic and social outcome expectations), Week 5 (academic and social goal progress, academic-
Cultural influences on attitudes toward treatment and presentation of mental illness in Tanzania
Brandon Knettel Lehigh University, United States of America; Janvier Rugira

Attributions, or beliefs about the causes of mental illness, have been shown to affect negative thoughts, emotions, and actions related to mental illness. Specifically, people who believe that mental illness is controllable report more negative emotions and endorse more stigmatizing behaviors toward people with mental illness (Corrigan et al., 2003). However, beyond a simple conceptualization of cause as either internal or external, research has shown that people hold a wide variety of beliefs about the causes of mental illness, including components that are social, genetic, spiritual, retribution for wrongdoing, fatalistic, or simply a result of chance (Marsh & Richards, 1987). In the current study, the researcher explores the applicability of current models of attribution and mental illness stigma in new global contexts. First, experts in international psychology from nations throughout the world are surveyed with the aim of exploring unique cultural attributions of mental illness. Second, existing models of stigma are brought to the cultural context of Tanzania, an East African nation at a crucial stage in its development of mental health services. Specific focus is given to the applicability of Western diagnostic and treatment models to this culture and the strengths and areas of growth for the field, with the ultimate goal of promoting the development of strong, culturally sensitive mental health services in Tanzania.
Research Area: Critical

“We are not like them” the intersections of gender, ethnicity and sexuality for second generation Muslim women
Lutfye Ali Victoria University, Australia
Following migration, migrant communities are faced with transitional and settlement challenges which can be experienced as a threat to culture and identity. The settlement process and identity negotiations for migrants and subsequent generations are related to the response of the receiving society through policy and discursive constructions of minority groups, who are frequently constructed as a racialised other in relation to the receiving society’s normative group. In this presentation, by drawing on post-structuralist and third world feminist theory, I focus on the gendered nature of ethnic community-making as it emerged in 21 conversational interviews with second generation Muslim women. I specifically focus on the intersections of gender, ethnicity, culture and sexuality, as the women negotiate their identity around hegemonic discourses, including we are different, threat and protection, and cultural boundaries. I highlight the ways in which remaking ethnic identity in a racialised context can act to preserve cultural and ethnic boundaries by reconstructing identity within essentialist and patriarchal discourses. Gender becomes a cultural capital for immigrant communities to assert cultural and moral superiority over the dominant culture. Whilst the broader ethnic community claims power that is compromised by racism, women forge their identity in a context that restricts their autonomy, decision making, mobility and body. This presentation highlights the ways in which the racialisation of communities perpetuates gendered oppression and the importance of considering culture and gender identity as it intersects with other identities within a broader context of social and political relations.

New directions for work and organisational psychology and civil society demands
Francesco Avallone University of Rome La Sapienza, Italy
There is a new call from civil society both in local and in global contexts. The challenge is to introduce new styles of living together and to transform work contexts into environments of civilization (eg. environment, justice, education, health and well-being). From this perspective, some cultural issues seem particularly evident and may become future goals of W/O Psychology: (1) the need to become not only more efficient but more effective, as individuals, as organisations, as systems; (2) to make management processes of integration and differentiation able to establish new sites of global civil; (3) the demand for transparency and ethical tension in business and organisational practices. W/O future goals can move along the dimension of discontinuity. These new targets may be based on some changes occurred during last decades and can be summarised as follows: (a) from individual to context: a lower centering on the individual and more attention to relationship that each of investigated subjects – individual, groups and organisations – relates with each context; (b) from mono-level framework to multidimensional analysis: research and adoption of integrated models that can account for diversity and interdependence of studied variables; (c) from individual customer to social customer. The areas and topics of research have in the past suffered too much for organisational needs. Most research has been produced on behalf and in favour of organisations and of companies in particular. W/O psychology can help to identify new strategies of living together in organisations and society.

Marching to the beat of a different drum: A discussion around the definition of ethics in the practice of psychology within various and changing socio-political contexts
Linda Blokland University of Pretoria, South Africa
This paper critically examines the application of set ethical codes in the discipline of psychology. It is maintained that such codes tend to be set from a narrow perspective often with little consideration of the socio-political context in which the profession is practiced. The paper engages in a discussion of various definitions of ethics as applied in the practice of the profession of psychology. The relationship between ethics, values, the law and cultural norms are explored. The role of formalised professional ethics in the development of professional practice is discussed. Examples drawing on case studies and literature from particular socio-political contexts are used to illustrate challenges to the profession in terms of approaches to understanding and treating mental health beyond the hegemony of so-called mainstream paradigms.

Issues around the impact of public health care disruptions on inpatients in psychiatric institutions
Linda Blokland University of Pretoria, South Africa
Politically organised disruptions in mental health care are common experiences within public health care systems. Such disruptions impact the daily operations of public psychiatric institutions with significant consequences for the treatment, care and well-being of patients. This paper discusses the various forms these consequences may take for patients amid notions of stigmatisation; suggested comorbid relationships between continued psychiatric services and the presence of psychiatric disorders; movements towards de-institutionalisation; and the needs of psychiatric patients in terms of treatment. Tensions between health care workers’ responsibilities towards patients and their own needs in terms of well being are explored in the context of government’s obligation towards its employees.

Talking about beauty: Identity category-maintenance and transgression of young South African women
Hannah Botsis Human Sciences Research Council, South Africa
Identity formation in post-apartheid South Africa involves multiple intersections of “category-maintenance” and “transgression” (Davies 1989, 29) of historical ideological racial categorization. Despite the official ideology of the post-apartheid government being one of non-racialism, there are still incongruent messages about identity from all quarters (including family, peers and the institutions in which we teach, learn and work) that need to be negotiated. In this paper, the management of this negotiation is considered through examining young South African women’s attitudes towards beauty as a terrain of desire upon which ideological (gendered, raced) subjectivities are formed. It is argued that desire is deeply invested in the psycho-social complex of what being “white” and “black” is assumed to stand for, especially in relation to what is considered to be beautiful. Currently, South Africans “can deviate from the identity descriptions attributed to them or to which they will attach themselves” (Davies 1989, 29). This deviation however, involves both transgression and category-maintenance work that simultaneously enables and constrains the subject. Through qualitative research with 26 young South African women (aged 16 to 24), it was found that normative whiteness is re-inscribed through constructions of desire as they pertain to beauty.

Looking for moments of Russianness: The challenges of locating national identification
Maria Brock Birkbeck College, London, United Kingdom
The paper will explore the psychoanalytic notion of identification and its explanatory power as we try to apply it to the context of a post-transition society such as Russia. Post-soviet Russia is frequently characterized as a country permanently stuck in a state of transition, which is ascribed to a lack of any clear political or societal project. This is seen to result in - or, alternatively, be caused by - the absence of symbolic functions or subjective formations with which Russians could identify; meaning that contemporary discourses of Russian identity are required to make reference to past signifiers in order to mobilize mechanisms of (national) identification. This crisis of identification that is perhaps specific to Russia is merged with, and possibly enhanced by, the crisis of meaning that has beset Western (post-)modernity - a crisis which Russia may be fated to repeat at an accelerated pace since it rejoined the trajectory of modernity. The challenge at hand is therefore both theoretical and methodological in nature: how do we determine whether an identification has in fact taken place, and how does national identification differ from the original Freudian account of this process? The paper will present results from an empirical study which seeks to combine the analytic insights of psychoanalysis into the affective investments in certain identities with the methodological procedures established by discursive psychology in order to examine how the social and ideological changes resulting from the end of the Soviet Union have affected current discourses of Russianness.

People behind the papers: Psychological research stories from South Africa
Sydney Butler University of South Africa, South Africa; Martin Terre Blanche; Eduard Fourie
The People Behind the Papers project presents a rich picture of the unique research milieu within South Africa’s psychological field via interviews.
with the authors of published research. Researchers from various backgrounds (both cultural and academic) have been interviewed, and speak candidly about the process of research over a time period in South Africa that saw extensive socio-political changes occur. Inevitably issues of race, power, culture and identity are interwoven with their narrative accounts. Short excerpts from the interview recording will be included in the presentation. The presentation will detail the process followed to acquire interview data from the various role-players as well as calling for participants from other spheres within the field who feel they may make a worthy contribution as content providers. The presentation will conclude by exploring some of the other facets of the project. Including, but not limited to, a qualitative data source, pedagogical research tool and rich archive for the sake of posterity.

Three troubling moments in Damasio’s neuroscience
Van Ommen Clifford Massey University, New Zealand

The last decade has seen the emergence of what may be called critical neuroscience, an academic pursuit comprised of multiple activities, agendas and foci which, broadly speaking, interrogate neuroscience both as a discipline in itself and as a resource for emancipatory programmes. This paper may be situated within this developing conglomerate. The particular focus here is on several moments in the classic text, ‘Descartes’ Error’ by neuroscientist Antonio Damasio, which speak to the conceptualisation of emotion, instinct and pain respectively. Staying well within his tradition, Damasio posit primary status to certain emotions, to instincts and to the sensation of pain. However, a close reading of the text begs a variety of questions and leads to the identification of internal contradictions which trouble such foundational assertions. Instead what is indicated is that the excluded other of the above key notions, that is, secondary emotions, social strategies and suffering, are concepts that are integral to the understanding of emotion, instinct and pain. These moments then illustrate the importance of the ongoing analysis of taken-for-granted interpretations of core notions in neuroscience so as to better ground its projects.

Publishing as social action: Building fair and inclusive editorial policies
Serdar Degermencioglu Cumhuriyet University, Turkey; Ben Dyson; Michael Schutz

There is a striking increase in the number of journals in psychology. The increase, however, does not necessarily mean diversity in terms of editorial policies. The status quo in psychology journals necessarily mean diversity in terms of editorial policies. The increase, however, does not mean that the role of love and harmony in the process of resilience and vision for the emerging world: Love and harmony
Mary Elizabeth Hargrow The Association of Black Psychologists, United States of America

Humankind has come about as far as we can go where separation, competition, and winning without considering the consequences to the other, define success. The destruction of life is left behind. Ancient knowledge and wisdom that remain intact support the theory that these practices are counter to balanced holistic human development. Resilience as a human quality that helps us survive and thrive under adverse conditions must include morality and ethics or it could lead us on to a destructive path. The role of love and harmony in the process of dissolving the practices that support anti-compasionate behaviours is at the heart-centre from which all else must be evaluated, including resilience. As we move further into action without considering the consequences of our actions on the “other” we

domination of English in psychology. English is given the status of royal road to journal pages and this practice not only puts potential authors whose native language is not English, at a clear disadvantage, but also privileges the English spoken in certain countries and/or social classes. If the editorial board includes individuals who are competent in a language other than English, and the board is designed to include who speak main linguistic lines in the world, the domination of English can be challenged. A key notion here is that journal publishing in and of itself is social action. Only if journal publishing is regarded as a social action process, can the status quo be challenged.

Has psychology been taken into hostage by neuroscience?
Jan Derksen Raboud University Nijmegen, Netherlands

During the last 20 years psychologists worldwide have actively changed their research topic from psychological phenomena and psychological theory to inquiries in biology; using brain imaging techniques and sophisticated computer programs to validate and produce psychological insights. Brain research, as a result of technical developments, has become very attractive and even seductive. Validation of psychological concepts of brain processes cover the psychologist research agenda, mental disorders are becoming brain disorders. Physiological psychology, social psychology and clinical psychology are rapidly moving away from its status as independent sources of knowledge and will soon be a chapter in the impressive book of social and cognitive neuroscience. In this presentation the development of taking psychology into hostage by neuroscience will be illustrated with many striking examples. The preconditions for being a hostage can be discovered not only in the attractiveness of neuroscience but also in the history of psychology itself. By taking behaviourism and the logical positivistic way of doing research as an example, the epistemological issues around the object of knowledge, empiricism, the status of theory and issues around objectivity will be touched upon. Besides admiration for the rapid advancement and contribution in knowledge as a result of neuroscience, the damage done to psychology in hostage will be illustrated for topics such as intelligence, adolescent psychology and psychotherapy. An epistemological solution for a brainless psychology will be presented.

Psychological research on unemployment: A (de)constructive critique
David Fryer Australian Institute of Psychology, Australia

The Director-General of the ILO recently stated: “Unemployment stands at more than 200 million, and is rising. The current rate of global jobs growth, at 1 per cent or less per year, will not replace the 30 million jobs lost since the crisis began in 2008 ... millions of workers have part-time jobs for lack of a better alternative ... or have given up looking for work altogether ... youth unemployment hovers ... at two to three times the adult rate ... we are on the edge of a global jobs recession that could last a whole decade.” Given that: High quality, methodologically diverse, international research has claimed to demonstrate that unemployment, under-employment, job insecurity and income inequality are responsible for costly individual, social, community and national consequences, influential theories of why negative consequences of unemployment ensue proposed, interventions to prevent distress and/or promote the well-being of unemployed people suggested and lobbying for policy changes undertaken, is this work collectively an exemplar of Psychology Serving Humanity? I will first briefly provide a road map to the relevant literatures, then offer critique of this work from a version of critical psychology with a community praxis. Thirdly I will propose questions which need to be answered and actions which need to be taken if humanity is to be served or at least if labour market violence is to be resisted, labour market oppression reduced, and labour market justice promoted.

The bodily and spatial form of inheritance in psychoanalytic thought
Claire Haggard University of Cape Town, South Africa

The body and its relationship to human subjectivity has been a prominent, but nevertheless contentious issue within the context of contemporary psychoanalytic thought. Perhaps most contentious is how the body is positioned and constructed within the analytic space or encounter. Contemporary theorists assert that the specificity of a psychoanalytic perspective is to invoke a fantastic dimension of the body - a body shaped primarily by fantasy and thus a body that is lived from within. Here, “subjectivity” is positioned as that which ends at, or is contained within, an inner psychic space whose “geography” relates less to the concrete spaces of self, other and environmental encounter, and more to an abstract society of self. The psychoanalytic notion of the subject is arguably a repressive device – an act of forgetting that the body and thus the self are possible in their particularity only through encountering other bodies within the temporal and spatial dimension of the face-to-face encounter. This paper draws on Sara Ahmed’s theoretical and literal explorations of migration and estrangement in an attempt to explore the impact of the dislocated psychoanalytic body on contemporary articulations of subjectivity.

Building resilience and vision for the emerging world: Love and harmony
Mary Elizabeth Hargrow The Association of Black Psychologists, United States of America

Humankind has come about as far as we can go where separation, competition, and winning without considering the consequences to the other, define success. The destruction of life is left behind. Ancient knowledge and wisdom that remain intact support the theory that these practices are counter to balanced holistic human development. Resilience as a human quality that helps us survive and thrive under adverse conditions must include morality and ethics or it could lead us on to a destructive path. The role of love and harmony in the process of dissolving the practices that support anti-compasionate behaviours is at the heart-centre from which all else must be evaluated, including resilience. As we move further into action without considering the consequences of our actions on the “other” we
experience a loss of something intangible that leaves holes in our psyche - a lack of fulfillment - emptiness. It is likely that these are experienced to the extreme by suicidal persons. Studying our war veterans, given their high suicide rate, will likely give us a sense of what is missing, and the missing elements that we as psychologists must work to replant. This address explores research that provides scientific evidence that love is successful in eliminating significant physical and mental diseases. This research shows that love and harmony interventions can be used to resolve practices that create destructive patterns of behaviour.

Power, participation and decision-making: A critical discourse analysis of triadic decision-making in oncology care
Coyne Imelda Trinity College Dublin, Ireland; Gemma Kierman; Faith Gibson; Aislinn Amory; Fin Breathnach
Background past research has not fully explored how the interaction between parent-doctor-child in the medical encounter can influence the active participation of the child. This qualitative research study combined grounded theory with Fairclough's (1992, 1993) three dimensional critical discourse analysis (CDA) framework to explore the power relations that emerge in clinical encounters and which shape the decision-making process. Over one year, we interviewed children with cancer aged 7-16 years (n=20), their parents (n=22) and healthcare professionals (e.g. doctors, nurses, social workers, teachers, play specialists) (n=40) about their experiences of triadic decision-making. The first discourse was the healthcare team's power and dominance. The life-threatening nature of childhood cancer, treatment protocol and cooperation on a journey were factors which predicated professional participation. The team employed a range of strategies to convey the notion of consent to decisions when refusal was not an option. Parents and children were aware of the 'tokenism' but nevertheless complied with expectations. The second discourse was the parent-child alliance to achieve collaboration in process of decision-making. Children used a myriad of actions to alter or negotiate decisions, and if unsuccessful resorted to distressed verbal and non-verbal refusal actions. Adults seldom address their decision-making roles explicitly. Rather, they discursively construct decision-making about treatment and care options in a covert manner. Reflecting on these discursive practices promotes awareness of the challenges that children face when trying to voice preferences and participate in decisions that affect their lives.

Poverty and psychoanalysis: The poverty of psychoanalysis?
Manasi Kumar University of Nairobi, Kenya
The paper reviews psychoanalytic scholarship on the themes of poverty and deprivation that is available on the Psychoanalytic Electronic Publications (PEP-web). The paper evaluates select definitions and explanations of poverty as illustrated in the scientific papers published in the PEP-web from 1933 to 2003 (covering 70 years) and finds that psychoanalytic scholarship has very little to say about poverty or the poor. In spite of references to the poverty of dreams, poverty of affect, poverty of intellect, there is in reality little engagement with 'real' poverty. The reasons and effects of this neglect are firstly traced to the attitudinal biases and beliefs held by the psychoanalytic authors which prevent them from acknowledging the poor and deprived as worthy of their attention. The review also points out great confusion, over simplifications and neglect shown in the use of poverty and related terminologies. Absence of fuller appreciation of poverty is then traced to some philosophical quandaries in psychoanalytic epistemology, such as the place of real vs. psychic, culture vs. individual, and need vs. value, to cite a few. A third reason for this neglect may be attributed to the uneven spread, reception and development of psychoanalysis in different geo-political locations, and the neglect in addressing these cultural differences could be the behind these social inequalities remaining unaddressed in the literature.

Immigration and otherness
Ilanam Mountain Manchester Metropolitan University, United Kingdom and UFMG, Brazil
This paper discusses dynamics of the discursive position of the migrant. This debate is based on previous research conducted in the UK on asylum seekers and refugees’ access to health services, as well as on the analysis of images of the immigrant broadcasted in the media. This analysis highlights mainstream discourses on the migrant that frequently oscillates between the victim, exotic and the mainstream discourses on the migrant that frequent-ly seeks and refugees’ access to health services, as well as on the analysis of images of the immigrant broadcasted in the media. This analysis highlights mainstream discourses on the migrant that frequently oscillates between the victim, exotic and the threat. In this positioning, the migrant appears as the ‘other’ in discourse. This discursive position reproduces particular effects and dynamics. In this paper I will focus on how this image articulates with discourses on multiculturalism and human rights, particularly on the debate of the policies of the ‘celebration of the other’ and on ‘discourses on
sameness’, whereby in both constructions the im-
mit is reified in the position of the ‘other’. Furt-
her, the juxtaposition between gender, race and
class is put forward as crucial in this field, partic-
ularly in relation to public policies and human
ducies. The aim of this debate is to highlight alter-
native discursive constructions of the immigrant,
crucial for process of inclusion.

Unlearning ableism in academia: Nurturing and connecting scholarship and activism

Akemi Nishida The City University of New York, Japan

Although it has been shown elsewhere that U.S. disability rights movements rose from university campuses, academia has also been a space that pathologises and standardises certain behaviours and mental, cognitive, and emotional states. Consequently, academia, including psychology, has been a major force in constructing and defining categories of disability, normalcy, and deviance. Differently valued, the categorisation leads directly to the social stigmatisation of people with disabili-
cties. For these reasons, there have been criticisms against psychology emerging within disability com-
munities. This presentation is an attempt to elab-
orate the historical and contemporary relationship between scholarship and activist communities (es-
pecially between psychology and the disability cat-
egory). Using a social justice framework, I will
conclude this presentation by highlighting acts of
critical resistance within disability communities
against scientific discipline, including psychology.
This conclusion will be framed with principle topics of
critical psychology, such as the politics of psy-
chological research practice as well as of knowl-
edge production. I believe that there is much psych-
ology can learn from critical disability studies and activism, and the cross-disciplinary learning needs to be done in an ethically and politically conscious way. These points are grounded in the
case study of a workshop my colleagues and I
developed for a disability studies conference in 2011 where scholars’ collective privilege and these
privileges’ inherent responsibilities to the commu-
nity were critically discussed.

Psychoanalysis and/or sociopolitical change

Bert Olivier NMMU, South Africa

The proposed paper is predicated on the psychoana-
litical notion that human subjects are characterized by their ‘singular’ desire, and that this marks a paradoxi-
 Balkness beyond skin: Fanon and the crisis of racial legibility in South Africa

Fernanda Pinto De Almeida Stellenbosch University, South Africa

The aim of this paper is twofold. Firstly, I examine the character of blackness both as an abstraction and as a medium for its physical expression, look-
ing at ways in which blackness has been visually identified with, or detached from skin in modern accounts of race in South Africa. Secondly, I crit-
ically engage Fanon’s “fact of blackness” to present the relations between blackness and skin not as transhistorical, but how it achieves a particular form in a particular historical and social formation. If the relation between blackness and skin is historically located, I argue that skin cannot be grasped imme-
diately, as the latter’s concrete expression is always mediated by the character of blackness and its value in social exchange. By locating skin historically, I aim to show how we cannot assume skin and race are separable, and indeed, that the representation of skin has become part of skin’s own “nature”. Look-
ing into the ways blackness animates the legibility of skin in South Africa gold mines from the 1950s to 1970s, I focus on the dis/appearance of skin in visual documents like films, pictures and x-ray photographs, and historical narratives, to question how skin is made identical with blackness in a particular historical moment, or detaches itself from it, in another. I argue that skin marks the perme-
ability between the materiality of blackness and its own representation, a permeability which Fanon’s accounts enact instead of solving.

Therapist-client reflections on language games within social therapy contexts in South Africa

Annie Pistorius University of Limpopo, Medunas, South Africa

In this paper I discuss the value for therapist and client to reflect on the language games they engage in during psychotherapy. I will present reflective notes that are based on my social therapy applica-
tions in South Africa. Social therapy is a cultural performatory approach that draws from post-mod-
ern Marxism, Vygotsky and Wittgenstein. A focus on how we speak about ourselves and our pro-
blems, and how this language is part of a cultural form of life, may serve as an invitation for the therapist together with clients to engage in a critique of the social environments they build for human development. This process entails a deconstruction of the language and relational activity tools per-
formed within therapy, which are formative for both our personal and social worlds. Some of my results include that it is in the activity of looking at what is being said (e.g., I feel depressed) as a relational performance (e.g., how we do your depression
here), that may free both client and therapist from being entangled in misleading pictures of the truth, themselves and what is wrong. The therapist-client relation and its power relation also have to become part of the reflection (e.g., where is our relationship and I in what you are doing). This minimises the danger of the critical reflection to become one more authoritarian power game with a pre-set outcome. I will conclude with building theory on the value of language games in the psychotherapy context.

Discursive construction of reproductive genetic disability screening/enhancement in U.S. public health rhetoric

Debra Swoboda York College/CUNY, United States of America

Using pre-implantation genetic diagnosis to identify embryos that are carriers of genetic conditions/disabili-
ties raises questions about what constitutes ‘nor-
mal’, the boundaries of parental rights, and the power of genetic science. To analyse how rhetoric about genetic technologies shapes understanding of repro-
duction and disability, public health discourse about using pre-implantation genetic diagnosis for disabili-
screening was examined in in-vitro fertilisation clinic web pages and promotional materials, medical/ technical accounts, legal and regulatory documents, American Board of Genetic Counseling training materials/codes of practice, and media reports. Using applied discourse analysis, texts were examined as socio-linguistic dispositive of medical knowledge which embed and transport social practices and ideo-
logical assumptions. Investigation probed participant actions in communication events and the character-
istics of discourse communities, focusing on how particular metaphors, recurrent motifs, story lines and images convey claims and shared assumptions concerning regulation and governance of reproduc-
tive genetic disability screening. Inquiry identified representations of disability and embodiment (e.g.,
normal and disabled, healthy and diseased), and who spoke for these perspectives. Findings evidence how master narratives about health and disability, parental

Narratives of ‘other spaces’: Reconfiguring culture and identity boundaries

Luccred Sabrina University of the Witwatersrand, South Africa; Jill Bradbury

Women scientists are living at a critical time in South Africa as the socio-political landscape is changing rapidly, effecting changes in many dimen-
sions of identification, particularly, ‘race’, gender and class. Drawing on preliminary data from in-
depth interviews with a cohort of Black women graduates in science, this paper illustrates how nar-
rative methods could be used to investigate the ways in which discursive, embodied and symbolic practices in, and through time with space, articulate in their intersectional identities. The focus will be on conceptualising how these women traverse spa-
tially embodied boundaries within white and male dominated spaces into ‘other spaces’ by reconfigur-
ning culture and identity boundaries. The signifi-
cance of this research lies in its contribution to understanding the transformation of collective boundaries, particularly for marginalised groups who come to occupy positions of power in both the production of knowledge and the functioning of society.
choice, and genetic technology’s role in eliminating genetic conditions/disabilities are produced, distribut-
ed, and contested in public health information, and
indicate the constitutive power of these narratives in
guiding genetic consumer and medical/regulatory de-
cision-making. This work informs scientific debate
among psychologists, medical professionals, and
ethicists about the nature of disability and ethics of
using genetic technology to alter the human genome.

Multicultural, intercultural, or just the cultural
(political) and psychological? Lilana Tal MGH, HMS, Psychiatry, United States of
America
In this paper I present my work as a psychologist,
inspired by postmodern theories such as relational
psychoanalysis that uses concepts like inter-subjec-
tivity and social constructionism to describe its
work. Since my work as a psychotherapist is con-
ducted with culture in mind,” the relational theory
offers me a broad space to further explore the
relationship between self and other, development,
dentity and historical context. Like many relational
theorists, I am too, a product of the 50’s, a “chal-
lenging authority” era in many parts of the Western
world that continued through the 70’s (the civil
genocide, the women’s movement, etc…). This new “air” of the time, thriving in highly po-
liticized campuses informed me and formed my
personal and professional self. Through clinical
stories from my office I will attempt to make clear
the relationship between my own history (my sub-
jectivity), the patient’s history (the other’s subjec-
tivity) and the co-constructed narrative of the
therapy relationship.

Submitting to the discipline of sexual intima-
cy: Online constructions of BDSM encounters
Saska Wolfordt University of Pretoria, South Afri-
can; Therese Bakker
BDSM (bondage, discipline/dominance, submis-
sion/sadism and masochism) has recently gained
greater visibility in dominant discourses around
sexuality. However, these encounters are often con-
structed in rigid ways to typically exclude experi-
ences of sexual intimacy. Despite this apparent
exclusion, constructions of subspace (an altered
mental state induced through BDSM encounters)
on online blogs intrigued me to consider it as an
alternative to widely accepted ideas of sexual inti-
macy. The first stage of my research involves the-
oretical grounding in preparation for the subsequent
empirical data collection stage. This serves as prepa-
ration in conducting an online ethnography in which I will explore the varied ways in which
self-identified South African BDSM participants construct meaning around sexual intimacy and
subspace. In this paper I report on the first stage where I familiarise myself with the context in which
BDSM participants might find themselves. This takes into account a brief look at the history of
BDSM, past research done on sexual intimacy, psychotherapy experiences of BDSM participants,
Attempts at depathologising BDSM experiences, the
role that informal online blogs, forums and social
networks play in supporting BDSM participants,
and how BDSM is represented in the media. Using
a social constructionist lens I explore how construc-
tions of intimacy in the BDSM community might
have been silenced through exclusionary definitions in
dominant discourses. I conclude with implica-
tions for how psychology responds to the experi-
ences of BDSM identities.

Critical psychology and public health: Possi-
bility of a mediating process
Vijay Kumar Yadavendu Kisan College, Sohsoarai,
Noland, India
This paper considers that with the rise of health
psychology, a new consciousness pervaded compri-
sing a more general heightened awareness and interest
in personal health. Heightened health awareness
along the lines of personal control and change may
prove beneficial for those who adopt a more health-
promoting lifestyle, where individuals are relatively
free agents with needs, desires, ‘rights’ and so on.
The individual is abstracted from his/her social lo-
cation and the solutions prescribed for disease are
essentially reductionist. The abstracted individual is
completely robbed of his/her collective identity.
Existing social institutions as well as institutional
changes are explained in terms of relatively free
individuals exercising their freedom of choice. Be-
aviour modification, self-help and self-care have
become the guiding principles of public health.
However, the social and economic influences on
choice of occupation, lifestyle, sanitary conditions
and a range of other factors that affect health remain
outside the control of the individual. The result was
an overemphasis on the determination of specific
etiology, development of curative medicines and
preventive vaccines, and promotion of individual
responsibility. It may, in the process, also have cre-
ated the illusion that individuals control their own
existence, and that taking personal action may im-
prove health and satisfy the longing for a varied set
of needs. Psychological dispositions and market fetish-
ism strengthen the case for biomedical and individ-
ual-centric approaches. This effectively obviates the
 dynamics of interaction between the individual and
his/her environment with its consequent impact on
health, and promotes individual risk and responsibil-
ity. It also meant that the sphere of the state’s respon-
sibility shrank progressively, away from the social
sector in general, and public health in particular.

Session Type: Posters

What is jo-sen (decontamination): Dis-
courses concerning the 3.11 Great Eastern
Japan earthquake and nuclear accident in
newspaper articles?
Yasuhiro Igarashi Yamano College of Aesthetics, Japan
The 3.11 Great Eastern Japan Earthquake and the accident of the Fukushima No. 1 nuclear power
plant have had a huge impact on Japanese people.
The death toll from the earthquake and tsunami
directly hit 20,000. In addition, hundreds of
thousands of people were evacuated from their
homes for fear of radiation contamination. After the
nuclear accident, the safety of nuclear power gen-
eration and counter-measures against nuclear disas-
ter became hot issues in the media. One of the
issues that frequently appeared after 3.11 is what
is ‘jo-sen (decontamination of radioactivity)’ and
how should it be done. Although the term ‘jo-sen’ is
written in two plain Chinese characters, it is diffi-
cult to understand hazards of radioactivity and to
determine the criteria to do decontamination work.
It is not clear what effects so-called low level of
radiation will have on us. Even experts cannot set
the criteria to do decontamination work without
these criteria being contested. Even for those who
lived in a ‘low’ contamination area, it is important
to decontaminate their community if they are to
return and rebuild their lives. What is ‘jo-sen’ and
how to do it, has been discussed by experts, gov-
ernmental authorities, victims of the disaster and
other parties before the government eventually set
the criteria as 0.23 µSv/h. Analysing newspaper
articles concerning radiation contamination, this
presentation examines how decontamination has
been socially constructed and what the conse-
quences might be.

Session Type: Invited Addresses
Psychology of napalm: Why do psychologists
avoid burning issues?
Serdar Deginmencolgu Cumhuriyet University, Turkey
This paper examines the response in psychology to
wars and weapons of mass destruction, using na-
 palm as a case in point. Napalm bombs have been
in use since 1945. The heaviest use was recorded
during the Korean War, but napalm became synon-
ymous with the one in Vietnam. Napalm became
well known in 1972 after a plane dropped napalm
bombs on a small village in South Vietnam: A
young girl, whose body was burned by napalm,
was photographed naked, running away from her
burning village. The psychological impact of na-
 palm was recognised during the Bertrand Russell
Vietnam War Crimes Tribunal. Thirty years after
napalm became world famous, Mark 77 firebombs
were used against Iraqi soldiers as Iraq was invad-
ed. Independent sources (e.g., Physicians for Social
Responsibility) see no difference between Mark 77
and napalm bombs. After the invasion was com-
pleted, the “big psychological effect” of napalm
was mentioned by some military sources. In an
interview published in a major newspaper published
in the USA, a commander from Marine Air Group
11, one of the units that used Mark 77 in Iraq, noted
that “generals love napalm,” thanks to the “big
psychological effect” of napalm. Psychology, how-
ever, has completely ignored napalm. There is no
work on napalm and similar firebombs in psychol-
ogy. Psychologists appear to devote little or no
attention to such weapons, refrain from disseminat-
ing what is known about napalm to the public, and
do not fight the production and use of napalm and
similar weapons.

Psychology in context: A critical approach to
social and cultural background of psycholog-
ical knowledge
Nestor Rosell CONICET, Argentina
Psychology is a science, that is, a conceptual system
aimed to explain human behaviour. But is also a
social practice or social activity that produces this
knowledge. In that way researchers, as social actors,
work in different settings, interacting with colleagues
in order to produce knowledge, and to spread it in
the scientific community and beyond into society
where this knowledge is used as technology. In that
way, science is a social institution, that is, a social
Cultural diversity or cultural competence: A
ing cultural competence to better services appears to
exists in psychology in that knowledge about cul-
tural diversity and inter-culturality. A similar problem
of psychiatry, few medical schools provide
awareness of cultural issues as a core component
pro-amnesty. In turn, on a micro level, there
popular movements, such as strikes and move-
tenments pro-amnesty. In turn, on a micro level, there
was dissatisfaction among psychology professors,
novs trained in Philosophy and Education, with
the new social psychology that came from the
United States. Accustomed to an essayistic method
and comparative studies between different areas,
proposals for an experimental study seemed to
them an artificiality, of dubious applicability to the
real needs of the population. Contact with fellow
Latinos and the same perception of poverty on the
continent led to the participation of many in the
popular education movement of Paulo Freire and
the based in communities of the Catholic
Church. There was almost a total abandonment
of the theoretical tools and a commitment to the
practice. The new social psychology focuses on
communities. There is growing need for theoretical
support, which is found in Vygotsky. In the
subsequent 30 years, other theoretical approaches
were added, creating a perspective of social psy-
chology now that permeates much of psychology in
Brazil.

Teaching the history of psychology through
the construction of the discursive contexts
Nestor Roselli CONICET, Argentina

As epistemic branch, the history of psychology is
especially useful to account for the dependence of
theories and models with respect to the social con-
ditions of emergence. But a real understanding of
the sociocultural foundation of the psychological
theories needs a non-encyclopedic approach to the
history of the science. The teaching of the history,
we propose, offers the opportunity (and the chal-
lenge) to immerse students into the discursive con-
text of each theory and the historical conditions of
their emergence. The challenge is the personal con-
struction (or recreation) of those discursive uni-
verses. To get that, it is essential that students carry
out an active research in all kinds of sources and
documental bases. This activity leads to the elabo-
ration of creative written reports, where the students
display the product of their personal involvement in
the discursive contexts they have analysed.

Optimising construction of psychological sci-
ence: Learning from consolidated branches
of knowledge
Nestor Roselli CONICET, Argentina

Science aims to describe the behaviour of the uni-
verse in terms of concepts and relations, and tech-
nology exploits this knowledge for the benefit of
humankind. This context is studied by epistemolo-
y. But it is also the fruit of activity and interaction
between humans and therefore influenced by moral,
culture, ethics and other social values. The second
field is the subject of sociology of science. One may
address these two scenarios disciplinarily, studying
epistemology and sociology of each area per se.
Another way is examining the epistemology of
several areas on one side, the sociology of various
areas on the other, and only then combining the
findings of both. We believe that psychology will
benefit from the second approach. The key is de-
termining the epistemological moment a certain
sub-area of psychology is at. identifying the same
moment in the evolution of an already consolidated
area (biology, chemistry, physics), and taking the
actions that most contributed to the advancement
of knowledge at that point/time. Taketani’s applied
philosophy is a convenient framework to assess
epistemological moments. Case studies, like the
development of quantum mechanics, will set the
social background. From the latter, one may learn:
(i) on the crucial role of a statesman, a researcher
who was not the greatest exponent, but who was
able to sew agreements and to trim edges of pas-
sion, tragedy and ambition among the great, this
way achieving the more noble goal of understand-
ing nature; (ii) that small and focused working-
conferences, involving the exponents, will improve
advancement speed.

Psychological research as a social practice
Nestor Roselli CONICET, Argentina

This presentation aims to claim for a concrete and
situated view of the psychological research, look-
ing at it as a social activity. Researchers, as social
actors, work in different settings interacting with
colleagues in order to produce knowledge and to
spread it in the scientific community and beyond
into society where this knowledge is used as
technology. In that way, science is a social institution, that is, a social activity submitted to institutional regulations, as any other social activity. These social regulations concern not only a simple and outlying organisation of the activity, but, in a deeper level, a particular logic of power distribution and a kind of relationship between actors. In fact, psychology is not only an epistemological object, but a social activity, and the scientific community can be viewed as a social system. It is important to analyse the narrow interactions, which are not easy to depict, between both epistemological and social dimensions. The presentation begins with an analysis of the micro-social systems of psychological research, but it focuses specially on the macro-systems, as the international scientific community. In all social systems there are three aspects that must be analysed: The social interactions, the norms and cultural values, and the psychological identity. In the international social system an aspect is specially important: The philosophical cultural traditions supporting theoretical and methodological traits of the research activity.

**View of the history of psychology in the frame of discursive contexts**

*Lucia Rossi* UBA, Argentina

The history of psychology is especially useful to evidence the social conditions of emergence of theories and models. Indeed, a real understanding of the development of psychological knowledge across time needs not only to examine theories and authors, but also the discursive context of this epistemic development. Each theory stands on a particular discursive context derived of the society in a specific time. The presentation will analyse the emergence of two theories, psychoanalysis and behaviourism, inside their sociocultural contexts. This view has important consequences for the teaching of psychology. The history of psychology becomes the social context de la science; it allows a more concrete perspective of scientific knowledge. But this teaching requires a non-encyclopedic approach to the science. The teaching of the history we are proposing offers the opportunity (and the challenge) to immerse students into the discursive context of each theory and the historical conditions of their emergence. The challenge is to get the personal construction (or recreation) of those discursive universes.

**Metaphor as a key to the power of Kahne-man’s psychology**

*Karl Scheibe* Wesleyan University, United States of America

This presentation will begin with a brief history of the use of metaphor in psychological theory, with special attention to showing how the metaphors psychologists prefer derive from the social and cultural context of their times. Freud’s metaphors were entirely different from those of Kahnemann. Both have proved to be poetic masters in the construction of psychological theory. Daniel Kahnemann has been called the most influential psychologist of our time. He is credited with major developments in founding the field of behavioural economics, with identifying major biases and heuristics in human judgment, with making fundamental contributions to our understanding of pleasure and pain, and with the establishment of a line of thinking known as "Prospect Theory" which focuses on a description of the exercise of purpose in making everyday choices. This paper provides an analysis of the use of metaphor in Kahneman’s psychology. Ostensibly, Kahneman’s psychology is supported by carefully constructed and executed empirical studies of human beings in laboratory and real-life settings. But I argue that the power of Kahneman’s psychology, the reason why it is so influential, derives from the quality of his metaphoric constructions. He has demonstrated a capacity to derive a fresh set of metaphors capturing the human actor in the everyday marketplace and has thus succeeded in transforming the common understanding of human frailty and human brilliance.

**Constructing psychological knowledge from the socio-epistemological context of other sciences**

*Piotr Trzesniak* Universidade Federal de Itajubá, Brazil

Science aims to describe the behaviour of the universe in terms of concepts and relations, and technology exploits this knowledge for the benefit of humankind. This context is studied by epistemology. Science is also the fruit of activity and interaction between humans and, therefore, influenced by moral, culture, ethics and other social values. This is the field of Sociology of Science. While the epistemological moment of some sub-area of knowledge establishes what research approach optimises the ratio between scientific advancement and efforts, the sociological context defines how this research will occur in practice and which particular sub-area will be at the forefront. Our proposal is that the development of psychological knowledge can greatly benefit looking at the consolidated areas of knowledge (biology, chemistry, physics). The key is identifying the epistemological moment of a sub-area of interest in psychology (i.e., which), searching for a corresponding epistemological moment in a consolidated area, and working along the most pertinent and fruitful steps in research (what) and social interaction (how) taken at that time in the latter. To illustrate, we will discuss the social background of the development of quantum mechanics, from which one may learn: (i) on the crucial role of a statesman, a researcher who was not the greatest exponent, but who was able to secure agreements and to trim edges of passion, tragedy and ambition among the great, this way achieving the more noble goal of understanding nature; (ii) that small and focused working-conferences, involving the exponents, will improve advancement speed.

**The adult educator in the constitution of the subject in early childhood: The other one that could indicate the singularity**

*Cristina Dias* USP, Brazil, Brazil

The context of teachers’ work in early childhood education puts into play the importance of their role in the constitution of the subject in early childhood. The place occupied by teachers is established within the scope of relations established between the child and adult educator, as well as the ethical position that latter takes in the social bond. In recent years, education has become a field where questioning and criticism are increasingly prohibited. Especially in basic education, the prevailing assumption is that children should be "educated" through practices that, in most cases, assume control and obedience as their primary educational strategies. In this sense, the teacher deals with a shared truth, which seeks to ensure balance and uniformity, eliminating any conflict or desire, that could put into play other kinds of knowledge in this environment. Thus, to format, order and control children have become the goal of education, which may indicate some principles contained in this social bond. In the relation teacher-child, conflict, difference and uniqueness are to be treated as a malaise by educators, to the extent that it challenges their position, setting up a permanent gap in which the child becomes the main object in satisfaction. From the standpoint of psychoanalysis, if we think lack and conflict as constitutive of subjecthood, with ethical consequences: how do we promote singularity?

**A clinical-political psychoanalytic practice as opposed to criminalisation and pathologisation**

*Miriam Rosa* USP, Brazil, Brazil; *Sandra Alencar*

Experiences of psychoanalytic treatment in communities marked by social and political exclusion, specifically with regards to immigrants, refugees and exiles, has given us the opportunity to elaborate the specifics of what we call “trauma clinic”. This clinical-political psychoanalytic practice poses challenges and requires strategies in two areas: that of the subject and that of social practices. On the side
of the subject we consider the issue of grief and mourning in its political appearance, i.e., the socio-political production of anguish and the impairment of the subjective processes of mourning. These are cases in which subjects have not built a metaphorical response, a symptom through which they can speak of their suffering and address a demand. We argue that in situations of lack and of addressing the Other, articulated with the dimensions of trauma and grief, mourning is often prevented or denied to peoples. Who suffer various forms of violence and disruptions. On the side of social institutions (educational, health, legal) we propose to consider the subtle forms of prejudice based on class, race or gender present in the mechanisms of individuation, criminalisation and pathologisation that are affected through so-called scientific practices that separate events of the personal, family, institutional, social and political scenes of actors. This paper illustrates, through a case example, how one can diagnose ongoing processes of exclusion and reverse the direction of practice, so as to allow everyone the occupation of their place in the social scene.

It's hard work to be a girl: A group of South African adolescent girls experiences of gender inequality in the home

Sherine Van Wyk Stellenbosch University, South Africa

Gender roles and constructions play a pivotal role in our lives. They are critical drivers of mental health, development and well-being. Since 1994, South Africa has taken great strides in establishing a democratic society built on a culture of human and gender rights. Children born post-1994 are often referred to as "Mandela's children" or "Born Frees". The aim of this study was to ascertain adolescent girls' experiences of gender equity in the home. I conducted focus group interviews with 61 girls from three low-income, peri-urban communities in the Western Cape. The data were collected from seven focus groups with Grade 7 and 8 learners, aged between 13 – 15 years. Each focus group met for four consecutive weeks. The findings suggest that despite the transformation and commitment to gender rights in the public domain, traditional notions of gender and gender roles seem to tenaciously persist in the private domain. Compared to their brothers, participants experience high levels of gender inequality at home, have less privilege, access to material goods, shoulder most of the household chores and are responsible for caring for their younger siblings. The perpetuation of male privilege could not only have costs to both girls and boys on a personal and interpersonal level, but also the transformation of this society as a whole. Interventions to address gender inequality on all levels of society should become the focus of mental health professionals.

Indigenous knowledges: What is the difference?

Patricia Dudgeon University of Western Australia, Australia

If psychology is part of the colonising project, where is there space for indigenous peoples to develop their own knowledges, put these into action, and commence a process of healing themselves? For Aboriginal and Torres Strait Islander peoples of Australia, our history of colonisation, resistance and adaptation and shifting government policies creates contemporary situations and issues related to our mental health. In mental health Aboriginal people's resilience and struggle to claim equality and cultural recognition is of fundamental importance. Australian psychology's key points of engagement with Aboriginal and Torres Strait Islander people will be examined and while it is acknowledged that the psychology profession has been part of the colonising process through cultural and institutionalised racism, there is reason for optimism in current times. The potential for empowerment and inclusion of Aboriginal and Torres Strait Islander peoples at all levels of mental health service provision is at hand. Part of the movement towards this includes a growing body of activity where indigenous people themselves are claiming space to develop cultural knowledges that are healing and give back a sense of positive cultural identity. Unique aspects of these new knowledges will be discussed.

Tools of coloniality used to examine the fruits of coloniality?

David Fryer Australia Australia

In her comments at "The Personal and the Political Panel", Second Sex Conference, New York in 1979, Audre Lorde asked "What does it mean when the tools of a racist patriarchy are used to examine the fruits of that same patriarchy?" and in the next sentence she answered: "It means that only the narrowestest parameters (sic) of change are possible and allowable". In her comments Lorde focused on difference of race, sexuality, class and age among women and of course arguments for focus on the role of difference within the lives of colonised peoples is at least as strong. The title of Lorde's comments, at least when published, is, of course, famously: "The Master's Tools Will Never Dismantle the Master's House." In this symposium we will read "the master's house" as "colonisation" and "the master's tools" as the theoretical, methodological, ideological and prevention/ intervention tools of mainstream psyche and be mindful of the points made forcefully by indigenous critical methodologist, Linda Tuhiiwai Smith, that research and the knowledges it constructs and legitimises are the battle grounds for colonisation in particular and oppression in general. In this symposium we will offer opportunities to think from a community critical psychology standpoint about the problematic and contested nature of colonising "knowledges", how they are constructed and legitimised, whose interests they serve and how reactionary colonising knowledges can be resisted, or at least subverted, and progressive decolonising knowledges co-constructed and deployed instead.

Beyond participatory action research

Dolores Miranda University of Puerto Rico, Puerto Rico

Community psychology has developed successfully in Puerto Rico academia, as well as in a diversity of social scenarios. In its effort to make a difference it resists dominant American and European psychology. However, during over 30 years of life it has positioned itself within the Participatory Action Research paradigm and, with the best intentions and love in mind, it has - to a certain extent - reproduced the so-called masters ideology, methods and knowledge. Although some progress is reported as a result of our interventions, we can agree that there has not been much improvement in the lives of those objects of our research. Furthermore, concepts such as: (a) community is addressed from a modern capitalist perspective; (b) empowerment is currently an artefact or technology of control; and (c) social transformation goes beyond psychological and academic. Yet within this general scenario, the author agrees that research should contribute to better societal conditions. With this purpose in mind, this paper discusses the challenges of de-colonising methods within a critical community psychology perspective in the colonial context of Puerto Rico. The colonial condition is a rather complicated time and space reality which problematises a linear, organised and systematised approach to doing research. The author invites researchers to engage in an exercise of looking through the wisdom and practices of the colonised. This implies the courage of letting go of certainty, and to feel the pain in order to continue the ongoing journey of the future.

Problematisation of colonisation's historicity from contexts of Australia and Puerto Rico

Carlos Rivera University of Puerto Rico, Puerto Rico

Colonisation is a taken for granted notion from its very historical grounds. Its signifier has been filled in by either the very action and moment of the initial invasion from one culture to another or by the analytical category referring to the subjugation of one group over another. Puerto Rico and Australia are here positioned as privileged laboratories in which to understand the very conception and historical constitution of colonisation, although not via a comparative approach. In this presentation I aim to elaborate the notion of colonisation from a genealogical perspective by problematising its historicity. I also aim to present critical ethnographic praxis in order to approach the phenomena of subjugation in the contexts of Puerto Rico and Australia from a decolonising position. Lastly I aim to present how this problematisation of the notion of colonisation can produce a conceivable subversion through dispositifs such as public policy or the structuring of programmes. In other words I aim to use the master’s tools to dismantle the master’s house. All these aims will rhetorically be presented as a proposal which, although grounded in preliminary experiences of research, is a project which is in process of being embodied within a University institution.
Language acquisition of young children: A socio-cultural perspective

Anjali Allahabad
Allahabad Degree College, India

Language and socialization are two interrelated terms. Language is a tool of socialization and through socialization a child learns to use language. In an extended family system, most prevalent in India, the network of kinship relations has a differential impact on the verbal environment of home. A child has a larger universe in terms of parental as well as grand-parental speech models. The present study examines the relative contribution of socialization agents i.e., mother, father, grand-mother, grand-father and siblings, to the linguistic environment of family and the acquisition of linguistic skills in children. 84 boys and girls (M=32 months) were taken from joint and extended families. A semi-structured interview schedule, consisting of 26 items, was used to measure the linguistic environment of the the family. The Grammar Comprehension Test, Word Meaning Test and Expressive Language Test were used to assess the language development of children. A multiple regression analysis was performed on scores of all five social agents obtained on the Linguistic Environment Inventory and three measures of linguistic skill. A comparison of beta weights revealed that the grand -mother contributed maximum variance to the linguistic environment as well as to the linguistic skills of children. The findings show that family structure is functionally important in language acquisition and grand-parents, particularly the grand-mother, play a strong role in Indian joint families.

A theoretical review of indigenous and modern entrepreneurship practices among Yoruba people of West Africa

Adoeye Ayinde Obafemi Awolowo University, Nigeria

This study explores the nature of the indigenous pattern of entrepreneurship among the Yoruba race in Nigeria, in comparison to what obtains in recent times, with a view to bringing the cultural and theoretical perspectives to the practice of entrepreneurship. The article underscores the similarities and differences in the indigenous and modern modes of entrepreneurship among persons of Yoruba extraction of Nigeria, where emphasis is placed on the entrepreneurial spirit of our forefathers and the people of the twenty-first century. Based on social cognitive learning theory, the conclusions drawn were that entrepreneurship has been in practice among Yoruba ethnic people for quite a long time, even though there was no specific name given to this practice at the time. It was also concluded that entrepreneurship is deeply entrenched in Yoruba social cultural values as various communities, clans and households were fond of aligning to a particular line of trade or business reminiscent of what might be described as trademark or the patent right in the modern entrepreneurship practice. Thus it is recommended that social cultural values should always be considered in promoting entrepreneurship in Nigeria.

Exploring psychedelic trance, rave culture and drug use in Goa

Leila Badyari
Christ University, India

Trance music, especially psychedelic trance or Goa trance, have been associated with the use of drugs such as LSD (Lysergic Acid Diethylamide), marijuana and ecstasy since the initiation of this type of trance in rave culture in Goa at the beginning in the 1960’s. It is interesting to note that an entire genre of music arose from a culture that began as a means of escape from a materialistic, mechanical world that many felt lacked the ‘soul’ that India had to offer in the 60’s, particularly the beaches of Goa. The main objective of this study was to document the experiences of rave attendees. The specific objectives of this study included exploring the association between psychedelic trance music played at the rave parties and the drug use by the rave attendees, second, documenting the subjective experiences of LSD use and, third, understanding the non-drug users’ perspective on this culture of music and drugs. Within the ethnographic framework, the researcher was able to implement the interview method wherein ten participants were selected, based on the method of purposive sampling, and subjected to a semi-structured interview. It was found that most of the participants placed a lot of emphasis on the sense of belonging and freedom that they experienced at rave parties. They felt that it was a place where people from diverse backgrounds could come together while still retaining their individual identity. The use of drugs was found to be highly significant in the entire experience as was the psychedelic trance music. LSD use was common among most of the drug users and they described their experiences as spiritual, religious and some also as elaborated synesthetic experiences. The study was able to capture the essence of the rave parties from the participants’ subjective viewpoints, giving greater insights into the culture.

Difficulties and challenges of post-migration family relationships for isolated men of Algerian origin

Anna Bayard
University of Picardy J. Verne, France

Our clinical research in psychology focuses on isolated men of Algerian origin, who have immigrated to France and live in a welcoming center in the south of France. About 80% of those we met mentioned being in a situation of complete alienation from their family who had migrated with them to France. A phenomenological approach has been used to collect and analyse precise clinical cases, which have been put into perspective by the text analysis software Alceste. This enabled us, through lexical analysis, to point out the significant structures and the underlying content of each of these life-time stories, which actually go far beyond the familial and individual dimension. We are trying to understand what is at stake in post-migration family relations: questioning each family member’s place and role in the family, changes in family values and questioning of their own identity. We shall also aim at giving sense to the verbal, psychic, symbolic and of course physical violence which may take place in these families. Through a complementarist approach mixing psychology and sociology, we shall throw light on the search for identity which underlies family conflicts. While highlighting the gap between the various migration experiences of the family members, we shall reveal the various strategies implemented by families and individuals to be
part of the host society and which often lead to families breaking up. We promote a closed and interculturalised clinical space to migrants.

Support group manuals on coming out and HIV/AIDS for LGBT people in Namibia
Christiane Berker CB Consult, Namibia
In 2009 the authors developed two manuals to be used by trained lay people to run LGBT self-help groups in the interest of expanding support and advocacy for LGBT people living throughout Namibia where same sex relations are open to criminal prosecution. The first manual is called PRIDE Coming Out Group. This is a multimedia interactive 20-session manual for those who are in the process of accepting and incorporating their sexual and gender identity into their everyday life. As a facilitator manual, it provides facilitation guidelines, information, instructions, illustrations and handouts. If resources permit, DVDs and CDs were selected to accompany the sessions. A unique manual, its intent is to provide a structure for culturally diverse Namibian LGBT people with limited access to non-judgemental support and information, opportunity to strengthen their self-image, reduce isolation and improve coping skills. The second facilitators manual is called HIV/AIDS Support Group for LGBT People and incorporates issues of identity with living positively with HIV. It covers health issues, sexuality, prevention, stigma, disclosure, ARVs, PMTCT etc. This user-friendly manual is created similarly to the Pride manual. We will share our experiences as trainers of a 3-week workshop for LGBT facilitators as well as the successes and challenges concerning special aspects of cultural influences when dealing with HIV/AIDS, sexuality and LGBT issues in Namibia.

Academically gifted African-American college students in science, technology, engineering, and mathematics: Identifying factors for success
Fred Bonner Rutgers University, United States of America; Mary Alfred
The objective of this study was to determine the factors that contributed to the success of academically gifted African American students in STEM disciplines who were enrolled in Historically Black Colleges and Universities (HBCUs). The population for this project included: Academically gifted African American students enrolled in STEM programs at four-year HBCUs. We also sought input for this project included: Academically gifted African American students in STEM disciplines who were enrolled in Historically Black Colleges and Universities at four-year HBCUs. We also sought input for this project included: Academically gifted African American students in STEM disciplines who were enrolled in Historically Black Colleges and Universities at four-year HBCUs.

Symptom expression and mental health literacy among low-income Latinas: A qualitative analysis
Drha Cortes Cambridge Hospital/Harvard Med , United States of America; Norah Mulvaney-Day
Low levels of mental health literacy (i.e., knowledge/beliefs about mental disorders that aid recognition) may contribute to adverse health effects and mental health service disparities. This qualitative study describes factors that characterize psychiatric symptom expression for Latinas during mental health intake sessions and generates theory to inform development of mental health literacy interventions. Videotaped mental health intakes of 20 Latinas drawn from a primarily low-income sample selected from a parent study of 129 intakes were analysed. The sample varied according to new versus previous history of mental health treatment and English versus Spanish speaking. A coding team identified factors related to symptom expression in the intake, and documented provider input. Four primary factors emerged: labelling of disorder; problem recognition; knowledge about mental health treatment; and social/cultural expressions of disorder. Most previously treated patients labelled disorders using psychiatric language, while new to treatment Spanish speaking patients used cultural idioms. Spanish speakers expressed somatic symptoms, but also utilised psychiatric terminology to describe mental health symptoms. Patients frequently linked symptom expression with social stigmas and cultural issues. Providers and patients combined sociocultural and medical explanatory frameworks when discussing symptomatology. Even patients new to treatment demonstrated some degree of mental health literacy. Mental health literacy interventions should address cultural idioms and somatic symptoms, but also expand to consider how providers could better address the intersection between social stigmas and psychiatric symptomatology with this population.

Return migration: Different expressions of gender issues when returning from Japan and the U.S. to Brazil
Sylvia Dantas Federal University of Sao Paulo, Brazil; Laura Ueno
The present study indicates gender as a crucial category on the understanding of return migration. Two qualitative studies based on grounded theory are compared. The first study was conducted in 2001 (DeBiaggi-Dantas, 2004). It was based on interviews with 10 participant families who had lived in the U.S. The second study was conducted in 2010 and 2011 with 14 participant families that returned from Japan. Whereas return to Brazil from the U.S. meant a contrast between what was before considered a more egalitarian arrangement and environment to a more conservative one, returning from Japan to Brazil meant the opposite. Japanese-Brazilians felt less social pressure for women in regard to gender role performance, even to the more traditional couples. Brazil has always been considered a country of immigrants. In the mid-eighties it also entered the international migration flow by having many leaving the country. Due to the country’s economic growth and new global order many Brazilians who were abroad now return to their home country. The comparison of two different groups of Brazilians that returned to their homeland indicates the importance and complexity of gender as category in understanding return migration.

Development of a culture assessor for a German airline company
Dominika Dej Tu Dresden, Germany; Ingrid Tout
We developed a culture assessor based on the empirical study and theory of cultural orientations as introduced by Thomas (1998). Participants were sampled within the employees of a German Airlines Company. Specifically, we conducted 75 semi-structured interviews with ground crew who interact with foreign passengers on a daily basis. Participants were asked to recall and describe an intercultural situation encountered in the work setting. After preliminary content analysis, we developed culture-specific assimilators for India, African countries, Japan and Russia. In the second step experts from each culture evaluated assimilators’ typicality on a four point scale ranging from “very typical” to “absolutely untypical.” Finally, we selected 20 assimilators who were evaluated by the experts to display critical situations realistically and precise. Obtained assimilators will be integrated in intercultural training to be conducted by the Airlines Company to measure the training’s effectiveness.

Exploring perceptions of intercultural harmony in a globalised South East Asia: A Malaysian perspective
Jessica Dunn University of Nottingham, Jamaica
Some South East Asian countries have performed well since the 2008 Global Recession (ILO, 2009). This has led to a significant influx of migrants to countries such as Malaysia (a society with its own intrinsic cultural diversity) for employment and education (Sirat, 2008; Lenn, 2004). This paper explores how a country with a combination of vastly different native cultures – predominantly Malay, Indian and Chinese – has responded to the relatively rapid influx of foreigners. It also seeks to determine how foreign residents acculturate, cope with the diversity, and how they perceive their reception from Malaysian nationals. While the social implications of these trends have been explored widely in Chinese and Japanese cultures (Salleh, 2005), there is still a paucity of empirical evidence looking into the socio-cognitive effects of these demographic changes in South East Asia. This paper draws on established cultural psychology theory including social comparison (Festinger, 1958); divergent construals of the self (Markus & Kitayama, 1994) and cultural dimensions (Hofstede, 2007 & Berry et al, 2002) to investigate cultural tolerance in the Malaysian context. 150 Malaysian citizens and 150 foreign residents, including students and skilled workers have been purposively selected to complete a survey exploring their intercultural attitudes. This included (i) cultural awareness; (ii) perceived differences in out-group and in-group norms, values and beliefs and (iii) cultural tolerance. Multivariate statistical analysis
will be conducted to determine whether intercultural attitudes predict cultural tolerance and facilitate intercultural harmony. Practical implications and future research directions will be discussed.

Different ways of feeling: Gender and disgust in Ghana and the United States
Vivian Dzokoto Virginia Commonwealth University, United States of America; Alexander Skolnick

While emotion has been identified as a universal psycho-physiological process, its experience, expression, display, and regulation is subject to cultural shaping. Previous emotion research, mostly conducted in Western populations, has identified gendered patterns of emotional displays. For example, consistent gender differences are found in scalar and behavioral measures of disgust in American and European samples. Cultural scripts that have been identified as impacting the expression of emotion in Western adults, but not Euro-American cultural spaces include a bias towards the somatic (Guerts, 2002) and a lower perceived importance of awareness of emotion (Dzokoto, 2010) consistent across genders. These differences in cultural scripts suggest that the gendered pattern of differences in the context of disgust may not be replicable within a West African context. Based on a comparison of self-reported perceptions about disgust, disgust-sensitivity, and reactions to disgust-evoking visual stimuli in male and female adults from Ghana (West Africa) and North America, gender differences in disgust in Ghana seem to be few and far between.

The findings of the study suggest that while gender shapes aspects of everyday life in West African and American settings, the impact of gender in Ghanaian settings does not extend to the experience and expression of disgust.

A study on life satisfaction, loneliness and psychological security of left-behind junior high school children and their relationships
Yuanyuan Gan Nanjing Normal University, China; Jiajuan Yu

Chinese government statistics show that more than 58 million left-behind children in rural areas whose parents have left home to search for work in the city, and their psychological development has drawn wide attention. In order to explore the characteristics of left-behind children’s life satisfaction, loneliness, psychological security and the relationship among them, 105 left-behind children and 123 non-left-behind children were respectively tested. The results indicated the following: (1) The friendship satisfaction, the environment satisfaction and the psychological security from the left-behind children score significantly lower than that from the control group, while the loneliness from the left-behind children scores much higher than that from the control group. (2) The type of guardianship is the main influencing factor for their life satisfaction, the frequency of parent-child agglomeration and the frequency of parent-child connection are the main influencing factors for their loneliness, while the duration of parent-child separation is the main influencing factor on their psychological security. (3) The certainty in control, the interpersonal security and the loneliness of the children could predict their life satisfaction significantly; the interpersonal security also could indirectly predict their life satisfaction through loneliness. According to the result, the conclusions draw as are follows: (1) Left-behind children show a low level of friendship satisfaction, environment satisfaction and psychological security and high level of loneliness. (2) Loneliness and psychological security of left-behind children are important as predictive variables for their life satisfaction.

What Chinese people value most and how it changes
Xi Le Gao Global Trend Consulting Co., China; Gonggu Yan; Xile Gao

China has made a great achievement on economic development with the open policy in the last three decades. Meanwhile, people’s values systems in China has showed a significant change as well. This study aimed to investigate the specific changes and its pattern in value systems by generation, and to figure out the mainstream values held by Chinese people. The Personal Value Inventory, designed by Chinese Scholars based on Rokeach’s model and Chinese traditional culture, was administered to 370 Chinese people whom were sampled randomly from nation-wide scope. It was found that: (a) Chinese people valued most highly Health, Happiness and Pleasure as their ultimate values, and value Kindness, Filial Piety and Credibility as instrumental values. (b) Elder groups (born before 1970) valued significantly higher Social Base factors, composed of Equity, Justice, Harmony and Compatibility, younger groups, on ultimate values. Elder groups also value significantly higher Benevolence factors, and lower Productivity factors, than younger groups on instrumental values. (c) Compared to elder people more specifically, younger Chinese highlight Freedom, Friendship, Ambition, Creativity, and Responsibility, Stability, Loyalty, Credibility, Frugality as less important. The findings indicated that Chinese traditional culture still plays an important role in modern Chinese society. The implication of the findings on the value changes between elder and younger generations were discussed.

Attachment to God, marital satisfaction, and mental health
Bagher Ghobari Bonab University of Tehran, Islamic Republic of Iran; Hossein Ali Shirazi; Marzieh Dousti

The aim of the current study was to investigate the relationship between attachment to God, with marital satisfaction, and mental health, in parents of children with hearing impairment, visual impairment and intellectual disabilities. To accomplish the stated goal, 372 parents of exceptional children were selected by means of stratified sampling in Zahedan, Muslim Spiritual Attachment Scale (Miner and Ghobary Bonab, 2009), Enrich Marital Satisfaction Scale (Enrich, 1983) and Symptom Check-list 90-R (Derogatis et al., 1973) were used. The results indicated the existence of negative significant relation between General Symptom Index (GSI) and secure attachment to God. (r = 0.69, p < 0.001). Moreover, significant correlation were found between the General Symptom Index (GSI) with avoidant attachment (r = 0.67, p < 0.001) and anxious attachment (r = 0.67, p < 0.001). Further analysis indicated a positive association between marital satisfaction and secure attachment to God (r = 0.72, p < 0.001). Data analysis also revealed that parents with avoidant, and anxious attachment to God were lower in marital satisfaction. Regress analysis revealed that 47% of variations of mental health in parents was explained by secure attachment to God. Moreover, secure attachment explained 51% of variations in marital satisfaction of parents. The results of the current study showed importance of quality of attachment to God in mental health and marital satisfaction of parents of exceptional children. Theoretical implications, practical applications, and future trend of research are discussed in the original paper.

Culture in context: A mixed-method exploration of the relationship between school climate and culturally relevant pedagogy in Bahamian secondary education
Niambil Hall-Campbell College of The Bahamas, Bahamas

A number of studies explore the relationship between teacher training and culturally relevant pedagogy; however, examples of the association between school climate and culturally relevant pedagogy are scarce. The purpose of this research is to examine school climate and culturally relevant pedagogy in a Bahamian context. Using a sequential exploratory design, perceptions of Bahamian pedagogy were obtained through semi-structured interviews (N = 7) and a focus group (N = 1) and used to devise Bahamian measures of culturally relevant pedagogy (Phase 1). In Phase 2, teachers and administrators (N = 227) were surveyed regarding their perceptions of school climate (Hoy et al., 2002), efficacy to enact culturally relevant pedagogy (as perceived in both Bahamian and American settings) and beliefs in the positive outcomes of using culturally relevant pedagogy (Siwatu, 2007). The results of this research demonstrate the validity and reliability of the scales and confirm a significant relationship between school climate and culturally relevant pedagogy. The qualitative data gathered provided rich insight into perceptions of Bahamian culture and its symbiotic relationship with education. It also helped to distinguish the practice of culturally relevant pedagogy in a Bahamian context. Quantitatively, the study supported the hypothesis that school climate is a significant predictor of culturally responsive pedagogical beliefs. Results demonstrate the importance of contextually specific practices and the use of school climate as a predictor of culturally responsive pedagogy while the implications of this study can be used to inform teacher education programs and professional development trainings for Bahamian and Caribbean educational systems.

Religiosity and psychological well-being
Zeenat Ismail IBA Karachi, Pakistan

The aim of the present study was to explore the relationship between religiosity and psychological well-being in a sample of Pakistani Muslims. Previous research has documented a positive relationship between the two factors. A sample (65 men and 85 women) with an age range from 18 to 60 years was chosen. Religiosity was operationalized as religious gatherings attendance, belief salience and frequency of prayer. Anxiety, loneliness and life satisfaction were chosen as dependent variables.
because they are important facets of psychological well-being. Consistent with previous research, correlation statistics suggested that a strong, negative relationship does indeed exist between religiosity and loneliness \( r = -0.4852 \) and between religiosity and anxiety \( r = -0.511 \). A strong positive relationship was also found between religiosity and life satisfaction \( r = 0.76 \). Thus, the results of the study supported the hypothesized association between religiosity and different facets of psychological well-being.

Beliefs about sleep paralysis and the Jinn among the general Egyptian population

Baland Jalal, The American University in Cairo, Egypt; Devon Hinton

SP displays great similarities in the way the experience is manifested across cultures, which results from the neurological roots of the experience. However, in spite of the similar symptoms cross-culturally, the phenomenon of SP is driven by cultural bound interpretations (Hinton, Hufford, et al., 2005). In the current study we explored whether the phenomenon of SP has lead to unique cultural interpretations and beliefs about the experience in Egypt. The Sleep Paralysis Questionnaire (e.g., Yeung, Xu, Chang, 2005) was orally administered to 137 Egyptian individuals. Results suggest that 71% of participants believed that SP was pre-cipitated by spiritual forces. Nearly half or 48% of participants specifically attributed SP to Jinn assaults and a little more than one fifth or 22% of participants disclosed that they thought SP was caused by the Shaitan (i.e., an evil spirit or a demon). Moreover, 37% mentioned that their SP episode was accompanied by either hypnopompic or hypnagogic hallucinations; out of these, 56% felt the presence of the Jinn, and 44% reported visual hallucinations. In 83% of cases in which visual hallucinations were reported participants would mention seeing a shapeless or shadow-like figure. Follow up analyses included a cross-cultural comparison with Danish individuals. Data suggest that Egyptians are more likely to endorse supernatural causes of SP compared to subjects from Denmark (71% vs.5%, \( \chi^2 = 74.7, p < .01 \)). The current study is the first to elucidate how SP has a generated a cultural unique interpretation of the phenomenon in Egypt, namely as Jinn attacks.

Cultural psychology and politics

Gordana Jovanovic, Belgrade University, Psychology, Serbia and Montenegro

The aim of this paper is to search for political implications of cultural psychology through its history. Cultural psychology is by its subject-matter explicitly linked to political issues. However, what is more challenging are political implications of its ways of theorizing and its reception in scientific and broader communities. The first versions of cultural psychology, Dilthey’s descriptive hermeneutic psychology and Wundt’s Völkerpsychologie, coincided with formation of psychology as an independent science, but they did not find a proper place in dominant historiographic memories of psychology. At the beginning of its history psychology was not understood as an eligible participant in political discourses of the time - on the contrary, it nurtured a para-mechanical myth of psyche. The second example is Vygotsky’s cultural-historical theory developed in the 1930’s in the Soviet Union. In that setting psychology was put on the political ideological agenda as a participant in the project of producing new man and new society. Ironically enough, Vygotsky’s theory which could provide conceptual and theoretical tools (social genesis of higher mental functions, formative role of symbolic tools) for such a project was banned. The renaissance of cultural psychology in the Western academic framework in the 1990’s, described by Bruner as a second cognitive revolution, coincides with dramatic social and political changes. How are we to understand flourishing cultural studies in times of growing social dissolution and missing grand social theories?

Intercultural expertise in the armed forces: Challenges on the strategic level

Stefan Kammhuber, University of Applied Sciences, Switzerland

Intercultural Expertise has become an important factor in training soldiers for international missions in many armed forces during the last decade. "Winning hearts and minds" is deemed to be an key factor for the success of any international mission. As intercultural research in the German Armed Forces shows, intercultural training of the individual soldier is not sufficient to reach this goal. Moreover, intercultural expertise has to be developed, also on the level of strategic military planning which has rarely been done up to now. In the paper, I will present how intercultural expertise influences the strategic, operational, tactical, and ethical level of military missions. Further, I will present some data from a project that has been conducted with the top leaders of the German Armed Forces regarding intercultural expertise.

Mental health issues of culturally and linguistically diverse clients in Australia

Nigar Khawaja, Queensland University of Technology, Australia; Michael Dunne, Vivienne Braddock; Rebecca McCarthy

Australia is one of the most culturally and linguistically diverse societies in the world due to increased international migration. A range of mental health services have been established in Australia to offer culturally sensitive and appropriate services to the culturally and linguistically diverse clients with the aim to promote their mental health well being. Queensland Transcultural Mental Health Centre (QTMHC) is one example of such service. It works in partnership with mainstream mental health services as well as ethnic communities and agencies. The present study examined QTMHC’s archived data (N = 1499 clients) collected over two years period (2007–2009). The demographic characteristics of these clients as well as their presenting complaints and psychological symptoms were studied by using descriptive statistics and Chi-squares. The results indicated that clients were referred from a range of sources and were generally adults. There were more women than men who sought services. At least half of the clients had language barriers and relied on bilingual workers. The most frequently expressed mental health issues were mood disorder symptoms, followed by symptoms of schizophrenia and psychosis and anxiety. Acculturation strains and stressors were described as the most common psychosocial issues. Mental health and psychosocial issues differed for age, gender and world regions from which these clients originated. The findings provided an understanding of clients who seek services at a transcultural centre. Various ways in which the cross-cultural services can be further improved are discussed.

Religious, juridical and professional discourses among Ugandan mental health workers on suicide and suicidal individuals

Birthe Loa Knoeck, NTNU, Norway; Heidi Helme-land; Charity Akotia; Eugene Kinyanda

Suicidal behavior is sanctioned legally, religiously and culturally in Uganda. Moreover, Uganda has a shortage of mental health workers, giving a heavy work load to each of them. On this background we studied mental health workers’ views on suicide and suicidal people as attitudes are important for the readiness to help. We conducted qualitative interviews with 30 mental health workers in Kampala, the capital of Uganda. These mental health workers consisted of psychiatrists, clinical psychologists, psychiatric clinical officers and psychiatric nurses. They were asked about their principle attitude towards suicide as well as their attitude towards suicidal people. They were also asked about their views on the current criminalization of suicidal behavior in Uganda. The mental health workers employed three different moral discourses in positioning themselves; 1) Religious moral reasoning, 2) Professional moral reasoning, and 3) Juridical moral reasoning. The religious reasoning was strong in all informants and sometimes overruled the other moral discourses, especially regarding a principle attitude towards suicide. The opposite was true with respect to their attitude towards suicidal people. On the basis of positioning themselves in a continuum between religious and professional rea-
soning the informants then took a standpoint towards suicide being criminal as positive, negative or ambivalent. These attitudes are important in the efforts to develop culture sensitive suicide prevention strategies that may be implemented by these health workers.

Dangerous boys or boys in danger
Asmah Lahlah Intervent, Tilburg Law School, Netherlands

Ethnic minorities account for a large share in juvenile crime both in United States and Europe. In recent decades studies convincingly show that child abuse exposure is consistently linked to an increased risk of juvenile violent offending. In addition, research has identified several risk factors associated to child abuse, which are also prominent in ethnic minority families. However, only few studies have comprehensively examined the extent to which ethnic differences in levels of exposure to child abuse exist and if so, to add to the differences in levels of violent offending. The current study seeks to expand our knowledge of the relationship between ethnicity, child abuse and violent delinquency in a sample of 477 Dutch and Moroccan-Dutch boys. Information from self-reports was analysed to determine whether prevalence of child abuse and violent delinquency varies by ethnicity and whether different types of child abuse mediate the effect of ethnicity on violent delinquency. For all types of child abuse, Moroccan-Dutch boys reported higher levels of exposure. In addition, these differences in exposure were of sufficient magnitude to partially explain the observed differences in levels of violent offending between Dutch and Moroccan-Dutch boys. A focus on both ethnicity and child abuse serves as a fertile ground for improving theory and research on juvenile delinquency. Cultural norms and values may serve to differentially expose adolescent boys to the consequences of child abuse. This information is essential for formulating proper intervention strategies to neutralise the consequences of child abuse.

Cultural priming effect in categorisation and evaluation of lies and truth-telling for antisocial and prosocial purposes
Ching-Man Lai Chinese University of Hong Kong, Hong Kong

While artificial lies told to benefit oneself at the expense of others are commonly regarded as undesirable, the evaluation of lie-telling behaviours for antisocial and prosocial purposes varies across sociocultural contexts. Previous studies revealed that the Chinese considered prosocial lie-telling less reprehensible than their Western counterparts. This study examined (1) the causal role of cultural knowledge on moral evaluation of lie- or truth-telling using cultural priming, and (2) the role of self-construal and social attribution in the process through which culture influences our moral evaluation of lie- and truth-telling. About 120 Chinese bicultural undergraduates were randomly assigned to the American culture, Chinese culture, or neutral priming conditions. The ambiguous social evaluation task tapping on participants’ social attribution tendency was administered followed by the Twenty Statements Task measuring one’s definition of self-construal. Participants were then requested to read twelve vignettes in which a protagonist either lied or told the truth to conceal/ confess one’s misdeeds/ good deeds, identify whether these statements were lies, and evaluate how “good” they were. The results showed that the Chinese culture primed group was more likely to honour modest lies than the American culture primed group. This study was among the first to demonstrate how moral evaluation about lying can be manipulated through activating one’s cultural interpretative frame. Findings of this study have shed light on inter- and multi-cultural communication about the desirability to tell the truth in a situation of modest-honest dilemma.

Cultural difference in the effect of paradoxical framing on creativity
Shyhnan Liu ICID National Cheng Kung University, Taiwan, R.O.C.

This study tests a cultural moderation model of the enhancement effect of paradoxical mindset on creativity. Previous studies proposed that the adoption of paradoxical frames, mental templates that encourage individuals to recognise and embrace contradictions, increases creativity. This paradoxical relationship creates a sense of conflict in individuals and enhances their ability to integrate contradictions, which in turn increases creativity. One of the fundamental aspects of Chinese naive dialecticism, according to Peng and Nisbett (1999), is the acceptance of apparent contradiction. The person with dialectical views attempts to reconcile the opposing propositions, and produces less sensitivity to contradiction. We argue, therefore, that dialectical reasoning should result in East Asians experiencing conflict less, thus engaging in integrating complexity less frequently than Westerners. In four laboratory studies, using different creativity tasks and different manipulations for eliciting paradoxical frames, participants who adopted holistic thinking (classified by cultural priming or holistic/analytic thinking styles test, Choi et al., 2007) were less creative than their counterparts who are analytic thinkers. Our results show that when primed with a paradoxical frame, dialectic thinkers neither experience a sense of conflict (study1,3) nor are they motivated to integrate contradictions (study2,4), thus they do not enhance creativity as analytic thinkers do. The paradoxical framing on creativity is culturally moderated.

Psychology Down Under: An indigenous orientation in New Zealand
Angus H Macfarlane University of Canterbury, New Zealand; Sonja Macfarlane; Catherine Savage; Angus Macfarlane

Research quality is multidimensional in form and often involves weighing up a balance of different concerns and approaches. For example, for any particular study, the issues of appropriateness of methods involve negotiations and choices among reliability, generalisability and validity. The literature around methodology that comes from traditional (conventional Western) streams, and Indigenous Research (IR) streams, are often perceived as incompatible – are not in balance. New ideas and new directions for research, such as IR, tend to lure researchers toward misconceptions about what IR stands for, philosophically as well as scientifically. Indigenous practices too are often dismissed as lacking rigour on account of being low on evidence. This presentation will challenge that thinking, and affirm a set of changing conditions in New Zealand – where traditional approaches and Indigenous Maori approaches are placed on a more equal footing.

The relationship between rock music and depression in adolescents
Daniel Martinez Carlos Albizu University, Puerto Rico; Lisandra Gonzalez-Ramos; Cesar Melendez-Villagies; Daniel Martinez-Ortiz

Music is one of the most effective ways of transmitting messages, emotions, and ways of thinking about the most mundane situations. It has been said that music is good for balancing one’s emotions, while others say that it causes behavioural problems in listeners. Anderson, Carnegy y Eubanks (2003) found that music videos with a high content of violence negatively influenced adolescents. It was also stated that the majority of adolescents did not pay attention to the lyrics of the song. The current investigation explored the relationship between rock music and depression in adolescents. The Beck Depression Inventory was used to measure the relationship. Results revealed a negative correlation between rock music and depression. It was hoped that by identifying the factors related to depressive symptomatology in adolescents, the family therapist would be able to promote healing in the family. Similarly, a content analysis was utilised based on quantitative and qualitative techniques with the goal of identifying the psychological contents of the lyrics in reggaeton music. A chi squared data analysis revealed 6 different psychological themes which will be presented to the audience in spoken and musical forms.

Respectful partnerships between Australian psychologists and Aboriginal people
Stephen Meredith Department of Health, Australia; Yvonne Clark

Australian Aboriginal people have experienced a long history of dispossession and oppression as a consequence of European colonisation. These experiences have resulted in a disproportionate burden of social and emotional distress amongst Aboriginal people. Because the number of Aboriginal Psychologists in Australia is currently disproportionately low, it is necessary that non-Aboriginal Psychologists play a role in providing services to help Aboriginal people in healing. In order to be effective, these services need to be delivered by culturally competent Psychologists, who are able to provide a culturally safe environment for Aboriginal people. Our experience provides evidence that this can best be achieved when non-Aboriginal Psychologists in these roles develop and maintain respectful partnerships with Aboriginal people. In this presentation, we describe a range of respectful partnerships exemplified through our own experiences and through a case study of a community mental health organisation in which partnerships were developed at a number of levels. We discuss the nature, development and maintenance of these partnerships over time and present data on their effectiveness in creating a culturally safe service. We conclude that, when non-Aboriginal psychologists take responsibility to develop respectful partnerships with Aboriginal people, it is possible for them to play a part in healing some of the damage that has been done to Aboriginal people by the process of colonisation.
Gender and other differences in the experience and coping with jealousy in intimate relationships
Sikhumbuzo Mfusi Walter Sisulu University, South Africa; Mags Bekinska

Jealousy is the emotional reaction to a perceived threat to an existing relationship. It becomes a possible reaction when a person believes that some other interest may seriously detract from the relationship or replace it. Typically, jealousy is created by the perception that one’s partner is attracted to someone else. Factors that are believed to be responsible for the existence of jealousy in a relationship include the self-esteem of the jealous partner. In addition, feelings of inadequacy in a relationship, dependency, and sexual exclusivity have also been related to jealousy. The experience of jealousy is a complex psychological process which involves several components such as the perception of a threat in an existing relationship as well as the severity of that threat. This paper presents the results of a study that was conducted using one hundred male and female undergraduate students. The criteria for selection was that participants were involved in a romantic relationship. A questionnaire was administered which contained items measuring the conceptualisation, experience and coping with jealousy in a relationship. Data were analysed quantitatively, and the results are discussed in relation to other studies involving the phenomenon.

An exploration of South African Muslim general practitioners’ perceptions of mental illness
Zaakiyah Mohamed University of the Witwatersrand, South Africa; Sumaya Laher

General practitioners (GP’s) are often the first point of entry when seeking medical treatment. They are responsible for treating members of the community of entry when seeking medical treatment. They are General practitioners (GP’s) and thus their understanding and conceptualisation of mental illness needs to be addressed. Furthermore, based on the above themes it can be concluded that socio-cultural factors as a predictor of reoffending while increasing health inequalities and social exclusion (Sindfield et al., 2009; Social Exclusion Unit, 2002).

Socio-cultural mediators of help-seeking for mental health difficulties in black or ethnic minority ex-offenders
Danielle Oliver Newman University College, United Kingdom; Keva Reid

This is an exploratory study to examine the reasons that may contribute to black and minority ethnic (BME) ex-offenders’ poor engagement with the mental health services. Brinded et al. (2001) puts forward that despite experiencing mental health difficulties this group refrains from help-seeking.

The aim of this study was to explore the issues related to help-seeking behaviour both in terms of past behaviour and future intent. The participants were five males and one female, with an average age of 44 years. The inclusion criteria were: previous offending history, BME origin, and an experience of mental health difficulty. Semi-structured interviews were conducted, transcribed and subsequently thematically analysed. The analysis revealed socio-cultural factors as a predictor of help-seeking. This theme was inclusive of factors such as religion, racism and discrimination, attitudes of friends and family and stigma. In most cases each of these factors negatively influenced help-seeking. The exceptions included family attitude and religion which were at times supportive of help-seeking, however this varied across participants. There are implications for understanding and improving the services for BME ex-offenders to decrease reoffending while increasing health inequalities and social exclusion.

Community factors and youth substance abuse in South Africa
Neo Morojele Medical Research Council, South Africa; Judith Brook; David Brook; Elizabeth Rubenstein; Chenshu Zhang

Substance abuse among young people in South Africa is a growing concern. The aim of the study was to examine the role of community and individual factors in adolescent substance abuse among a sample of South African adolescents from three cities: Durban, Cape Town, and Johannesburg. The participants comprised 2,195 adolescents aged between 12 and 17 years (mean age=14.6; SD=1.8). Just over half of them (54.3%) were female. The participants were recruited via a multi-stage stratified sampling procedure, and interviewed in their homes. Structural equation modelling was used to analyse the interrelationships between cultural factors (violent victimisation, and legal and illegal drug availability), personal factors (depressive symptoms, low self-esteem, and health problems) and cigarette smoking and alcohol use. The results indicated that cultural factors were both directly and indirectly associated with both alcohol and tobacco use. The association between cultural factors and alcohol and tobacco use was mediated by the personal factors. In addition, there was a significant association between smoking and alcohol use. The findings suggest the need for both community and individual level interventions to address substance abuse among young people in South Africa.

“Inzilo (mourning) is not what you wear”: Discourses of mourning among rural and urban amaXhosa in the Eastern Cape
Hlonelwa Ngqangweni University of Fort Hare, South Africa

Mourning is a universal practice following the death of a significant other, but is culturally specific. Among amaXhosa the death of a person is marked by a tradition called ‘ukuzila’ – the Xhosa equivalent of the mourning process. The discriminatory nature of the practice and some of the detrimental effects to the widows’ health and safety is well documented, but the reasons for its continuity remain largely unexplored. Taking into account the fact that culture is not “homogenous but always exists in situated, dynamic, largely subjective, versions, and hence is always in tension...constantly in a process of being constructed and reconstructed” (Geertz,1973, p. 29), this paper explores the discourses deployed in men and women’s constructions of ‘ukuzila’ specifically focusing on spousal mourning. It is argued that it is these discourses that sustain the practice in spite of the recognition of its discriminatory nature and its detrimental effects to the widows’ health and safety. The research was conducted through focus group discussions held with younger and older urban and rural men and women, as well as interviews held with widows and widowers and key cultural informants. Key discourses identified were the familial – ‘ukwenda’, ‘lonhipha’/respect, and male sexual drive discourse. The positioning of men and women within these discourses is also examined.

Psychology of a community that hides behind trees
Minati Panda Jawaharlal Nehru University, India

The present paper studies through the folklore and the contemporary folk narratives (obtained through interviews) of a tribal community called Saora (an oral tribe that lives in the Southern part of Odisha, India), the impact of new contacts, institutions, modern artifacts and concepts on their mind and subjectivity. The paper critically analyses one cultural concept called Saora that combines two words, Sa and Ra: Sa means behind and Ra means tree, and locates it discursively in a web of concepts called Yama, ganru, danton etc., that together shape the consciousness of Saoras and their actions. Analysis of the Saora narratives reveal how Saora becomes an ontological category with the help of other related cultural concepts and metaphors like Yama, ganru, danton etc. These folkloric subcategories stay deep in their self and construct their collective consciousness. The belief that they are a community that hides behind trees is so ingrained in Saora mind that it predisposes Saora children and adults to participate and act in certain ways in modern institutional spaces of school, college, health services and other developmental projects. In fact, the Saora children’s relatively poor success in school education as shown in our MLE data can be explained by these psychological phenomena. Vygotsky’s cultural historical psychology and the postcolonial theory of Franz Fanon are used to discuss why proximity breeds fear in these societies, how these values and beliefs evolve historically and are embodied, and how the modern democratic institutional practices sustain these discursive and embodied selves.

The psychology behind skin bleaching in Jamaica
Petra Robinson Rutgers University, United States of America

Slavery and colonialism’s remnants and legacies are well documented in postcolonial and social sciences literature. Notably, the oppressive and dominant nature of slavery and colonialism taught subjugation, and racial and social discrimination in multiple ways. Within the context of Jamaica, a small island nation
with a history of colonialism and slavery, Eurocentric values, including light skin color as an indicator of beauty, sit within a space of privilege. This paper presents the findings of a qualitative research study which sought to examine the psychological and socio-cultural factors that influence the practice of skin bleaching in the postcolonial society of Jamaica. Additionally, the study outlined the nation’s efforts to combat the skin-bleaching phenomenon. The study explored how Jamaicans perceive light skin color as a form of social capital, how their history influences this perception, and how various elements of culture promote stratification based on skin color. The findings, based on 15 in-depth interviews, describe efforts to negotiate, manage, and attain this social capital, particularly evidenced by the practice of skin bleaching. Through skin bleaching, individuals seek to improve beauty and obtain this capital (light skin), and make efforts to convert it to other kinds of capital and thus increase social standing and other opportunities. This study also examined the community education campaigns and the perceptions of these education efforts as a national adult education strategy.

Experiences of emotional distress and strategies of coping for Xhosa women in a South African township
Sarah Rubin Case Western Reserve University, United States of America
Life in a township near Cape Town, South Africa includes many hardships and reasons for emotional distress. For Xhosa mothers with young babies, these hardships may be intensified or more difficult to cope with, at least that is what current psychology research on perinatal mental health leads us to expect. Psychological anthropology approaches human suffering from a local, subjective, cultural perspective, asking, “How do people in a specific cultural community experience, narrate, and derive meaning from their everyday lives?” Ethnographic, qualitative interviews and home/community observations of 40 Xhosa mothers over an 18 month period illuminates a culturally and contextually unique engagement with suffering that minimises personal anguish while strengthening social bonds. These Xhosa mothers perceive the hardships of their daily lives as part of a community of suffering and find personal strength and relief in this communality and perceived normality. This paper discusses some of the experiences that Xhosa mothers find emotionally distressing and how they successfully cope, or struggle to cope, with their suffering. Through this discussion, we can gain a better understanding of how Xhosa women who are distressed and struggle cope with hardship, can be helped by mental health services and other local resources. It also offers an alternative way of understanding how poverty and culture affect emotional experience, sharpening the tools of psychology to serve humanity in all its diversity.

Psychology of acculturation: New advances and future directions
David Sam University of Bergen, Norway
Psychology of acculturation is a young area within the broad field of cross-cultural and social psychology. Nevertheless, it is the fastest growing area as evidenced by changes in the published articles in journals. The interest and growth of acculturation psychology undoubtedly is in response to the unprecedented increase in worldwide migration and globalisation, and this interest will continue unabated for years to come. As a growing field, the issues being addressed and emphasised are still in flux, and the field is at crossroads in terms of future direction. In particular, the field has received major criticism regarding methodological approaches, such as how constructs should be operationalised, the conceptualisation of central concepts such as acculturation itself, and how to apply research findings to improve the welfare of people involved in acculturation. However, in spite of or partly due to these criticisms, efforts have also been made by many researchers to consolidate and further develop the theoretical grounds and empirical models exploited in acculturation research. It is against this background that this address will be made. The address will review some of the main theoretical perspectives in acculturation research taking the ‘ABC’ of acculturation as a starting point, together with contributions from acculturation and developmental psychologies. Some research findings will also be reviewed and how these can be integrated into a comprehensive theory of acculturation examined. The implications and methodological challenges the new perspectives raise will also be discussed.

Trajectory equifinality model as the tool for depicting chronogenesis in human life
Tatsuya Sato Ritsumeikan University, Japan
Trajectory Equifinality Model (TEM) is a psychological tool of cultural psychology for describing and understanding human life development with in specific time and place. Traditionally, psychologists have discussed the “Nature and Nurture” problem for a long time. Efforts to decide the gravity of relative influence results no answer. Cultural psychologists think that human development is influenced by both factors. Cultural psychologists abandon the simple “cause - effect” way of explanation. Elementalistic causality (factor X causes Y; e.g., “intelligence” causes success in problem solving; or “culture” causes “girls being shy”) is not important for cultural psychology (see Toomela, 2012). Instead, cultural psychologists take system theory seriously for constructing the new methodology. Cultural psychology uses ways of generalisation that are based on systemic analyses of singular phenomena (Valinser, 2003a). TEM is not a technique of psychology. TEM is a methodology of psychology, especially cultural psychology. TEM has many conceptual tools to describe human life course within irreversible time. In the globalisation era, psychology should abandon the ambition to construct general laws of human psyche. Instead, we should describe and understand human life in culture politely. However TEM also aim to general knowledge of human being in culture using the notion of sign. Sign mediated behaviour is a key point for constructing general knowledge. TEM provide the conceptual tools, for example Equifinality Point (EFP) and Bifurcation Point (BFP), for such professional activities.

Barack Obama in Hawaii and Indonesia: The making of a global president
Dinesh Sharma IIICS St Francis College, United States of America
The first 18 years of President Obama’s life, from his birth in 1961 to his departure for college in 1979, were spent in Hawai’i and Indonesia. These years fundamentally shaped the traits for which the adult Obama is noted – his protean identity, his nuanced appreciation of multiple views of the same object, his cosmopolitan breadth of view, and his self-rooted ‘outpost’ patriotism. 'Barack Obama in Hawai’i and Indonesia: The Making of a Global President' is the first study to examine, in fascinating detail, how his early years impacted this unique leader. Existing biographies of President Obama are primarily political treatments. Here, the author, cross-cultural psychologist and marketing consultant, explores the connections between Obama’s early upbringing and his adult views of civil society, secular Islam, and globalization. The paper draws on the author’s on-the-ground research and extensive first-hand interviews in Jakarta; Honolulu; New York; Washington, DC; and Chicago to evaluate the multicultural inputs to Obama’s character and the ways in which they prepared him to meet the challenges of world leadership in the 21st century.

Issues in cross-cultural teams
Yanyang Shi Shanghai Jiao Tong University, China
Ningyu Tang
With the emerging of world economic integration, cross-cultural teamwork is becoming an important part of the company’s daily business activities. In this context, this paper reviewed the current studies on cross-cultural teams, which mainly dealt with three questions. First, what’s the definition of cross-cultural teams? Second, what individual factors and team process factors predicted the cross-cultural team adaptation as well as the cross-cultural team effectiveness? Third, how does information technology change cross-cultural teams? Based on the analysis of the current studies, the authors found the team leaders’ characteristics and the team members’ cultural intelligence together with the mutual trust and communication between the team members would predict the cross-cultural team adaptation and effectiveness. Besides, with the development of information technology, the cross-cultural virtual teams played a more and more important part in today’s organisations.

Culture, family and cognitive behaviour
Aradhana Shukla Kumaun University SSI Campus, India
In recent years the relevance of cultural variables in psychological enquiry is accepted and the quality of pertinent studies is improving considerably. It is supported in these studies that people hailing from an enriched cultural setup have been found to be much better compared to their counterparts living in impoverished cultural setup. Keeping these views in consideration this study was planned and it aimed to find out the developmental patterns of memory and metamemory in tribal and non-tribal children of Kumaun. 200 7- to 12-year-old children served as participants and they were arranged according to the requirement of 5x2x2 factorial design with 5 sub-cultural groups (Bhotia, Tharu, Buxa, Raji and General Kumaun), 2 levels of sex (Boys, Girls) and 2 levels of age (7-9-10-12 years). Measures of metamemory and potential memory were administered on
them and it was found that differentials in metem-memory and potential memory were more pronounced in General Kumauni and Bhotias followed by Tharu, Buxa and Rajis, respectively. In addition, it was found that the metem-memory – potential memory discrepancy was relatively low among older girls. Moreover, findings were also compared with the family climate of the children and it was noted that the family climate of General Kumauni and Bhotia was supportive for their children. Findings were discussed in light of the culture – cognition relationship.

Determinants of organisational development
Anna Smirnova Saratov University, Russian Federation
The search for cultural characteristics of the organisation which determine innovative development is an important scientific problem. We have held empirical research on the results of which the socially-psychological model of innovative culture of the enterprise has been constructed. The method included supervision, interviewing, an expert estimation, an interrogation by special technique which we have created. The empirical basis of the study involved the innovative enterprises created on the basis of higher schools, and traditionally developing large industrial enterprises. Two parameters have been put on the basis of innovative culture model designing: Time and sphere of planning. These two parameters form horizontal levels of models: 1. Level of mission. 2. Level of professional work. 3. Level of current (professional) activity. All three levels of the model have the same cultural characteristics.

How parenting style and family function affect perfectionism in Chinese university students
Shanggui Song University of Jinan, China; Lei Song
Perfectionism is defined as a high standard of performance accompanied by a tendency to critical self-evaluation. According to Frost, maladaptive perfectionism consists of two dimensions: Concern over mistakes and doubt about action. The present study examined the predictive powers of parenting style and family function in the development of perfectionism. 538 university students in China completed the measures of parenting style, family function, and perfectionism. Regression analyses indicated that parenting style such as mother overprotection, father overprotection, family functions such as problem-solving, affective response, denial and rejection were significant predictors of perfectionism in university students. These five factors accounted for 17.1% of variance in predicting perfectionism. The current findings suggested that parenting style and family function play a key role in perfectionism. The results supported the social action model.

Growing up Indian and Hindu in Southern California
Sujata Sriram Tata Institute of Social Science, India; Maryam Aakhte; Mohamad Hosein Fallah; Neda Eshaanashi; Taherreh Moradi
This paper examines how Asian Indian adolescents in San Diego, Southern California, develop an understanding of what it means to be Hindu. The Asian Indian population in the United States is the largest growing ethnic minority group, and is dominated by families of Hindu origin. Interviews with 25 Hindu adolescents indicated that there was a conflation of the Indian and Hindu identities. Most families had a temple corner or shrine in the house, with statues and pictures of popular Hindu deities. Festivals were celebrated with vigour in the families, and family membership in religious organisations helped children understand the nuances of being Hindu in a culture dominated by the Judeo-Christian ethic. The presence of Hindu temples in the city helped provide the spiritual connection that migrant populations seek in an alien culture. Celebration of religious festivals with other Hindu families helped children understand what it meant to be Hindu. Religious instruction was provided through weekend programs for children and youth, organised to instruct them on the details of being Hindu, using stories and myths from Hindu epics and scripture such as the Mahabharata, the Ramayana and the Bhagvad Gita. Participation in religious functions provided the opportunity for social interactions for families. While children took part in religious ceremonies and events, their knowledge about the ceremonies varied. It was seen that when children entered high school, their participation in religious activities declined.

Emotional expressions of Chinese people in Batam Island, Indonesia
Wills Srisayekti Padjadjaran University, Indonesia
Chinese is one of the majority ethnic groups in Batam Island, Indonesia. The social history experienced by the members of this ethnic group in Indonesia has influenced their emotional expressions, particularly in the public domain. Earlier empirical findings reported that their idiosyncrasies of emotional expression often provoked misunderstandings and precipitated interpersonal conflicts in their interpersonal relationships, in particular with other ethnic groups. This study was aimed at revealing emotional expressions of the Chinese people, and comparing them to those of non-Chinese people in Batam Island. Adapted self-report questionnaire Display Rules Assessment Inventory (DRAI) developed by Matsumoto & Yoo (2007) was administered to 195 Chinese students (99 males, 96 females) and 160 non-Chinese students (80 males, 80 females), age 16-18 years, in Batam Island. The results describe the similarities as well as the differences between the emotional expressions of 7 basic emotions in public and private situations, displayed by Chinese and non-Chinese students.

Impact of globalisation on young Asian Indians
Sonia Suchday Yeshiva University, United States of America
Globalisation in emergent economies like India necessitates adaptation to socioeconomic and cultural changes in the social infrastructure similar to acculturation. However, research on the meaning and impact of globalisation is limited. College students from Mumbai, India (N=56, Age=19yrs, 95% Female) responded to open-ended questions about changes in their culture as a result of globalisation. Two independent raters identified common themes in participants’ responses and three additional raters grouped similar themes together. Each theme became an item on an Impact of Globalisation scale. Principal component analysis computed on 211 participants’ (42 Male, Mean Age = 18.65 years) responses to items on a 4-point Likert scale (Range: 1=Almost Never to 4=Almost Always) showed four factors comprised the scale: Sociocultural Changes (Internal Reliability (IR)=.95), Increased Unhealthy Behaviors (IR=.84), Materialism (IR=.61), and Deterioration of Traditional Values (IR=.70). Factor scores were negatively related with self-rated socioeconomic status (SES; r=-.20, p

Culture and expertise of citizens in criminal information processing
Shinkichi Sugimori Tokyo Gakugei University, Japan
Judicial information processing is supposed to be aligned to expert legal reasoning. Azuma(2000) has compared responses of Japanese and U.S. students to a simple question: “Student A has intentionally injured teacher B. Is A guilty or not guilty?” Most American students have answered “guilty, since the student’s deed was intentional and the teacher was actually injured,” whereas the majority of Japanese students answered “this information is not enough to make appropriate judgment, because the teacher might have invoked the student’s aggression.” Responses to the next question about “what kind of information is necessary to make firm judgment?” have shown strong cultural difference. The American students required legally appropriate information such as the age or past criminal deed of A, while the Japanese students asked about what A was feeling when he was injuring the teacher, and how he is currently feeling. Azuma(2000) has concluded that American students has processed the criminal information through “courtroom metaphor”, while the Japanese students has “family member metaphor”, just as if A was part of their family. This study has compared the Japanese lay and expert cognition of criminal act using the same procedure of Azuma (2000). Participants consist of three types of different degree of expertise in legal judgment: lay persons, graduate students with some legal knowledge, and legally trained expert graduates. The result has revealed strong reliance of lay persons to family member metaphor, and expert students’ strong reliance to courtroom metaphor.

Effective leadership factors and successful school development: A case study
Hechuan Sun Shenyang Normal University, China
In changing our schools, school culture plays a powerful role. To build up a strong and powerful school culture, an effective leadership is needed. However, what are the effective leadership factors that may help to build up a strong and powerful school culture in which teachers’ instructional quality, students’ learning and psychological development, school’s quality may have the possibilities to be enhanced? This paper presents a remarkable case study on how to change the school culture of a failing rural school, named Dulangkou Junior Secondary School (DJSJ) in Shandong Province in the northern part of China, into a successful one (over 250,000 visitors have visited this school by the end of 2011; it is now called the Dulangkou Model) by the Ministry of Education in...
China). This paper focused on finding the effective leadership factors for shaping and reshaping a school’s culture, for students’ learning and development, and for improved classroom instruction. Hofstede’s model and organisational theories were used to analyse the Dulangkou Model. As a case study, it describes the cultural reshaping process and school improvement process of DJSS. The paper carefully analyses the major factors that influenced the changing and cultural-reshaping process of DJSS. The most valued personalities of the school Principal, Qisheng Cui, are also presented in this paper.

The adaptation of global employees in China: The effect of cultural intelligence and acculturation strategy
Nguyu Tang Shanghai Jiaotong University, China; Bo Zhu
In the past 20 years, China has attracted many multinational companies to invest, or set up their subsidiaries, in this emerging economy, which brings many foreigners to work and live in China. Previous studies show that while cultural diversity will be good for flexibility, innovation, creativity and decision-making (McLeod, Lobel & Cox 1996; Leung et al., 2008), dual-cultural working and living experience will cause some negative psychological results (Tang et al., 2010). This paper aims to study how cultural intelligence (Earley & Ang 2003) and acculturation strategy (Berry 2003) will affect global employees’ adaptation. The study surveyed 134 global employees (77 male, 57 female, 70% of them having been in China more than 1 year) with cultural intelligence, acculturation, cultural distance and adaptation questionnaires. By using hierarchy linear regression, the results revealed that (1) After controlling age, time in China and language, cultural intelligence had signiﬁcant relations with psychological and socio-cultural adaptation of global employees in China; (2) The group with high acculturation with both home country and China; (3) Cultural distance moderated the relationship between cultural intelligence and socio-cultural adaptation which means that the bigger the distance between global employees’ home culture and Chinese culture, the more signiﬁcant the relationship between cultural intelligence and socio-cultural adaptation; (4) In the group with low acculturation with Chinese culture, those with higher cultural intelligence adapted to the Chinese situation better.

Cross-cultural context of stress-coping research
Kryukova Tatiana Kostroma State University, Russian Federation
This work explores the possibilities and obstacles of an inter-cultural dialogue in three sample populations: Russians, West and East Europeans (French, German, Czechs and Poles). The inner and outer groups have been analysed through the main variables of social representations and attitudes, measured by coping scales (CIS, WCQ), E. Bogardus Social Distance Scale, and psychosematic methods. The findings show that Russians are facing psychological difficulties: their values and goals were previously collectivistically-oriented, but they have to join individualistic cultural values and norms more and more often today. Modern Russian mentality turns out to be rather indifferent to “others” (especially far distance is measured between Russians and Poles, Russians and Czechs – representatives of those cultures who shared the same historical, ideological background – socialism – 20 years ago). This could be a manifestation of post-totalitarian efforts to separate, defending national interests and values, partly unconscious. The main coping strategies in the Russian sample are ambivalent: problem-oriented coping is thoroughly combined with seeking social support and collective coping. The data show a non-productive way of identifying “others” and a collective Self in Russia which simplifies the processes of social perception, enhances other cultures’ stereotypical images, and deforms reality. Some differences between auto-and hetero- stereotypes as a barrier to a true inter-cultural dialogue are deﬁned. Fortunately, a great number of similarities in social representations of the younger part of the sample – students – may serve as a resource of coping with cross-cultural difficulties.

Addressing mental health needs across borders
Pernille Terlange Department of Psychology, Denmark
It is widely accepted that psychosocial support interventions in post-disaster settings need to be culturally appropriate and sensitive. This paper presents an exploration of what cultural sensitivity means in practice, and how it is interconnected with perceptions of coping and resilience. I advocate for the use of cultural historical and socio-ecological approaches to developing appropriate interventions, based on my research data from the Dominican Republic and Haiti, working with Haitian children and their families who were evacuated to the Dominican Republic for medical emergency treatment after the earthquake of January 12, 2010. The presentation also draws on a literature review of the cultural-historical relationship between Haiti and the Dominican Republic.

Predictability of interpersonal problems from the frustration among Mizo exposed to immigrants
Zokai Thaugli Mizoram University, India
This study investigated the impact of intercultural interaction. The predictability of interpersonal problems, from regression, fixation, resignation, and aggression of the frustration subscales due to the pressure experienced by the Mizo exposed to immigrants was determined. In all, 2x2 factorial designs (2 insurgency (participated as insurgent and non-insurgent) and 2 fatal experience (experienced fatal episode and non-experienced)) were employed, and an equal number of 50 participants each who were exposed to immigrants completed the measures to assess predictability of interpersonal problems and frustration scales. Results showed that frustration experienced emerged to be positively related to interpersonal problems, and frustration significantly predicted the interpersonal problems by the Mizo. The findings suggest that the consequences of intercultural interaction can be predicted from frustration experienced by the interacting cultures.

The Devadasi system and its impact on their children
Shwetha Tumkur Shivakumar S.D. M. College, India; Manjula M.Y. S.D.M. College, India
The Devadasi system has existed in India for centuries. It is the practice of ceremonially offering an unmarried girl as a wife to god. Over a period of time this has become nothing more than commercial sex work in the name of god. Children born to such mothers bear the stigma of being ‘Devadasi’s children’ and lack a father figure. These children are often looked after by their grandparents or care-takers because most of them can’t stay with their mothers. These children miss out on parental care and guidance during crucial periods of their development. We need to understand these children’s feelings, their opinions about this practice and its impact on them. A purposive sample of three boys and four girls was selected. Unstructured interviews were used for data collection. Most of them report that the children got to know that their mother was a devadasi around the age of 10 years and they felt very sorry about it. They don’t blame the mother as they perceive her to be a victim of the system. Themes that emerged in the discussion are these: The children do not want to be labelled as ‘Devadasi’s children’, they want this system to be eradicated, and they get perturbed if people ask them about their biological family. Neither the boys nor the girls want their family members to become Devadasi and they feel that it is an oppressive practice. It is certain that the younger and disapp-proval towards the society that is responsible for their current downtrodden status.

Perceptions of an older adult’s cross-cultural population on adjustment to aging, age representation and subjective age: A multiple correspondence analysis for latent constructs
Sofia Von Humboldt ISP, Portugal; Isabel Leal
This presentation investigates latent constructs that can act as major determinants in the adjustment to aging (AtA), age representation (AR) and subjective age (SA), and to explore relations between these constructs in an older adults cross-cultural population. Measures were completed using a variety of culturally appropriate methods, including demographics and interviews. Complete information on 33 older adults aged between 74–101 years (M = 86.2; SD = 5.4) from eight different nationalities, was available. The data were subjected to content analysis. Representation of the associations and latent constructs were analyzed by a Multiple Correspondence Analysis (MCA). Standardised instruments measured regular cognitive abilities. Findings showed a model for each pre-category. SA was explained by a two-factor model: ‘age-cautious’ and ‘young-at-heart’. A three-dimension model formed by ‘maximisers’, ‘optimisers’ and ‘essentialists’ was indicated as a best-fit solution for AtA, and AR was best explained in a three-dimension model by ‘past-oriented’, ‘present-orien-ted’ and ‘future-oriented’. AtA is shown to bear associations with individuals’ SA and AR in a model composed by ‘enjoyers’, ‘engaged’, ‘regardful’ and ‘conciliated’. AtA is therefore related to SA and AR in older adults. Enhancing AtA on shared perceptions of SA and AR might be an important target to improve older adults’ interventions’ outcomes in aging well.
Cultural narratives in TAT responses: A thematic analysis of stories told by Mamelodi adolescents.

Theunis Vorster
University of Pretoria, South Africa; Ilse Ruane
Delivering psychological services in a culturally diverse society like South Africa, demands understanding how cultural narratives influence the tools used by mental health practitioners. In South Africa, where a large portion of the population live in townships, it often happens that professional and client do not share much of a cultural context. Cultural knowledge is pertinent to generating a complex and thorough interpretation of assessments. The aim of this study was to explore possible cultural narratives evoked in the responses to the Thematic Apperception Test (TAT) so that cross-cultural use of the test would be more effective in the Mamelodi township. The research was done from a narrative point of view; the idea that lived experience is understood by organising it into structured narratives or stories that repeat throughout an individual’s life. The pictures of the TAT were viewed as a context that could elicit such life narratives from respondents. TAT stories from five adolescent residents in Mamelodi were thematically analysed as a method of identifying common stories that could be reflective of the cultural narratives that young persons in Mamelodi draw from, to make sense of their world. The results indicated common narratives concerning the following: The experience of violence; the experience of close relationships; dealing with challenges; and the role that clothes play. It is suggested that these findings, and findings from similar future research, might aid psychologists towards a better understanding of the TAT in the township context.

Using virtual reality exposure therapy to treat test anxiety: A pilot study

Guangxin Wang
Beijing Forestry University, China
Virtual reality exposure therapy (VRET) is an altered form of behavioral therapy and may be a possible alternative to standard in vivo exposure. Test anxiety has become a highly frequent problem in our society. The study aims to explore the effectiveness of a set of virtual reality environments for emotionally significant responses in Chinese students with high level of test anxiety. Thirty students with high test anxiety participated in the study and were randomly assigned to imagination exposure group, virtual reality exposure group and waiting list group. Test anxiety was measured pre-treatment, post-treatment and at a three-month follow up. The improvement achieved using virtual reality exposure was superior to a WL and similar to that achieved using Velour. Results support the efficiency of VRET for the treatment of test anxiety.

Emerging issues in ethics in Africa

Douglas Wassenaar
UKZN, South Africa
Efforts to develop and institutionalise psychological ethics in Africa have been varied. There have been international efforts to improve research ethics capacity, and these will be outlined in brief. Given the poverty levels, cultural differences, and the call for mental health research in many areas of Africa, the need for attention to cultural issues in research ethics is increasing. This presentation will discuss some of the unique ethical features associated with research in Africa, with special attention given to the South African context.

Producing films that teach cross-cultural concepts

Mary Ann Watson
Metropolitan State College of D., United States of America
Professors of social and clinical psychology attempt to find supplemental materials to demonstrate, in the classroom, many psychological constructs. Particularly challenging, is material that illustrates cross-cultural differences and similarities. This presentation will feature three presenter-produced videos with an accompanying Instructor’s Guide that serves in this capacity. Film footage of college students and faculty was collected at the University of Axum in Ethiopia and then matched with similar footage in Denver, Colorado. The same number of students and faculty from each institution were matched by age and educational attainment. The ongoing principle guiding these video projects, is to provide college and university students with dynamic slices of real life experience in disparate cultures. Core concepts provide insight for the following questions: What makes United States and Ethiopian students happy? What constitutes a “meaningful life” in both cultures? How do these two cultures differ on Hofstede’s “Five Dimensions of Culture”: Individualism/Collectivism, Masculinity/Femininity; Uncertainty Avoidance; Power/Distance; Long-term/Short-term Orientation? Findings reflected in the film footage indicate differences on certain constructs, and similarities on others. This presentation will be led by the psychologist/senior producer and the series videographer. Discussion will include videographer input on the richness and difficulties in cross-cultural filmmaking.

The unifying psychology in China makes a positive contribution in art

Zhong Weidong
The Unifying Psychology Work shop, China
Art represents a combination of sincere, true feelings, relaxation and basic skills. Kinds of elements (space, shapes, colors, sounds, etc.) in events causing physical pain and emotional hurt can leave traces in people. Due to the stimulation caused by these elements, an artist won’t necessarily produce a relaxed, cheerful, beautiful and natural emotion when they face the same or similar scene. For instance, an injury from the foetus period will last long with and be represented with black. This connection is drawn between black and physical pain. Therefore, in tradition, people recognise the common concept, “away from black, towards the light.” This will greatly block the artist’s creativity to express feelings with these stimulating colors or shapes. The Essence of Beauty is, however, not concerned with physical pain or emotional hurt or anything of lower self-awareness. The Unifying Psychology in China is thus dedicated to help artists to eliminate influences from injury or accident, to restore their natural, true, beautiful feelings to natural objects.

Towards a practitioner’s cultural empathy and humility: Exploring postmodern methods for engaging with indigenous Australians

Arthur Wouters Tabor, Victoria, Australia
What opportunities exist for perspective transformation relevant to training future practitioners? How can students of psychology and psychotherapy experience their own biases and presuppositions and engage vitally with Indigenous Australians and different cultural views in a cross-cultural setting? Can a structured field trip create the necessary dissonance to develop cultural empathy and humility? These questions shaped this exploratory study which drew upon applied elements of Jack Mezirow’s (2000) theory of perspective transformation, Reuven Feuerstein’s (1990) theory of Structural Cognitive Modifiability and Mediated Learning Experience, and the adoption of a postmodern form of inquiry associated with Narrative Therapy (White, 2007) and Collaborative Therapy (Anderson, 2007). A group of 16 Melbourne based Psychology and Counseling students were prepared through a series of readings to provoke dissonance, personal reflection and dialogue. They subsequently met in Darwin, the capital of the Northern Territory for a week long series of structured live-in experiences which involved their being paired up with other practitioners who worked with Indigenous Australian young people. This period of experiential learning was punctuated by collaborative reflective activities involving the coordinators and local practitioners using methods adapted from the Narrative practice of Definitional Ceremonies (White, 2007) and Collaborative Therapy’s practice of Triologues (Wagner, 2007). Various qualitative indicators suggesting perspective transformation are presented in this paper by way of readings from collective documents and documented testimonies.

Cross-cultural adaptation of South Korean students in China

Wenhua Yan
School of Psychology and Cognit, China
The objective of this research is to explore cross-cultural adaptation of South Korean students in China. Both qualitative and quantitative methods were used. In the qualitative study, 10 South Korean students in China were interviewed individually. Grounded theory was used for qualitative data. Results showed there were some factors affecting students’ adaptation, such as motivation for coming
to China, preparation, host language competency, self efficiency, personality, perceived social support, adaptation strategy, and their perception of Chinese students, as well as perceived Chinese society and environment. For quantitative research, 151 South Korean students from four cities (Shanghai, Beijing, Guangzhou and Chengdu) in China answered a questionnaire. Correlation and regression analysis results showed that there were positive correlations among psychological health, life satisfaction and socio-cultural adaptation. In four cities, students’ socio-cultural adaptation in Beijing was significantly better than that in Shanghai and Chengdu, while their socio-cultural adaptation in Shanghai was significantly better than that in Chengdu. Students’ emotional stability, culture empathy and openness were positive indicators of psychological adaptation and flexibility was a negative indicator of psychological adaptation. Openness was positive indicator of life satisfaction, and flexibility was negative indicator of life satisfaction. Host language competency, cultural empathy and departure knowledge were positive indicators of socio-cultural adaptation.

What makes people happy and what makes them unhappy?: A cross-cultural qualitative study on the sense of happiness

Oyama Yasuhiro Kyoto University, Japan; Masuo Koyasu

This study involves cross-cultural qualitative research on subjective well-being. It aims to determine the psychological components of happiness and unhappiness with regard to people in different countries. In a study on happiness, conducted by a group of psychologists from Kyoto University, over 8,000 respondents from 13 countries (seven languages) were required to complete a sentence-complementation test (SCT) via the Internet. The questions pertained to what makes them happy, what makes them unhappy, and how they define happiness. The collected data were translated into Japanese and were analysed through text mining and category coding methods. In order to determine cross-cultural differences accurately, results from seven countries, including South Africa, were discussed in depth. The result shows that the component factors of the sense of happiness are different from those of the sense of unhappiness and that the definition of happiness does not always correspond with the sense of unhappiness. Some findings with regard to the interdependent self-construct in East Asian cultures were also discussed. For instance, the Japanese sense of happiness is strongly affected by the relationship with the generalised others, and participating in an activity with others is considered more important than merely being together. The overview of the differences between people of the seven countries highlights the need for a more comprehensive framework that can facilitate the understanding of cross-cultural issues beyond ones understood between groups of a dichotomy such as Europe and North American versus East Asian cultures.

Dealing with cultural conflicts: In case of Asian international students in China

Wang Yujue East China Normal University, China

This study aims at exploring how Asian international students in China deal with cultural conflicts. Qualitative methods were used. There were 5 students from Japan, Korean, Malaysia and Vietnam interviewed (4 males and 1 female). The interview time lasted from 1 hour to 1.5 hours, and each interview text contained an average 150,000 words. Based on the Grounded Theory, data were analyzed with Nvivo8. Eight categories were discerned, and they could be divided into three levels: behaviour changes, cognitive adjustments and emotional reshaping. The model was named the Conflict Resolution Model. The main information derived from this model was: From a cognitive aspect, people identified conflicts, processed conflicts, and then developed diversity perspectives to deal with differences. From the behavioural aspect, people experienced three stages of avoiding conflicts, resolving conflicts and after-effects. From the emotional aspect, people lost the self-efficacy to cope with conflicts, and then retained it. Compared with the existing theories of intercultural conflicts, cultural distance might affect the conflict-reaction mode and when the host country belonged to the same cultural circle of the original country; people experience fewer conflicts in such cases. Based on these findings, it was suggested that the foreign students developed multiple perspectives to deal with cultural differences and to establish Conflict-Coping-Efficacy, rather than just to be told what’s right and how to do it. The limitation of the study is the small size of respondents, which means it’s hard to identify the differences between nationalities and sexes.

The relationship between Innovation Culture and Transformational Performance of small and medium firms in China

Wei Zhang Hangzhou Dianzi University, China

Previous studies have found a positive effect of Organisational Culture on organisational performance. The aim of this study is to probe the structure of Innovation culture by means of Exploratory Factor Analysis (EFA) and Structural Equation Modelling (SEM) and then discuss the relationship of Innovation Culture and Transformational Performance with SEM. Using empirical results from a sample of 175 Chinese firms in a period of transformation, the study identifies the conception model of Innovation Culture by means of EFA. Innovation Culture is made up of six key elements in the Chinese cultural context: namely, market-oriented organisational change, participation in decision making, leading action, sharing in collaboration and risk-taking. The results show that the six structural characteristics of Innovation Culture have a significant positive effect on transformational firms’ Innovation Performance, Competitive Performance and Potential Performance. The results also show that Innovation Culture has a significant impact on the ways of Organisation Innovation Adoption. Therefore, the study points out that Innovation Culture has a remarkably positive effect on Transformational Performance.

Recognition of emotional facial expressions of varying intensities: An American-Chinese comparison

Fang Zhang Assumption College, United States of America; Xiao Ang Wan; Sarah Cavanagh; Maria Parmley

Although the recognition of facial expressions such as anger, sadness, and happiness has been considered universal, recent research suggests that differences in cultural nuances promote an in-group advantage in the recognition of these expressions. The present study examined this among Chinese and American judges. These two cultures differ in values, customs, and conduct rules—while Americans value self expression and tend to be expressive in showing emotions to others, Chinese value restraint in expressing emotions in social situations and tend to be less expressive in showing emotions. These cultural differences in social experience suggest differences in recognition of facial expressions over and beyond the in-group advantage. 194 American undergraduates and 213 Chinese undergraduates viewed and labelled angry, sad, happy expressions of 15%, 30%, 45%, 60% and 75% intensity levels as well as neutral expressions of 4 European targets and 4 Chinese targets (2 males and 2 females in each culture). Repeated-measures ANOVAs revealed a clear in-group advantage in the recognition of anger expressions, a partial in-group advantage in the recognition of sad expressions, and no in-group advantage in the recognition of happy expressions. Further, American participants were more accurate than Chinese participants in labeling sad expressions of low to moderate intensities of both cultures, suggesting Americans showed greater sensitivity to sad expressions than the Chinese. Overall, the findings provide unique insight into the influence of culture on the perception of facial expressions beyond the in-group advantage.

Session Type: Posters

Development of cross-cultural psychology in post-Soviet Kazakhstan

Ahnar Almaganbetova Kazakh National University, Kazakhstan; Laura Alzhanova; Olga Almaganbetova

Modern Kazakhstan represents one of the economically developed states formed after the disorder of the Soviet empire. Today, a representative of 140 various ethnicities and cultures lives here. They are representatives of the Asian and European race, Moslems and Christians, and representatives of other religious faiths. In this connection there is a special urgency for cross-cultural psychology directed on studying the similarities and distinctions between different cultural and ethnic/cultural groups. Features of the Kazakh culture as nomadic don’t allow a fixed writing of the first stages of the formation of cross-cultural researches in Kazakhstan. However the feature of a site of republic which at all times were a place of crossing of geographical ways and cultural directions, forced Kazakhs to look narrowly to adjacent national societies, to define features of their character and to fix them in oral national creativity, using proverbs, sayings, and fairy tales. The following stage in developing psychology cross-culturally is connected with the names Al-Farabi, J. Balasaguni etc. Directly scientific research of cross-cultural studies appeared only in a XIX-th century, and they are connected with names of S.Ulahanov and A.Kunanbaev. Since 1930 XX-th centuries in the conditions of totalitarian societies, directed on unification of national features, cross-cultural research have been forbidden. Today we became witnesses of the present explosion of the development cross-cultural psychology. So, from this year lectures on cross-cultural psychology are read in the Kazakh national university. Thus, cross-cultural research in Kazakh-
stan are defined by a real multicultural situation, as Euroasian territory.

Ethnic stereotypes in post-Soviet Kazakhstan
Alnara Aimaganbetova Kazakh National University, Kazakhstan; Akhmet Almaganbetov

The urgency of cross-cultural features of ethnic stereotypes research, is determined by the fact that modern post-Soviet Kazakhstan represents a multicultural state where representatives of more than 130 ethnoses live today. The purpose was to study stereotypes’ features and characteristics for representatives of students’ youth, among two of the largest ethnic groups, Kazakhs and Russians. The analysis of an emotionally-estimated component of ethnic stereotypes has shown differences in parameter of ambivalence: Kazakhs – 0.52%; 0.36%; 0.53%; 0.54% and Russian – 0.5%; 0.38%; 0.51%; 0.44%. In expressiveness, studying of an emotionally-estimated component of an ethnic stereotype, following quantity indicators have been received: Kazakhs – 0.19%; 0.21%; 0.17%; 0.22% and Russian – 0.14%; 0.2%; 0.25%; 0.26%. The orientation of diagnostic factor of an ethnic stereotype is presented by following quantity indicators: Kazakhs – 0.3%; 0.5%; 0.31%; 0.29% and Russian – 0.37%; 0.51%; 0.33%; 0.38%. In general, research has shown that ethnic stereotypes of Kazakhs and Russian ethnic groups’ representatives, is characterised by a positive orientation.

Social-psychological features of young Kazakh repatriates acculturation in modern Kazakhstan
Laura Baimoldina Kazakh National University, Kazakhstan; Davlet Dusenbekov

This research deals with the social-psychological peculiarities of young Kazakh repatriates’ adaptation to living conditions in modern Kazakhstan, and their acculturation to a new ethnical environment, social-legal demands and professional challenges. An analytical study allowed us to distinguish three fields where young repatriates face social, legal and cultural difficulties. The first sphere embraces social-economic adaptation connected with a rather long term (up to 5 years) of legal naturalisation, and finding job and accommodation. The second sphere, cultural-ethnical adaptation, connected with non-coincidence of cultural, national and confessional standards of left country, and the new cultural environment, linguistic adaptation connected with non-coincidence between norms of Kazakh language spoken abroad, for instance by Kazakhs in China, and similar norms of Kazakh as State language. The predominance of the Russian language in major social and professional activities, especially in big cities can also be mentioned. Empirical research had been conducted by using the diagnostic technique of social-psychological adaptation developed by assessment of stress-resistance and social adaptation levels, testing of legal and civil consciousness, testing means of personality and linguistic anxiety, and testing of cultural-value orientations, in 150 subjects. By means of non-parametrical statistics, research data processing allowed us to divide them into 2 groups according to rank of social-psychological transformation (positive and negative), that occur during the adaptation process. The intermediate conclusion of continuing research: young Kazakh repatriates’ acculturation effectiveness, depends on adaptation success among members of the closest environment (family, friends), and reconstruction of socially and culturally meaningful personality traits.

Experimental research of ethnic identity features of modern teenagers
Svetla Berdibayeva Kazakh National University, Kazakhstan; Almagul Ayagana
ova

The purpose of experiment consist: in revealing of ethnic identity features of Kazakh teenagers by studying their heterostereotypes concerning representatives of Russian nation. For the first time we had been carried out measurement of ethnic identity through heterostereotypes on basis of a technique National stereotypes in our updating 25 personal qualities. In research participated 93 Kazakh teenagers. The analysis of distinctions between indicators of control and experimental groups was spent by calculation of by criterion Mana Whitney. U-empirical = 106; U-critical = 56; H0 accepted, < 1 it is rejected, there are no significant distinctions in expressiveness of heterostereotypes concerning Russian respondents. Conclusion: research of ethnic identity of modern Kazakh teenagers by measurement their heterostereotypes concerning Russian and their comparison with indicators of control group has found out among groups-teens and senior generation both lines of similarity, and line of distinction between them. Similarity of heterostereotypes concerning Russian in control and experimental groups is shown in absence of statistically significant distinctions between modal values of all indicators, and also in similarity of private structures of both heterostereotypes. Thus, modern Kazakh teenagers in general don’t differ in their heterostereotypes concerning Russian from teenagers of more elder generation. At the same time in comparison with them they show a little more an appreciation readiness to endow for the losing personal interests for others and slightly more low estimates such quality as pride of their nation.

Ethnopsychological features of the political leader recognition
Svetla Berdibayeva Kazakh National University, Kazakhstan; Aiman Kelamatov; Janat Sarybekova; Almagul Ayagana
ova

Purpose: to reveal the ethnopsychological features of political leader preference. Subjects: there were 60 respondents in general (32 male, 28 female), divided in two groups (kazakhs and russians). Age of the subjects was 20-60 years old. Methods: Kettle’s 16 factor personal methodologies FLO-105-D; Questionnaire developed for revealing the most preferred political leader. For analysing the data we used – U-criterion of Manha Whitney and H- Test by Kruskal-Wallis one-way analysis of variance. Results: Research revealed ten psychologica

Conclusion: One ethnopsychological distinction caused by a choice of the political leader is revealed only. There is an identification of nonbased ethnoses to the given political leader and they, project their expectations on political culture of Kazakhstan “hope” that the person of any ethnoses living in territory of Kazakhstan can become the political leader of the country. Also On the first place on the importance in choice of the preferred political leader there is a force factor, i.e. ability of the political leader to provide in the country calmness to give sensation of reliability and trust.

Understanding and celebrating diversity! An organization and relationship systems coaching experience
Jennifer Campbell INAASO, Netherlands

Understanding and celebrating diversity are great ways to enhance relationships of any kind in communities, organisations and societies. Being aware of differences, thoroughly understanding them and collaborating from a place of mutual respect, however, isn’t always easy. In this paper and workshop we’ll experience ways to understand and celebrate diversity, by experiencing tools from the Organisation and Relationship Systems Coaching (ORSC) perspective. ORSC is a ground-breaking model for coaching relationship systems in organisations, groups, teams, partnerships and couples. One or two ORSC tools, called ‘Lands Work’ and ‘Deep Democracy Process’, will prove to be quite adequate for the exploration and understanding of diversity and finding common ground. Participants will have an experience of how these methods work and how they: enhance awareness of the diversity between people and/or groups in a non-judgemental and respectful way; create openness to hearing all (diverse/multicultural) viewpoints, opinions, feelings or ‘voices’ within the group to any (conference related) topic at hand; facilitate in understanding, respecting and celebrating diversity; eventually enable participants to name new possibilities and ingredients for collaboration within a multicultural society. After the workshop a summary of experiences from this workshop will be presented to the conference organisation. The aim is to contribute to the implementation of the conference conclusions and to enhance implementation projects.

Mother–infant interaction and maternal strategies during infant feeding in British and Italian communities
Cristina Costantini University of Portsmouth, United Kingdom; Vasudevi Reddy; Clare Wilson; Alessandra Fasulo

Patterns of maternal behaviours and responses towards infants’ needs and requests have been largely investigated, however, little is known about mother–infant interaction during feeding, particularly when the first complementary food is introduced in infants. Furthermore, maternal strategies during infant feeding, such as the use of distractions, have been rarely investigated in non-clinical populations in Western and non-Western countries. This short-term longitudinal study investigates patterns of maternal behaviours, mother-infant interaction during feeding, and maternal emotional responses towards infant feeding in two European communities, British and Italian, UK and Italy. Thirty British and
thirty Italian mothers of infants aged between 3.5 and 7 months were interviewed at three different points in time: Before and after weaning, and when the infant was 7 months. Mealtimes were also video-taped on the second and third visit. Finally mothers completed the Infant Behaviour Questionnaire Revised on the first and third visit. The results show a variability of mother-infant interaction, in terms of verbal and non-verbal communication, maternal behaviours and use of distractions during feeding, with different patterns in the British and the Italian mothers. Maternal emotional responses towards feeding are similar before and after the introduction of complementary food in both communities. Mother-infant interaction during feeding may be linked to cultural values and habits, but also to maternal beliefs and behaviours. More research is needed to investigate mother and infant interaction in non-clinical populations in Western and non-Western countries, to highlight different beliefs and habits which may influence positively or negatively the infant feeding.

Generation, education, language and social-support as predictive measures that modify Hispanic gender roles in USA

Shaina Fieldstone Nova Southeastern University, United States of America; Dyoma Augustin; Danette Betra; Sarah Cooper; John Lewis

In contrast to United States mainstream, Hispanic gender roles are clearly defined. Latino men are defined with the term machismo, while less is known and studied about the female counterpart marinismo. The purpose of this study is to determine how marinismo changes to a more egalitarian role when residing in the US. We hypothesise generation, education, language and social-support will have predictive value in determining the extent Hispanic females will identify with marinismo. Ninety-eight Hispanic females residing in South Florida participated in exchange for inclusion in a raffle. In addition to providing level of education and generation in the US, participants completed the Short Acculturation Scale for Hispanics (α=0.92), which assesses friend-ships preferences and language acquisition (Marin et al., 1987) and the Marinismo Beliefs Scale (α=0.76), which assesses attitudes towards traditional gender roles within 5 pillars (Castillo et al., 2010). Descriptive statistics of 98 participants show a range in age (18-65 years), education (4-20 years) nationality (including Cuban, Brazilian, Peruvian, Nicaraguan, etc.) and generation (first = 36%, second = 44%, third or more = 10%). We will analyse the sample with a forced entry multiple regression to examine which variables account for changes in marinismo. The results of this study will provide insight into the predictors for changes in gender roles among Hispanic female populations within South Florida. This research will facilitate further understanding of characteristics affecting marinismo beliefs and how they subsequently affect the self-esteem and self-image among immigrating populations.

Cognitive strategies used by Korean white-collar workers in adjusting to the Japanese workplace

Lee Geonsil University of Tokyo, Japan

In Japan, the issue of foreign workers has attracted growing interest in recent years, due to the increasing number of such workers in Japanese society as a result of globalisation, and concern over the country's declining birth rate. However, little research has been carried out on foreign white-collar workers in Japan to date. For historical reasons, this is particularly the case for Korean white-collar workers. This study aimed to throw light on the strategies used by Korean white-collar workers in adjusting to the Japanese workplace. Data were collected from Korean white-collar workers through semi-structured interviews and analysed using the grounded theory approach. Working in Japan, Korean white-collar workers' acculturated identity wavers again. They are reluctant to fully embrace Japanese culture and tend to stick to their national identity. However, because they came to Japan to further their career, they try to adjust to the Japanese workplace. Analysis of the data showed that the workers interviewed for this study used at least two different adjustment strategies: 1) Revealing aspects of their identity to Japanese colleagues that could be comfortably shared, and 2) controlling the degree to which they revealed their national identity. These cognitive strategies are not only a kind of internal globalisation, but also the adaptation strategies of a minority, as the workers are using them to further their careers. However, because they only result in superficial coping, it is important for psychologists to provide mental-health support and to take interests in their life career planning.

The expression of depression in different cultural contexts

Jennifer Gradt University of Heidelberg, Germany; Manfred Cierpka; Annette Kaemmerer

The influence of culture on the expression of depression has been topic of substantial theoretical discussion. Emphasis in this research field has been placed on the investigation of somatic or psychologi- cal symptom presentation and empirical research to date has mostly been limited to compar- isons between North-American and Asian samples. The focus on the comparison of these two main cultures has been a topic of frequent complaint in the research fields of cross-cultural and cultural psychology. With the aim of extending this limit and exploring the cultural influences on the expres- sion of depression in a South-American and West- ern European Sample our study investigates soma- tisation (and psychologisation) tendencies in Chile and Germany. Symptom presentation is examined in depressive patients in a mixed-method design, comparing spontaneous problem report, structured clinical interview and symptom questionnaire meth- ods. This multi-method approach serves two pur- poses: Firstly it provides the opportunity to explore the role of different clinically relevant diagnostic contexts in the way patients express their depres- sion. The diagnostic approach is considered to in- fluence the symptoms patients elicit in a clinical setting. Secondly the use of multiple assessment modalities addresses the problem of culture related response bias, which seems to mainly affect the answering of self-report questionnaires with Likert-type scales. As possible mediators between culture and somatic symptom presentation the role of stigmatisation of mental illnesses and communi- cation style (High-Context vs. Low-Context Com- munication Style) are examined.

Illuminating profiles of binge eating disorder symptomatology among Cuban American women

Hillary Howrey Nova Southeastern University, United States of America; Marissa Snell; William Dorf- man; Christian Delucia

An abundance of research has acknowledged that symptoms of disordered eating (DE) may present differently cross-culturally. An increasing amount of research has focused on Binge Eating Disorder (BED) as the diagnosis has been slated for inclusion in the DSM-5 and chronic overeating symptom patterns are included in the ICD-10. Until present, cross-cultural research on DE has focused on iden- tifying definitive differences between racial groups (e.g., Black Americans and Hispanic Americans); however, studies have suggested symptomatology may vary more within than between racial groups. Factors such as immigrant/refugee status and cul- tural history have a large impact on psychosocial factors that influence the development and clinical presentation of psychopathology. While most His-panic families living in the United States emigrated voluntarily, the subgroup of Cuban Americans is different in that most hold refugee status. Further- more, Cuban Americans are less likely than Hispa- nics to utilize DE interventions. This study will use the Psychosocial Risk Factor Questionnaire and the Eating Disorder Inventory, 3rd edition (EDI-3) to compare the risk factors and multidimensional symptom profiles of Cuban American women (n=50) with BED to a sample of Hispanic American women (n=150) with BED. We hypothesize that Cuban American women will experience qualita- tively different psychosocial risk factors and clinical symptoms on the EDI-3 compared to Hispanic American women. It is crucial that clinicians un- derstand the differential manifestations of symp- tomatology across cultures in order to make an accurate diagnosis and to provide appropriate inter- ventions to promote positive mental health.

Other-oriented achievement motivation in Japan and Korea

Tadahiro It& Gakushuin University, Japan

East-Asian people, who have interdependent self- construal, place emphasis on interpersonal relations- ships in achievement situations. Some previous studies (e.g. Azuma (1994)) revealed that Japanese people were likely to have other-oriented achieve- ment motivation that was a motive to achieve for meeting family members' peers', and other people's expectation. But Koreans are known to have more respect for elders than the Japanese. So it was predicted that Korean people are likely to display other-oriented motivation in achievement situations. The main purpose of the present study is to investigate the difference of achievement mo- tivation between Japan and Korea. About 600 Jap- anese and Korean undergraduates gave responses to the questionnaire including the self- and other-orien- ted motivation scale (Ito, 2004). This scale was developed to measure five attitudes toward self- oriented motivation (SM) and other-oriented moti- vation (OM) (the emphasis on SM, the emphasis on OM, the perceived negative aspect of OM, the SM as an ultimate motive, and the integration of OM and SM). Additionally, the scale measuring con- tents of expectation from parents was included in the questionnaire. The results showed high correla-
tion between the expectation of having good relationships with others and acquiring other-oriented achievement motivation. In addition, the difference between Japan and Korea in achievement motivation style and expectation from parents was suggested. Conclusively, the role of expectation from others on acquiring OM was discussed.

The power of African cultural arts: Promoting holistic health, healing, and community building in the African Diaspora

Adann Johnson Loyola University Maryland, United States of America; Jamilla Codrington

Final African cultural art forms are powerful tools for promoting holistic health and healing of individuals, collective healing, and community building throughout the African Diaspora. This proposed poster presentation will explore how African-based forms of dance, drum, and orality have historically been used to promote optimal functioning of mind, body, and spirit, heal from trauma, transmit cultural values, and build and sustain communities. Examples provided will illustrate how these art forms can be innovatively applied to the process of holistic healing and community building with individuals and communities of African descent. Presenters will discuss how the vibrations and rhythms inherent within African cultural art forms can be used to promote optimal functioning through awakening of the spirit, creating harmonious states, and restoring balance. The unique ability for African cultural art forms to enable individuals and communities to heal themselves is addressed by examining how these art forms provide a) connection to spirit b) ancestral connection, c) cultural transmission, d) a remembrance of who we are as African beings, and e) ritual drama for the process of coping with trauma. Additionally, because they have traditionally been incorporated into rituals within societies throughout the African Diaspora, African-based forms of dance, drum, and orality serve an important function in the intergenerational transmission of ancestral wisdom and building and strengthening communities.

A social-psychological study of interpersonal family relations in Kazakhstan

Maira Kabakova Kazakh National University, Kazakhstan; Musa Kundyz; Serikbayeva Gulzina

The aim of this study was to examine spouses’ evaluation of interpersonal relationships in families. The study employed two instruments to examine the assessment of interpersonal relationships, specifically, Kabakovs Marriag Satisfaction scale (1997) and Aleshina, Gomzan and Dubovskayas Marriag Satisfaction test (1987). A total of 120 couples (240 persons) participated in the study. The participants were divided into two groups. Group 1 consisted of married couples in marital relationships of varied periods: 40 couples with 0 - 4 years of marriage (average term – 2 years; the so-called young family period) and 40 couples with 5 - 19 years of marriage (average term – 11 years 6 months; adult period). An additional 20 young married couples (average term 2 years 6 months), who had experienced marital crises were also included in this group. Group 2 consisted from 20 divorced couples. The data indicated high marital life satisfaction in Group 1, compared to Group 2. Correlation analysis between evaluation of marriage satisfaction and general communication evaluation of each couple shows a positive connection (p < 0,05). It was also found that over the years spouses evaluated their satisfaction of family relationships increasingly lower (< 0,05). The data also indicated that the character of interpersonal relationships depends on mutual understanding and good communication as reflected in the evaluation of marital satisfaction.

The perception differentiation toward the dying process in Balinese elderly on doing japa

Putu Eka Prayastiti Kefani University of Udayana, Indonesia; Ni Putu Nataluya

Recently, various studies have strongly indicated the undeniable role of spiritual practices in resolving issues related to dying. Timms (2010) defined spirituality as experiences of a deep-seated sense of meaning and purpose in life a sense of belonging, a sense of connection of “the deeply personal with universal acceptance, integration and a sense of wholeness. Dying is the process of approaching death, as well as the choices and action involved in that process. There is a wide range of spiritual practices from the religious to secular – which may not be obviously spiritual. This study will research the perception differentiation towards the dying process in Balinese elderly who practise japa and those who do not. This research is quantitative research. Data will be collected by questionnaires and the method of sampling is stratified sampling (random sampling). This research will be analyzed by T-Test. The participants are Balinese elderly. The results of this research we assume will show the perception differentiation towards the dying process in Balinese elderly who practise japa and and those who do not, and that Balinese elderly on doing japa will have a more positive perception towards the dying process.

What does it mean being lazy? Cross-cultural research of the phenomenon

Anna Leybina Raffles College of Education, Singapore; Hui Zhong Ong

Attitudes and stereotypes towards laziness may affect people, work environment, and the process of education. Thus it is important to explore cross-cultural stereotypes towards laziness and lazy people. The goal of this research is to explore how Asians (a collectivist culture) and Europeans/Americans (an individualist culture) view lazy people and if there are any ethnic stereotypes towards laziness involved. The general assumption of the research was that cultural differences could affect the perception and attitudes toward laziness. A total of 274 subjects participated in this research. They selected a word from each of 49 pairs of words related to psychological features that best represents their idea of a lazy person. They also were provided with 8 photographs (4 males and 4 females) of people from Malay, Indian, Chinese and Caucasian roots, breaking their ethical and moral values.

The conceptions and actions in mental health services of primary health care professionals

Aluisio Lima Universidade Federal do Ceará, Brazil; Meire Lima; Eliany Oliveira; Aline Andrade; Arístides Pontes Filho; Luís Tolfo

This poster aims to present the conceptions and actions of mental health, more specifically in the field of crack, alcohol and other drugs, of Family Health Centers – CSF, professional team members, in the city of Sobral Ceará in Brazil, about customers, drug use, problems related to abuse and/or dependence and harm reduction. Data indicates how these ideas and actions are co-ordinated with social, moral and political values. The results show potentials and limitations of the adoption of harm reduction actions targeting drug users in those CSF. The methodology used in this investigation was descriptive quantitative, using a questionnaire administered face-to-face, in a population of 300 members of the CSF team (Doctors, Nurses, Nursing Assistants, Community Health Workers). The survey results offer a diagnosis on the level of acceptance of the harm reduction proposal, on the knowledge of its ideological foundations and on the values that support professionals work, providing evidence of the limitations and problems that can mischaracterise and make mental health actions unviable in primary care, and harm the health of people who use drugs and seek treatment in these health services.

Media role in public consciousness as psychological factor in forming cultural identity

Ilmihanovna Lyazzat Kazakh National University, Kazakhstan; Jakupov Satybaldy; Perfenbetov Mukhan; Komelbayeva Lyazzat; Satybaldy Dzhakupov; Alfiya Mussakieva; Gaziz Telebayev

Negative information has a destructive effect on the psyche, in the subconscious. The severity of this problem is also due to the increasing number of foreign media in Kazakhstan. Distribution of pro-Western and pro-American culture on the territory of Kazakhstan may lead to the loss of their own roots, breaking their ethical and moral values. Ethno-political thinking not only reflects the realities of the ethno-political situation in the country and the world, but also has a significant impact. The nature of this influence, the degree of conservatism and reactionary or, conversely, democratic and progressive depending on the type of thinking – the old or new. According to the survey: “Do you think that the media, along with other entities in the Republic of Kazakhstan, played a positive role in the development of ethno-political processes?” 76% of respondents gave a positive answer. In terms of regions of the maximum number of consonants with this response, respondents living in the North (51.9%), Central Kazakhstan (51.7%). A total of 27.4% of respondents believed that the media shapes public opinion in a positive way, 18.2% respondents believed that the media can create educational programmes about the historical roots of
What is responsible for happiness? Cross-cultural comparison of quality-of-life indicators

Sherri McCarthy Northern Arizona University-Yuma, United States of America; Kyle Hawkey; Jas Jaafar; Aisha Zubair; Boone Rountree

To determine level of happiness, 1942 respondents from Malaysia and Indonesia completed the Oxford Happiness Inventory and reported the meaning of happiness and things that made them happy on an open-ended questionnaire. Their levels of happiness were comparable to those reported in other areas of the world. Based on their responses of what made them happy, a 15-item questionnaire listing the most-reported indicators was developed. As a pilot project, approximately 350 young adults from Malaysia and the U.S. were given the questionnaire and asked to rank the items most responsible for their happiness. On most indicators, responses were similar although indicators related to group welfare were rated higher overall among Malaysians while those related to achievement were rated higher, overall, by U.S. respondents. This paper reports the findings and discussions, from the perspective of culture and socialisation, similarities and differences.

Development process of communication skills of children
Sakae Nakata Sophia University, Japan

Research conducted on children who achieve low scores on social skills has shown that picture card, video modelling and role-playing are the most effective methods for teaching children how to improve social behaviour.

Mental health stigma in the Caribbean: A review of cultural and religious belief systems
Kristyn Neckles Carlos Albizu University Miami, Grenada; Anabel Alvarez; Rafael Martinez; Jennette Vernezo; Jussethy Cortina

There has been a call to action by the World Health Organisation (2011) for more research to measure mental health awareness and systems in the Caribbean. Despite major strides through research and investment by similar international bodies, it is recognised that perceptions of mental illness are still very much impacted by religious and cultural beliefs. Relevant literature reviewed suggests that both religion and culture play a prominent role in Caribbean populations and directly influence current stigma associated with mental illness. Unfortunately, the degree to which stigma impacts the perception of mental illness, help-seeking behaviour and treatment within this population is grossly under-researched. Current research also notes considerable methodological gaps between public knowledge of mental illness and its treatment in the Caribbean. Attribution theory is considered by the literature as the most effective in addressing stigma and is utilised as a model in the conceptualisation of these issues. Results of this review indicate that identifying lay conceptions of mental health prevalent in Caribbean populations is critical if systems and treatment are to be considered culturally adaptive. To dismiss the impact of these influences has potential consequences for the acceptance of a psychiatric diagnosis, adherence to treatment and functioning within the community.

Interdependent self and subjective well-being: Relational harmony as a mediator
Xiaopeng Ren Institute of Psychology, CAS, China; Xin-wen Bai; Hong Xie; Rui Zheng

A survey in an interdependent nation (China) was used to examine the hypothesis designed to link culture and Subjective Well-Being(SWB). The hypothesis is that people achieve SWB through actualising the respective cultural mandates in their modes of being. By the age-stratified random adult sample from mainland China, independent and interdependent self-construals (Markus and Kitayama,1991) are the determinants of SWB. Furthermore, although relational harmony can fully mediate the relationship of interdependent self-construal and SWB, self-esteem cannot mediate the relationship of independent self-construal and SWB. The analysis controlled factors of age and and gender as well as education.

Cross-cultural features of family relations of the Kazakh and Uzbek married couples
Nazym Satybaldina Kazakh National University, Kazakhstan

This investigation of cross-cultural family relations of the Kazakh and Uzbek couples is significant due to the fact that modern globalisation trends are in conflict with the spiritual foundations of the national family. The connection between cross-cultural and socio-psychological variables of family relationships in modern Kazakh and Uzbek families were found. The aim of the study is to reveal the influence of cross-cultural families’ satisfaction with the marital relationship. The study uses such techniques such as “The measurement of units in a married couple”, “Determination of the consistency of family values and role in setting the couple”, “The distribution of roles in the family,” “Marital satisfaction”. The results showed that the spouses of Uzbek families attach great importance to raising children. For them, it is also meaningful parenting and household functions. The Uzbek family relations are patriarchal. Kazakh couples attach great importance to entertainment and material support of the family, the visual attractiveness and partner identification with her husband. The high level of performance of the spouses of Kazakh families may indicate that greater consistency of expectations and attitudes in the family, that is, indicate higher satisfaction with the marital relationship. Women of Uzbek families to a lesser extent rely on psychotherapeutic support of her husband, are mainly concerned for children and are extremely dependent on their husbands in material terms. Women of Uzbek families less satisfied with marriage than men.

Post-Soviet Kazakhstani scientists did not acknowledge fully the role of culture in psychology
Zharas Seiltur Kazakh National University, Kazakhstan

Post-Soviet Kazakhstani scientists didn’t acknowledge fully the role of culture in psychology. The reason is that highly qualified psychologists were trained mainly in Russia. As for the Soviet empire, it wasn’t interested in doing research works of other countries culture. As a result of being under Soviet colonization, the Kazakh people lost many things in relation to cultural-historical identity. The Kazakhs were discriminated against from an ethno-cultural point of view, so there wasn’t any possibility of doing psychological research work. Totalitarian Moscow completely controlled psychological science. Research was carried out in the shade of a psychological paradigm that adhered to a euro-centric position. Indigenous psychology which could reflect cultural peculiarities of the people did not develop. There was a threat that psychological science could lose its status as the science supposed to research human psychology. According to methodologists it worsened the situation of psychology in permanent crisis. As a science, psychology and its studies must give opportunities to reveal human behaviour in any cultural environment, that is why the culture category should be included to psychology. Usually we use terms like “social person”, “political men”. Nowadays social practice (international relations, cultural exchange, business, psychological consultation, education and etc.) requires taking into account the term “cultural person”. So we should develop cross-cultural psychology in our country.

Japanese social skills learning for international students through a psycho-educational session
Tomoko Tanaka Okayama University, Japan

To develop a cross-cultural social skills learning session for international students in Japan, a small group session was conducted based on cognitive and behavioural learning techniques. Three international graduate students, from China and the USA, who studied at a Japanese university and were interested in learning about Japanese culture joined the four days session for cross-cultural adaptation and the last day was assigned for Japanese social skills learning. The international students learned cognitive and behavioural social skills that focused on culture-specific interpersonal behaviours in Japan. Two Japanese graduate students who were interested in cross-cultural education also joined the session as helpers of learning. During the skills learning session, they learned about the ways of asking direction to a Japanese person with language handicap, Japanese drinking communication, visiting Japanese professor and Japanese indirect refusals. Each session included lectures about Japanese behaviour patterns and cultural backgrounds. They learned about situations through target behaviours, situational role plays, feedback, a second role play and finally discussion. Participants reported more understanding to Japanese culture and more interest in Japanese cultural behaviours increased self-confidence and greater motivation to experience cross-cultural contacts. As a result of the evaluation their role play in video tape, their improvement of the performance had been shown. It is suggested that this psycho-educational session would enhance their social-cultural adjustment during their studying abroad.

A Chinese theory of making interesting contributions to scholarly inquiry
Thomas Li-Ping Tang Middle Tennessee State Univ, United States of America; Theresa Tang

Culture
Many multinational corporations have outsourced their manufacturing and production processes to China. Research and Development in the US has been turned into Receiving and Duplicating in China. Academic research follows a similar pattern. Scholars have urged Chinese researchers to go beyond the Theory of Chinese Management that makes limited intellectual contribution to theory and develop the “Chinese Theory of Management”. This article advocates a Chinese Theory of Making Interesting Contributions to Scholarly Inquiry that is indigenous and important in and to China. We turn our attention to two Chinese words meaning learning and asking a question, a process of gaining knowledge. According to Confucius (551 BC–479 BC), “Learning without thought is labor lost; thought without learning is perilous”. The core competence of knowledge creation can be traced to two major roots of action: Studying and asking questions. Furthermore, strong, interesting, theoretical contributions come from well constructed logical arguments, full of novel insight, adequate conceptual development, and a deep appreciation of the relevant literature.

Core self-evaluations and job performance: Entrepreneurs in China

Thomas Li-Ping Tang Middle Tennessee State Univ, United States of America; Clark Tang; Xiao-Yan Li Small and Medium Enterprises (SME) in the People’s Republic of China represent about 99% of all enterprises, 45% of GDP, 45% of all exports and 38.7% of tax revenue. They have contributed significantly to China’s economic development. This study investigates the relationships between Chinese core self-evaluations (CCSE) and job performance among entrepreneurs of private SME in China. In Study 1, we incorporated two indigenous constructs: Team leadership, self-esteem, personal characteristics, and community. We revised existing core self-evaluation scale, and developed a newly revised 13-item, 4-factor Chinese Core Self-Evaluations construct based on collected data from 300 Chinese entrepreneurs. In Study 2, in a second sample of 306 entrepreneurs, we tested the relationships between our 13-item, 4-factor Chinese Core Self-Evaluations Scale (CCSES): Namely, personal self-esteem, team leadership self-esteem, self-competence and personal integrity; and overall, three components of the 16-item, 3-factor Job Performance Scale i.e. social performance, task performance and contextual performance. The relationships were significant. Furthermore, males had significantly higher CCSES scores than females. There were no differences across age and educational background. Chinese entrepreneurs with high CCSE scores believe that they can achieve high levels of job performance. The synergy of combining numerous entrepreneurs in these SME centres in China may fuel the fire that contributes significantly to China’s economic development.

A cultural comparison of solution styles of school teachers in Japan, China and Taiwan

Rieko Tamo Doshisha Women’s College, Japan

The purpose of this study is to consider the conflict resolution styles supported in three East Asian counties. Solution styles are different even in Asian neighboring counties. Which principles of solution-finding are supported and handed down from teachers to children in each country? Evasive ways of conflict are especially focused upon in this study, and the views of 199 elementary school teachers (48 Japanese, 70 Chinese, 81 Taiwanese) are analysed as regards to conflict solutions. These were represented in three famous typical stories in Japanese and Chinese elementary school texts in a questionnaire survey. The results were as follows: (1) There is a significant difference of the estimations in three countries, and Japanese teachers put much higher value on avoidance strategies. (2) Chinese and Taiwanese teachers have much lower valuation of avoidance, especially in the case where the characters made an abortive effort to change the enemies’ malicious intentions. While Japanese teachers expressed sympathy to the characters portrayed, Chinese and Taiwanese teachers saw the characters’ behaviours – namely, naively expecting enemies’ change – as rash. These results may suggest that different cultures in East Asia have different ideas of conflict resolution styles taught by school teachers.

Undergraduates’ career development education: A structure perspective modified the psychological separation impact on career development

Chin-Lun Tsai Department of Psychology, FJU, Taiwan, R.O.C.; Chih-Min Dhou; S.F. Wang; Kang-Lin Yang; James Vyathapan

Many previous theories about career development, include career decision or career indecision as individual perspectives. Prior research has shown that individual psychological separation can directly or indirectly impact on career development. It did not, however, reveal how the social structure will influence these relationships. This research is a pilot study based on Gottfredson (1981) circumscription and compromise theory. By using a qualitative method, we investigate that the structure factor. The participants include American, Philippine, and Taiwanese undergraduates who studied in college during 2010–2011. Adults included 11 males, 24 females (ranging from 19–24 years old). The participants agreed to the interview or focus group. The research found that positive structure character can modify the relationship of individual psychological separation impact on career development (career decision or indecision). It can also reduce individuals’ degree of compromise.

The difference between achievement goals of Korean students and Japanese students

Hitsashi Uebuchi Tokyo Gakugei University, Japan; Kotono Yamada; Marie Uebuchi; Akiko Tonegawa; Akinori Sakai; Takahiro Saito; Ryosuke Onoda; Shotaro Kakuta; Mayumi Oie; Tadahiro Ita; Tsutomu Fuji

This purpose of this study is to find the difference between achievement goals of Korean college students and Japanese college students. 500 Korean students and 500 Japanese students submitted self-reported scales of achievement goals (Tanaka & Fujita, 2004). Results were: (a) Koreans’ performance-avoidance goal was higher than Japanese, (b) there was no significant difference of mastery goals between Korean and Japanese students, and (c) Koreans’ performance-approach goal was higher than Japanese students. These results were discussed by industrial development and religion. Korea was thought to be a more competitive country than Japan. So, Koreans’ performance goals were higher than Japanese performance goals. And Koreans assign credence to Confucianism that adds emphasis to effort. But Japanese also prefer effort. Therefore, no difference between mastery goals was found.

Perception of value of children in the Baduy tribe

Laila Wardani University Kebangsaan Malaysia, Indonesia; Amalia Ramadhantri; Inda Sabisimi; Resty Pratandani; Siti Khadijah; Fanny Aryani; Regina Ariana; Nurul Adiningtyas; Anivela Metalika

The objective of this research was to study the perceptions of parents of children in the Baduy tribe. This study also can tell the difference of perceptions on the value of Bedouin children generally, and was conducted by a survey of Bedouins. The Baduy tribe are very strict about filtration culture from the outside and is bound by customary laws. The data retrieval techniques used are face to face interviews. Through this research, it is expected that the results obtained can be used as a basis for making strategic human resource development plan in the Baduy community.

How Balinese adolescents consider the importance of ritual in maintaining their social identity: Indigenous psychology approach

Ni Nyoman Wiranti University of Udayana, Indonesia; David Hzikia Tobing; Ida Ayu Gede Sri Evitasari

Adolescence is a critical period because it’s the period that leads to a developed individual identity. Bali has rituals and a culture that has been handed down from generation to generation. In addition, in Balinese life, ritual and culture are important to strengthen ethnic identity. Rituals in adolescence are called Rajawesala, Mepandes and Otonan in local wisdom. Balinese adolescents experience an ambiguity between traditional Balinese, which is full of local wisdom, and modernisation, with the impact of tourism and global trends. It is interesting to understand how Balinese adolescent dynamics help to find self-identity, and what efforts are taken to preserve Balinese identity in this global era. This research is aimed at exploring how adolescents perceive social identity, related to rituals they perform in that period using a qualitative with a collected data method, and also open-ended questionnaires, and in-depth interviews with 150 senior high school students. Data analysis of this research is used for categorisation response and thematic coding. The result of this research is that there are various views on the rituals that they perform, to build and strengthen their identity. The dynamics of formation of self-identity in Balinese adolescents, engaging the culture context will be explained in greater depth.

The implication of local wisdom at school in preventing unwanted pregnancies in Balinese adolescents

Ni Nyoman Wiranti University of Udayana, Indonesia; Ida Ayu Gede Sri Evitasari; David Hzikia Tobing

This research aims to describe the implication of local wisdom in Bali as an alternative method in preventing unwanted pregnancies in Bali. The Baduy tribe lives in the highlands in the West to East of the Banten province, Indonesia. In this study, we interviewed the Baduy tribe people who live in the Baduy community near the city of Bogor. The Baduy tribe follows the Arab law and is bound by customary laws. The Baduy tribe are very strict about filtration culture from the outside and is bound by customary laws.
preventing unwanted pregnancies in Balinese adolescents. Balinese local wisdom such as Tri Hita Karana, Desa Kala Patra and Karma Phala can be beneficial in preventing and addressing unwanted pregnancies in Bali that are caused by free sex among students. These concepts have the same function as providing the foundation for shaping character and human behavior. These concepts have highly humanitarian values. When Balinese adolescents have a good understanding of these concepts it can shield them from juvenile delinquency. The methods that were used in this research are study literature and qualitative research which uses open-ended questionnaire and in-depth interview to 150 senior high school students. In this research we found that implantation of local wisdom was more effective in addressing adolescent problems. The impact of implantation of local wisdom in preventing unwanted pregnancies will be discussed later.

A psycho-analysis of bereavement in African cultures
Sibongile Yawa University Of South Africa, South Africa; HE Roets
The role and impact of African rituals in the bereavement process are often overlooked, as a result of the exposure of psychologists to the Western processes of bereavement. This study investigated the process of bereavement in Xhosa, Zulu and Tswana cultures. The study argued that although psychologists are, to some extent, aware of the bereavement process in the African Black culture, they often lack training, exposure and knowledge on how to handle the counseling process. Using qualitative research methods, semi-structured interviews were conducted. One cultural expert from each group, and one bereaved family, were selected to participate in the research process. Data were collected by recording responses from participants using tape recorder, written notes and by observation. Furthermore, a qualitative thematic analysis was employed. Findings seemed to concur with the view that the process of bereavement in the African culture is different from the Western culture. The process of bereavement in the Western culture seems to be more focused in the intrapersonal processes of bereavement than on interpersonal processes. In addition, the study revealed that the process of bereavement is similar among the Xhosa and Zulu and Tswana cultures compared to the Tsawa culture. Lastly, that although there are differences among the Xhosa, Zulu and Tswana ethnic groups, the similarities are more compared to the Western process of bereavement. Based on the findings, the study makes recommendations on how psychologists and educators should handle the process of bereavement in the Xhosa, Zulu and Tswana cultures.

The embodiment of beliefs and practices: Unpacking Chinese somatisation
Xiaolu Zhou Hunan Normal University, China; Yunshi Peng; Shun Peng; Andrew Ryder
The tendency of depressed patients in China, to emphasise somatic symptoms is widely acknowledged from cultural psychopathology. Proposed explanations characterise somatisation either as a pathological, or a strategic way of presenting depression; these explanations are rarely tested. The current study examines explanations of Chinese somatisation of depression in terms of beliefs and practices. Two studies were conducted in Changsha, China. In study 1, Chinese students (n = 214) completed the Chinese Personality Assessment Inventory somatisation subscale (CPAI-S). In study 2, Chinese depressed out-patients (n = 281) completed a battery of questionnaires, including the Chinese Personality Assessment Inventory modernisation (MOD) and somatisation (CPAI-S) subscales, Center for Epidemiological Studies Depression Scale, General Health Questionnaire, and Chinese Health Questionnaire. In study 1, confirmatory factor analysis (CFA) confirmed a division of CPAI-S into 2 correlated factors: beliefs (preferences for bodily solutions) and practices (bodily responses to psychosocial stressors). Study 2 confirmed this structure in clinical sample, and then used structural equation modelling to show that beliefs and practices have independent associations with modernisation values and the somatic symptoms of depression: MOD was negatively predicted by preference for bodily solutions; somatic symptoms were positively predicted by bodily responses to psychosocial stressors. The two factors predicting different variables suggest that Chinese somatisation not only is a direct bodily experience but also an approach to the social world. The findings suggest that previously proposed pathologising and strategic explanations for somatisation can be integrated.

Balance between shu and nu: A Chinese perspective on forgiveness
Ting Ting Zhu Nanjing Normal University, China; Lin Jon Tao; Hong Fu
The purpose of this paper is to find out the conception of Kuan shu and improve forgiveness intervention in Chinese culture and broaden the cultural perception of forgiveness. In Chinese kuan shu is the best word to express forgiveness or to forgive, and shu is the core. Etymologically, the ancient Chinese used the same character to express both shu and nu (which means anger) and eventually separated it into two characters. Semantically, shu means understanding, excuse and one Confucian ethics category. In summary, in Chinese culture kuan shu (1) happens after aseious interpersonal transgression, (2) happens based on understanding the transgressor, (3) is a balanced situation between negative and positive mental states. It is easy to associate the definition of kuan shu with Taiji, a Chinese philosophical concept. As yin and yang, shu (forgiveness)and nu (anger) are two opposing elements of the psychological situation after an interpersonal transgression. From intervention point of view, following the Chinese way of thinking, Chinese clients would understand kuan shu more easily, and therapists can develop intervention plans based on Chinese culture. From the theoretical view, the Chinese ancestor used the same character to represent both shu and nu, to a certain degree this finding supports the evolutionary view of forgiveness and revenge (McCullough Kurzbam & Tabak, 2010). So the authors believe humans have the ability and disposition to forgive, but in different cultures there are different ways to express this.

Psychosomatic research of ethnic self-determination features of Kazakhs
Zhanar Zhukheseva Mental Technology Institution, Kazakhstan; Murat Moldagaliy
In Kazakhstan there is a marked discrepancy of ‘ethnicity’ of the individual and other representations about ‘standard identity.’ The given research based on self-determination theory Edward Desi (E.Deci) and Richard Rajana (R.Ryan) which frameworks transition of the motives connected with external forces, and management of motivation of the person, is investigated, revealing ethnic self-determination features of Kazakhs. From the analysis of the placing of images in semantic space (drawing 1), it is clearly visible that Kazakhs with positive identity civil identity (r=0, 68) prevail. They are proud of the ethnic accessory (r=0, 70) and consider themselves as patriots of Kazakhstan (r=0, 82). In Kazakhs with positive identity, the image of the person who is ashamed of the national identity (r=0, -82), and an image of the person, indifferent in relation to the national identity, (r=0, -93) is negatively estimated. The analysis of semantic (sense) spaces provides the chance to speak about qualitative distinctions in features of ethnic self-determination of people in one ethnic group. Presence of these distinctions specifies motivators in participation in the formation of ethnic identity of people, both external and internal.

Racial and ethnic health disparities in an international context: A multi-level perspective
Norman Anderson American Psychological Assn, United States of America
Differences in health outcomes, among racial and ethnic groups around the world, pose both a scientific and a major public health puzzle. Understanding and eliminating these disparities will require taking them into the multiple interacting factors that operate across the life course. The purpose of this presentation is to provide an overview of recent research from several countries that have systematically explored the causes of health disparities at multiple levels of analysis, and to highlight some successful efforts to eliminate such disparities.

Social relations in an aging society: Future directions
Toni Antonucci University of Michigan, United States of America
As we move through the 21st century, it is clear that our population demography is permanently changing. We are having fewer children, more generations are alive at the same time, and people are living longer. These changes represent important achievements in public health and technology, and in the natural, physical, and social sciences. Nevertheless, they have significant implications for society as we know it. Social relations remain central to our society, although the structure and function of these relationships are changing. Individuals, families, and communities will need to be both innovative and creative if they are to be successful as they face the challenges of an aging society. This presentation will consider the current state of research evidence concerning the positive and negative potential of social relations in an aging society, and outline potential best case scenarios to maximize the potential of social relations in the aging society of the future.
Toward a cultural psychology of located action
Kevin Durheim University of KwaZulu-Natal, South Africa; Jaehee Choi
Mainstream approaches in social psychology have primarily sought to explain the cognitive mechanisms underlying human thought and behavior. Where they have focused on context, this has been viewed as a passive container of human action, providing cues for thinking and constraints for acting. Some approaches to cultural psychology have followed suit, speaking about culture in the cognitive language of beliefs. This presentation seeks to develop an approach to cultural psychology that focuses on what people actually do. It argues that psychological contexts and subjects are constituted in the articulation of talk and embodied action. This argument is developed via an analysis of a ‘culture’ of racial segregation in post-Apartheid South Africa. The cultural psychology of located action that is developed in the presentation is then used to explain the tenacity of racism in contexts of social change and to develop a non-essentialist account of race.

Efficacy, effectiveness and adaptation of HIV/STD risk-reduction strategies: A reasoned action approach
John Jemmott The University of Pennsylvania, United States of America
The HIV pandemic continues to exact a heavy toll on young people. Sexual behaviour is a key mode of HIV transmission and young people are also disproportionately impacted by other sexually transmitted infections and unintended pregnancies. Behaviour-change interventions are therefore urgently needed to address sexual risk behaviours among young people. Such interventions are likely to be most effective if they draw upon evidence-based behaviour-change principles and are tailored to the specific population of young people. This presentation will describe a series of randomised controlled intervention trials that used such an approach to address a variety of sexual behaviour outcomes with young people both in United States and in South Africa.

Cultural neuro-science: Brain plasticity in varying social contexts
Shinobu Kitayama University of Michigan, United States of America
Cultural neuro-science is an emerging field that examines the interdependencies between culture, mind, and the brain. By investigating brain plasticity in varying social contexts, it seeks to overcome the nature-nurture dichotomy. Here, after a brief overview of the field, I will illustrate its potential by reviewing evidence for cultural variations in the brain mechanism’s underlying cognition (i.e. dispositional bias in attribution), emotion (i.e. emotion control), and motivation (i.e. self-threat). Directions for future research will be discussed.

Positive immigrant youth adaptation in context
Frosso Motti University of Athens, Greece
Globally, staggering numbers of people have left their home country for a new one. Many of these immigrants have a strong commitment to putting down roots in their new countries, as evidenced by the fact that they stay throughout their lives, and over generations. The successful adaptation, then, of immigrant youth is a high-stakes issue for multiple stakeholders in many countries, since their future is inextricably linked to that of the receiving society (Masten, Liekind, & Hernandez, 2011). The focus of this presentation is on individual, and ethnic group, differences in immigrant youth adaptation, and on individual and contextual predictors of these differences. I will first present a conceptual framework, integrating a risk and resilience developmental perspective, with key concepts and evidence from acculturation and social psychologies, to account for who among immigrant youth succeeds, and why (Motti-Stefanidi, Berry, Chrysochou, Sam, & Phinney, 2011). Secondely, I will present results from our Athena Studies of Resilient Adaptation project (ASIRA) that test elements of this framework. The quality of adaptation of over 2000 immigrant adolescents, and their nonimmigrant classmates, was examined in two studies, one cross-sectional, and one three-wave longitudinal. Their adaptation with respect to three core developmental tasks, i.e. school achievement, positive conduct and popularity, was assessed using multiple methods and informants, and their adaptation with respect to acculturative tasks, as well as their psychological well-being, were assessed through self-reports. Based on the integrative framework, the presentation of the results will be organised around three questions: Firstly, are societal level contextual factors, such as immigrant status, social adversity and discrimination, risk factors for immigrant youth adaptation? Secondly, do personality attributes and proximal context, i.e. school and family variables, independently predict individual differences in immigrant youth adaptation? Finally, do these individual and proximal context variables mediate, and/or moderate, the relationship between societal level risk and adaptation? The implications of these findings for interventions and social policy will be discussed.

Psychology in Indian tradition
Koneru Rao Indian Council of Philosophical, India
Psychology in the Indian tradition, known as Indian psychology, is embedded in Samkhya-Vedanta theories, Buddhist phenomenology of consciousness, and yoga practices. In the Indian tradition, psychology is the study of the person (jiva). The person is a composite of consciousness, mind and body, a unique blend of thought, passion and action. Consciousness is perceived as changeless and the permanent base of all knowledge and awareness. Mind is the interfacing instrumentality, a necessary link between consciousness and the body. The body is the physical base, and the frame that constrains and moulds consciousness reflected in the mind of the person. The person, in the existential condition, is seen as conditioned, her consciousness is clouded and consequently unable to know the truth and realize her full potential. This is considered to be a state of ignorance and suffering that needs to be overcome. The goal of Indian psychology is to understand the human condition and to explore ways to elevate it to higher levels of being, to clear the clouds of ignorance, and to enable the person to attain a state of bliss where the truth is known and the person becomes perfect. Such an end state is variously described as kaivalya, moksha, nirvana and so on, which is a state of absolute freedom and perfection. Three ways of achieving such a state are suggested: work (karma marga), worship (bhakti marga), and wisdom (jnana marga), which appear to cater to the three basic aspects of the mind: volition, emotion and cognition. In essence, each of these is a distinct way of deconstructing the ego, which is believed to be the main obstacle to transcending existential limitations. The implications and applications of Indian psychology include (1) holistic understanding of human nature, (2) exploring the extended spectrum of the human condition, (3) exploiting the hidden potentials for the common good, and (4) cultivating altruism in the person and conflict-free conditions in society. The veracity of Indian psychology is exemplified to a degree in the lives of Mahatma Gandhi and Mother Teresa (karma marga), Chaitanya Mahaprabhu and Bhakta Tukaram (bhakti marga) Ramakrishna Paramahamsa and Ramana Maharishi (jnana marga).

The two-way interplay between nature and nurture: Concepts, findings and prospects
Michael Rutter United Kingdom
The modern understanding of genetic influences, of environmental effects, of mental disorder, and of inheritabilities will be described. The practical utility of finding susceptibility genes with a very small effect will be questioned. The empirical findings and implications of developmental perturbations, epigenetics, gene-environment correlations and interactions will then be discussed. It is noted that the genes involved in gene-environment interactions may be concerned with susceptibility to all environments and not just adverse ones.

Culture and its effect on the naming practices of the Sharqiyya Bedouins of Oman
Amel Salman Sultan Qaboos University, Oman
The growing field of ethnophysiotherapy postulates that there are cross-linguistic and cross-cultural variations in how people categorize the environment. More specifically, different communities perceive their surrounding landscape in different ways and these alternative worldviews are reflected in the features they choose to communicate and name. This study investigates the Arabic place names of the Sharqiyya region in Oman, with a focus on toponyms related to sand and sand dunes. The region, known for its varied topography and vast desert, is home to the largest number of Bedouins in the country. A linguistic analysis and identification of the semantic features of toponyms such as al Hail (an unstable and collapsing heap of sand), guides us in determining the cultural significance of naming practices and helps us to further our understanding of which landscape features are universal and which ones are language and culture specific.

Mobilising compassionate critical citizenship and psychologies in the service of humanity
Mohamed Seedat University of South Africa, South Africa
Critical psychologies have tended to obtain activation through initiatives that promote social justice, resist the influences of disabling ideologies and disciplinary traditions, and work, in support of
transformative forces in society. In many respects, such psychologies continue to be influenced by contradictory forces, such as historical disciplinary continuities, contemporary intellectual innovations, neo-liberal market dynamics, and global social movements. An in-depth review of selected critically-driven psychological work may shed light on the social, ideological, economic and geographical particularities that shape critical psychologies, especially those in marginalized regions of the world. Lessons drawn from such psychologies may also provide a much-needed impetus for global conversations about the form, structure and focus of twenty-first century psychologies. Such conversations may well obtain currency at a time when democratic voices are asserting themselves through multiple expressions of agency aimed at challenging the new modes of social, economic and health inequalities. Accordingly, this presentation will be centred around several aims. Firstly, the author will describe the developmental trajectory, and intellectual and social focus of a South African-based institute working in the social and health sciences to illustrate how notions of relevance, social justice and struggle, inspire community-centred psychologies. Secondly, the case illustrations will be used to explain how compassion, criticality and insurgent citizenship may be mobilised in the service of humanity. Thirdly, in conclusion, the delicate and yet complex interactions between compassion and criticality in socially conscious psychologies will be closely analysed.

Community cultural development and indigenous empowerment: Perspectives from community and liberation psychology

Christopher Sonn Victoria University, Australia

Race remains a significant issue in the lives of many people in Australia. For example, indigenous Australians’ lives continue to be marked by social and economic disadvantage, and everyday experiences of exclusion. Within this context the Community Arts Network (CAN WA) use community cultural development to promote change and work towards empowering indigenous groups. With an emphasis on community strengths and resources, CAN WA use arts practice to create, promote and improve opportunities for participation, network development and empowerment. In this presentation I explore these projects from a community psychology orientation, which is committed to developing opportunities for inclusion, and exposes the workings of power in everyday settings. Although there have been many positives that have resulted from the different activities with communities, there have also been significant barriers to transformative practice, in particular, issues of racialization and continuing colonisation. I discuss our efforts aimed at understanding and disrupting racialized oppression, which include engaging with critical race theory and whiteness studies, within the context of indigenous and non-indigenous partnerships for change. The aim is to build on our proposal for a decolonising standpoint, that is, a perspective grounded in critical social sciences that will allow us to promote deeper critical thinking and reflexivity, as well as political and epistemic transformation.

Cross-cultural psychology in plural societies: The case of South Africa

Fons Van De Vijver Tilburg University, Netherlands

Various developments have taken place in psychology in South Africa since the abolishment of apartheid in 1994. A common thread is the emphasis on including culture and diversity. It is argued in this presentation that psychology in South Africa can learn much from models of mainstream psychology that are usually developed in Western countries. The focus of the presentation will be on assessment as one of the most important applications of psychology in South Africa. Blindly copying instruments, which is sometimes seen, is counterproductive for the development of psychology in South Africa. Delineating what can be adopted from Western psychology and what should be developed specifically for South Africa is an important issue that is still insufficiently addressed. I will argue that viewpoints in cross-cultural psychology on the patterning of cross-cultural differences and similarities can yield an important framework for addressing the question of what can be imported from the West and what should be developed from scratch. There is strong evidence that basic features of personality, emotions, values, and cognitive processing are universal. Still, simply copying Western instruments for use in South Africa can run into two problems: (1) The basic structure of psychological functioning, as found in the West, may yield an incomplete coverage of the corresponding constructs in South Africa. This problem will be illustrated on the basis of a large-scale personality project in South Africa in which it is found that Agreeableness, one of the factors in the five-factor model of personality, is split up into different factors and that social aspects of personality are inadequately covered by Agreeableness to describe South African personality. (2) Even if constructs are applicable to South Africa, there is no guarantee that all the items that work in Western cultures also work in South Africa. Behavioural or attitudinal referents of constructs are not necessarily identical across cultures. This problem is exacerbated by the absence of instruments that have been employed across all main ethnic groups in South Africa. This cautious attitude toward Western tests, based on the desire to adopt Western tests while acknowledging their shortcomings, requires test development procedures that combine universal and culture-specific elements. Procedures to develop instruments in this so-called combined emic-etic approach are described and illustrated. It is argued that this balanced approach is the most efficient way of dealing with cultural diversity in South Africa, as it avoids the problems of bias inherent to imported tests on the one hand and the development of completely new instruments on the other hand.

Session Type: Invited Symposia

Symposium title: Developmental trajectories of vulnerable boys

Convenor: Oscar Barbarin

Individual and parental moderators of social development

Kirsten Scott Tulane University, United States of America; Esther Jean-Baptiste

The third presentation explores the role of individual cognitive factors and parental involvement practices in the promotion of social competence and in moderating the relationship of social competence to academic achievement. The cognitive factor associated with social competence include abstract reasoning and the ability to order, organize and predict outcomes in social situations. These fundamental cognitive skills undergird social reasoning and are associated with pro-social approaches to conflict resolution in young children. Parental beliefs proved to be important because they are associated with actual socialization behaviors and practices. Traditional adult centered versus child centered beliefs have proven to be important in the growth of boys’ competence because they are differentially related to parental practices related to control, support, criticism, use of explanations and scaffolding and the allowance of autonomy. Moreover the extent to which families provide enrichment of the child through extracurricular activities (music, drama, sports, arts, reading) and are involved in schools by connecting with and collaborating with schools is associated with higher social competence and better academic outcomes.

Symposium title: Indigenous science and science education: Does culture matter?

Convenor: Douglas Medin

Resisting the nature/culture bisection: Science teaching and learning in indigenous communities

Megan Bang University of Washington, United States of America
