The cerebral brain-derived neurotrophic factor (BDNF) is an important modulator of synaptogenesis, neuropaclastia, cognitive functioning, and memory. Changes in BDNF expression in serotonergic and dopaminergic neurons have been found in pathological behaviour. Serum low BDNF concentrations have been associated with dementia in Alzheimer and Parkinson diseases. Neurocognitive disturbances were recognised in HIV patients, which can be associated with disturbances in dopamine and serotonin regulations as well as depression and other psychological dysfunctions. The serum BDNF concentration and neurocognitive functions in HIV infected patients were examined in this study. The BDNF concentration was compared with that of healthy and non-infected subjects as well as across gender. The study included 88 HIV-infected patients aged 32 ± 3,4 years (15 women and 73 men) and 63 healthy subjects aged 28 ± 1,3 years (30 women and 30 men). The concentrations of BDNF in the serum of subjects were measured by sandwich-ELISA method using commercial test. The neurocognitive functions were assessed using the International HIV Dementia Scale (IHDS). The HIV-infected subjects were found to have a statistically significant lower mean level of serum BDNF than non-infected subjects (p<0,001). There are no statistically significant differences between infected and non-infected women and men. A strong linear positive correlation between serum level of BDNF and neurocognitive functions measured by IHDS in HIV infected patients was found. This preliminary study suggests that HIV can decrease the level of BDNF and may be a risk in terms of neurological complications associated with this infection.

The personal-political dialectic in HIV narratives: Implications for treatment and disclosure

**Jacqueline Zaina** South Africa

This exploratory study conducted within a social constructionist paradigm, attempts to explain the ways in which cultural and political discourses surrounding HIV and AIDS within the South African context, function discursively to silence people living with the disease. It seeks to understand how the range of subject positions available to people with HIV and AIDS influences their opportunities for treatment and disclosure. The author challenges the liberal humanism underpinning the Western individualist paradigm, implicit in economic theories of health behavior, on the basis that by constructing people as ‘rational’ and ‘responsible’, they not only negate social constraints on individual choice, but tend to attribute guilt to people living with HIV and AIDS. The narratives, elicited in personal interviews and discussions held within the context of support groups, suggest that such discourses constitute a form of disciplinary power in a Foucauldian sense. This positions people living with HIV and AIDS defensively, limiting their options for ‘positive’ self-definition, thereby foreclosing possibilities for treatment and disclosure. This has implications for interventions aimed at people living with HIV and AIDS, highlighting the importance of attempting to understand the local and idiosyncratic nature of their constructions of HIV and AIDS. It also advocates considering people’s lives in context and suggests that identity processes, in terms of the need to negotiate a ‘moral self’ in a wide range of social relationships, mediate decision-making in relation to HIV and AIDS.

**Session Type: Posters**

**HIV knowledge and sexual practices among learners with intellectual disabilities and non-disabled learners in Nigeria**

**Toyin Aderemi** Ethiopia; **Basil Pillay**

Individuals with intellectual disabilities are rarely targeted by the current human immunodeficiency virus (HIV) response thereby reducing their access to HIV information and services. Currently, little is known about the HIV knowledge and sexual practices of young Nigerians with intellectual disabilities. Thus, this study sought to compare the HIV knowledge and sexual practices of learners with mild/moderate intellectual disabilities (LMD) and non-disabled learners (NDL) in Nigeria. This cross-sectional, comparative study utilised mixed-methods to investigate HIV knowledge and sexual practices among LMD and NDL in Nigeria. LMD (300) and NDL (300) within the age range of 12-19 years drawn across schools in Oyo State, Nigeria, completed a structured questionnaire to assess their knowledge of HIV transmission and sexual practices. Data were analyzed using SPSS 15.0. There were significant differences between LMD and NDL in their reported sexual experience (p = 0.002), inconsistent condom use with boy/girlfriends (p <0.001) and casual sexual partners (p <0.001), and non-use of condom during the last sexual activity (p <0.001). Among females, LMD were more exposed to sexual violence than NDL (p = 0.053). LMD also demonstrated lower HIV transmission knowledge scores than their non-disabled peers (p < 0.001). Findings suggest that adolescents with intellectual impairments are at higher risk of HIV infection than their non-disabled peers. This gap could be addressed through interventions that target Nigerians with intellectual impairments with accessible HIV information and services.

**PTSD and HIV-related PTSD**

**Melissa Boulind** Rhodes, South Africa

In today’s society everyone is exposed to, or affected by, HIV in some way. There appears to be a growing body of literature targeting HIV-related PTSD and the
symptoms thereof. South African studies have found the prevalence of PTSD among HIV-positive individuals to vary between 0.7% (Freeman et al., 2007) and 54% (Martin & Kagee, 2008). There appears to be a growing interest in HIV-related PTSD (the diagnosis of HIV being the significant traumatic event), with prevalence varying between 4.2% (Freeman et al., 2007) and 40% (Martin & Kagee, 2008).

The current study took place in a 300-bed district hospital, south of Durban, KwaZulu-Natal. Using random sampling, 159 adults (18-50 years) were included in the study with an average age of 34 years (±6.6). The current study found 62% having reported some kind of traumatic event in their lifetime and nearly 29.6% meeting the criteria for PTSD, and the prevalence of HIV-related PTSD was reported by 40.9% of participants. This supports previous suggestions that the rate of PTSD is high amongst HIV-positive individuals (Brief et al., 2004). The high rate of HIV-related PTSD within the current study, together with supporting evidence from prior research (Martin & Kagee, 2008), shows that being HIV-positive, and living with HIV/AIDS, qualifies as a traumatic stressor sufficient enough to result in PTSD symptomology.

Being HIV-positive and living with HIV
Melissa Bouling Rhodes, South Africa

In South Africa there are high rates of the types of trauma which may result in PTSD. Studies have shown that HIV-positive patients display above-average reactions to trauma which may warrant therapeutic intervention (Pedersen & Elklit, 1998).

In addition to the stress of receiving an HIV-positive diagnosis, those who live with HIV are constantly confronted with the trauma of stressful life experiences associated with a life-threatening disease and its progression (Rivkin, Gustafson, Weingarten & Chin, 2006). Smith, Larkin & Flowers (2009) state that the use of an Interpretative Phenomenology Analysis (IPA) approach to explore the individual experiences of health and illness is becoming more common. The employment of IPA in this study illustrates the exploration of people’s experiences of living once they have been diagnosed as being HIV-positive. The current study took place in a 300-bed district hospital south of Durban, KwaZulu Natal. Six participants were selected for detailed interviews from 159 adults. Common appraisals include: the belief that they are contaminated; they fear dying; the belief that they may have deserved it; the paradox of disclosure in an attempt to access support, yet anticipating rejection, as well as a number of compensatory behaviours.

Using the cognitive theory model of Ehlers & Clark (2000), to assist with the explanation and comprehension of the persistence of PTSD symptoms, we can understand how they continue to distress already-traumatised individuals.

Psychosocial variables related to HIV infections in native and adolescent immigrants in Spain
Angel Castro University of Zaragoza, Spain; Gualberto Buela-Casal; Maria Bermudez; Angel Barrasa

One of the main objectives of the Spanish Ministry of Health is to encourage the engagement in safe sexual behaviours that prevent adolescents, in a multicultural context, from contracting HIV. The aim of the present research is to assess several psychosocial variables (socio-demographic variables, variables related to STI/HIV, variables related to gender inequalities, and other psychosocial variables) that could influence STI/HIV sexual risk behaviours in two samples of adolescents: native Spaniards and Latin American immigrants living in Spain. Participants were 1,041 adolescents. Of them, 60.5% were native Spaniards and 39.5% Latin Americans. They completed an instrument to obtain information about these variables. A logistic regression analysis was performed to determine whether the group of variables are predictors of risk of STI/HIV. Results showed that significant differences exist as a function of origin, thus, the Latin Americans, those who have less knowledge of HIV, those who have more negative attitudes towards condom use, and those with less control over relationships, were at a higher risk of STI/HIV. In conclusion, the importance of cultural differences related to STI/HIV is highlighted. The need to adapt HIV prevention programmes to the cultural and gender inequality differences is commented on in the discussion.

Socio-behavioural characteristics of Brazilian men and women aged 50 years and older living with HIV/AIDS
Maria Clara De Paula Couto UFRGS, Brazil; Laissa Prati; Silvia Koller UFRGS, Brazil

This study aimed to describe social-behavioural characteristics of men and women aged 50 years and older living with HIV/AIDS. The sample included 104 people living with HIV/AIDS from Southern Brazil (Mđage = 56 years, range 50 to 73 years, 39 men and 65 women). Participants answered individually a questionnaire comprising queries on socio-demographic characteristics, routes of HIV infection, HIV/AIDS knowledge, and sexual behaviour/substance use. Bivariate analyses were performed to test associations between the social-behavioural variables and sex (p < .05). Findings showed that as compared to men, women reported lower incomes, less schooling years, and an inactive employment status. Men reported more often to be single while women reported being married or widowed. Sexual relations were the main route of infection. Men reported earlier sexual debut and a greater number of casual partners within the last year. However, as compared to men, women reported lower condom use with the last sexual partner. Self-reported history of STDs as well as substance use was more prevalent among men. Men and women are differently exposed to HIV. Women seem to be more exposed to social factors (e.g., impoverishment and sexism) while men seem to be more vulnerable to behavioural ones (e.g., risky sexual behavior). HIV prevention programs should therefore not overlook gender roles. It is important to develop educational strategies focusing on changing men’s attitudes towards sexual behaviour so as to protect them and their partners from HIV infection.

Preliminary results from an assessment study of services for HIV positive children living in Soweto
Susan Hawes Antioch University New England, United States of America

This poster will present assessment results of ongoing assessment services provided on a volunteer basis to HIV positive children being served by a Johannesburg NGO. The assessments, taking place annually during August, developed from a request by NGO’s director of community services. The author had inquired, on her second visit as a volunteer, if there were any professional services she might be able to provide to the children. Efforts were made to develop a group of assessment tools that could have less western biases and a cooperative process was developed with the NGO’s nonprofessional careworkers.

Using: KABC-2 MPI version, Bender-II, HOME Inventory, BERS-2, KFD & KSD, BYI-1, BDI. Recognising that the optimal and most just assessments would use tools developed for children speaking a range of indigenous languages and culturally grounded in their current social contexts, the author determined that it did not make sense to deny services based on what will surely be a worthy long-term objective. Feedback will be actively sought out from viewers of this poster.

The impact of substance abuse on the health status of patients attending HIV
Rehana Kader MRC, South Africa; Charles Parry; John Koch; Rajen Govender; Soraya Seedat

There is growing concern about the effects of substance use on the health status and treatment compliance of people living with HIV and AIDS in South Africa. The study aimed (i) to determine the prevalence of substance abuse as measured by the Alcohol Use Disorders Identification Test (AUDIT) and the Drug Use Disorders Identification Tool (DUDIT), and (ii) to determine the relationship between substance abuse, CD4 count and antiretroviral (ARV) adherence. HIV positive patients were selected from 8 HIV community health clinics in the Cape Metropole. Tier 1 of the study consisted of a cross-sectional study design (n=1503) and Tier 2 comprised a matched case-control study design (n=607). Of the 1503 participants in Tier 1, 37% screened positive for harmful and hazardous drinking on the AUDIT and 12.8% screened positive for drug related problems on the DUDIT. Of the participants who abused any substance, 27.7% stopped ARV medication compared to 11.1% non-substance abusers (p = 0.000). Substance abusers were twice as likely (n = 145, 58.2%) to miss taking ARVs than non-substance abusers (n = 72, 25.0%, p = 0.000). AUDIT scores were negatively correlated with CD4 counts (r = −0.106, p = 0.010), that is more problematic alcohol use was associated with lower CD4 counts. Substance abuse is high among patients attending HIV clinics. This has a negative impact on their health status with respect to ARV adherence and HIV disease progression. Patients treated for HIV should be screened for substance abuse and referred appropriately.

The attitudes of young people (youth) to female condoms and the availability of the female condom for them
Prudence Mdletshe Witwatersrand, South Africa; Mzikazi Nduza

The high incidence rate of HIV/AIDS is maintained mainly through heterosexual intercourse, with the highest incidence amongst young women. Female-controlled prevention methods such as the female condom are yet not part of mainstream response. This thesis explores the perceptions that young people in Johannesburg have about the female con-
Socio-cultural influences in decision making involving sexual behaviour among adolescents in a South African township
Kelvin Mwaba University of Western Cape, South Africa; Leickness Simbayi; Nousindiso Ntshakala
Sexually transmitted infections, including HIV, and unplanned pregnancy are considered to be among the most serious problems facing South African adolescents. While the country has intensified campaigns to increase safer sexual practices among young people, the concern remains that many adolescents are still engaging in unprotected sex. This study sought to explore socio-cultural influences in decision making involving sexual behavior among adolescents in a South African township. In-depth interviews were conducted in isiXhosa with female adolescent first time mothers aged between 15-17 years. The potential role of cultural beliefs and social norms in adolescent sexual practices and decision making were investigated. The results indicated the importance of influences such as peer pressure, alcohol consumption and limited parental involvement. Traditional gender role beliefs and social norms were found to be strong influences with regard to risky sexual behavior. Implications of the study findings for effective intervention strategies are discussed.

HIV-positive pregnant women’s experiences of participation in a structured support group
Nkateko Ndala-Magoro University Of Pretoria, South Africa
Individuals who are diagnosed HIV positive are often reluctant to seek counseling and treatment due to the fear of being rejected and discriminated against. There are limited formal networks for HIV support and psychological help in the South African context. Considering this, structured support groups were implemented for recently diagnosed HIV positive pregnant women. The women were recruited from antenatal clinics. Six support groups were implemented. This project is part of the larger study called Serithi project in which interviews were conducted with 317 HIV positive pregnant women from disadvantaged communities of Tshwane. Based on these interviews, support group intervention was developed. This research forms part of the evaluation of the support group intervention. The aim of this study was to explore the experiences of women who attended the support groups. Women who attended were selected and interviewed individually using semi-structured interviews. The data was analyzed, using qualitative research methods, from an interpretative phenomenological approach. This involved systematically studying meanings, themes and general descriptions of experiences by the research participants. The main findings in this study showed that women who participated in support groups adopted positive coping and behavior that is conducive to their livelihood, learned more about HIV and AIDS, seem to have a positive future outlook and are overall empowered. The findings highlight the importance of social support in the form of support groups in effectively assisting HIV positive women in their journey to adjust to psychosocial consequence of the disease.

HIV/AIDS

Creation and proof of construct: Combination of patient report and objective measures of cognition in HIV
Lisa Palladini McGill University, Canada; Nancy Mayo; Marie-Josee Broutille
Clinicians are usually, at first, confronted by patients voicing concerns about cognitive functioning, of which the clinical significance has been questioned. The objectives of this study were to estimate the extent to which a calibrated measure of cognition, which combines items of patient-reported cognitive difficulties and items from neuropsychological testing, can form a hierarchical uni-dimensional construct by using Rasch modelling, and to validate this measure using known clinical predictors. 76 HIV+ individuals completed a brief computerised battery of tests, the Montreal Cognitive Assessment (MoCA), and a self-report measure (PDQ), all measuring aspects of cognition. The items were Rasch analysed to create a measure of “cognitive ability”. Step-wise linear regression then evaluated various clinical factors, e.g. age and gender and their effect on total scores of the indices used in the measure of “cognitive ability”. The measure had good statistical fit to the Rasch model, and covered 6 logits of the theoretical construct, where items ranged from -2.5 to +3.9 (target is -4 to +4). Regression showed the total MoCA score was associated with education and language (r2: 0.06, 0.15 respectively), total PDQ with depression (r2: 0.4), and scores on the new measure with depression only (r2: 0.19). This type of measure is novel in HIV, and allows researchers to understand the mathematical relationship between these two concepts. Additionally, the validity and uniqueness of this new measure has been proven, as it shares the same predictors as a well-used self-report measure.

Psychologists’ reflections on the facilitation of group psychotherapy for HIV positive students
Lynn Primo-Naidoo PsyCaD, South Africa; Lizelle De Wee
Students diagnosed and living with HIV/AIDS at Higher Education Institutions face numerous challenges that can hold dire consequences for the personal and academic success of a person living with HIV/AIDS. This context may however be beneficial to the success of initiatives for the mitigation of HIV/AIDS challenges. The World Health Organisation (WHO) and Joint United Nations Programme on HIV/AIDS recommend the provision of psychosocial support, particularly group psychotherapy, as one of the key elements in HIV/AIDS care and support. Several Higher Education Institutions offer care and support programmes intended to alleviate the negative impact of living with HIV/AIDS however, the outcomes and challenges associated with such programmes are limited in the literature. The authors facilitated a series of group psychotherapy sessions with students diagnosed with HIV/AIDS. Through critical analysis of the transcribed sessions, the following recurring themes were identified as prominent features that informed the facilitation of the support group: incorporating a balance between dealing with emotions and stressors at the university and HIV/AIDS medical information; psycho-education regarding psychotherapy; continuous revision of group norms; sub-grouping among group members; group members’ involvement with other HIV/AIDS programmes; the interface of structured psychosocial topics and the termination process. Students showed more negotiation and self expression with the progress of sessions, which also became evident in their involvement with other extra-curricular activities at the university.

Investigating the mental well-being of patients accessing HIV treatment at a public health facility in KwaZulu-Natal, South Africa
Ravikanthi Rapiti UNISA, South Africa; Jacques Livingston; Eduard Fourie
KwaZulu-Natal, one of nine provinces in South Africa, has the highest HIV/AIDS prevalence rate. The district of eThekwini has the largest population, and public health facilities are on a drive to initiate treatment. Comprehensive Care, Treatment and Management (CCMT) focuses on side-effects of the drug regimen, and treatment compliance with little focus on mental wellbeing. There is a need to examine the mental wellbeing of patients who are on treatment. iKhusasa ARV clinic based at Addington hospital provides ARV initiation and follow up treatment to eligible patients residing within a thirty kilometer radius. The facility provided a platform to review the mental wellbeing of a sample of patients on treatment. Eligible patients had to meet several criteria, which included receiving treatment for three months or more, eighteen years old and more, accessing treatment from iKhusasa, understanding informed consent, comprehending and speaking English or isiZulu, and excluding patients already receiving psychosocial support. The review comprised a baseline of mental well-being issues in terms of (a) treatment adherence, (b) social support, and (c) coping mechanisms. The study’s progress to date suggests: a) treatment adherence is associated with mental wellbeing, b) scaling up psychosocial support at facilities c) educating patients about mental wellbeing. It is evident that the current mandate on mental wellbeing of patients accessing HIV treatment is insufficient and developing appropriate, and sustainable, measures at public health facilities may not only im-
prove patients’ mental health but treatment outcomes as well.

Subjective processes of people living with HIV/AIDS: A Freudian reading in the Western Amazon
Clara Miranda Santos Universidade Federal de Rondônia; Lucas Matos

Despite its identification for three decades, HIV/AIDS remains among the most serious infectious and epidemiological diseases that the world has ever known, its fast dissemination has led the population, at first, to a climate of panic and the occurrence of many psychosocial problems, especially for those infected. AIDS was not easily understood by society because it involves a complexity of social issues that affect the imagination of the population, notably by being linked to sexually transmitted diseases. This paper intends to describe the subjective processes of people living with HIV/AIDS, aiming to understand the psychological aspects that are developed after receiving the diagnosis. The regarded subjects were specially subsumed by Freudian theory. The method used was exploratory with a qualitative approach to the collected materials of the research named ‘Sources of Stress in People Living With HIV/AIDS’. It was analysed via 40 semi-structured interviews, conducted in the Specialised Treatment Unit in the city of Porto Velho, Rondônia, a state in the Western Amazon. It is observed that after the discovery of the diagnosis, the individual begins to be affected not only the physical body, but also by the feeling of having been a victim of himself, and of being exposed to a serious disease of society: prejudice. There is, finally, the necessity of further training of the health professionals to deal with patients during the whole treatment, but especially at the time of delivery of the diagnosis.

The impact of sexist attitudes in the efficacy of AIDS prevention programmes in secondary schools
Silvia Ulibos University of Burgos, Spain; Ulibos Silvia; Golburu Eider

Two studies will be presented. The first will examine the influence of levels of sexism in the results of an AIDS sexual prevention programme. The second will analyse the programme’s efficacy when sexism levels are reduced. The sample consisted of 517 Spanish secondary students in the first study and 530 in the second. Instruments used were the Double Standard Scale (Caron et al., 1993), the Ambivalent Sexism Inventory (Glick & Fiske, 1996), and the Distorted Thoughts on Women and Violence Inventory (Echeburúa & Fernández Montalvo, 1997). Also included were different scales on knowledge, attitudes and behaviours towards AIDS and sexual activity prevention. The study consisted of a pre-experimental design without a control and sexual activity prevention. The study consisted of the Impact of the adoption of sexual prevention programmes will improve the efficacy of these programmes.

HIV prevention: Revisited
Maretha Visser University of Pretoria, South Africa

Despite claims that HIV prevention works, there is doubt about whether behavioural interventions are effective. The prevalence of HIV in Southern Africa remains high. Serious efforts are needed to reach the goal of zero new infections by 2016. With this in mind a social assessment was done in Botswana, funded by World Bank, to identify socio-cultural drivers of risk to inform new generation HIV prevention. The study involved 129 key informant interviews, 50 focus group discussions and a behaviour survey (n=2016). The survey assessed high risk sexual behaviour, variables that contributed to HIV risk and protective behaviours. Key findings include that HIV prevention in Botswana is state-of-the-art, that the PMTCT, ARV and HIV testing and condom distribution are success stories, and that a risk index, based on the number of sexual partners and condom use, indicated that 27.2% respondents are at risk of HIV. 44.2% men and 25% women reported multiple sexual partners in the past year. HIV risk was influenced by gender, age, perceived control, perceived social norms and acceptance of traditional gender roles. Men mostly justified their risk behaviour as being culturally acceptable. The major challenge to face is the discrepancy between what people know and believe, and their actual behaviour. Prevention should challenge structural barriers to behaviour change to empower all people to take control over their own sexual behaviour. Gender norms and harmful cultural practices should be challenged and positive cultural practices promoted. Legal changes are suggested to include some protection for the uninfected.

Session Type: Invited Symposia

Symposium title: Jacobs Foundation (Switzerland), National Research Foundation of South Africa, IUPsyS. Change fellowship presentations
Convenor: 2012 ICP

Growing up positive: Opportunities and challenges faced by Kenyan adolescents living with HIV
Aminu Abubakar KEMRI/WTRP, Kenya

Adolescents are becoming an increasingly important demographic group in the HIV epidemic. It is widely acknowledged that the youth are one of the high risk groups. Little is known of the social-cognitive and educational outcomes of adolescent with HIV, particularly in sub-Saharan Africa (SSA), despite SSA being home to 90% of the world HIV positive children. The current study aims to provide in-depth data on opportunities, challenges, stigma, and other psychosocial issues experienced by HIV positive adolescents at home and school as well as their educational aspirations and outcomes of these adolescents. This is the first study of a larger program to evaluate the socio-cognitive and educational outcomes of a large cohort of vertically infected HIV positive adolescents in Kenya. 10 adolescents living with HIV, 10 healthy adolescents and 15 key informants (5 health providers, 5 caregivers of adolescents living with HIV and 5 educationalists) will be involved in the study. In-depth interviews, audio diaries and a seven-day recall will be used to collect data. Tape recorded material will be transcribed and analysed in NVIVO using a grounded theory approach. Results and implications of our findings will be discussed.

Improving self-esteem and promoting self-management in HIV-positive adolescents (funded by change fellowship award)
J Anitha Menon University of Zambia, Zambia

Adolescents living with HIV and AIDS in developing countries are a particularly vulnerable group. Positive self-esteem has been established as a resilience factor in stress, whereas low self-esteem in adolescents, is linked to poor health. Research suggests low self-esteem to be common in HIV-positive individuals, and positive self-esteem to be associated with better health-related behaviour. The aim of the study, and presentation, is to evaluate the impact of a peer support intervention to improve self-esteem and self-management of HIV-positive adolescents, their self-esteem, and self-management. A total of 30 participants will be recruited from five anti-retroviral (ART) clinics. Personal Data Sheet, Semi-structured interview schedule to evaluate measure self-management, Strengths and Difficulty Questionnaire Youth version and Parent/Caregiver version and Self-Esteem Rating Scale, will be used to collect data before, and after, 12 weeks’ intervention. Children will be grouped by age and gender. One child in each group will be randomised to the intervention peer support, or wait list group, by choosing a numbered slip. A ten week intervention, with a meeting every week, will involve reviewing group rules, imparting information on HIV and AIDS using an information leaflet, participating in child-initiated talk time, group activity, free play, and snack time. The comparison of scores for the intervention group and wait list group as compared to baseline scores will be presented. A follow up will be made, 12 weeks after the intervention, to ascertain the sustainability of the intervention.

Session Type: Symposia

Symposium title: HIV-Related Stigma: Recent Research Advances
Convenor: John Pryor

Stigma-by-association and psychological distress in family members of persons with HIV in South Africa
Arjan Bos Open University, Netherlands

Stigma affects families as well as persons possessing a stigmatising condition. In this research we examined experiences of stigma-by-association (SBA) among South African university students who had family members with HIV. A cross-sectional survey of 198 HIV- undergraduates who had HIV+ relatives assessed affective, cognitive and behavioural reactions to having an infected relative. We examined potential relationships between these reactions and the following factors: perceived community reactions to persons with HIV (PWH), psychological distress, feelings of closeness to the infected relative, and social support provided to the infected relative. Results: Among the cognitive, affective and behavioural reactions, the cognitive reactions to SBA (i.e., expectations about negative community treatment of the family) were most strongly correlated with variables of interest. These
cognitive reactions also predicted higher psychological distress as well as lower feelings of closeness to the PWH. While cognitive reactions to SBA also predicted less social support provided to the PWH, this relationship was fully mediated by reductions of closeness. SBA represents an important dimension of how the epidemic of HIV-related stigma has affected communities. Because experiences of SBA are related to lower levels of social support, SBA impedes the health and wellbeing of PWH. Other research from our labs has found that stigmatising treatment from family members is a particularly important determinant of psychological distress among PWH.

HIV status disclosure among HIV-positive African and Afro-Caribbean people in the Netherlands

John Pryor Illinois State University, United States of America; Sarah Stutterheim Illinois State University, United States of America

HIV status disclosure is a reasoned process whereby the costs and benefits to oneself and to others are weighed. This study investigated reasons for and against disclosure among a population disproportionately affected by HIV, namely African and Afro-Caribbean people living with HIV (PLWH) in the Netherlands. 42 PLWH of African, Dutch Antillean, or Surinamese descent participated in face-to-face semi-structured interviews employing a structured protocol of theory-based open-ended questions with follow-up probes. Interviews were recorded, transcribed verbatim, and analysed with QSR Nvivo 2 using a general inductive approach. Reasons for nondisclosure were fear of stigmatisation, previous negative experiences with disclosure, having observed the stigmatisation of other PLWH, shame, the desire to protect others from stigmatisation by association and/or worrying, and the belief that one’s HIV status is private. Participants reported disclosing because they were in a close and supportive relationship, disclosure led to emotional release, disclosure could lead to emotional or financial support, they felt a perceived duty to inform, and they had a desire to educate others about sexual risk-taking. The findings suggest that stigma plays an important role in disclosure decisions among these populations. They further point to a need for HIV-related stigma reduction interventions in African and Afro-Caribbean communities and culturally sensitive counseling for PLWH whereby caregivers do not automatically assume that disclosure is best.

Contextual factors as predictors of hiv-related stigma: A representative community based sample in the Rustenburg area, North West province, SA

John Pryor Illinois State University, United States of America; Anna Meyer-Weitz

Objectives: HIV-related stigma poses barriers to HIV prevention, support and treatment. The complexities of HIV-related stigma require an understanding of social and contextual level influences. Methods: Randomized cluster sampling was used in a cross-sectional survey to select a representative household sample (realized sample N=351, ages 18-49). Assessed in this survey were demographics, social cohesion, social distance towards persons living with HIV/AIDS, fear of HIV Counseling & Testing (HCT), and HIV-related stigma. Results: The majority respondents were female (60%) and Black African (85%). A regression analysis showed the full model explained 40% of the variance in HIV-related stigma [F(8,311) = 25.91, p<.001]. The demographic variables contributed 16% of this variance while the other scales explained an additional 24% after controlling for the demographics, [AR2 = 0.24, F change (3,311) = 41.566, p<.001]. In the final model the following were statistically significant: Fear of HCT (β = .399, p<.001), SES (β = .129, p<.010), Education (β = .118, p<.021) and Sex (β = -.114, p<.010). Conclusions: Contrary to expectations levels of social cohesion did not predict AIDS stigma while SES measures, social distance to persons with HIV and fear of HCT played a significant role. Fear of HCT seems to imply a form of self-stigma people were afraid of being labeled HIV+ themselves.

HIV-related stigma: Discussion

John Pryor Illinois State University, United States of America

Dr Pryor will present a discussion of the other papers in this symposium. The epidemic of HIV-related stigma continues to thwart both prevention efforts and care and treatment of persons living with HIV/AIDS. Stigma has some universal dimensions and yet grows out of a cultural context. The four presentations in this symposium focus upon research conducted in sub-Saharan Africa or else upon populations of African descent, all populations with a high prevalence of HIV/AIDS.
Integrating traditional healing methods in therapeutic practice: Enhancing cultural competence in working with Muslims

Amber Haque UAE University, United Arab Emirates; Sanjay Pattananyak; Roomana Siddiqui

With increasing multicultural populations in the West, there is growing interest in the mental health professional community in the indigenous beliefs of people from different parts of the world. This paper outlines the nature of spiritual healing from Islamic perspectives that include writings of early Muslim scholars, practices of the Sufis and a discussion of common traditional Muslim healing practices useful for clinical application. Some of these practices include cognitive restructuring using the Quran and traditions, the Alchemist, the concept of the evil eye, Ruqyah, remedies for possession by the Jinn and use of talismand. Recommendations for professional practice and future research are also offered.

Religious coping strategies for dealing with isolated sleep paralysis among Egyptian individuals

Bamo Jalal The University of Copenhagen, Denmark; Devon Hinton; Baland Jalal The University of Copenhagen, Denmark

While the phenomenology of isolated sleep paralysis (ISP) displays great similarities across cultures, interpretations of ISP have been found to vary. Recent research (Jalal, et al., under review) suggests that a high number of Egyptians (48%) having experienced ISP believe it to be caused by the Jinn, spiritual beings with roots in Islamic tradition. In the current study, we sought to explore the various religious coping strategies individuals from Egypt use to deal with recurrent episodes of ISP. The Sleep Paralysis Questionnaire (e.g., Yeung, Xu, Chang, 2005) was orally administered to individuals (N = 123) from Cairo, Egypt. Results suggest that out of the 48% of participants who thought ISP to be caused by Jinn assaults, 95% would recite verses from the Qur’ân during ISP as a means of protection against the Jinn. Moreover, 9% of those who attributed ISP to the Jinn would increase the number of prayers they performed on a daily basis; and 4% would place the Qur’ân under their pillow prior to going to sleep to prevent assaults by the Jinn. Among the participants who believed that ISP was caused by the Jinn, 26% would consult the local Muslim priest for advice about their ISP episode. In conclusion, this paper outlines the various religious coping strategies ISP suffers in Egypt use, in addition to providing case examples from individuals with high and low SES, thereby shedding in-depth light on how ISP is understood and dealt with in this region of the world.

Cultural inclusivity in psychology: The effective use of Masekitlana in psychological assessment and intervention

Sally John McCord Hospital, Durban, South Africa; Nerine Odendaal-Hinze; Mokgadi Kekoe-Moletsane

In this article the researchers present the findings of three studies conducted in order to investigate the use of a South African indigenous stone play (Masekitlana) in child psychological assessment and intervention. The purpose of the studies was to investigate an indigenous form of stone play as a projection medium and intervention in child psychological assessment and intervention. The theoretical framework was grounded in indigenous knowledge, cultural and indigenous psychology. A qualitative research approach, guided by an interpretivist epistemology was applied. Intrinsic case study designs were employed and participants were purposefully selected. Data collection methods consisted of interviews and observations of participants during Masekitlana sessions. According to the findings, the participants’ projections during Masekitlana correlated with the background information given by their parents and caregivers. With regards to the participants who experienced trauma, the progress was noticed after intervention with Masekitlana. Masekitlana helped them to face and resolve their fears and to gain control, dignity and empowerment in dealing with their trauma. Masekitlana proved important as a therapeutic tool in child psychotherapy. It healed participants in distress in that it gave them a different perspective on past events by providing them with an opportunity to re-experience what had previously been too painful for them to absorb. The limitation of these studies is that they focused on small samples, which produced in-depth information but the results might not be generalised. It is suggested that studies be conducted on a larger scale on the assessment and intervention of children with Masekitlana.

Treatment of mental illness by Afrikaans speaking church leaders in Polokwane, South Africa

Quenessa Kruger University of Limpopo, South Africa

Indigenous Knowledge and Healing Systems
South Africa has a growing rate of mental health care users. As a result of the lack of health resources and personal beliefs, many of these mental health care users consult with their church leaders. A study done in South Africa in 2009 suggests that only 1 out of 4 respondents with a mental illness received treatment from the official mental health care system. The treatment of mental illness by clergy in South Africa is largely undocumented. The primary objective of the research study was to explore and describe the treatment of mental illness by Afrikaans speaking church leaders in Polokwane, Limpopo province. To gain a deeper understanding of the views held by the Afrikaans-speaking church leaders, a qualitative approach was utilized. 10 Afrikaans speaking church leaders were interviewed using semi-structured interviews. The interpretative analysis method was used in analysing the data. The results tend to suggest that most of the respondents use a combination of supportive therapy and teachings from scripture to treat mental illness, irrespective of the specific mental illness they encounter. The data also suggests that many of the respondents do believe in spiritual healing but this is limited to certain conditions.

Diviners’ conceptualisation of the HIV stigma: A qualitative study
Nikeke Lesolong University of Limpopo (Turfloop), South Africa

Most studies that have investigated HIV and AIDS infections in South Africa have tended to focus on this problem from a Western medical perspective. This approach has often ignored the cultural realities that inform help seeking behaviour by those infected and affected by HIV and AIDS. In this study, the researcher focused on ‘diviners’ conceptualisation of the HIV stigma and their own understanding of the treatment of this debilitating condition from the context of the African world view. A qualitative approach, and in particular the grounded theory method was used in this study. Using purposive sampling, thirty indigenous healers (male = 10; female = 20) were approached and asked to participate in the study. The study found that diviners have a potentially positive role to play in reducing the HIV stigma by being compassionate towards people living with AIDS (PLWA) in their healing practices. It was further found that indigenous healers tended to do whatever was necessary (e.g. by involving the patients’ families, showing love and being compassionate) to deal with their patients. The study is concluded by suggesting that there is a need in South Africa and other developing countries to involve diviners in the treatment of HIV and AIDS, particularly when it comes to the involvement of family members in the treatment programme.

Morita therapy: Theory and practice in the treatment of trauma
Peg Levine Monash University, Australia

Morita therapy was developed by Morita Shoma Masatake, MD (1874-1938), and is shown to be effective in treating trauma in Asia and Australia. There is a growing interest in this paradoxical therapy, particularly since the more recent arrival of Mindfulness Therapy, and Acceptance and Commitment Therapy. As contemporary and reader of Sigmund Freud, Maria Montessori, and William James, Morita created a four-stage therapeutic practice that places the client within the context of daily living. This author uses Morita methods in Laos when working with human-trafficked women, as well as in Australia with U.N. veteran peacekeepers, and refugees. The progressive four stages of Morita therapy include complete bedrest, art activity, diary writing, gardening, and animal care, with other ecological activities. Morita therapy is designed as an experiential therapy that facilitates more than behavioral and cognitive change. The evolution of the four stages leads clients to a clearer understanding of the contradictions embedded in living a responsive life. Paradoxical methods and engagement with nature are essential to outcomes. While mulling over the cultural proclivity that has kept Morita out of mainstream literature, the presenter will illustrate Morita’s theory and practice via a documentary film she has produced. (LeVine trained in Japan for over ten years under the late Akihisa Kondo, MD, and was the recipient of the Shoma Morita Prize in Japan in 2011.)

Conceptualization of childhood mental illness by the Sepedi-speaking elderly in the Mankweng community, Limpopo Province, South Africa
Chuene Jones Magabgo University of Limpopo (Turfloop), South Africa

The aim of the study was to explore the notions of childhood mental illness by Sepedi-speaking elderly people in the Mankweng community of Limpopo Province (South Africa). Using the phenomenological method, the researcher sought to understand these elderly people’s notions with a view to: i) describing their conceptualizations of childhood mental illness; ii) determining their notions of the types and causes of mental illness; and iii) describing their views regarding the management of childhood mental illnesses. A total of 8 participants who were selected throughsnowball sampling were interviewed using unstructured interviews. The results of this study suggest that most of the respondents believe that childhood mental illness is a result of witchcraft, prenatal complications and inappropriate conduct, genetic predisposition and unsuccessfully treated postnatal sicknesses. Furthermore, the elderly people believe that childhood mental illness can best be treated by indigenous healers. The results are discussed in the context of the psychological literature on multicultural counseling and psychotherapy.

Exploring the role of songs as psychological liberators among Africans
Tlou Morokane UNISA, South Africa

Music, like love, is said to be a global language that is felt and understood by all. How it is celebrated, what it does, its style and its role are part of what comprises its uniqueness. With the latter statement in mind, Africans are generally better known to be the unique, fervent singers that tend to use almost every situation as a platform to sing, play music and dance. The creative collective performance of songs and dances during intense adversity seems to be one of the aspects that uniquely distinguish black South African communal culture from many in the world. My interest is to explore and find out more about the effect of songs, from a psychological point of view, on the being of Africans in contexts that are expected to bring intense fear, anger, dysphoria and other known negative feelings.

Djembe drumming: Circles beyond the notion of entertainment
Melusi Mbatha University of South Africa, South Africa; Juan-Pierre Carstens University of South Africa, South Africa

The djembe drum has its origin in Africa. The word “djembe” means “everyone gather together in peace” and defines the drum’s purpose. Through its utilisation in African healing rituals, the djembe gained the prestige of a healing drum. In our experiences of djembe drumming, we have found that drumming offers a truly holistic healing approach, as it breaks down social barriers, promotes freedom of expression, non-verbal communication, unity and cooperation, and also serves as a form of physical exercise. At a health care centre in Pretoria, South Africa, we offered one-hour drumming sessions over a period of two weeks to a diverse group of participants. The group consisted of working staff, patients with physical disabilities and stress-related disorders. After the drumming sessions it was found that drumming awakened dormant memories and unexplained feelings of excitement, peace, and ecstasy for patients and the working staff. Whereas drumming performances are often seen as a form of entertainment, in the discourse of the dominant western culture, we experience them to be powerful forms of expression, sending vibrations throughout the whole body. Our interest lies in exploring the culture of djembe drumming as a mechanism for psychological healing, self-expression, stress reduction and connection.

Decoconstructing African identity and Black consciousness: A coconut, a creative ontology defining Blackness
Mzamo Mbuli University of South Africa, South Africa; Beebe Makuwa University of South Africa, South Africa

The main objective of the study is to describe how ‘coconuts’ construct their own ontology/identity and to determine both fundamental and cosmetic factors that makes coconuts perceive themselves as Black/Africans or non-Black. Furthermore, to provide a directive of how to tackle the issue of racism and Black inferiority, as well as providing an antithesis to racism and Black inferiority. In depth interviews will be used for the study. Furthermore, in analysing the qualitative data Interpretative Phenomenological Analysis (IPA) shall be used. 36.2. Indigenous perspectives on racism 25.15. Liberation psychology: The ‘coconut’ is a term commonly used to describe indigenous Black South African children who are perceived to be physically Black but whose speech and behaviour is that of White people. In other words a ‘coconut’ is an indigenous Black South African youth who has assimilated a White identity. The ‘coconut’ is Black cosmetically and White ontologically. The ‘coconuts’ perception of self and others, world view, intellect and way of being, are perceived to be usurped by Western ideology and ontology hence the term ‘coconut’; Black on the outside and White on the inside. The
participants of the study will be young indigenous Black South Africans (male/female) who perceive themselves to be 'coconuts.'

The role of the traditional healer at South African tertiary institutions: Issues, challenges, and the way forward

Nhanhla Mkhize University of KwaZulu-Natal, South Africa; Zinzini Bomoyi

Tertiary institutions in South Africa have become more diverse and this raises questions about the extent to which student counselling services have adapted in order to address the social and psychological needs of students from different cultural backgrounds. In-depth, open-ended interviews and focus group discussions were held with students, psychologists and the University of KwaZulu-Natal leadership in order to determine not only their views on the infusion of traditional healing practices into the counselling process in general, but also to establish the extent to which the training of student counsellors has been adapted to accommodate the social and clinical realities of the diverse student population. The University of KwaZulu-Natal was ideal for a study of this nature, as it has experimented with traditional healing in one of its campuses for a number of years. The results indicate that the benefits of the infusion of traditional healing practices into the counselling process in general, are due in part to the congruence in worldviews between the healer and the students. The benefits as well as the challenges of providing counselling in indigenous languages are highlighted. The study concludes by highlighting the ethical implications of the practice of traditional healing in spaces historically reserved for the individualistic paradigm of counselling.

Worldview and context determine the sense of self

Letta Mosue South Africa

The African sense of self is determined by the worldview that is communal, in that it is based on the proverb that summarises this worldview as follows: "Mothe ke motho ka batho ba bangwe" (I am because we are). So when in psychology we speak about a sense of self, we take it for granted that it is universal. In this paper I compare how the African worldview relates to these concepts, is explored and discussed. Metaphysics as it manifests in an African Ubuntu philosophy is explored and linked to viewing Ubuntu as an ideology. This is discussed with reference to attaching universal, as opposed to contextual, value to the philosophy of Ubuntu. The roles of culture, tradition and intercultural influences in Ubuntu philosophy are explored and critically evaluated. The term 'moya' has in current African academic literature been proposed as a culturally appropriate substitute for the contextually inappropriate Western term 'psyche'. The place of moya in an Ubuntu worldview is explored. New possibilities opened up by both the expansive view of a moya psychology and a therapy of Ubuntu are finally explored in contrast with Western and more individualistic understandings of psychology and therapy. The spiritual basis of an ubuntu therapy opens up the possibility of viewing the psychotherapist as a healer who cannot bring healing to others without him/herself also receiving healing through the healing he/she brings in therapy.

Reflections on ubuntu as a psychology and a therapy

Tobie Muller UNISA, South Africa

Ubuntu has been described as the basis and the edifice of African Philosophy. The inseparable concepts of African ontology and epistemology provide the possibility for co-existence of the notions of motion and rest. How an African worldview relates to these concepts, is explored and discussed. Metaphysics as it manifests in an African Ubuntu philosophy is explored and linked to viewing Ubuntu as an ideology. This is discussed with reference to attaching universal, as opposed to contextual, value to the philosophy of Ubuntu. The roles of culture, tradition and intercultural influences in Ubuntu philosophy are explored and critically evaluated. The term 'moya' has in current African academic literature been proposed as a culturally appropriate substitute for the contextually inappropriate Western term 'psyche'. The place of moya in an Ubuntu worldview is explored. New possibilities opened up by both the expansive view of a moya psychology and a therapy of Ubuntu are finally explored in contrast with Western and more individualistic understandings of psychology and therapy. The spiritual basis of an ubuntu therapy opens up the possibility of viewing the psychotherapist as a healer who cannot bring healing to others without him/herself also receiving healing through the healing he/she brings in therapy.

Memory healing processes and community intervention in grief work in Africa

Augustine Nwoye University of KwaZulu-Natal, United Republic of Tanzania

Western literature on bereavement acknowledge the tendency to pathological grieving among some bereaved persons. The phenomenon of pathological mourning, however, is rare in Africa because of the presence of coherent and transformative rituals of mourning. This presentation argues that such ritual and performative experiences heal by addressing four principal aspects of the memory of the bereaved individual. The paper elaborates on the content, process, symbolic meanings, and clinical potency of these rituals. The principal significance of the paper is to show that while Western researchers have largely been concerned with the individual’s reaction to loss, the African perspective focuses on the spiritual/systemic/interactional nature of healing in grieving and the resources which the community makes available to bereaved persons. The objective of the presentation is to showcase the African community’s contributions to facilitating healing in the other factors like culture and patient quality of life (QOL). Breast cancer can impact patients psychologically as well as organically. Little is known about the cultural beliefs and quality of life of women of African descent with breast cancer. A qualitative design was used to explore cancer-related beliefs and QOL among black women with breast cancer in one provincial hospital in Limpopo Province (South Africa). In-depth, semi-structured face-to-face interviews were conducted with ten black cancer patients receiving treatment at Polokwane Hospital. Additionally, a Life Satisfaction Questionnaire (LSQ) was administered. The results are discussed within the context of culture and illness, that is, the relationship between culture, chronic pain/illness and wellness. The paper is concluded by arguing that psychologists and other health professionals will need to understand and treat people of African descent taking into account their cultural context.

Shattered consciousness, fractured identity: Black psychology and the restoration of the African psyche

Wade Nobles San Francisco State University, United States of America; Shanggui Song; Lei Song

The author will discuss the intentional destruction of the African mind resulting in the ‘shattering of consciousness and the fracturing of identity’ for both continental and diasporic Africans throughout the world. Guided by ‘Sahku Djaer/Sheti’, an African centered analysis developed to advance Black Psychology, this discussion will illuminate how the African systems of knowing have been systematically morphed by colonialism and slavery resulting in a mental barrier for African development, and identify strategies for restoring African consciousness and identity. He will demonstrate that African resistance has always been resistance to de-Africanisation and dehumanisation and suggest the importance of African (black) psychology and the restoration (suruja ta) of the African psyche in Africa and throughout the diaspora as fundamental to the success of the African Renaissance and the advancement of the world-wide African family.

Afrocentric psychology: Conceptual perspectives from Bemba authors

Richard Mukuka University of KwaZulu-Natal, Zambia

The year is 1884. Somewhere in central Africa (in the land surrounded by Lake Tanganyika in the north, Luapula River in the west, Lake Bangweulu in the south, and Muchinga Escarpment in the east) is a vast Bantu kingdom known as Bemba. The people are ababemba. Somewhere else, and unbe-named to ababemba, European nations are sharing African land, including that of ababemba. Western history books record this as the Scramble for Africa. Consequently to the scramble, ababemba find them-selves in a British-controlled arbitrary amalgamation of ethnic groups called Northern Rhodesia (later, Zambia). The Bemba socio-political system collapses. Energetic Bemba men are forced into mine labour to raise tax money. Mine towns bring together cultures from Northern Rhodesia, Nyasaland, Southern Rhodesia, Tanganika, India, South Africa, and Britain. For ababemba, this period is characterized by a multi-layered psychological disequilibrium. Taking advantage of the onset of the written text, Bemba authors delineate for their kinsfolk an Afrocentric space around their new socio-political reality. These novelists are neither psychologists nor conventional philosophers; but, are educators, writers, and politicians. That notwithstanding, their literary treatment of the African psyche has a profound psychological dimension. This paper presents key tenets of the Afrocentric psychology of ababemba. Currently, Afrocentric psychology is an “aggregated” voice without clear links to substantive knowledge about specific African cultural communities. This paper provides one such link.

Quality of life and breast cancer: A study of black women breast cancer survivors at Po-lokwane provincial hospital, Limpopo prov-ince, South Africa

Shai Nkoana University of Limpopo, South Africa

Psychology, this discussion will illuminate how the African systems of knowing have been systematically morphed by colonialism and slavery resulting in a mental barrier for African development, and identify strategies for restoring African consciousness and identity. He will demonstrate that African resistance has always been resistance to de-Africanisation and dehumanisation and suggest the importance of African (black) psychology and the restoration (suruja ta) of the African psyche in Africa and throughout the diaspora as fundamental to the success of the African Renaissance and the advancement of the world-wide African family.

Indigenous Knowledge and Healing Systems
bereaved. It is believed that such an account will complement the work already done in the bereave-ment field by Western investigators.

**Australian aboriginal counseling: Ten years of change in New South Wales**
Robina Otrupeck Bourke Aboriginal Medical Service, Australia; Christine Darcy

By the year 2000 there was widespread recognition that indigenous people in Australia were suffering tremendous loss and grief, much of this transgenerational, and that they were expressing this grief in anger, drug and alcohol problems and poor health. Non-indigenous health care workers were frustrated by the seeming rejection of their help, and by the lack of ability of indigenous groups to fit in to established health care programs. We had to find another way to help these people or risk losing a large proportion of an amazing group of people that have been enriching the lives of newcomers for over 200 years. This presentation will give some indications of the gradual change of approaches to aboriginal mental health in NSW over the last ten years. Initially, practitioners attempt to find out how best to engage effectively with indigenous groups. Skills and knowledge are then developed within these groups. Eventually, the roles of non-indigenous mental health care workers are reduced as language groups begin to take on their own self-care in their own way. I will present a few of these endeavors of healing and of empowerment generated in New South Wales. The innate skills in indigenous people were always there but the trauma of colonization and the transculturation as they have learnt to survive in two cultures have disempowered the elders of these groups that so successfully lived by their own laws and lore for 60,000 years.

**Yarning to explore healing systems in indigenous disabled children in the west australi-an goldfields: A pilot study**
Jillian Pearsall-Jones The Centre for Cerebral Palsy, Australia; Marie Blackmore; Marie Blackmore; Caris Jolla

The aims of the study were to: 1) explore health and educational needs, and barriers to access, for Indigenous families; 2) establish a collaborative Reference Group for mutual, reciprocal interaction between services in Perth and Kalgoorlie. Yarning was recognised as a legitimate methodology in Indigenous research. Yarning, social, research, collaborative and therapeutic, can be used to empower Indigenous communities. Social and collaborative yarning allows researchers to initiate engagement and establish relationships of trust. This pilot project utilised social and collaborative yarning as an informal means to establish trust and relationships between Indigenous people and service providers. It was found that (1) access was impeded by lack of cultural competence of service providers, trust and transportation, the child’s disability, family challenges; (2) carer and family structures significantly impacted health and education outcomes of Indigenous children with disabilities; (3) Indigenous perceptions of disability are holistic, having implications for services; (4) current successes in the region included mobile services; open clinics; provide transportation and meals; and services run and owned by the Indigenous community. A collabora-tive Reference Group between families, disability and specialist services, health organisations and other stakeholders in Perth and Kalgoorlie was established. Future projects aim to use research and therapeutic yarning as a tool to build the capacity of Indigenous communities, and individuals in the lives of Indigenous children and adolescents with disabilities, to increase participation, up-skill Indigenous families and enhance service delivery. Yarning can be used as a tool to improve healing systems of Indigenous families.

**Localising the standards of care: Transgender health care**
Liesl Theron Gender Dynamix, South Africa

What does it mean in South Africa and other Afri-can countries to talk about access of medical care for transgender and intersex individuals? In a country and a continent where transitioning by medical and surgical methods are not always successful, many creative ways are invented, and different negotiations take place, to narrate trans- and inter-sex lives. Do medical and health practitioners not overlook a very large community of trans-people’s needs because they do not fit in the pages of the Standards of care [SOC]? Gender Dynamix [GDX] hosted, in 2010, a trans-health pre-conference. During this very important event, interested participants indicated the need to allocate more time to focus on this area of work. In March 2011 GDX hosted the first such focus group, bringing trans-activists, sango-mas and traditional healers together to discuss the intersection of western medicine and indigenous knowledge. This presentation will share some of the discussions that formed the background information of the recommendation paper that was later released. GDX and interested participants will continue working in the field of Indigenous Knowledge, and advocate for a model that can be used for transgender people accessible in primary health care settings, clinics and rural or remote areas.

**Social cognition research on the mental har-mony of minority students of China**
Xue Wang Beijing Forestry University, China

Mental harmony includes self harmony, family harmony, social attitude, and the cognition of mental harmony and relationship harmony. Self harmony, family harmony and social harmony are three levels of psychological harmony ranging from the narrow to the broad. It is of great significance to study the cognition of mental harmony among different minorities of China. Mental harmony plays an important role not only in the mental health of Chinese minority students, but also in the national and social harmony of China. Using a survey method, we investigate the mental harmony of 450 Chinese minority students. The results show that there are significant differences in mental harmony for different nationalities, genders and family addresses. Moreover, students of the Han and the Hui nationality pay more attention to family harmony, while those of the Mongol nationality, Uigur and Tibetan pay more attention to self harmony. Students of Mongol nationality believed that interpersonal relationships were more important, while those of Hui nationality selected social peace. More and more students sing high praise for interpersonal relation-ships and family harmony. These results show that the Hui students focus on social harmony, while Uighur and Tibetan students focus on self harmony. Based on the study, future work should pay more attention to minority students’ mental health, which will not only improve minority students’ mental harmony level, but also strengthen Chinese national unity and promote social harmony.

**The dynamics of diabetes management for individuals in Indonesia: Exploratory indige-nous study on health**
Kwartinri Yuniarti Faculty of Psychology, Indonesia

This is an integration of four studies on diabetes seen in relation to illness perception, stress, depres-sion, social support, and self management. Three studies were using a qualitative approach, whilst study four used a qualitative approach. Sobel-test was used to examine on the mediation statues of the variables, and regression was then executed for hypotheses testing. The qualitative study used phi-nomenology and indigenisation-without from a foreign theoretical foundation. Self-acceptance is significantly related to depression ($r$: -.14, $p$: .05) without being mediated by perceived social support ($r$: -.16, $p$: .05). Religiosity proved to be significant-ly related to stress ($r$: -.69, $p$: .05), mediated by self acceptance ($r$: -.36, $p$: .05). “Easily being tired in work, compared to the previous condition” was identified by most of the study participants as the cause of stress. It was also discovered that illness perception and coping strategies were not directly association with self-management in general. This study suspected that there are multi-co-linearity among components of illness perception (yielding 8 sub-components), coping strategies and self-manage-ment. Results from the qualitative study show that center of management is the mother, positive and negative emotion was associated with the ex-ternal control management by the mothers. It was also found that all study participants were not able to accept the illness as it is, and having relatively limited knowledge on the illness. Local belief in-volved that diabetes was perceived as something bad, inherited by family.

**Session Type: Posters**

**Lessons learnt at the University of Kwazulu- Natal from delivering a contextually relevant certificate programme**
Nontobeko Butelezi University of KwaZulu-Natal, South Africa; Bonisile Mathe; Nlanhla Mkhize; Nwabuco Okeke-Uzdokle; Beverly Killian; Phindile Mayoba University of KwaZulu-Natal, South Africa

The Certificate programme offered by the African Centre for Childhood (ACC) is successfully offered in ten African countries. The training and support of the ACC is the initiative of the University of KwaZulu-Natal (UKZN) in partnership with the Region-al Psychosocial Support Initiative. The second cycle of the 18 months programme commenced with 1063 students in 2011. The delivery of the innova-tively situated, supported distance learning programme for those working with children and youth provides access (even in remote areas), meaningful participation, and recognised formal qualifi-cation for the community care givers. The UKZN provides quality assurance and an enhanced capac-
ity to affiliated African academic institutions who offer the ACC programme by producing mentor guides, setting assessments and providing external moderation. This paper presents the methodology, experiences and reflections of the academic team involved in the ACC certificate programme. It also reflects not only on the contribution made by the UKZN within the African continent, but also on the lessons learnt during the implementation of the programme. Curriculum design based on cross-cutting themes from six modules each running over three months is highlighted, and the paper describes briefly how the curriculum has been revised to embed the Afro-centric epistemology which is the foundational philosophy of this programme. The paper concludes by outlining the vision of the programme within the African continent and its potential role within the international arena.

Charting the reach of indigenous African knowledge
Andrew Harris Monash University, Australia

This presentation reports on a PhD study which commenced in 2006 as a counterpart to the provision of culturally informed therapeutic practice. The objective of the study was to develop strategies to assist in building the capacity of western counseling practitioners in providing appropriate therapeutic interventions to the target groups. Initial participants were women who had entered Tasmania, Australia as refugees from the African continent. Specifically from Egypt, Sudan, Sierra Leone, Liberia, and Ethiopia. All participants identified with traditional communities from within these countries. The initial phase of the study consisted of phenomenologically oriented interviews with a total of 16 men aged from 25 to 65. The researcher also participated in a range of community gatherings and family settings to obtain ethnographic data, and an extensive literature review was conducted on forced migration, ethnography, and medical anthropology. The outcome was a collection of "phenomenological statements" which were tested with two consensus groups each consisting of five men, from South Sudan and Sierra Leone. The current phase of the study involves interviews with and participant observation in intact traditional African communities to enable a thematic comparison between displaced and non-displaced communities. Issues raised include the marginalisation of historical representations of African-derived knowledge and expertise within western research, and the application of African ideas of self and community to problems presented by western clients.

Psychological constructs of healing and survival from Africa and its diaspora
Denise Hinds-Zaami Lock Haven University, United States of America

Psychology generating from Africa and its Diaspora, has been little known or considered until now, and can provide important insights. How could any group of people exist from the beginning of time and during severe life and social circumstances? What has gone unrecognised or even unwritten as psychological constructs, skills and tools used by people of African descent is explored and revealed herein. Such constructs have existed in different locations throughout the Diaspora. How are such constructs, often used in response to deplorable human conditions such as slavery, discrimination, child soldiers, disease and rape, able to serve humanity now? Using qualitative research, including field interviewing and observations, as well as literature review, these issues are addressed, as well as answers and insights provided. Aspects of health, healing and survival are presented, as well as tools and practices unknown to many. It is concluded in this paper that psychology in Africa and in the African Diaspora is not just a branch of European and American psychology or an afterthought from their development, but has roots and rites of its own long ago which have not been widely known or considered. Psychology from Africa and its Diaspora is also shown to have been the forerunner of many comparable legacies in self-sustaining, healing and uplifting attitudes, as well as in successful human interaction patterns of yesterday and today that can serve all of humanity in the future.

South African Hindu psychologists’ perceptions of mental illness
Sumaya Laher University of the Witwatersrand, South Africa; Priyanka Padayachee

Conceptualizations of mental illness are not universally applicable, as culture shapes the expression, perceptions and treatment preferences thereof. Consequently, if one is to effectively understand diverse communities, an exploration of the impact that cultural and spiritual beliefs have on community members’ perceptions of psychological disturbance is imperative. By focusing on the perceptions of Hindu psychologists regarding mental illness, this study aimed to provide a deeper understanding of the impact that religious beliefs have on such conceptualizations. Semi-structured interviews were conducted with six Hindu psychologists around the Johannesburg area. Responses were analysed using thematic content analysis. From the findings it was evident that religion plays a critical role in the understanding and treatment of mental illness. Additionally, it was found that a tension existed between psychologists’ awareness of the influential function of religion, particularly amongst collectivist communities such as the Hindu community, and their occupational understandings and practices, which are deeply rooted in Western thought. Furthermore, it was suggested that the fear of stigma prevented Hindu clients from reaping the benefits of seeking help from culturally competent psychologists.

Perceptions of mental illness amongst South African Muslim psychiatrists
Sumaya Laher University of the Witwatersrand, South Africa; Tasneem Bulbulia

The definition of mental illness is in itself a disputed concept. As such it is perceived differently amongst different groups of individuals. The way in which the West conceptualizes mental illness is often considered to be limited in their understandings of cultural and spiritual conceptualizations. There is therefore a need to incorporate alternative understandings into diagnosis and treatments in order to adequately understand and treat patients from non-Western backgrounds (Ally & Laher, 2007). This study aimed to explore the perceptions of mental illness amongst South African Muslim psychiatrists, with a specific focus on the role of Islam, if any, on these perceptions. A non-probability sample of seven Muslim psychiatrists were interviewed for the study. Thematic content analysis was used to analyse the data obtained from the semi-structured interviews. The findings of this study suggest that psychiatrists attempt to remain objective and to not impose their religious and cultural beliefs on their patients. However, their conceptualization of mental illness is undoubtedly influenced by their religion and culture. Furthermore, all the participating psychiatrists highlighted that they always draw on Islamic values when treating their patients. This study also found that there is a great need for an Islamic psychology. However, it is imperative that further research and literature be produced in this area as Islamic conceptualizations of mental illness as well as Islamic psychology are relatively unknown.

Mental illness as conceptualised in Islam
Sumaya Laher University of the Witwatersrand, South Africa

This poster focuses on Islam’s view of mental health from the time of the Prophet (p.b.u.h) to today. Specifically, it addresses whether Islam distinguishes between mental, physical and spiritual health and illness. The etiology of mental illnesses as specified in Islam will be discussed as well as the treatments advocated by Islam. These will be contrasted with Western, Hindu and African approaches to mental health with a view to commenting on the viability of an Islamic Psychology.

Traditional folkloric music as a therapeutic intervention: Bomba and plena of Puerto Rico
Daniel Martinez Carlos Albizu University, Puerto Rico

The first sounds that we hear in our mother’s womb are the rhythms of her breathing and the beating of her heart. Babatund Olatunji stated that rhythm is the soul of life. The universe moves in rhythm as does every human action. From the shamans of Mongolia to the healers of Mimiamka in western Africa, the therapeutic techniques that implement rhythm have been used for thousands of years to strengthen and maintain physical, mental and spiritual health. The ties between positive feelings and music can explain why certain songs and melodies can promote a wave of memories and feelings, the music of the Beatles is a perfect example. The Bible states that David played his harp to reduce King Saul’s depression. Evidence based interventions have included the use of music in therapy for patients with Alzheimer’s (Bernstein and Johnson), cancer patients (Turry), patients suffering from Multiple Sclerosis and Parkinson’s (Thaut), addiction (Stevens), psychiatric rehabilitation (Longhofer), and stress (Quinn). Stress basically occurs when one disconnects from the earth, forgets how to breathe, and thinks that everything is an emergency. Life without music is simply seeing things in black and white. Music adds colour to our experience. Bomba and plena music have their roots in Africa and Spain. This presentation will explain the different patterns of the plena and bomba music of Puerto Rico and how they are used therapeutically.
Participants will be invited to play and/or move to the different rhythms which will be presented.

Evaluation of an HIV and AIDS training programme for faith healers in the Vhembe district municipality of Limpopo Province in South Africa

Tshilidzi Mashamba University of Venda, South Africa

The purpose of this study was to evaluate an HIV and AIDS training programme for faith healers. A quasi-experimental design was used. The population comprised United African Apostolic Church members. A sample of 103 faith healers was selected using convenience sampling. Participants were divided into two groups: a control group of 45 and an experimental group of 58 participants. Both groups received pre- and post-assessment at times 1 and 2 respectively. Data were collected using a questionnaire. The training was conducted using an HIV/AIDS training manual. Data were analysed using SPSS. Participants showed adequate knowledge on HIV/AIDS/STI. Their knowledge of risk perceptions, and attitudes, was found to be both poor and adequate. For HIV/AIDS/STI management, their knowledge was poor. Most participants knew the correct facts about HIV transmission routes. They knew less about sexual practices that increase the transmission of HIV. Cultural practices such as widow cleansing, widow inheritance, arranged marriages, and polygamy, put women at risk of contracting HIV. Faith healers are against these practices. All the participants in the post-tests approved of distributing condoms. When asked if participants used condoms, there was a slight increase because condoms are not very popular in Africa. Few participants reported that they talk about HIV/AIDS/STI during church services and few reported keeping condoms at church. A minority reported not to know where to get VCT.

Conceptualisation of mental illness by young people in Mamelodi Township, Gauteng Province

Rubin Ramaboea University of Limpopo, South Africa; Tholene Sodi South Africa

The aim of this study was to investigate the conceptualization of mental illness by young people in Mamelodi township, Gauteng Province. Specifically, the researcher sought to: i) explore young people’s conceptualization of mental illness and to understand their explanations of the causes of mental illness; ii) investigate and describe the young people’s understanding and explanation of the types of mental illness; and, iii) investigate and describe the young people’s views regarding the treatment of mental illness. A qualitative research approach was used. In particular, the researcher utilised the grounded theory method which is primarily concerned with the generation, rather than testing of theory. A total of 12 participants, selected through purposive sampling were requested to participate in the study. Among others, the results show that young people have some clear understanding of mental illness, including the causes and how this condition of ill health can be managed. The results are discussed in the context of the national and international efforts aimed at understanding and documenting indigenous knowledge systems, particularly in the area of culture, youth and mental illness.

The second wave: Birth and rise of evolutionary indigenous psychology

Zhimin Wu Jiangxi Normal University, China; Meirong Chen

The first wave is the publication of “Cinization of psychological research: The hierarchy and direction” (Yang Guoshu, 1980). As a symbol, it opened a prelude to the localization of Chinese psychology. Chinese Indigenous psychological research has made fruitful achievements, but there were some problems in the past 30 years. From the dilemma comes the evolutionary perspective to study Chinese indigenous psychology, hoping to set off the second wave. This study puts forward the concept that the evolutionary indigenous psychology combines indigenous psychology with evolutionary biology, and evolutionary psychology. This study analyses the backgrounds of the birth of evolutionary indigenous psychology, its subject characteristics, research methods, research content, and its relationship with the evolutionary culture psychology; its limitations and it may be subject to criticism and its prospect, etc. With the rise of evolutionary indigenous psychology, it is bound to promote further research of Chinese psychology and behaviour.

Respectful partnerships between Australian psychologists and Aboriginal people

Stephen Meredith Department of Health, South Aust, Australia; Yvonne Clark

Australian Aboriginal people have experienced a long history of dispossession and oppression as a consequence of European colonisation. These experiences have resulted in a disproportionate burden of social and emotional distress amongst Aboriginal people. Because the number of Aboriginal Psychologists in Australia is currently disproportionately low, it is necessary that non-Aboriginal Psychologists play a role in providing services to help Aboriginal people in healing. In order to be effective, these services need to be delivered by culturally competent Psychologists who are able to provide a culturally safe environment for Aboriginal people. Our experience provides evidence that this can best be achieved when non-Aboriginal Psychologists in these roles develop and maintain respectful partnerships with Aboriginal people. In this presentation, we describe a range of respectful partnerships exemplified through our own experiences and through a case study of a community mental health organisation in which partnerships were developed at a number of levels. We discuss the nature, development and maintenance of these partnerships over time, and present data on their effectiveness in creating a culturally safe service. We conclude that, when non-Aboriginal psychologists take responsibility to develop respectful partnerships with Aboriginal people, it is possible for them to play a part in healing some of the damage that has been done to Aboriginal people by the process of colonisation.

Psychotherapy in ancient China: Humanising practice on trauma in traditional medicine literature

Tak Ho Lam HKSAR Government, Hong Kong

With history of numerous wars, natural disasters and epidemics, it is reasonable to assume a large number of people suffered from psychological trauma in ancient China. Ancient Traditional Chinese Medicine (TCM) practitioners may therefore have the richest clinical experience in trauma work. In the earliest Chinese Medicine classic, the Yellow Emperor’s Classic of Internal Medicine Basic Questions (Huang Di Nei Ching Su Wen), there is a chapter called “Discourse on Moving the Essence Changing the Qi” (yi jing bian qi lun), it discussed healing without using acupuncture or medication as well as the principles of doing such work. Therein lay the foundations of psychotherapy in TCM. My paper aims to give participants more inspiration to
an idiosyncratically integrated framework embedded in ancient wisdom of TCM. The first part of this symposium signifies the author’s recent research work on Post-traumatic Stress Disorder (PTSD) in TCM, with conceptual mapping of the symptoms of PTSD to diseases under TCM (“bing”) by conducting systematic search and qualitative content analysis in classical TCM literature from pre-Han to Qing Dynasty. In addition, several case records in Chinese Medicine classics, show the practice of psychotherapy by ancient TCM practitioners from Song to Qing Dynasty. They elucidate the humanising approach and advantages of TCM in dealing with psychosomatic complaints and psychological problems over thousands of years. These have implications for contemporary practice.

Brief introduction to our symposium
Weidong Wang Guang’ an men Hospital, CACMS, China; Shitong Li; Fang Wang; Hui Du; Xueyu Lu; Lan Hong
As great group unconscious strength, culture plays a prominent role in peoples’ mental health. Thus, psychological treatment should pay attention to culture effect. Our workshop will illustrate such a theme “Clinical Psychology in the Background of Culture Collision between the East and West”. Presenters will demonstrate their achievements in this field which involves basic theory as well as psychotherapy methods. For example, Thought Imprint Psychotherapy under Lower Resistant State(TIP) is an indigenous psychological therapy, which is established by Professor Wang, reflects the Chinese culture impact on Chinese psychology. Self-consciousness, attachment between generations, emotion expression is different between East and West. Clinical practice has proved TIP is an effective method for depression, insomnia, etc. Other methods, take acupuncture for example, are widely used in China. These methods also are effective. In the symposium, experts will illustrate them. The wide horizon will probably bring a new perspective of the Oriental for the world.

Symposium title: Themes and issues in African psychology: Voices from the continent
Convener: Tholene Sodi
Epistemological realignment of psychology in South Africa: Challenges, contradictions and myths
Lesiba Baloyi United States of America
The transition from the colonial and apartheid era to a democratic South Africa did not transform psychology both as a field of study and practice. The philosophy, theories and focus of the current psychology, including how this field is practised in South Africa is still firmly rooted in the Western epistemology paradigm. This prevailing situation raises serious questions about the relevance and legitimacy of Western psychology which psychologists in South Africa and Africa ought to interrogate. In this paper I argue that psychology that is at variance with the lived experiences and cultural practices of Africans cannot claim epistemological and ontological legitimacy. Similarly, Western psychology cannot fully explain the world views, behaviour and practices of Africans without misrepresentations, misinterpretations and contradictions. This theoretical paper disputes the myth of a single dominant psychology that is presumed to be applicable in all contexts. The thesis posited in this paper is that an authentic African psychology should be predicated on and informed by the African epistemology.

An expository study of umhayizo: Mass hysteria among learners
Thandeka Moloi Independent Practice, South Africa; Simcha Mdaka; Maureen Mbense; Smangele Magwaza
The current trends in umhayizo (commonly understood as mass hysteria) attest to high prevalence among black African learners at all levels of schooling. Several studies have been conducted in the area of umhayizo within the schooling system, but there is paucity of research on the cultural determinants and manifestations of umhayizo. Most researchers engage purely Eurocentric paradigms to gain empirical insights into this phenomenon despite its predominance among black African learners. The study therefore sought to explore the following research questions: What is the nature of umhayizo? What are the cultural determinants and triggers of umhayizo? What are the cultural manifestations of umhayizo? What are the perceptions of umhayizo by parents as well as educators and learners from African and other cultures? A qualitative research design was used to explore the participants’ subjective experiences and cosmic meanings of umhayizo. Fifteen educators, thirty learners twenty and ten parents from three schools which had experienced episodes of mass hysteria were interviewed using unstructured interview schedules. Qualitative analysis generally indicated that the experiences of umhayizo and its manifestation make sense if contextualised within African epistemology. The paper is concluded by arguing that these cultural experiences can provide useful insights that can help advance the agenda of African psychology.

Themes and issues in African psychology: Voices from the continent
Tholene Sodi South Africa
This symposium questions the dominant Eurocentric models of psychology and provides a platform for the expression of some of the voices that call
for the development of African psychology. The first paper by Baloyi critically looks at African epistemology and how this forms the basis of African psychology. In the second paper, Mkhize looks at the twin concepts of Ubuntu/botho and Maat, and presents some of the major tenets of an African-based psychology, amongst which are the primacy of the life principle, the idea of be-ing, the sociality of the self and the multiplicity (dialogic conception) of selves in African thought. In the third paper, Mdaka, Gumede and Mbense present the results of a study that focused on umhayizo (mass hysteria) in selected schools in Kwazulu-Natal (South Africa) and conclude by arguing that these cultural experiences can provide useful insights that can help advance the agenda of African psychology. The fourth paper by Sodi looks at aspirational ethical principles guiding indigenous healers in three African communities in South Africa and concludes by arguing that dingaka (indigenous healers) are guided by an ethical code that is enforceable through some ancestral spiritual sanctions. In the fifth paper, Matoane focuses on Ubuntu Therapy as a form intervention that takes into account the role of local culture in understanding and resolving psychological problems. The sixth paper by Magwaza looks at the history and objectives of the Forum of African Psychology and moves on to identify the opportunities and challenges associated with this initiative.

Aspirational ethical principles guiding indigenous healers in African communities in South Africa
Tholene Sodi South Africa

In this paper, I present the results of a study that sought to understand and describe the notions of ethics as understood by indigenous healers in selected communities in South Africa. I start by giving a brief overview of a larger study that investigated indigenous healing among the Venda, Tsonga and Northern Sotho communities of Limpopo Province. Specifically, I present the findings relating to the ethical and professional issues that indigenous healers in these communities consider important in their work. I then discuss these ethical and professional issues in the context of the aspirational ethical principles of non-maleficence, fidelity (and responsibility) and the respect for people’s rights and dignity. I conclude the paper by arguing that indigenous healers in these communities are guided by an ethical code that is enforceable through some ancestral spiritual sanctions. This, I argue, is in contrast to ethical codes in Western psychology that are enforceable through ethical standards, rules and procedures that are prescribed by regulatory bodies like the American Psychological Association (APA) and the Health Professions Council of South Africa (HPCSA).
Organisational climate: A case study in a Brazilian public organisation
Monica Aparecida De Oliveira Universidade de Brasília-UNB, Brazil; Onofre Miranda

Culture is always characterised as the way that people think, act and feel, while organisational climate has been conceptualised as workers’ perceptions of their organisational environment. Considering studies on organisational climate, many works have addressed its positive and negative aspects as well as the employees’ satisfaction concerning organisational aspects such as: leadership, co-workers, organisation’s structure. In this sense, this study aimed to investigate the perceptions’ workers of organisational climate in a Brazilian public organisation as well as the positive and negative aspects of it and their satisfaction concerning on many organisational aspects. We conducted a case study with a descriptive survey to a sample of workers to gather information on what they think about their organisational climate (co-workers, leadership, commitment, activities performed and quality of life programs).

The results showed that employees perceive the positive organisational climate (72.2%), as much as satisfaction (66.6%). Most participants realise that the satisfaction is due to the activity performed (41.6%) and workers commitment (27.7%). These results confirm the positive aspects that influence the organisational climate indicated by respondents as well as other factors, such as leadership (58.5%), payment (55.5%), commitment (83.3%) and activities (91.5%). It is also observed that participants consider the lack of investment in quality of life programs (78%) as a negative aspect to the organisational climate. The results are discussed concerning theories, and suggestions are proposed for the organisation and for future studies.

The relation between work engagement and work-family conflict: The moderating role of perceived family support
Maede Arzabezegan University of Isfahan, Islamic Republic of Iran; Abolghasem Nouri; Hamidreza Oreyzi

Most of past research was aimed at the positive consequences of work engagement in organisations, however, a few studies emphasised the negative aspects of work engagement. This study identified the relationship of work engagement and work-family conflict relating to the moderating role of perceived family support. Data were collected from 183 employees of an industrial company, who were selected by stratified sampling. The instruments in the present study consisted of Utrecth Work Engagement Scale (UWES, Schaufeli et al., 2002), Work-Family Conflict Questionnaire (Netemeyer, Bole, & McMurrian, 1996) and Questionnaire of Family Support (Procidano & Heller, 1983). The moderated regression analysis was used for the assessment of the moderation role of family support. The results indicated that family support moderated the relationship between work engagement and work-family conflict. According to the findings, when people involve in work, their energy for family functions reduce, but when their families support them, despite high work engagement, they feel less conflict between work and family duties.

Research Area: Industrial/Organisational/Work

Session Type: Papers

Police culture and organisational socialisation as predictors of prosocial and ethical behaviour of officers of the Nigerian police force
Aderemi Alarape University of Ibadan, Nigeria

An official priority concern for the Nigeria Police Force is unethical behaviour by police officers. There is little indication that the organisation is effectively overcoming this problem. The present study was designed to examine the roles of police culture and organisational socialisation on prosocial and ethical behaviour among a sample of Nigeria police. Using a cross-sectional survey design, data was collected from 193 participants drawn from officers of the Nigeria Police Force, Ogun State Command, Sagamu, Nigeria. Results of the multiple regression computed reveal that police culture themes of solidarity, isolation and cynicism and organisational socialisation were significantly predictive and explained 28% of the variance in police officers’ prosocial behavior; while only police culture themes of solidarity and isolation were significantly predictive and explained 12% of police officers’ unethical behaviour. These findings were discussed in the context of socio-dynamic theory, socialisation theory and ethical theories, while the practical implications for the training of officers of the Nigeria police were discussed.

Attitudes toward organisational change: The influence of emotional intelligence and personality
Aderemi Alarape University of Ibadan, Nigeria

Previous research on organisational change has mainly focused on organisational factors neglecting the individual-oriented factors. This study examined the influence of emotional intelligence and personality on attitudes toward organisational change in the power sector in Nigeria. A survey of 200 employees of a public corporation in Lagos State, Nigeria was taken with a questionnaire. The result of the correlational analysis showed a significant positive relationship between openness to experience, agreeableness, conscientiousness and attitudes toward organisational change. In addition, the result of the multiple regression computed showed that extraversion and conscientiousness independently predicted attitudes toward organisational change. Twenty-four percent of attitudes toward organisational change was accounted for by employees’ personality and emotional intelligence. The findings imply that personality and emotional intelligence are relevant for positive attitudes towards organisational change among power sector employees in Nigeria.

The effect of antecedent variables on accepting career bridge employment in retirement
Mohadd Amiri Isfahan University, Islamic Republic of Iran; Abolghasem Nouri; Hamid Oreyzi

It is almost three decades that retirement is viewed as a process. Persons entered in bridge employment - that as an analogy compare it to a bridge that link the world of work to work withdrawal. The current research was to investigate personal characteristics, job related psychological variables and other variables related to retirement design and planning in bridge employing in their job before retirement, and the effect of precedent variables on their decisions. The current study design is longitudinal research and the participants were geriatric retirees who continued their careers in their former job and compared to fully retired persons. Instrument were self reported inventory, included demographic information (namely age and educative) and health, financial status, job tension, job satisfaction and thought about retirement. In order to analyse data the stratified logistic analysis, odd ratio, chi square test for goodness of fit of the model, and R2 effect size estimation were used. Results indicate that personnel expected to retire, that adopt bridge employment in their former career in industry were younger, more educated, healthier, experienced less job tension and were more satisfied with their job, however their financial status were better. The last finding was surprising at first glance, however it is the result of their educational level that, if not correctly planned, may lead workers to suffer because of psychological tension and economical constraints.

Outcome evaluation of ‘successful self’, a program to prevent psychosocial distress among new health professionals
Mikayo Ando Okayama University, Japan; Shinihiro Ando Okayama University, Japan

This study evaluated the impact of ‘Successful Self’, an intervention program focused on self-understanding, coping under difficult situations, and communicating with others to improve social competence and self-efficacy and to prevent psychosocial distress among various kinds of first-year health professionals in a general hospital. Five physicians, 16 nurses, and two pharmacists attended the program in 2010 (the 2010 group). In 2011, four physicians, 15 nurses, and two pharmacists attended a program, modified by the evaluation of the 2010 group (the 2011 group). Participants attending the program in both groups completed surveys before Time 1 and after Time 2. The intervention program included four weekly sessions covering self-understanding, self-control, interpersonal relationships, problem-solving, conflict resolution, and stress management. To improve the 2011 program, an occupational health physician acted as facilitator and experienced nurses acted as co-facilitators. For all participants, there were no significant differences at Time 1 between the 2010 group and the 2011 group. At Time 2, depression and confusion were significantly lower in the 2011 group than in the 2010 group. For nurses, there were no significant differences at Time 1 between the 2010 group and the 2011 group. At Time 2, anxiety, depression, fatigue, and confusion were significantly lower in the 2011 group than in the 2010 group. The intervention program effectively prevented some aspects of psychosocial distress among new Japanese health professionals.
The relation between work engagement and employee health: The moderating role of perceived organisational support
Maede Arabzadegan University of Isfahan, Islamic Republic of Iran; Abolghasem Nouri; Hamidreza Oreyzi
Employee health is affected by many organisational factors. Research shows inconsistencies between the relationship of work engagement and employee health, which may be affected by other variables. This study examined the relationship of work engagement and employee health, with consideration to the moderating role of perceived organisational support. Data were collected from a sample of 223 employees of an industrial organisation in Isfahan, who were selected by a stratified random sampling method. The instruments used in the study consisted of the Utrecht Work Engagement Scale (UWES, Schaufeli et al., 2002), General Health Questionnaire (Goldberg 1970) and perceived organisational Support Questionnaire (Rhoades and Eisenberger, 2002). The moderated regression analysis was used for the assessment of the moderating role of organisational support. Findings indicated the negative relationship between work engagement and employee health, but this relationship is moderated with organisational support. We conclude that work engagement decreases the physical energy for countering health threatening elements which, with organisational support, reduces the negative consequences of work engagement on health.

Relationship of work engagement and employee health with considering the mediating role of work/family conflict
Maede Arabzadegan University of Isfahan, Islamic Republic of Iran; Hamidreza Oreyzi; Abolghasem Nouri
With the appearance of positive psychology, emphasis on positive skills and behaviours has replaced attention to behavioural incapability. The emphasis on positive skills and behaviours has been reinforced with the appearance of positive psychology, emphasising the importance of human strengths and virtues. This study tested a mediational model consisting of importance of information security and organisational change perception toward practices, and security practices-related attitudes as the mediator variable. For this study, an instrument composed of four ten-point Likert scales was used. Three scales were developed and validated to measure the practices, attitudes and behavior toward 61 statements. A ten-point scale was used to measure the organisational change perception toward 30 statements. All the scales presented a two-dimensional structure. Data were collect from 623 cases in a Brazilian public organization by on-line survey. Descriptive analyses, exploratory factor analysis and regression analysis were conducted. The results showed that security practices-related attitudes mediated the relation between the organisational and individual levels, that is, in so far as the organization implements security practices, the individuals perceive radical organisational change (R2 = 0.279) and present positive security practices-related attitudes, which in turn, impacts on information security behavior (R2 = 0.158).

Quality of work life: Increasing productivity by delivering recognition, a case study in Mexico
Fernando Arias-Galicia Morelos State University, Mexico; Francisco Barroso-Tanoira
The construct of quality of work life (QWL) may be considered to be composed of several factors. In this paper attention is focused on recognition (how the employee’s work is valued and appreciated). The goals of this research were: (a) to determine workers’ degree of recognition received, and (b) to determine if there was a significant relationship between recognition and productivity. The study was performed in the maquiladora (in bond) industry dedicated to jeans manufacturing in Yucatán, Mexico. This firm was selected because it hires workers from all states in the south-east of the country, as well as for its size and organisation. There are 2,800 workers in five plants (cutting, sewing, laundry, dry process and care). A random representative sample (n = 329) of workers was surveyed by means of a questionnaire designed to ascertain QWL; recognition was one of the measured variables. This study is correlational. Participation was voluntary. No one worker refused. Results showed a significant difference among the workers depending on age and job position. The most interesting result was a positive significant correlation between recognition and the percentage of goals reached (an indicator of productivity). It can be argued that an intervening variable is motivation. It is recommended that performance continues to be recognized. One way to achieve this goal is to launch a permanent training program for supervisors. These results are relevant for an intervention in the firm for building a QWL model for this kind of enterprise.

Information security and organizational change perception: Influences on security attitudes and behaviors
Talita Arantes Unb, Brazil; Elaine Neiva
Information plays a strategic role in the organizational environment, therefore its security is crucial for organizations to remain competitive. It is important to pay attention not only to technology resources, but also to people that are an essential factor of information security. This paper aims to understand individual security behavior in the work environment, testing a mediation model which identifies two antecedents of security behavior: Organizational practices of information security and organisational change perception toward practices, and security practices-related attitudes as the mediator variable. For this study, an instrument composed of four ten-point Likert scales was used. Three scales were developed and validated to measure the practices, attitudes and behavior toward 61 statements. A ten-point scale was used to measure the organisational change perception toward 30 statements. All the scales presented a two-dimensional structure. Data were collect from 623 cases in a Brazilian public organization by on-line survey. Descriptive analyses, exploratory factor analysis and regression analysis were conducted. The results showed that security practices-related attitudes mediated the relation between the organisational and individual levels, that is, in so far as the organization implements security practices, the individuals perceive radical organisational change (R2 = 0.279) and present positive security practices-related attitudes, which in turn, impacts on information security behavior (R2 = 0.158).

Perceived organisational climate and job characteristics as mediators of the relationship between core self-evaluations and job satisfaction
Nasrin Arshadi Shahid Chamran University, Islamic Republic of Iran
This study tested a mediational model consisting of job satisfaction as dependent variable and core self-evaluation (CSE) as an independent variable, with perceived job characteristics and perceived organizational climate as its mediators. Using structural equation modeling (SEM), the relationships were examined in a sample of 294 full-time employees in an industrial organisation in Iran who were selected by stratified random sampling methods. The results revealed that a) CSE was positively related to perceived job characteristics and perceived organizational climate, b) CSE was positively related to job satisfaction, and c) perceived job characteristics and perceived organizational climate partially mediated the relationship of CSE with job satisfaction. Discussion and implications of the results are presented in the study.

Leader-member exchange and subordinates’ job satisfaction and organizational commitment: Mediating role of organizational justice
Nasrin Arshadi Shahid Chamran University, Islamic Republic of Iran; Maryam Ghannadi
The purpose of this study was to test a model consisting of job satisfaction and organizational commitment as dependent variables and two dimensions of LMX as independent variables. LMX is conceptualized as a two dimensional construct, LMX-Conflict and LMX-Affect. Perceptions
of procedural, distributive, and interactional justice are hypothesized to mediate the relationship of LMX with dependent variables. Data were gathered from a sample of 216 employees of an industrial organization in Iran, who were selected by stratified random sampling method. Of this sample, 71.3 percent were men and average age was 40 years. The instruments used in present study consist of LMX, Organizational Commitment, Job Satisfaction, and Perceived Organizational Justice Questionnaires. Structural equation modeling (SEM) through AMOS-16 and SPSS-18 software packages was used for data analysis. The overall results supported most of the hypotheses. Discussion and implications of the results are presented in the study.

Designing and testing a model of some precedents and outcomes of job stress
Nasrin Arshadi Shahid Chamran University, Islamic Republic of Iran; Hojat Damiri; Abdolkazem Neisi
The aim of this research was designing and testing a model of some precedents and outcomes of job stress. The proposed model consisted of role stress (role ambiguity, role conflict and role overload) and effort-reward imbalance (ERI) as precedents of job stress and work motivation, job performance and turnover intention as outcomes. Further, organizational based self-steam (OBSE) was considered as a moderator of the relationship between job stress and its outcomes. The sample consisted of 286 employees of Iranian National Drilling Company (INDC), who were selected by simple random sampling method. Structural equation modeling (SEM) through AMOS 16 and SPSS 18 software package were used for data analysis. Moderated regression method was used for the analysis of moderating effects. Findings indicated that the proposed model fit the data. The results also revealed the moderating role of OBSE.

Retaliation following mistreatment: The ‘not so simple’ role of victim emotional appraisal and victim traits in the development of a deviance spiral
Neal Ashkanasy The University of Queensland, Australia
Workplace mistreatment involves verbal and non-verbal abusive behaviour intended to intimidate, humiliate, obstruct, and undermine. Although there is evidence that mistreatment leads to negative organisational and individual outcomes, little is known about how and why these manifest. We focus here on retaliatory behaviour. Retaliation is important because it can create a deviance spiral, leading to further mistreatment and ineffective organisational performance. Based on affective events theory (Weiss & Cropanzano, 1996) and the transactional theory of stress (Lazarus & Folkman, 1984), we hypothesised that victim primary appraisals (negative emotional reactions) following mistreatment leads to retaliatory behaviour. We also hypothesised from trait activation theory (Tett & Burnett, 2003) that retaliation would be predicted by trait aggressiveness (verbal aggression, hostility and anger). To test our hypotheses, we surveyed, at two points in time, 120 Australian professional service firm employees, 82 of whom had experienced mistreatment. Results confirmed that victims appraise their mistreatment experiences negatively, with females experiencing more negative reactions than males. More specifically, we found that feeling disturbed as a result of mistreatment related to organisational retaliation, and feeling annoyed related to retaliation against others. We found further that negative reciprocity norms related to feelings of frustration and retaliation against perpetrators, and that hostility related to feeling disturbed and organisational retaliation. Finally, anger also related to retaliation against perpetrators and the organization. These results suggest the presence of more complex mediatory relationships between mistreatment, individual differences, and retaliation, which we will discuss in reference to the three theories.

Burnout and shift work rotation: Absence and proactive personality as moderators
Vishwanath Baba McMaster University, Canada; Dilek Nayir; Louise Tourigny
We investigate the dynamics of burnout among hospital nurses in Turkey, using an interactive approach. We focus on the roles of personality, behaviour and context in altering the dynamics. We analyse the 3-way interaction effect of emotional exhaustion, proactive personality and absence behaviour on diminished personal accomplishment and depersonalisation for both fixed and rotating shifts. The sample is composed of 402 nurses, 230 of them working in rotating shifts. We used a questionnaire survey to collect the data. Hierarchical moderated regression with a split file based on types of shift is the analytical technique employed. Results reveal a significant 3-way interaction effect for diminished personal accomplishment and depersonalisation respectively, but only for nurses working in rotating shifts. Absence has a buffering effect in the case of diminished personal accomplishment but only for nurses who are highly proactive. Findings highlight the recuperative role of absence for nurses who are proactive in the context of shift work rotation. Results show that the dynamics of burnout is complex in the sense that the impact of emotional exhaustion can be altered by personality and behaviour. It is also contingent in the sense that the work context can yield different outcomes as found for shift work rotation. The implications for burnout research and human resources management in health care are discussed.

Changes in work control: How important are goal characteristics?
Carolina Bahamondes Pavez University of Freiburg, Germany; Heinz Schapbach; Allam Wael
Several changes have taken place in the world of work in the last decades. The assignment of tasks has become highly output-oriented. Employees become increasingly responsible for both the working process itself, and the achievement of set goals, and the performance assessment of employees is attached to goal attainment. Goal setting research has mainly focused on the relationship between goal characteristics, motivation and performance. Little research has highlighted the effects of goal setting on well-being. We expect a negative effect for well-being when goals are inappropriate, and resources for their attainment are not available. This study examines how goal characteristics are associated with well-being. The characteristics of the goals employees have to achieve might also have an influence on the work demands. Data from 300 employees of three German companies was obtained by questionnaire which assessed goal characteristics and work demands. Indicator of well-being impairments was the Irritation scale. The results show that goal characteristics (e.g. goal attainability) positively anticipated negative consequences when goals remain unattained and are negatively linked to well-being. However, the effect of these goal characteristics on well-being is completely mediated by work demands. Goal characteristics influence aspects of the working situation and are thereby associated to well-being. If we intend to achieve healthy working conditions, special attention has to be paid to the characteristics of goals. These results and their implications will be presented and discussed at the conference.

Effects of vertical conflict between critical team member and team manager on shared mental modes, team external activities, and team performance
Xin-Wen Bai Institute of Psychology CAS, China
The current study aimed to examine the effects of vertical conflict between critical team member (CTM) and team manager on shared mental models (SMMs), team external activities, and team effectiveness. Authors proposed that vertical conflict had a detrimental effect on team performance, and such negative effect would be mediated by SMMs and team external activities. Based on the survey data from 131 teams from a large telecommunication corporation in China, series of hierarchical regression analyses indicated that (a) vertical relationship conflict between CTM and team manager was negatively related to team performance (β = -0.33, p < 0.01), while the effect of vertical task conflict on team performance was significant and positive (β = 0.22, p < 0.05); (b) similarly, a negative effect of relationship conflict (β = -0.24, p < 0.05) and a positive effect of task conflict (β = 0.26, p < 0.05) on team external activities; (c) task conflict had a negative relation with task-related SMMs (β = -0.50, p < 0.01), and relationship conflict was negatively associated with team-related SMMs (β = -0.26, p < 0.01); finally, (d) both SMMs and team external activities failed to mediate the effect of vertical conflict on team performance. Results were discussed in terms of the importance of the vertical conflict in investigating the conflict-team performance relationship, and the importance of differentiating CTM from other members in theory and practice of work teams.

The impact of individual and situational characteristics on trainee reactions and post-training self-efficacy
Foroozeh Bakhtiarz Esfandagheh Payame Noor University, Islamic Republic of Iran
The purpose of this study was to examine the impact of agreeableness, emotional stability, and pre-training motivation (as individual characteristics) and perceived organizational support (as a situational characteristic) on trainee reactions and post-training self-efficacy (as an affective outcome of learning). Data were collected from 278 male
employees entering a training program on mental health in organizations. The research was conducted in two stages, before training and immediately after training. Consistent with the hypothesized model, agreeableness, and pre-training motivation were significantly and positively related to trainee reactions, which were significantly and positively related to post-training self-efficacy. Furthermore, perceived organizational support was also found to have a positive and significant relationship with pre-training motivation. Support was not found for the significant relationship between emotional stability and trainee reactions. An alternative model was also tested. The results showed stronger support for the hypothesized model. The study highlighted the importance of individual characteristics, such as agreeableness, that have been less empirically researched on trainee reactions and post-training self-efficacy. Moreover, this research expanded our knowledge of the role of perceived organizational support in a training context. Future research should continue to examine these and other factors that influence training outcomes.

Talent management systems: Friend or foe?

Werner Barkhuizen Saville Consulting, South Africa

The use and application of talent management systems and solutions within organisations are increasing significantly. More vendors purport to provide integrated talent management systems and solutions. The objective of this presentation would be to critically evaluate the meaning of integrated talent management systems and solutions, and the real-world applications required to create meaningful and value-adding integrated talent management systems and solutions. Two case studies (N=6583), from the financial service industry are shared and the benefits obtained in each example will be elaborated upon. The presentation will include a complete overview of the talent management models applied as well the implications for succession management, leadership development and employee engagement.

New developments in organisational leadership

Julian Barling Queen’s School of Business, Canada

The nature, antecedents and consequences of leadership have attracted considerable research since the end of the World War II. Transformational leadership remains one of the most frequently researched topics in organisational psychology, with intriguing lessons that have implications that extend well beyond the confines of organisations. First, because most leadership research has focused on transformational leadership, which has a wide array of applications, the central tenets and lessons of transformational leadership will be offered. Second, recent research on apologies and humor have illuminated the importance of humility to the nature and consequences of leadership. Third, gender issues regarding transformational leadership provide fascinating challenges to conventional thinking about leadership. Fourth, extending the lessons from transformational leadership to teaching and parenting will be explored. Emerging issues will also be discussed, and these include our research on the nature and effects of leaders’ mental health.

To slaughter for a living: Employee wellness in an abattoir work setting

Ha Barnard UNISA, South Africa; Antoni Barnard Work and non-work spill over has been noted in industrial psychology research in various work settings. The spill-over effect of violence at work may threaten employee wellness. Slaughterfloor employees in an abattoir are constantly confronted with violence and death. The objective of this study was to explore the impact of slaughtering on employee well-being. A qualitative study was conducted in the slaughter section of a leading abattoir in the meat processing industry in South Africa. Purposeful, non-random sampling was used to select 11 slaughterfloor employees to participate in the study. For triangulation purposes two managers and two supervisors (also occasional slaughterers) also participated. Data were gathered through in-depth interviews, related performance documentation and observation of slaughterfloor activities. Thematic analysis yielded 19 themes and these were clustered in three categories depicting the physical, social and psychological effects of slaughtering. Data revealed evidence of substance abuse, socially deviant behaviour, negative social labelling, dreams and nightmares, emotional detachment, depression and anxiety. Results provide evidence of a negative spill-over effect of slaughtering on the general wellness of employees. Slaughterfloor employees display a high risk potential to suffer from Post Traumatic Stress disorder. This was the first study researching the wellness of slaughterfloor employees in South Africa. The high risk to employee wellness substantiates a dire need for further research to affect pro-active wellness interventions in an abattoir setting.

Ethical leadership: Inputs from leader personality and influences on organisational performance

Angel Barranco University of Zaragoza, Spain; Mirko Antino; Francisco Gil; Margarita Marti; Angel Castro

This research investigated the link between personality, ethical leadership and organisational performance through quantitative and qualitative methods. Most research on ethical leadership to date has focused solely on the consequences of ethical leadership, and in less quantity on its antecedents, but not as an complete input-process-output model with ethical leadership serving as the process. In the current study, leader personality is studied as a potential antecedent of ethical leader behaviour by using leaders’ (41 corporate directors) main/primary motivations (power, affiliation and achievement). The leaders were interviewed in order to obtain a qualitative register of their motives. Ethical leadership behaviour patterns are obtained from different companies by administering questionnaires to members of their respective management teams (124 leaders’ subordinate officers). Ethical leadership scales include leadership behaviours as perceived by subordinates: modesty, face-saver, humanitarian orientation, integrity, and malevolent (inverted). Organisational outcomes were obtained from objective data provided by the companies’ financial directors (overall increase in income, sales, asset account, or number of employees). Results largely confirm how the main motives of leaders (power, affiliation and achievement) were strongly associated with different ethical leadership behavioural patterns, such as integrity or humane orientation. Results also provide support for a positive direct relationship between ethical leadership and organisational performance. Finally, consistent with the proposed model, the effects of personality motives on organisational performance are mediated by ethical leadership behaviours. These results are discussed, and practical suggestions are provided for future research.

A case study exploring a behavioural approach to managing people risk in organisations

Carin Bergh SHL, South Africa, South Africa

A considerable amount of research has focused on the relationships between organisational citizenship, counter-productive work behaviours, and personality. One example is Digman’s Alpha (Digman, 1997), which brings together three of the Big Five constructs (i.e. Conscientiousness, Agreeableness and Emotional Stability) into a factor which has been described as ‘…the most important trait that needs to be systematically measured among job applicants’ (Viswesvaran, 2001). This factor has particular application in service-oriented roles where incumbents need to be reliable, work well with others in a team and interact positively with customers. The purpose of this presentation is to discuss how assessment tools can help organisations take stock of the people risks among their customer service teams, and to provide suggestions on how to address these risks. This will be done by sharing a case study from a financial institution in Southern Africa, which focused on a business area where the service-orientation of the position requires employees to be highly customer focused. Employees completed a short criterion-oriented personality scale (COPS), and their results were compared to performance ratings provided by their managers. At the macro level, such data provides intelligence to the organisation of where may lie potential sources of behavioural best practice, and areas where the organisation has potential risk. At the micro level insight was provided to individuals and their managers to help them understand the key behaviours they needed to address.

A diary study on the effects of leadership style and emotion work on leaders’ exhaustion and satisfaction

Laura Bernhardt Goethe-University, Germany

Leadership as such is an emotional process. Thus, emotion work is an important factor in leader-subordinate-interactions with effects on leaders’ well-being and job satisfaction. We argue that leaders’ emotion work, in form of different emotion regulation strategies, in interactions with subordinates is dependent on their leadership style. We hypothesise that the more relationship-oriented the leader, the more deep acting and automatically regulated they are. The more task-oriented the leader, the more surface acting and deception is used. Furthermore, we hypothesise that leaders’ emotional intelligence and gender both influence the leadership style as well as the emotion regulation strategies. Moreover, the different emotion regulation strategies have differential effects on emotional exhaustion and job satisfaction. We conducted a diary study with 165 leaders who completed a questionnaire each and up to five diaries, resulting in 520 recorded emotionally important interactions with subordinates. Results of multilevel analyses
confirmed our hypotheses that emotion regulation strategies are used depending on the leadership style in the interaction. Further, that emotional intelligence is positively associated with deep acting and automatic regulation. Results also revealed that emotional exhaustion is higher in connection with surface acting and deviance and that job satisfaction is higher in connection with automatic regulation. Gender has moderating functions. One practical implication is that relationship orientation has not only positive outcomes for subordinates, but also for leaders. Another implication is that organisations can train their leaders in emotion regulation because two of the strategies are associated with lesser exhaustion and more satisfaction.

Examining gender in formal mentoring relationships
Sarika Bhana University of Witwatersrand, South Africa; Grace Khomou
Mentoring is the exchange of information, social capital, and support from mentor to mentee. Mentoring can be distinguished into two distinct categories: Psycho-social support and career development. Research shows that mentoring can aid career development for women, as women tend to face a glass barrier in the workplace. Research on gender and mentoring has been criticized as merely descriptions of learning. Current literature reports varied results as to the role of gender in mentoring effectiveness as some studies have reported that gender is at least a partial moderator in the relationship whilst other research claims no relation at all. The study aimed to explore and understand the experiences of mentors and mentees and the role of gender in these mentoring experiences in a South African auditing firm. A qualitative study was performed with a purposive sample of two male-female mentor-mentee pairs, one male-male mentor-mentee pair and two female-female mentor-mentee pairs. Semi-structured interviews were conducted. Thematic content analysis was used. The themes emphasized the importance of the interactional role of gender in the mentor-mentee relationship as well as critical structural elements of the program itself. This has strong implications for the way in which such programs are structured and for diversity management in South Africa. This research also found more support for the psycho-social aspects as opposed to career development objectives of the program.

The relationship between computer user efficacy, job satisfaction, self-rated tasks and contextual performance
Reyhan Bilgic Middle East Technical University, Turkey; Onder Ersen
The aim of the present study was to investigate the relationships between computer user efficacy, job satisfaction, self-rated tasks and contextual performance. There were 143 people with different educational backgrounds participating in the study, and they completed the measures of task and contextual performance, job satisfaction, and computer user-efficacy. Of these, 53 were female (40%), 81 (60%) were male and 7% did not indicate gender. The results showed that the efficacy subscale predicted both job satisfaction and job performance. In addition, job satisfaction totally mediated the relationship between total efficacy score and task performance. However, the contextual performance was not predicted by any of the computer efficacy subscales. The results were discussed in the light of relevant literature.

The influence of proactive personality on employees’ organizational citizenship behaviours
Li Bin Central China Normal University, China; Shujun Tang; Bin Li
The primary goal of the present study was to examine the relationship between proactive personality and employees’ organizational citizenship behaviours. The employees sample consisted of 112 male and 73 female, for a total sample of 185 participants whose ages ranged from 23 to 60 years. The proactive personality was measured with the 11-item Chinese Proactive Personality Scale (C-PPS, a=.82) by using a 3-point rating scale (1 = strongly disagree to 5 = strongly agree). The organizational citizenship behaviours were measured with the 21-item Chinese Organizational Citizenship Behaviour (C-OCB, a=.86), which includes 7 items for each subscale of individual’s organizational citizenship behavior (OCBI), organizational citizenship behavior (OCBO) and intro-role behavior (IRB). The results showed that PPS was positively related to OCBI (r=.38, p<.01), OCBO (r=.47, p<.01), IRB (r=.43, p<.01) and OCB (r=.57, p<.01). While controlling for demographic factors (such as sexual, age, education, income), the analyses of hierarchical regression showed that PPS was positively related to proactive behaviors (b =.40, p<.001). These results show that having a proactive personality was associated with more organized citizenship behaviours.

The impact of supervisor’s safety profile on workers’ safety performance
Margherita Brondino University of Verona, Italy; Margherita Passini; Maria Milena Citt; Barbara Barbara
Safety climate (SC) has been one of the most frequently studied antecedents of safety performance since the nineties. Many studies highlight the importance of analysing safety climate at group level, but at group level no studies attempted to compare the impact of the agreement degree about safety climate between supervisor and his group on workers’ safety performance. Safety climate and safety outcomes were measured on a sample of 868 blue-collar of 11 Italian manufacturing companies. SC was measured at the organisational (OSC) and the group level. Group level SC consisted of 2 measures, one related to the supervisor (SSC) and one related to the co-workers in the work-group (CSC). The same measures were gathered also on 40 supervisors of each work-group (SSC in a self-evaluation). A cluster analysis was conducted on supervisors, considering their perceptions about OSC, SSC and CSC, and four profiles were identified: the Judge (low OSC and CSC scores, and high SSC scores); the Easy-going (high scores for all the scales); the Pro-management (higher OSC scores, similar but lower SSC scores and low CSC scores); the Realist (similar medium size OSC, SSC and CSC scores). A significant relation was found between supervisor profile and safety outcomes, i.e. safety behaviour (compliance and participation). One-way ANOVA, with profile as the independent variable and behaviours as the dependent variable, showed higher values of safety participation for workers with a Realist supervisor. The lowest safety participation values were found for workers with an Easy-going supervisor.

Can organisational culture really be measured? A case study
Daniel Burger Accenture South Africa, South Africa
The measurement of organisational culture has long been a topic of both great interest and contention. Whereas more traditionalist theorists strongly support the quantitative analysis of this construct, others maintain that it is too complex to be quantified, and that alternative forms of assessment such as ethnographic methods are required. This paper proposes that organizational culture can indeed be successfully quantified and demonstrated, that the instrument applied is firmly grounded in both theory and practice. To illustrate this proposition, a case study is provided of a large-scale organizational transformation effort, where the organization’s culture was assessed by means of an assessment known as the Organization Value Analysis (OVA). Insight is provided into not only the theoretical foundations and properties of the OVA, but also the role that this diagnostic played in identifying key barriers to the case study organization’s objective of entrenching a high performance culture. Moreover, it is shown how the results from the culture assessment were utilized to inform the design and implementation of a comprehensive transformation effort that would ultimately drive the alignment of the organization’s culture to its strategy and the achievement of its business objectives. Finally, key features of OVA and culture assessment process which are aimed at supplementing the quantitative approach are highlighted, thus demonstrating one approach to developing comprehensive and thorough culture transformation process.

The role of colour landscape photographs to facilitate employee wellness in a psychiatric health-care environment
Waldemar Busslahn Tshwane University of Technolo, South Africa
The mental and physical working context in which mental health care providers spend their day is an extremely stressful environment, specifically with regards to mental and physical well-being. This environment is shaped by influences such as job demands, patient related stresses and political and economic pressures. These factors may result in high levels of staff burnout, decreased work efficacy and increased overall stress. The primary objective of this study was to facilitate wellness amongst mental health-care providers in a psychiatric hospital by manipulating the visual lived environment through the introduction of colour landscape photographs with an emphasis on physical positioning and content. The photographic intervention consisted of two installations over a six months period. A qualitative analysis focused on positioning with written participant feedback, indicating that ‘the photos add new dimension and depth to the ward’ and ‘loved the photos in the passage by the entrance
of the ward’. A Likert scale survey questionnaire was used to assess feedback with regards to content. A quantitative analysis of the survey results indicated an overall improved experience of the lived environment. Measured experiences under the headings of don’t like, acceptable, and like a lot, have increased between the two installations for the following content categories: veld and trees +2%, autumn +13%, and colourful flowers +4%. A waterfalls category was introduced in the second installation with a score of 82%. The leaves and autumn category remained the same, with trees and desert scoring lower in the second installation by 10% and 14% respectively.

Policy environment for returned overseas entrepreneurship in China: A research based on gem model
Xue Jun Cai Chinese Academy of Personnel Science, China
The Chinese government launched a series of programs to encourage returned overseas High-Tech entrepreneurship in recent years, but the effects of these programs and the satisfaction of entrepreneurs have received limited attention in research. This study evaluated the benefits and/or restrictions imposed by state government in China, by using the conceptual model of Global entrepreneurship monitor (GEM) as a research framework. This paper conducted two independent studies: (1) 1188 returned overseas High-Tech entrepreneurs participated in this study to rank the importance and satisfaction of the policy environment in China. (2) A content analysis was conducted on 357 policies towards returned overseas Entrepreneurship to figure out the condition of policy supply by Chinese government. Then a comparison between the policy demand and supply was conducted. The results indicated that environmental conditions played an important role in developing opportunities and in enhancing entrepreneurs’ propensity and ability to enterprise. The Financing, Transformation and Infrastructure environment was ranked as the most important and less satisfied factors by the returned overseas High-Tech entrepreneurship. Implications for the research results and the limitations of the study are discussed.

The development of a firm-level diversity management competency framework
Jennifer Carstens Stellenbosch University, South Africa; Francois De Kock Stellenbosch University, South Africa
An emerging perspective of organisational diversity proposes that a diverse workforce may hold inherent advantages for organisational performance. According to this perspective, the effect of diversity on firm performance is contingent on how diversity is managed. Little empirical evidence exists to support this view, which may be partly due to a lack of operational frameworks for diversity management at the firm level. The present theoretical study develops a firm-level diversity management competency framework that outlines specific clusters of diversity management practices expected to contribute to firm performance by means of enhancing key intermediate diversity management outcomes. To generate the diversity management competencies, prior literature was reviewed and the critical incident method was used to conduct subject-matter expert (SME) interviews with firm executives. Finally, the derived competencies were operationalised into diversity management competency (DMC) questionnaire items and piloted in a sample of firm executives. The proposed competency model, and accompanying measuring instrument, can assist firms to identify development areas to target with diversity suitable management practices in order to improve diversity management outcomes and firm performance. In a subsequent phase of the research, the competency model will be tested empirically by relating the diversity management competency levels of publicly listed firms to diversity management outcomes and firm financial performance.

Homophily, workplace stress and management style
Kirk Chang Oxford Brookes University, United Kingdom; Hong Chen; Julie Taylor
This study explored the role of homophily and cultural values in Taiwanese Organisations, whether employees preferred a manager from the same ethnic background as their own. Based on literature suggesting that cultural values may present as one source of workplace stress, the relationship between manager ethnicity preference and stress perception at work was examined. Psychological acceptance and job tenure were also measured to examine their potential moderating effect on stress perception. An anonymous questionnaire survey was dispatched to three types of foreign (UK and US) companies operating within Taiwan, including: subsidiaries, branches, and representative offices; 515 Taiwanese employees responded. Management Style Suitability (MSS) of managers and psychological acceptance (PA) were assessed via a series of standardised scales. Statistical analysis indicated that Taiwanese employees would prefer Taiwanese managers. This ethnic homophily was expressed in terms of a lack of understanding between Taiwanese employees and foreign national managers. Moreover, a relationship was revealed between MSS and stress and this relationship was moderated by both job tenure and PA. The findings supplement the literature on management style suitability and its relationship with workplace stress. In terms of enhancing harmony within the workplace, some key suggestions emerge, for example, prior to engagement new foreign national managers may benefit from workshops to initiate them into Taiwanese culture, new employee inductions may also benefit from mentoring schemes. The association between management style suitability and workplace stress is of considerable relevance to HR practitioners and organisational leaders in Taiwan.

Guanyi’s effect on Chinese managers’ business unethical decision-making
Lijun Chen Zhejiang University, China
Guanyi has great institutional value in Chinese business activities. However, we should not ignore its negative influences. In this paper, we examined Guanyi’s ethical value. We measured three independent variables, Guanyi orientation, Guanyi usage, Guanyi pressure, and one dependent variable, business unethical decision-making. By giving 1,900 questionnaires to managers across China, we collected 226 valid samples with 142 male managers and 84 female. The results supported our hypothesis that Guanyi pressure could lead managers to make unethical business decisions. The higher the Guanyi pressure was, the more serious unethical decision-making would be. Renqing and face can make managers lose integrity, violate rules, and damage justice. It also verified there was a causal relationship between Guanyi pressure and degree of Guanyi use. Under the pressure of Renqing, face, and emotion, managers usually took Guanyi into consideration in decision-making. Renqing, face, and emotions resulted in Guanyi pressure and the different degrees of Guanyi pressure brought about different Guanyi input, Guanyi origin, and Guanyi quality. Finally, we compared Guanyi orientation, Guanyi usage and Guanyi pressure to respondents’ demographic profile. It demonstrated that managers’ Guanyi orientation, Guanyi usage and Guanyi pressure were significantly different on age, and business ownership. Older managers perceived higher pressure of Guanyi and were more oriented by
Does income level matter in the relationship between transformational, transactional leadership and leadership effectiveness?

Wenjing Chen, BUPT; Beijing Uni. of P. and T.; China; Kan Shi

Despite clear support for the impact of transformational, transactional leadership on a host of organizational outcomes, the underlying influence processes are still vague. In our study, we explored the moderating effects of income level and the rank of subordinates between transformational, transactional leadership and leadership effectiveness (performance, OCBI, OCBO and job satisfaction) based on the data from 383 subjects, that is, 419 pairs of leader-subordinate. Regression analysis by SPSS17.0 showed that the leadership effectiveness of transformational leadership would decrease as the rank of subordinates increased, while the leadership effectiveness of transformational leadership would increase as the rank of subordinates increased. In addition, transactional leadership is positively related to the effectiveness when the level of the subordinate income is low, but negatively related to the effectiveness when the level of the subordinate income is high. However, the income level of the subordinate could not influence the leadership effectiveness of transformational leadership. For different levels of subordinates, leaders should follow different leadership styles.

How SME owners learn from action learning: A case based on ‘Gu Yuexu’

Yanni Chen, GERG; SOM, Zhejiang University, China; Zhongming Wang

Based on experiencing learning theory and team dynamic theory, this research project (NSFC 70732001) used a case study to explore how Chinese SME owners changed their entrepreneurial decisions and actions during action learning processes, and which factors on team level influenced these changes and how. One entrepreneur named ‘Gu Yuexu’ and her set was randomly selected from an action learning program which was specific for SME owners. The program lasted for five months with an action learning module in each month. She was traced during the whole process, including the 45 minutes interview before the program, her set’s discussions, business plan and storytelling, and 90 minutes interview two weeks after the program finished. Exploratory analysis was used to examine how her entrepreneurial decisions and actions changed. Another three 90 minutes interviews with her facilitator and other two sets’ members were implemented after the program finished. Content analysis was used to analyse which factors promoted her entrepreneurial changes. It was found that individual’s entrepreneurial commitment and entrepreneurial motivation promotes the changes in entrepreneurial action learning. Team reflection promoted individual’s reflective observation to reframe entrepreneurial goals, knowledge sharing helped the participant to find and select the alternatives, entrepreneurial role identity motivated the entrepreneur to action immediately. The study contributed to group dynamics theory and action learning theory and had practical implications in China’s management education.

A study of the relationships among employees’ distributive fairness, organisational commitment and turnover intention

Pei Ren Min University of China, China; Yuan Dong; Wei Shi

This study examined the relationships among employees’ distributional justice, organisational commitment and turnover intention in Beijing’s state-owned enterprises. The data were drawn from 150 employees of 6 state-owned enterprises in Beijing, and the conclusion included four parts: (1) Distributive fairness had a significant positive impact on organisational commitment, (2) organisational commitment had a significantly negative impact on turnover intention, (3) the impact of fairness on turnover intention included two sides, on one hand, distribution fairness had an immediately negative impact on turnover intention, on the other hand, distribution fairness had an indirect negative impact on turnover intention partly through organisational commitment’s two dimensions (Utilitarian Commitment, Spirit Commitment). Fair distribution’s indirect effect partly through the intermediary variable of utilitarian commitment on turnover intention. However, fair distribution’s indirect effect partly through the intermediary variable of spirit commitment on turnover intention is more than its direct impact on turnover intention.

Strategic professional network and HR configurations for professional jobs in China

Dusheng Chen, Zhejiang University, China; Zhongming Wang; Yuan Li

With the development of knowledge economy and globalization, the mobility of professional talents emerges, especially the cross-border flow. There has been a great need to develop a more strategic occupational network of qualification standards and competency certification systems for the internationalisation of professionals in China. This study adapted the framework of Occupational Information Network (OINET) which is widely used in the US to both the professional job level and the strategic HR configurations for professional jobs. An assessment system with an international qualification indicator framework was developed using the strategic HR methodology including a multi-role in-depth interview, a HR supervisor/manager focus group discussion session, strategic job modelling, and a key competence certification assessment survey. The assessment system was conducted among 450 HR managers and professional representatives from three different categories of occupations such as financial professionals (banks, insurance firms and securities), automobile professionals (designers, R&D technicians and professional services), human resource professionals (HR directors, personnel managers and consulting/training professionals). A HR configuration approach was used in analysis of internationally-qualified professional competencies and occupational standards as well as the career development system indicators. A strategic professional network (SP*NET) was then formulated with an internationalised framework of indicators. Implications of this study for developing more international HR configurations and developmental strategies for professional jobs were discussed for further research.

Integrating work and family: Lessons from women leaders and others

Fanny M. Cheung, Chinese University of Hong Kong, China

Balancing between work and family has been a major practical challenge for women in the workforce, and poses an implicit barrier for women’s advancement. Previous research has focused on work-family conflict with balance as the goal. More recent studies have expanded the model to include enhancement in a revised paradigm of work-family integration. Learning from the success stories of women leaders, I examine the identity integration and the strategies that American and Chinese women at the top of their professions adopt to integrate their roles. I review recent literature that supports this integrative framework. Cross-cultural similarities and differences will be discussed. These findings are relevant to both women and men in the modern workforce.

The effects of individual career management of Chinese sport coaches

Zhang Chonghui, Chongqing University, China; Hongyu Ma

Individual career management is hot. A great amount of research on this topic has been conducted in Western countries. However, it is questionable to apply those findings directly to China, especially for Chinese coaches, because of social-cultural differences. Based on former indigenous research on the career development of Chinese coaches with grounded theory, this study further investigates the effects of coach’s individual career development (ICDM). Study I utilises factor analysis to conceptualise the coach professional environment (CPE) and CICM, and test the reliability and validity of CPE, CICM and achievement motivation (AM) in order to make sure that they are psychometrically acceptable. CPE consists of three factors including team support environment, event management environment, and athlete professional environment. CICM consists of three factors including caring information, professional exploration, and self-disclosure. Study II is an investigation with 328 Chinese coaches. Confirmatory factor analysis shows that CPE has significant positive effects on CICM (p<0.01) and coaches’ professional titles and AM have significant effects on CICM (p1<0.01; p2>0.01). Hierarchical regression analysis indicates that team support environment and AM have significant interaction effects on CICM (p>0.01). Thus, combining the former indigenous research and this research, it can be concluded that in a Chinese cultural background, professional title, AM, CPE and the interaction effect of AM and CPE have significant impacts on CICM.

Systems psychodynamic leadership coaching

Frans Cilliers, UNISA, South Africa

The objective of this poster is to describe the systems psychodynamic leadership experiences of lea-
In-group criticism by highly identifying in-group members: Group protection or psychological distance?
Monique Crane Macquarie University, Sydney, Australia; Michael Platow
Research by Crane and Platow (2010), demonstrated that highly identifying group members were more willing to express in-group criticism than low identifiers when group member behaviour contravened group injunctive norms. The authors suggest that criticism from highly identifying group members is an opportunity to preserve the in-group's identity. An alternative explanation is that the expression of in-group criticism is used by disenfranchised highly identifying group members to achieve psychological distance from the in-group.

The present study examined the plausibility of the psychological distance explanation for in-group criticism by highly identified group members. Two-hundred and fifty-two third-year psychology students participated in the study. The design of the study was a 2 (behaviour violates injunctive group norms: yes, no) x 3 (prevalence of injunctive norm violating behaviour: single group member, minority, majority) between-subjects design with a single measured predictor variable: in-group identification. In-group identification was measured at two time points: prior to and following the reported intention to disagree with the group. The dependent measure was the level of intention to express disagreement with the group. The results support the analysis of in-group criticism given by Crane and Platow (2010). That is, high identifying group members criticise the group to preserve the in-group identity. Future directions, theoretical and practical implications are discussed.

Creating strong HR systems in MNEs
Rita Cunha Nova School of Business and Eco, Portugal; Joaquim Pinto Coelho; Jorge Gomes
An already significant body of research reported positive associations between human resource management systems and organisational performance. These studies focus on the impact of several specific HRM practices or ‘bundles’ of practices. What has not been specified is how/why this association occurs (Guest, 2011). In order to shed some light on this link between HRM and company performance, Bowen and Ostroff (2004) argue that Strength of the HRM System moderates the HR-performance link, because it refers to how the HRM function can send unambiguous signals to employees about what are appropriate responses, leading to a common set of perceptions and a strong organisational climate. It is obviously relevant, for any company, to be able to identify these process characteristics, but it is even more so in the case of multinational enterprises (MNEs), where the complexity of the HRM System, in a certain strategic context, is added by the geographical and cultural dispersion. The purpose of this conceptual paper is to raise some questions and propositions about the characteristics that HRM systems may assume, in terms of the signals sent to employees in head-quar ters and subsidiaries of MNCs. In particular, we discuss that as the corporate HR roles vary according to different levels of interdependence between head-quarters and subsidiaries, so do the features that allow MNCs to create strong HR systems.

Can emotional intelligence be taught in a classroom: A practical case study in the insurance industry?
Lauren Davis JVR Consulting Psychologists, South Africa
To answer the question: can Emotional Intelligence (EI) be developed through classroom-style training programmes, 105 delegates within in the Insurance Industry attended 2 day training programmes with the objective of enhancing EI. The training used the EQi assessment results and various didactic and experiential learning methodologies. A follow-up assessment was conducted between 8 & 12 months post training for quantitative comparisons in results. 360 questionnaires were used to gather qualitative data on observed behavioural changes. Results indicate a slightly significant increase in the quantitative EQI assessment results. The qualitative data, however, revealed more significant results in that observable behaviour change was noted and the delegates themselves reported a significant paradigm shift in the way they are able to make emotionally intelligent choices and decisions. The shift was more observable in those delegates who had completed the training more recently. Those who had completed 12 months previously reported being more aware of themselves but did not revert to some more habitual behaviours. The 360 results for these delegates revealed similar findings. Classroom-style training may provide some paradigm shift and create a heightened level of awareness. However, it does not appear that this shift is significant enough in the long term to ensure sustainable behaviour change. Classroom-style training to develop EI is therefore not sufficient to ensure long term results. For such an intervention to be successful in the long term there needs to be focused follow-up support.

Psychological empowerment, work engagement and turnover intention
Jacob De Villiers North West university, South Africa; Marius Stander North West university, South Africa
This study investigated the relationship between leader-member exchange, role clarity, psychological empowerment, engagement and turnover intention within a financial institution in South Africa. A cross-sectional survey design was used. A convenience sample (N = 278) was taken (males = 31%, females = 69%; 88% younger than 35 years; 57% with 2 – 5 years service) from the total population (N = 889). They completed the Leader-Member Exchange Questionnaire (Liden, Wayne, & Stillwell, 1993) Role Conflict and Ambiguity Questionnaire (Rizzo, House, & Lirtzman, 1970), Measuring Empowerment Questionnaire (Spreitzer, 1995), Engagement Questionnaire (May, Gilson, & Harter, 2004) and Intention-to-leave Scale (Sjöberg & Sverke, 2000). A path model was tested with SPSS to determine the relationships of the variables. Furthermore, a theoretical model was tested through the use of structural equation modelling (Arbuckle, 2008). The latent variables included LMX (consisting of two parcels), role clarity (consisting of two parcels), psychological empowerment (consisting of four variables, namely meaning, competence, impact, and self-determination), work engagement (consisting of two parcels), and turnover intention (a manifest variable). Role clarity mediated the relationship between leader-member exchange and psychological empowerment, while psychological empowerment mediated the relationship between role clarity and work engagement as well as turnover intention. Leader-member relations lead to better understanding of roles, while role clarity empowers and engages employees.
Flexibilisation strategies in small and medium-sized enterprises

Uwe Debitz Technische Universität Dresden, Germany

The rapidly changing global markets force enterprises to proactively identify and respond to relevant trends in order to survive and to guarantee the jobs of their employees. The “Flexicurity-Approach” of the European Union stresses the inevitable role of flexibility as to technology, work organisation, and employee competencies to secure economic growth. We interviewed verbally and by a standardised questionnaire the management of 48 randomly selected small and medium-sized enterprises as to the perceived necessities of changes and the intended and implemented activities concerning personnel, work organisation and technology. Main results are: Irregular order situations concerning personnel, work organisation and technology. Most of the managers are depreent strategic planning. Theoretically we test the applicability of the approach of “learning organisations” for small and medium-sized companies.

Intercultural competence as a resource for employees of international companies

Dominika Dej Tu Dresden, Germany; Verena Behrend; Susanne Porzelt

The ability to communicate effectively, and to demonstrate adequate behaviour while dealing with members of different cultures is of central importance for employees within international companies. However, the role of intercultural competence has not yet been explored, from the Job-Demand-Resources perspective. This represents a substantial research gap, as intercultural competence may act as a job resource that helps employees to effectively deal with cultural differences in the organisational context. According to the Job-Demand-Resources Model (Demerouti et al., 2001, Bakker & Demerouti, 2007, Demerouti & Bakker, 2011), job demands are associated with burnout, and job resources with work engagement. Moreover, personal resources have been found to buffer the negative relationship between job demands and adverse health outcomes, and to mitigate the positive relationship between job resources and work engagement (Xanthopoulos, 2007). In line with the model, we hypothesise that intercultural competence moderates the negative relationship between job demands and burnout, and mediates the positive relationship between job resources and work engagement. Participants (N=134) were sampled in German high tech companies, whose employees interact with people from different cultures on a daily basis. The results, as well as implications for theory and practice will be presented.

Work characteristics’ effects on entrepreneurs' health and success

Dominika Dej Tu Dresden, Germany; Ute Stephan; Marjan Gorgievski

To date, research has paid little attention to entrepreneurs as a specific occupational group. This is unfortunate, as by studying entrepreneurs who are architects of their jobs, we are able to learn more about job crafting, and transfer this knowledge into the field of salaried occupations. Thus, this study addresses the research question of how classical job demands, job control, and social support affect entrepreneurs’ health and success. It also investigates how self-efficacy, work engagement mediate the positive relationship between job resources and success. Drawing on a sample of 325 entrepreneurs operating in the gastronomy and information technology (IT) industries in Germany, Poland, and the Netherlands, we tested hypotheses derived from the job demand control (support) model (Karasek, 1979) and found support for the proposition that job situations characterised by severe psychological job demands and low job resources are associated with poor psychological health, whereas high levels of all work characteristics are associated with entrepreneurs’ engagement and success. Furthermore, based on the conservation of resources theory (Hobfoll, 2001), we supported that self-efficacy and work engagement, taken as a set, mediate the positive relationship between job resources and subjective success (i.e. work satisfaction and perceived company success). This study's unique contribution is that it combines entrepreneurship, job design, and job crafting research. The study’s results can be applied to promote entrepreneurs’ and salaried employees’ health and performance through active alteration of job demands and job resources as well as stimulation of personal resources (i.e. self-efficacy).

Views on antecedents and outcomes of post-retirement work in a German aerospace company

Juergen Deller Leuphana Universität Lüneburg, Germany; Anne Woehrmann

Continued or re-employment of experts, in retirement, is one option to manage the predicted skills shortage due to demographic change. At the same time, it can provide a source of wellbeing for individuals. Research has shown that post-retirement work is related to retirees’ retirement, and life, satisfaction (Kim & Feldman, 2000). The purpose of this explorative qualitative interview study, was to identify barriers and facilitating factors, as well as the benefits and downsides of post-retirement work, by examining the prospective views of German engineers. To this end, 22 employees of an aerospace company (14 engineers in total, as well as eight experts from the same organisation, i.e., managers, HR specialists and senior managers as well as members of the works council) participated in semi-structured interviews. Interviews were taped, transcribed and analysed through content analysis. Inter-coder reliabilities ranged from α = 0.73 to 0.75. Categories for barriers and facilitating factors for the engagement in post-retirement work, were generated on individual, organisational and family levels. Expected benefits included, amongst others, mental and physical fitness as well as social integration, whereas the downsides contained, for example, the restriction of recreational activities and conflicts in the workplace. This study extends the knowledge on determinants of post-retirement work. Recommendations for work place design can be derived.

The role of social cognitive career theory in post-retirement career planning

Juergen Deller Leuphana Universität Lüneburg, Germany; Anne Woehrmann

Post-retirement work has been an area of research in North America more than 20 years. In times of increasing life expectancy and skills shortage, research interest in post-retirement career planning is also increasing in Europe. The purpose of this study is to examine if Social Cognitive Career Theory (SCCT, Lent et al., 1994), which is based on Bandura’s Social Cognitive Theory (1986), can be adapted to post-retirement career planning. In our study 129 German working individuals (aged 49 to 65 years) took part in an online-survey. The core constructs of the SCCT, i.e. self-efficacy, outcome expectations, interest, goals, and contextual support and barriers, in relation to post-retirement career activities were assessed. Multiple regression analysis revealed that both positive and negative outcome expectations were related to the intention to engage in post-retirement career activities. This was also true for interest in career-related activities and expected social support. Occupational self-efficacy on the other hand did not prove to be significantly related to this intention. The results suggest that SCCT provides a useful framework for post-retirement career planning to some extent. This study extends the knowledge on the application areas of SCCT and on post-retirement work. It also provides starting points for interventions. For example, if outcome expectations are influenced through counseling or informative meetings on post-retirement career activities, this could lead to more individuals planning to work in retirement.

Job characteristics as mediation between relationship of job involvement and passion of activity

Shadi Derakhshan Isfahan University, Islamic Republic of Iran; Hamid Reza Oreyzi

Recently there is ongoing interest in the application of positive psychology in work settings. Job involvement, work engagement, flow, and passion for work are some construction of this sort. Passion is a strong inclination toward an activity that one invests time and energy in. Two forms of work passion is obsessive and harmonious passion. In obsessive passion, workers find it impossible to fully disengage from thoughts about the activity. While in harmonious passion, workers achieve to and it impossible to interact with people from different cultures on a
was adjusted according to work setting and cultural bases. The structure of the scale was supported by Eigen values greater than 1 and factor loading greater than 0.35. Factor indications of confirmatory such as CFI, GFT, TLI, and RMSEA supported two factor solution. Barron and Kenny procedure for mediation analysis supported mediation role of job control between job involvement and passion for activity. Sobel test confirm an indirect mediation path. It is recommended to “give opportunity to self-controlled” workers, so they have a true love for their work.

A dynamic role conflict analysis of managers responsible for retrenchment
Craig Donald Edith Cowan University - Perth, South Africa

A person’s role provides a major contribution in linking the individual and organisational systems. Role analysis techniques are well suited to an examination of the individual’s context and psychological contracting within the organisation, yet provide further insight into group, organisational and even community levels. However, role conflict research has largely been dominated by broad-based role conflict scales, providing limited understanding of transitions and wider system dynamics including organisational crises. The current research examined how role experiences of 50 senior managers from 16 organisations who were personally responsible for conducting retrenchment exercises. Using a retrenchment process model involving stages of decision making, design and preparation, announcement, post announcement, and aftermath stages, the research employed interviews and qualitative analysis to examine individualised responses to the role set pressures involved at each stage. The research highlighted that the different types of role conflict, namely person role, intrasender, interrole and role overload, vary considerably within different role episodes associated with stages of retrenchment, involve different sets of expectations, and impact on overall role stress in a complex manner. Specific issues relating to the managers’ experience of the types of role conflict are mapped out to illustrate how these occur within each stage of the retrenchment process. The research highlights the importance of viewing role dynamics with changing levels of competence on the strategic exercise. Possible personality factors reducing included emotionality, apprehension, careful thinking (16PF) and a judging type personality preference (MBTI). The level of experience and reasoning ability did not consistently aid or constrain performance. The findings indicate that personality factors may serve to constrain leaders from exploring opportunities within increasingly unfamiliar and complex contexts. At the same time, the degree of complexity and the rate of change in each business were seen to be important mediating factors when determining appropriate business roles and development plans. The study presents research questions that may aid practitioners assisting entrepreneurial leaders.

Facilitating age diversity through leadership
Daniela Eberhardt Zurich Univ. of Applied Science, Switzerland

Age-related leadership can be described as the individualised leading of employees according to their age (Ilmarinen, 2004, Ilmarinen & Tempel 2002, Braedel-Kuehner, 2005). The perceptions, attitudes and behaviours of N=395 leaders in Switzerland and Germany were analysed, measured through a further development of the individualised age-related leader scale of Braedel-Kuehner (2005) (Eberhardt & Meyer, 2011). This questionnaire covers employability, leading older people and early retirement for measuring attitudes as well as behavior. Perception scales measure capacities and skills of older employees and self-perception as well as age stereotypes. Descriptive analysis, T-Tests for dependent samples and multiple regression analysis are used. Data show, in general, positive attitude and less, but also positive behaviour towards most scales and items. Individual personal leadership style in relation to age of the employees, is less positive than other scales. Interestingly details are found within different scales. Perception of the development of capabilities and skills of an aging workforce, and self-perception of aging is almost similar and realistic. Multiple regression analysis shows some impact of perception and personal as well as organizational factors in age-related leadership. In group comparisons, some differences between Switzerland and Germany, leadership position, gender and company size were found and will be discussed. Knowledge of various aspects of age-related leadership is available, to use diversity as a resource in organizations and strengthen leaders in their leadership behavior.

Does organisational justice predict employees’ organisational survival? A five year study
Constance Elb Stockholm University, Sweden

The empirical evidence on the relationship between organisational justice and turnover, is still in question. Most studies have explored the relationship between procedural justice, and turnover intentions. Studies on actual turnover are rare and have also only focused on procedural justice and found inconsistent results (Posthuma, Maertz, & Dworkin, 2007). Recently, a shift from specific justice dimensions towards the consideration of overall organisational justice has been proposed (Ambrose & Schminke, 2009). Stepwise logistic regression is used to explore the importance of organisational justice, among other predictors for actual turnover that have been proposed, such as variables from the stress and job content field (Griffith, Hom, & Gaertner, 2000). Survival analysis as the adequate statistical tool neglected so far, will be applied to study whether overall organisational justice predicts belonging to the group of the remaining, or left employees, which provides a more stringent test for the issue. Questionnaire data comes from Swedish accountants who were administered over the course of five years. Preliminary results hint at that organisational justice perceptions, indeed, were significantly lower in employees who left the organisation. Also, trust was lower, salary, job satisfaction and commitment, whereas role conflict, job insecurity and health complaints were higher. The described analyses follow. This study helps to clarify inconsistent findings regarding the relationship between organisational justice and turnover, introduces the new perspective of overall organisational justice, and tests whether the relation to turnover is specific to procedural justice.

South African case study: Assessing entrepreneurial leadership potential in small software companies about to be fast-tracked
Hazel Dunker Jara People Consulting, South Africa

This case study examined attributes that contribute towards or hinder entrepreneurial leadership potential. It presents the practical value of assessment when assisting fast-tracked entrepreneurs. As part of an entrepreneurial investment programme, 18 leaders from 6 small software companies participated in a one day assessment centre to determine their current leadership competence and leadership potential. The assessment centre included Myers-Briggs Type Indicator (MBTI), Sixteen Personality Factor (16PF), validated strategic planning exercise, Cognitive Process Profile (CPP), Raven Progressive Matrices reasoning ability assessment, and a structured psychological interview. A number of themes were identified through comparative analysis on the potential relationship between the assessment results on four entrepreneurial leadership competencies; namely Analytical ability, Entrepreneurial orientation, Strategic ability, and Judgement. The results indicate that although individuals showed the capacity to cope well with complexity as measured by the CPP, many did not demonstrate a high level of competence on the strategic exercise. Possible personality factors reducing included emotionality, apprehension, careful thinking (16PF) and a judging type personality preference (MBTI). The level of experience and reasoning ability did not consistently aid or constrain performance. The findings indicate that personality factors may serve to constrain leaders from exploring opportunities within increasingly unfamiliar and complex contexts. At the same time, the degree of complexity and the rate of change in each business were seen to be important mediating factors when determining appropriate business roles and development plans. The study presents research questions that may aid practitioners assisting entrepreneurial leaders.

Team diagnostic survey applied to sport: Team mental model similarity as mediating factor between independent factors and team performance
Per Eiesele BTH, Sweden

The team diagnostic survey (TDS) was created to assess mental models in work groups and has been found to have sufficiently high internal consistency, to be able to distinguish between low and
Validation of the team diagnostic survey and a field experiment to examine effects of an intervention to increase team effectiveness

Per Eisele BTH, Sweden

The aims of the present study were to validate the Swedish version of the Team Diagnostic Survey (TDS), and to examine the effects of an intervention to increase team effectiveness. TDS is based on Hackman’s (2002) theory of group effectiveness which describes three main criteria of performance and 14 factors that should affect team effectiveness.

Participants were employees (N=533) across several different workplaces. The analyses were done at the group level and data from 97 teams was included in the final material. The sample (N=237) for the randomized field experiment consisted of 31 real life work teams from the larger sample (N=533/97).

Results from the field experiment indicated that there was an overall increase in self-reported team effectiveness from first to second measurement, on several factors significantly higher for teams receiving TDS-based feedback.

Effects of a team effectiveness intervention using the team diagnostic survey

Per Eisele BTH, Sweden

The aim of the present study was to use the Team Diagnostic Survey (TDS) both as an intervention tool and as an investigation tool. The TDS has been validated in the U.S.A. (Wageman, Hackman & Lehman, 2005) and in Sweden (Eisele & Profit, 2011), and validation studies are at this moment being conducted in several countries, for example, in Switzerland and Taiwan. The present study is the first attempt to use a before-after design within this framework. The sample consisted of real life work teams from different occupations in Sweden. Data is being collected successfully and should be analysed before the end of 2011.

Fosteringmulticulturally and internationally competent individuals and teams

Nurcan Ensari Alliant International University, Turkey; Andrea Schlaert

In today’s global environment, we should be prepared to work with individuals and teams who are diverse not just in traditionally defined ‘multicultural’ dimensions such as gender or race, but also internationally, in terms of nationality, location, language and so forth. Despite the threats of group separatism, assimilation, and ethnic hierarchies, organizations, in general, desire to acquire a diverse workforce in an attempt to maximize human capital, creativity, collaboration, and competitive advantage in the global market. Understanding these competencies, and creating an organizational culture and structure that supports individual and team development, are the key components of truly multicultural organizations.

This is a theoretical review paper that will focus on the personal, interpersonal and team challenges that diverse teams face operating in global and virtual settings. It will incorporate relevant social psychological and management concepts that are useful for understanding and responding to these challenges. This paper will make suggestions related to the complexities of working with multicultural and international individuals and teams require the development of a broader set of knowledge, skills and attitudes that previously required in a domestic setting. The presentation will conclude with a framework of competencies for individuals and teams organized into two dimensions, namely level (individual, interpersonal and team competencies), and context (fundamental, multicultural and international/global). It will also make suggestions for future directions in multicultural research.

Moderational relationship between emotional intelligence and job performance

Nurcan Ensari Alliant International University, Turkey; Tara Smallidge

Emotional intelligence plays an important role in positive workplace outcomes, such as salary increase and job performance, by enabling managers to regulate their emotions so as to cope effectively with stress and adjust to organizational change (Lopes et al., 2006). Emotionally intelligent managers are more successful in communicating on the values and mission of the organization to their employees, and are able to understand, manage, use and identify their emotions so as to cope effectively with stress and adjust to organizational change (Lopes et al., 2006). Emotionally intelligent managers are more successful in communicating on the values and mission of the organization to their employees, and are able to understand, manage, use and identify their emotions so as to cope effectively with stress and adjust to organizational change (Lopes et al., 2006). Emotional intelligence is positively associated with constructive conflict management, and this relationship was stronger for non-leaders than leaders. Contrary to our predictions, age was not a significant moderator. The limitations and implications are discussed in terms of psychometric issues, use of emotional intelligence in leadership development and to facilitate problem solving and for the further development of a constructive organizational culture.

The linkage between self-development and organisational development in the South African context

Haroon Essa South Africa

This research presents a newly developed model of the linkage between self-development and organisational development in the South African context. The method and process that was followed for the creation of the model, namely an in-depth literature review followed by qualitative research, is described briefly. After the literature review, a provisional model was developed. The qualitative research that was undertaken used Grounded Theory techniques, specifically, Interpretative Phenomenological Analysis. It was aimed at refining the provisional model. The final model, currently referred to as the ‘X’ Model, was based on empirical evidence to date. From an interpretative phenomenological analysis of the data, the core themes that emerge are leadership, strategy, adaptability, coordination, and relationships. Each of these core themes contains several sub-themes that further help to refine the description. The value of the model lies in its potential to be used as a frame of reference for the design of organisational development diagnostic tools. Although it was developed for a South African organisation, it may well be possible that the ‘X’ Model is internationally relevant given current globalisation trends.

Developing a competency model for returned overseas high-tech entrepreneurs in the 530 program

Wei Fan Chinese Academy of Personnel Science, China

The 530 program is a recruitment project of global talents which plans to attract 30 foreign high-tech...
entrepreneurs within 5 years by Wuxi Municipal Government in China since 2006. As of 2011, more than 600 entrepreneurs had returned overseas through the 530 program and post 530 program. Technological aspects of entrepreneurship are often emphasised, competence models of entrepreneurs have received limited attention from the government previously. The purpose of this research was to build a competency model of returned overseas high-tech entrepreneurs. On the basis of the competency-based job analysis technique and critical incidents interview with entrepreneurs, a competency scale was designed. 110 returned overseas high-tech entrepreneurs participated in this study. Based on content analysis and the structural equation method, the data collected from the two studies provided strong evidence for a competency model comprising 6 categories with a summary of the associated behavioural descriptions. Example competencies included market orientation, achievement orientation, and initiative. Implications for the competency model and the limitations of the study are discussed.

Understanding employees’ deviant behaviour: The role of job satisfaction and conscientiousness

Hadi Farhadi National University of Malaysia, Malaysia

The relationship of job satisfaction and personality traits, especially conscientiousness, with deviant behaviour was previously examined by another researcher. This study focused on the joint relationship of job satisfaction and conscientiousness with workplace deviant behaviour. The study also looked at the influence of conscientiousness on the relationship between job satisfaction and deviant behaviour in the workplace. Data were collected from 212 subjects who were working as civil servants in Malaysia, using a set of questionnaires that measured the variables studied. The results showed that both job satisfaction and personality traits predict workplace deviant behaviour. Results showed a negative relationship between job satisfaction and conscientiousness with workplace deviance. It was also shown that conscientiousness moderates the relationship between job satisfaction and workplace deviant behaviour. Implications for future research are discussed.

A research on the impact of China civil servants’ values on performance: The mediation effect of tacit knowledge

Ming Feng Chongqing University, China; Jing Jiao; Huayong Ren

The performance of the civil servants is the priority for the government considering that they are the decision-makers and executives of government. Value is a key factor that affects people’s behaviour and choices, while it also influences civil servants’ performance. Furthermore, compared with traditional intelligence, tacit knowledge could better forecast performance in work situations. So we come up with “values-tacit knowledge-performance” logic in this article, analysing the relationships among them by questionnaire survey. The survey involved almost 700 civil servants. Firstly, we use the valid questionnaire to build the performance model and tacit knowledge model by EFA (Exploratory Factor Analysis) and CFA (Confirmatory Factor Analysis). The results show civil servants’ performance includes administrative performance, dedicated performance, adaptive performance, and interpersonal performance. And the model of civil servants’ tacit knowledge has seven dimensions: Serving the masses, thought righteousness while getting benefit, performing power in fairness and justice, influence others, official work, attention to details, and morality. The value is measured by the existing questionnaire named Chinese Value Survey developed by Chinese Culture Connection in 1987. Finally, through the correlation analysis and regression analysis among three variables, we find that value has a significant positive effect on tacit knowledge and performance, tacit knowledge has a significant positive effect on performance. Furthermore, tacit knowledge plays a partial mediator between value and performance.

Exploring organisational and individual antecedents of work engagement in Brazilian samples

Maria Cristina Ferreira Salgado de Oliveira University, Brazil

Work engagement has emerged as an important construct in the realm of positive organisational psychology. It consists of a positive state that has an affective-motivational nature and contributes to employee well-being. Originally conceptualised as a positive end of burnout, it is now studied in its own right. The studies concerning work engagement antecedents have been conducted mainly with European and US samples and have focused on organisational antecedents of the construct. Therefore, its individual antecedents as well as its correlates in Latin American samples are to date unexplored. Based on those considerations, the present study aimed at investigating the inter-relationships of organisational practices, global organisational justice, social support and self-core evaluations with work engagement. The sample was composed of 854 Brazilian employees from 24 organisations from both public and private sectors. The employees answered self-report instruments designed to cover all the variables included in the study. The analyses made at individual level showed that organisational practices that stimulate the employee initiative, the perceptions that organisation is fair with its employees, the perceived social support and the self-core evaluations were positive and significant predictors of work engagement. Implications of these results for the adoption of management practices that foster the employee engagement are discussed.

The nature and significance of newcomer socialisation in small manufacturing firms: A newcomer's perspective

Robert Field Eastern Institute of Technology, New Zealand

Organisational socialisation (OS) is a critical process that all newcomers experience, and the efficiency and effectiveness of the OS process impacts on a newcomer’s ability to learn and adjust, as well as key individual and organisational outcomes. The purpose of this paper is to examine the nature and significance of the OS process and resultant outcomes in small manufacturing firms from the perspective of newcomers. Data were collected from 20 newcomers through semi-structured interviews (incorporating the Critical Incident Technique) and analysed using content analytic procedures. Key findings of this qualitative study were: (1) Social networks play an important role in the pre-employment socialisation of newcomers, (2) a range of selection methods were employed that facilitated newcomer learning and adjustment, (3) a combination of formal and informal socialisation approaches are used to socialise newcomers, and (4) key outcomes of the socialisation process include intention to quit/remain and work performance. The nature of the socialisation process differs between small and large firms. The ability of small firms to effectively and efficiently progress newcomers through the OS process is critical in facilitating newcomer learning and adjustment that result in positive OS outcomes. Human resource practices such as recruitment, selection, training and development contribute towards the socialisation of newcomers. Further studies of newcomer socialisation in small firms that includes an organisational perspective, and extended to different types of industries and locations, would be useful to researchers, practitioners and planners who have an interest in the small firm sector.

Employee wellness: Measuring the impact of investment in workplace wellness programmes

Bianca Filmalter CSIR, South Africa; Mariana Otto

In a concerted effort to address the health and emotional wellness needs of employees, most large organisations offer Employee Wellness and Assistance Programmes. Despite literature on the positive impact of such programmes on employees there is very little information available on what the actual return on investment in such programmes are. This is mainly due to the lack of actual measurement indicators for wellness initiatives. In the absence of these, such programmes are generally seen as an add-on or nice-to-have for organisations; they are also the first items to be cut from budgets during difficult financial times. This paper, based on the assessment of a wellness programme implemented over the past two years in a large science council, proposes performance indicators that should be used to gauge the success of wellness initiatives in the workplace and how these can be translated into monetary value for an employer. The schedule of performance indicators are the outcome of a literature review, interviews conducted with employees, and assessment of data related to absenteeism, exit interviews and EAP usage.

Validation and utility of the Utrecht work engagement scale (UWES-9) in people with mental disorders

Franco Fraccaroli University of Trento, Italy; Cristiano Baldacci; Marc Corbiere; Patrizia Villotti; Sara Zaniboni

The purpose of this study is to determine the validity of the work engagement construct among mentally ill workers, and to develop a nomological network delineating work engagement’s relationship with its antecedents and its consequences in this specific population. Using a longitudinal design study, 310 people with mental disorders employed in Italian social enterprises filled out the Utrecht
Work Engagement Scale (UWES-9) and questionnaires on severity of symptoms perceived, and social support from co-workers and supervisors. Individuals who were still eligible at the 12-months follow up phase of the study completed a questionnaire on future working plans. To validate the UWES-9 and test its nomological network, confirmatory factor analysis and path analysis were used. Results showed acceptable confirmatory factor analysis fit indices and psychometric properties of the UWES-9. Acceptable fit indexes were also found for the model tested. The study highlights that the UWES-9 is a useful instrument for measuring work engagement not only in the general working population, but also in workers with mental disorders. Furthermore, the study provides an investigation of how work engagement, as well as its drivers, impacts on important work outcomes in workers with mental disorders. In particular, the important role that the vigour dimension plays in this population as a mechanism through which individuals feel better at work and feel ready to take the further step, that is, to work in the open labour market, is highlighted.

Impact of organisational justice on cortisol after awakening response (CAR) and decline through the day

Niklas Friedrich, Hamburg University, Germany; Monika Keller; Tim Vohle-Hinz; Jan Dettemers; Eva Bamberg
A growing body of research addresses health impairing consequences of Organisational Justice (Elovainio, Heponiemi, Sinervo, & Magnusiva, 2010). However, relatively few studies investigate the relationship between organisational justice and bodily responses to stress. The cortisol after awakening response is a reliable marker for the HPA activity (Pruessner et al., 1997) and therefore suitable to examine this relationship. Also (Tepper, 2001), there is, to date, no study which investigates the relationship between cortisol and organisational justice. Using random coefficient modelling we tested whether organisational justice is related to cortisol after awakening response. Moreover we investigated whether this relationship is mediated via negative emotions as suggested by Greenberg (2010). In order to address our hypothesis, we conducted a diary study examining emotional state once a day for 4 days. Saliva cortisol samples were collected from 50 participants four times a day. On a personal level we measured procedural and relational justice. First results confirm our hypotheses that justice influences cortisol.

Chinese college graduates’ career decision-making self-efficacy and social support: The moderating role of social comparison

Ying Fu GERC, Zhejiang University, China; Zhongming Wang
Faced with severe employment trends, Chinese college graduates need guidance and support for their career decision-making. As an effective predictor of employability, career decision-making self-efficacy (CDMSE) is influenced by factors such as social support and social comparison, but the relationship between them has not been revealed yet. Based on theories of self-efficacy from former researches, this study invited 193 Chinese college graduates as sample, using Career Decision Making Self-Efficacy Scale and scales of social support and social comparison to explore the status of college graduates’ CDMSE and to analyse the correlation between the CDMSE and social support, and also the moderating role which social comparison tendency played in this correlation. The results are: The level of Chinese college graduates’ CDMSE is above average with significant individual differences, while the self-efficacy of targeting and problem solving is relatively low, there is a positive correlation between social support and the CDMSE, in which social comparison tendency played a moderating role. For the graduates who own a high social comparison tendency, social support contributes less to their CDMSE than those who own a low social comparison tendency. The results indicated that we should make great effort to build and strengthen social support systems for college graduates. The graduates themselves should scientifically use social comparison information and search for social support resources synthetically, to improve their career decision-making self-efficacy, and thus make career decisions properly for their interest and ability.

The significance of social networks for learning about change in a Brazilian public organisation

Carolina Fussi, Universidade de Brasilia, Brazil; Valdenis Silva, Universidade de Brasilia, Brazil; Elaine Neiva; Eduardo Farias; Daniel Barbosa, Universidade de Brasilia, Brazil
By using qualitative research, this work examines the perceptions of employees’ learning social network structure, in a Brazilian judiciary institution that impacts on the process of organisational change. The context of the change under study is characterised by the adoption of a new technology that changed the workflow, by digitising parts of the legal process. Once the adoption of new technologies includes learning new skills to deal with informational tools, the aspects of social networks related to transactional contents of learning, related to the behaviour of individuals in the changing context, may influence the acceptance and the mechanisms of resistance to change. Thirteen groups, with 12 participants each, were interviewed by using the semi-structured approach, addressing the participants’ perceptions about the change and learning processes, and the exchange of knowledge among employees. For evaluating the learning network, the respondents identified the people whom they approached for assistance in learning the new skills. The questionnaires are now under scrutiny and the results shall be presented during the congress.

Good soldiers or good actors: The effects of prosocial and impression management motives on organizational citizenship behaviors

Riguang Gao, Jiangxi Univ Finance and Econ, China; Biyong Wang, Jiangxi Univ Finance and Econ, China
Organizational citizenship behaviors are often likely undertaken not only by good soldiers doing good but also by good actors looking good. The effects of prosocial and impression management motives on organizational citizenship behaviors were explored by empirical analysis on the paired data from 302 employees and their workmates. The results showed that prosocial motives had significant effects on organizational citizenship behaviors toward other...
people and toward organizations. Also, impression management motives had significant effect only on organizational citizenship behaviors toward organizations. And impression management motives mediated the relationship of prosocial motives and organizational citizenship behaviors toward organizations, that was, the stronger the employee’s impression management motives, the lower the correlation of prosocial motives and organizational citizenship behaviors toward organizations.

Organisational justice: Predictor of psychological well-being of employees

Pooja Garg  Indian Institute of Technology, India

The present study attempts to investigate the relationship between perception of justice (Greenberg, 1983) in the workplace and psychological well-being (Ryff, 1989) of employees, from the perspective of life satisfaction. A total sample of 200 managers was randomly selected from the banking and automobile sector. The collected data were subjected to factor analysis on the basis of Principal Component Analysis with Kaiser’s Varimax Rotation, Pearson correlation and Multiple Regression Analysis. The research findings indicate that justice is a significant predictor of psychological well-being. The present study has been initiated with the viewpoint that research pertaining to the dyad and dynamic combination of organisational justice and psychological well-being would be a nascent area of study in management discourse. The findings revealed that employees who are cognitively satisfied experience well-being in the workplace, which has a spill-over effect on the other domains of life, and generates morally relevant behaviors, leading to life satisfaction.

Stress and its associated factors among primary healthcare doctors, medical assistants and nurses in government health clinics in Malaysia

Siti Raudzah Ghazali  University Malaysia Sarawak, Malaysia

This study aims to explore the prevalence of stress, and its associated factors, among primary healthcare doctors, assistant medical officers and staff nurses at government health clinics in the State of Kelantan, Malaysia. This study adopted a cross sectional design. Data were collected from 1st June until 31st August 2010. A total 248 respondents consisting of 34 doctors, 73 assistant medical officers and 138 nurses participated in the study. The Malay version of the validated Depression, Anxiety and Stress Scale (DASS–42), and Karasek’s Job Content Questionnaire were used as research instruments. The prevalence of stress among primary healthcare doctors, assistant medical officers and nurses was 7.3%. Multiple Linear Regression (MLR) analysis of stress scores among doctors showed that lack of supervisor support and hazardous conditions were significant associated factors for stress. For assistant medical officers, MLR analysis revealed that job insecurity, lack of supervisor and co-worker support were the significant associated factors for stress. MLR analysis of stress scores among nurses showed that duration of employment, number of children, decision authority, job demand, job insecurity and physical exertion were significant associated factors for stress. Social support from supervisors, ensuring job security, and reducing hazardous conditions are essential to reduce the stress level among Malaysia health care professionals. Staff with longer duration of employment should be encouraged to undergo a stress prevention and management programme. Findings of this study are useful for intervention strategies in preventing stress among primary healthcare providers.

Performance coaching: Soft skills for the hard-core

Neville Goldin  South Africa; Ann Carvalho; Hilton Rudnick

Direct qualitative measures of the success of coaching interventions in corporate environments are rare. Using this research we were able to get a measure of the ROI amongst a group of hard-core engineers and technical specialists. We embarked on a coaching assignment with fifteen executives, mostly technical specialists of an international engineering company. Seven experienced coaches were deployed to provide the intervention, utilising a coaching methodology best described as Performance Coaching (McLeod, 2004) wherein the main focus of the session is on moving steadily towards goals which are set in the initial sessions. These goals were partly determined by the CEO of the company. Almost all of the coachees had at least one goal centred on interpersonal skills – the focus of attention of this research. We utilised a qualitative approach in addressing the research question. Subsequent to the coaching we asked a set of structured questions to each coachee, covering aspects of interpersonal development which were addressed in the coaching sessions. Coachees were asked to reference their answers only in regard to where changes could be attributed directly to the coaching process. In addition a colleague of each coachee was asked a similar set of questions in regard to observable changes they had noticed. The results of the research presented strong qualitative evidence that the coaching had impacted directly and positively on the interpersonal style of most of the group.

Behind innovation clusters: Individual, cultural, and strategic linkages

Jorge Gomes  ISEG/Technical Univ. Lisbon, Portugal; Mariana Silva

Reasons for clustering in the modern economy are various. In the innovation literature, for example, knowledge is created and shared within clusters (Vaz & Nijkamp, 2009). Porter and Sölvell (1998) explain that a cluster allows the development of a common language, social bounds, norms, and values. According to Pounder and John (1996), managers and decision-makers in a cluster share values, cognitive references, and experiences (called normative isomorphism), hence they tend to establish connections and follow the same patterns of organizational behaviour. The goal of the current study was to explore and understand the microdimensions (i.e. individual and social) behind macro structures (i.e. clusters). Two organizations in the same cluster were analysed. A case study approach was followed, with several instruments: 1) a questionnaire to measure corporate culture; 2) interviews; 3) observation; and 4) document analysis. Data analysis revealed that, although closely interdependent, both companies had a distinct pattern of cultural and strategic orientations and profiles, which suggests a low level of isomorphism. This goes against Pounder and John’s (1996) idea that a cluster has a shared cultural and strategic profile. The study further showed that informal relationships between individuals from both companies strengthen the cluster. Other linkage factors, such as trust, common historical development and growth, and family-type companies, are also discussed.

Individual, social, and cultural linkages in innovation networks: A psychological perspective

Jorge Gomes  ISEG/Technical Univ. Lisbon, Portugal; Sofia Bernardo

Clusters have become an important part of modern economical and even social organisation. Since Porter’s (1990, 1998) seminal work on the importance of clusters to national and regional economies, authors have tried to understand the structure and dynamics of clusters and clustering. More recently, the concept has originated other related concepts, which deal with a more specific phenomenon within clusters. Such is the case of “networks of innovation”, which provide a framework to analyse the rules, norms, conventions or shared practices that form national or regional patterns of interactions among institutions. The current research addressed the following questions: How are institutions relating to each other? and how do they create networks of innovation? These questions were approached from sociological and psychological perspectives. One single case study was observed and investigated. This single holistic case is composed of several entities within an innovation network, of which 6 participated in the study. Interviews, document analysis, and observations were carried out in all of these entities. Results show that formal relationships are strongly supported by informal ones, and that cultural ties linked to the specific type of cluster also give support to the creation, maintenance, and reinforcement of the network. The paper ends by drawing some important implications for theory, research, and practice. Political implications are also highlighted.

Skills training in multimodal virtual environments

Daniel Gopher  Technion Israel Institute of Technology, Israel

Multimodal, immersive, virtual reality (VR) techniques open new perspectives for the study of skill acquisition and training, and in particular the training of perceptual-motor skill trainers. They also introduce new risks and dangers. This lecture will describe the benefits and pitfalls of multimodal training, in the context of the current theoretical thinking on skill acquisition and knowledge representation. I will also delineate the cognitive building blocks of a multimodal, VR training system.

Effort-reward imbalance, work-home interference and health: A longitudinal study among nurses in Europe

Marjan Gorgievski  Erasmus University Rotterdam, Netherlands; Hans Hasselhorn; Arnold Bakker; Beatrice Van der Heijden

This study set out to test the postulation of the effort-reward imbalance model (Siegrist, 1996) that a dissonance from reciprocity in transactions, defined as an imbalance of high extrinsic effort and low extrinsic rewards, leads to strain, and sets into motion a
negative spiral of increased mental exhaustion and work-home interference. Herewith, this longitudinal study is one of the rare studies investigating an additional effect of the effort-reward imbalance on top of the main effects of efforts and rewards. Moderated Structural Equation Modeling (MSEM) was used to analyse longitudinal survey data from 26,106 nurses from six European countries. Mean age was 38.21 years (sd = 8.89), 11.7% was male, and 88.3% was female. Effort-reward imbalance, measured as the effort-reward ratio, was treated as a special type of interaction term in MSEM. As expected, high extrinsic efforts and low extrinsic rewards at Time 1 predicted more mental exhaustion and more work-home interference at Time 2. Moreover, effort reward imbalance at Time 1 additionally predicted work-home interference at Time 2, both directly and through increased exhaustion at Time 1. Surprisingly few cross country differences were found, which will be discussed. To conclude, effort-reward imbalance not only appeared to predict impaired health, but also spills over into the private domain, partly through mental exhaustion. Improvements are possible through decreasing effort (demands) and increasing rewards, as well as reactive strategies aimed at recovering from mental exhaustion.

The expectations, perceptions and experience of members of the South African Police Service of Employee Assistance Services: An empirical study
Anton Grabler
University of the Western Cape, South Africa; Yvonne Joubert
Shanghai Jiao Tong University, China

The objective of this research is to determine the expectations, perceptions as well as the experience that South African Police Service (SAPS) employees have regarding the Employee Assistance Services (EAS). No sampling strategy was used, with the result that all available employees were included in the study (N=37 816). The questionnaire was designed using eight cross-cutting principles in the EAS (referred as factors), namely (i) information; (ii) support and understanding; (iii) accessibility; (iv) EAS (referred to as factors), namely (i) information; (ii) support and understanding; (iii) accessibility; (iv) inclusivity; (v) (v) availability; (vi) responsiveness; (vii) confidentiality; (viii) the proactive/empowerment approach. The measuring scale is a 5-point Likert scale. The respondents’ expectations and perceptions regarding these principles were measured with two sets of eight explicit questions. The experience was measured by isolating the responses of those employees who have used the services of the EAS in the past year. The results indicated a high overall expectation of the EAS regarding all eight principles (combined average of 4.5), followed by a slightly lower overall perception (combined average of 3.2), and a combined average of 3.5 regarding the overall experience of participants who have used the services of the EAS in the past year. Statistical significant differences in the overall experience dimension were reported between the different race groups, rank groups as well as employees who have used (or did not use) the services of the EAS.

Social capital and team: The mediating roles of team psychological safety and learning behaviour
Qinxuan Gu Shanghai Jiao Tong University, China; Lihong Wang

There is very little literature available on the mechanisms between social capital and team innovation. This study aims to fill the gap by exploring psychological safety and learning behaviour as mediators between the three dimensions of social capital (the structural, cognitive and relational capital) and innovation at team level. Our sample comprised 146 R&D teams with 559 members from eight Chinese high-tech companies. Among 146 R&D teams, the average tenure of the members in the teams was 37.28 months (s.d.=35.46), the average team size of 3.83 members (s.d.=1.65, range=2-10). Data on team social capital, psychological safety and learning behaviour were collected from 559 members, while data on team innovation were collected from leaders of 146 R&D teams. Hypotheses were tested by using structural equation modelling. Results showed that the three dimensions of social capital were positively related to team innovation, and that both psychological safety and learning behaviour partially mediated the relationship between the structural capital and team innovation, whereas it fully mediated the relationship between the cognitive and relational capital and team innovation. Finally, managerial implications are discussed and future research directions offered.

How does LMX influence employee creativity? The roles of creative self-efficacy, creative role identity and job autonomy
Qinxuan Gu Shanghai Jiao Tong University, China; Lihong Wang; Xiaoling Wan

Many studies have examined outcomes and antecedents of leader-member exchange (LMX), but few studies have explored how LMX influences followers’ creativity. The purpose of this paper is to examine the influence process by exploring the mediating roles of creative self-efficacy and creative role identity, and the moderating role of job autonomy. Our sample comprised 208 leader-follower dyads within organisations situated in the People’s Republic of China. Hypotheses were tested by using structural equation modeling and linear regression analysis. As predicted, results showed that both creative self-efficacy and creative role identity fully mediated the relationship between LMX and employee creativity, while unexpectedly, job autonomy did not play a significant moderating role in the relationship between LMX and employee creativity. However, we found that job autonomy negatively moderated the relationship between LMX and followers’ creative self-efficacy. Implications for the theory and practice of leadership in the Chinese context are discussed. Some recommendations for future research are provided.

Doing business in India: Cross-cultural issues in managing human resources
Seeta Gupta IMT Ghaziabad, India

This research focuses on the issues surrounding business in India where cultural differences can create potential barriers when conducting business overseas. India is achieving a 7% economic-growth and is one of the largest emerging markets worldwide. With an abundant availability of competitive resources, human and material, it offers immense opportunities for businesses to flourish. The objective is to understand how Multi National Corporations (MNCs) can be successful when doing business in India, while also managing human resources. This is an exploratory research involving fifteen senior vice presidents working in overseas/Indian MNCs. In-depth interviews were conducted with fifteen respondents, average age 38.4 years. They represent different sectors and have served globally in India/abroad. Interviews were video-recorded and notes taken for further analysis. Responses are classified under four themes: (1) Why MNCs want to do business (2) Challenges of doing business (3) Cultural routes to doing business (4) Doing business - Human Resource perspective. Responses from global managers highlight the need for a deeper understanding of Indian culture before any MNC begins to do business here. The challenges of managing aspirations of a young and large local work-force requires offering a Unique Value Proposition with challenging roles and professional growth opportunities. High levels of compensation alone, are not effective in retaining an individual in this dynamic business scenario of high attrition.

Organisational role stress and personality: An interface
Vibhuti Gupta Delhi University, India

The aim of this empirical research is to investigate if the two levels of management (upper and lower management) and males and females in public sector organizations differ significantly in their experience of organizational role stress. The study also aims to investigate the extent to which the individual’s personality dimensions affect their perception of organizational role stress. For this purpose, two standardized questionnaires, namely the NEO Five Factor Inventory by Costa and McCrae, 1991, and the Organizational Role Stress Scale by Udai Pareek, 1981, were administered to a sample of 120 employees working in two public sector organizations in Delhi, India. For statistical computation, t-test and Pearson’s product moment correlation was used. Results indicate significant gender differences in inter-role distance, with women being significantly high on it. Personal inadequacy and role stagnation also showed a trend towards being significant. There were significant differences between lower and upper management in regard to role isolation, personal inadequacy and self role distance. Role expectation conflict showed a trend towards being significant. For the total sample size (N=120) Neuroticism correlated significantly with role erosion (negative correlation). Extraversion with role erosion (positive correlation), and Conscientiousness with role expectation conflict, personal inadequacy and self role distance (all three negative correlations). The results are discussed in light of existing research and further subsequent interviews with 10 employees. Limitations and implications of the study are highlighted. Future suggestions are given.

The effects of group faultlines and diversity orientation on change decisions: A post-merger team integration process
Lifeng Han Zhejiang University, China; Zhongming Wang

Acquisition is a major event for focal organisations, which will have a substantial impact on the people involved. The main characteristic of post-merger organisation lies in the composition of its employees becoming more diverse regarding new teams composed of people coming from two different organisations. How to manage the emerging diver-
sity becomes an important issue throughout the post-merger team integration process. This study (supported by NSFC70232001) examined the effects of group faultlines and diversity orientation on team collective self-verification, processes, and decision quality. An experiment of 46 three-person groups using a 2 (strong/weak group faultlines) × 2 (high/low diversity orientation) factorial design revealed that diversity orientation moderated the effect of group faultlines on team collective self-verification, processes, and decision quality. Specifically, the negative effects of group faultlines on these variables will be reduced when diversity orientation is high, than the situation when diversity orientation is low. We then proposed that group faultlines hampered team members’ endeavour for acquiring self-verifying feedback, which in turn impaired members’ sense of connectedness to the team and cut off information-sharing among them. Finally, processes loss was related to poor decision quality. Three parallel statistical approaches showed that both self-verification to connectedness path, and self-verification to information sharing path, fully mediated the relationship between faultlines and decision quality respectively. Implications for diversity management in post-merger teams were discussed.

Pay satisfaction as a mediator of the relationship between perceived organisational justice and organisational commitment Davood Hayati Islamic Republic of Iran

This study tested a mediational model consisting of organisational commitment as dependent variable, and pay satisfaction, organisational justice, procedural justice, and interactional justice as independent variables, with job satisfaction as mediator. Data were gathered from a sample of 170 employees of an industrial organisation in Ahvaz who were selected by a stratified random sampling method. Of this sample, 98.8% were men and the average age was 39 years. The instruments used in the present study consist of the Organisational Commitment, Organisational Justice, and Pay Satisfaction Questionnaires. Structural equation modelling (SEM) through AMOS-16 and SPSS-16 software packages was used for data analysis. The results supported components of the proposed model, that is, perceived organisational justice (distributional justice, procedural justice, and interactional justice) predicted pay satisfaction, which in turn predicted organisational commitment. In addition, pay satisfaction partially mediated these relationships. Discussion and implications of the results are presented in the study.

Four dimensions of pay satisfaction and turnover intention: Mediating role of job satisfaction, organisational commitment, and work motivation Davood Hayati Islamic Republic of Iran; Abdolakazem Neisi

The aim of this study was to test a model consisting of turnover intention as dependent variable, four dimensions of pay satisfaction as independent variables, with job satisfaction, organisational commitment, and work motivation as mediators. Data were gathered from a sample of 273 employees of NISOC in Ahvaz, Iran, who were selected by stratified random sampling method. Of this sample, 95.2 percent were men and the average age was 44 years. The instruments used in the study consist of Turnover Intention, Organisational Commitment, Job Satisfaction, Work Motivation, and Pay Satisfaction Questionnaires. Structural equation modelling (SEM) through AMOS-16 and SPSS-18 software packages was used for data analysis. The results supported components of the proposed model, in that four dimensions of pay satisfaction predicted turnover intention. In addition, job satisfaction, organisational commitment, and work motivation mediated these relationships. Discussion and implications of the results are presented in the study.

Work-family conflict and work engagement among working mothers: Personality as a moderator Carolina Henn University of Johannesburg, South Africa; Tracy Opie

The study utilised the Job Demand-Resources model to investigate the effects of work-family conflict on work engagement among working mothers. The moderating roles of conscientiousness and neuroticism on the relationship between work-family conflict and work engagement were also investigated. A quantitative, cross-sectional, survey design was used. The sample was comprised of working mothers from several organisations. Data was gathered using the Work-to-Family Conflict Questionnaire (Netemeyer, Boles & McMurrian, 1996), the Basic Traits Inventory (BFI) (Taylor & De Bruin, 2005) and the Utrecht Work Engagement Scale (UWES-9) (Schaufeli, Salanova, González-Romá, & Bakker, 2002). Results indicated that work-family conflict negatively predicted work engagement. Conscientiousness positively predicted work engagement, and neuroticism negatively predicted work engagement. In terms of interaction effects, a significant interaction effect was found for conscientiousness but not for neuroticism. More specifically, for participants that are high in conscientiousness, work engagement decreases significantly more with an increase in work-family conflict, than for participants that are low in conscientiousness. The study contributes to the limited information available in terms of work-family conflict among South African mothers. Results indicate that employees that are high in conscientiousness and low in neuroticism have significantly higher levels of work engagement, which has implications for selection. Organisations and employees should investigate ways to reduce work-family conflict among conscientious female employees to counteract the negative effect thereof on their engagement levels.

Employee responses to work design: Integrating the job demands-resources model and self-determination theory Severin Hornung Hong Kong Polytechnic Univ, Hong Kong; Juergen Glaser; Matthias Weigl; Peter Angerer

Idiosyncratic deals (i-deals) are nonstandard arrangements in which individual workers negotiate with their employer to make jobs better fit personal needs and preferences. Differing from related proactive behaviors, i-deals imply mutuality: Employees initiate and employer authorization. Moreover, i-deals are heterogeneous: Development i-deals have been found to relate positively to motivation, commitment, and satisfaction. Flexibility i-deals predominantly reduce work/non-work conflicts. As previous research has paid only cursory attention to issues of status and bargaining power, we seek to clarify who gets what kind of deal – and who doesn’t. We analyzed a sample of 155 German hospital physicians, where hierarchy and status are highly important. The sample included 59 residents at the lowest level, 47 fully certified, 30 senior, and 19 head physicians at the highest rank. Modifying a previously used measure and comparing means and frequencies across groups, we found that lower ranking employees not only reported a lesser overall extent of developmental i-deals, but were also more likely not to seek out and/or be denied such arrangements; this pattern was reversed for high status workers. Flexibility i-deals were largely confined to lower level part-time workers. High status employees attributed successful negotiation to their achievements and bargaining power. Lower ranks saw i-deals largely at the discretion of their supervisors. We discuss theoretical and practical implications of the risk that in hierarchical settings i-deals aggravate inequalities and lead to cumulative disadvantages of high status workers.
The interactive effects of psychological safety and accountability on organisational learning under change
Honghao Hu; Zhejiang University, China; Zhongming Wang

Quite a few scholars have examined the relationship between psychological safety and organisational learning and found that psychological safety would significantly affect organisational learning. Drawing on the literature on organisational learning and accountability, we argued that psychological safety only in coordination with accountability would accelerate organisational learning and hypothesised that there was an interactive effect of psychological safety and accountability on organisational learning both at the individual and organisational levels. After controlling for demographic factors (company size and company tenure) and using the regression analysis on the data from 39 Chinese manufacturing companies, the results supported the hypothesised interactive effect. Findings suggested that when accountability was high, psychological safety was significantly and positively related to organisational learning; and when accountability was low, there was no significant relationship between psychological safety and organisational learning. These results have important implications for building psychological safety climate while adequately emphasising accountability among the employees in order to facilitate organisational learning practice, which could be a strategy to nurture an effective learning context for those Chinese traditional manufacturing firms involving in the business upgrading and industrial transfer. The implications of this study (NSFC-70232001) for organisational learning capability were highlighted from the perspectives of accountability and psychological safety for Chinese entrepreneurial organisations.

The interaction between ethical leadership and perceived accountability under organisational change
Honghao Hu; Zhejiang University, China; Shenzhen Mo; Zhongming Wang

Accountable team members are important in order to achieve team success, especially during the phase of organisational change. However, there always exists a tradeoff between increasing the teammates’ accountability and reducing the work stress. Since leaders who practice ethical leadership behavior can significantly shift work-related accountability from individuals to the team as a whole, this study tries to test the interactive effect of perceived accountability and ethical leadership on individual performance. Data was collected from a sample of 37 functional teams from companies which are experiencing organisational change. The three-member’s responses to team-level ethical leadership were aggregated into team-level data after verifying the internal consistency of intra-group data. Based on the hierarchical linear modeling and regression analysis methods, the results show that the perceived accountability of individual teammate is positively related to individual performance, which sequentially contributes to the whole work team. And ethical leadership as a team-level variable positively predicts team performance. More importantly, ethical leadership significantly moderates the relationship between individual perceived accountability and his/her performance. This study reveals that the individual perception of formal accountability is critical for individual work output when implementing the dependent tasks. However, in a collective working setting, particularly in the Chinese context, team ethical leadership can enhance team performance while relieving the individual work stress resulting from too much perceived accountability. The implications of this study (NSFC-70232001) for developing the accountability and leadership strategies in the teamwork setting under organisational change were discussed.

A multilevel study on team accountability and its effects among Chinese outsourcing industrial firms under change
Xiaohong Huang; Zhejiang University, China; Zhongming Wang

Accountability involves an agent who, potentially, is subject to evaluation so that the agent needs to justify the decision behaviour. As team becomes the main work pattern in many industries including outsourcing, there is no study on team accountability. Thus, based on meso-level theory of accountability, and Chinese vendor team as subject, this study (NSFC 70732001) explored team accountability and its effects. Firstly, three sub-studies explored the conceptual dimensions of team accountability. In sub-study one, semi-structured interviews with leaders and members from five teams were conducted, and three dimensions emerged by adopting content analysis, including responsibility, transparency, and response. Based on sub-study one, sub-study two compiled team accountability scale to 157 participants from 31 teams, and 14 items were finally formed after exploratory factor analysis. In sub-study three, confirmatory factor analysis was applied to 212 participants from 36 teams, and the results supported the three dimensions of team accountability. Secondly, the study explored multi-level effects of team accountability. Four hundred and eighty-nine leaders and members from 120 teams as participants, five scales as tools, including team accountability scale, team cohesion scale, job tension scale, turnover intention scale, and team performance scale, and multilevel structural equation modelling as analytical method, the results showed that team accountability affected turnover intention, and the relationship was mediated by job tension. The study also compared the results between vendor team and general team, indicating the context specificity of team accountability effect mode under outsourcing.

Team accountability and outsourcing decisions under change: A neuro-behavioural perspective
Xiaohong Huang; Zhejiang University, China; Zhongming Wang

Accountability refers to the expectation that one may be called on to justify one’s beliefs, feelings, and actions to others. Outsourcing challenges the social contingency model of accountability, in that vendor project team, wandering between vendor and client, is accountable to both of them. Thus, based on social contingency model, this research (NSFC 70732001) explored the behavioural and neural decision mechanism of team accountability and the moderating effect of need for cognition. Team leader accountability, defined as team leader takes full accountability and subordinates are accountable to leaders, is common among team accountability modes. Assuming team leader accountability as mode, the behavioural study employed undergraduates as subjects and a coin toss game as experimental scenario. The results showed that when accountable to single audience, no matter who was vendor or client, the individual adopted conformity to please the audience. When accountable to a dual audience with conflict of interests, individual engaged in preemptive self-criticism, that is, she/he considered dual interests to achieve satisfactory results for both of them. Need for cognition moderated the coping tactics when accountable to dual audience, people with low need for cognition relied on evasion more than the ones with high need for cognition. With the same research paradigm and college students as subjects, event-related potentials study revealed N1 elicited by stimuli during vendor accountability was significantly larger than the ones elicited by stimuli during non-accountability and dual accountability separately, reflecting the discrimination process of decision and the different intentions of discrimination efforts.

A study of the relationship between managers’ competencies and management performance
Jiehua Huang; Guangzhou University, China

The purpose of this paper is to study managers’ competencies which are the key elements to ensure the survival and growth of enterprises. Based on literature review, group discussion and expert evaluation, a 129-item questionnaire was constructed to test managers’ management competencies. This, together with the questionnaire of management performance, was used as research tool to obtain the data. 462 women managers from enterprises in Guangdong province participated in the study, with 154 top managers and 308 middle managers. Using confirmatory factor analysis and structure equation model, the results find a five-dimension management competencies model, which includes self-management ability, leadership, task management ability, innovation management ability and social responsibility. Each dimension has its sub-dimensions. Meanwhile, women managers’ management competencies significantly influence enterprises’ management performance. This study offers insight into the relationship between managers and management performance in enterprises, providing foundation for in-depth studies on management competencies. The management competencies model is useful for practitioners in management positions in organisations, who can enhance their management skills through the understanding and practice of management competencies. Therefore this study can be used as a tool by organisations to improve organisation’s strategic vision and for individual improvement purposes. The implications for human resource management, e.g., enterprise managers’ selection, evaluation, training and development, are discussed.

The relationship between mood, social motivation and Organisational Citizenship Behaviour
Gang Huangfu; Beihang University, Beijing, China; Lijia Zhu

Organisational Citizenship Behaviour (OCB) refers to employees’ altruistic behaviour in an organisation.
This study aimed to explore factors that may influence OCB. Two factors were taken into account, mood and social motivation. Eighty employees from two medium-sized Chinese enterprises were recruited to participate in the study. Their OCB levels were evaluated by their supervisors in the organisation. Social motivation was measured by decomposed games. Positive or negative mood was induced by happy and sad music, then measured by a self-reported scale Positive And Negative Affect Scale (PNAS). Results showed that employees’ mood affected their immediate OCB performance. Positive or negative mood can cause changes of OCB, positive mood increased the immediate OCB performance, while negative mood decreased OCB, showing working in a positive mood may lead to more altruistic behaviour, which may imply higher performance. The study also showed that most employees’ social motivation is in a pro-social category, but there was no significant correlation found between social motivation and OCB in the study. Further research needs to be done to explore more factors that may enhance OCB.

The effects of trustworthiness demonstration versus distrust regulation on trust following a transgression

Ma Huawei Tianjin Normal University, China; Gao An Yue; Qi Yao

Prior research on trust repair has focused on the effects of specific repairing tactics on integrity-based trust and/or competence-based trust after a transgression. Although the findings have enhanced our understanding of trust repair, repairing tactics have seldom been considered in isolation from each other. Based on two different underlying mechanisms for trust repair, i.e., trustworthiness demonstration and distrust regulation, present studies categorised the transgressors’ responses after trust violation into demonstration tactics and regulation tactics, and investigated their effects on integrity-based trust and benevolence-based trust after violation. Two studies, using samples of employees, were conducted involving a context in which an organisation has violated an employee’s trust by improper behaviours during layoff. Study 1 revealed that the violation of benevolence-based trust was more difficult to repair than that of integrity-based trust. In addition, the distrust-regulation tactics were more effective for repairing benevolence-based trust than for repairing integrity-based trust. Furthermore, for integrity-based trust, the trust-demonstration tactics were more effective. Study 2 introduced the variable of institutional trust to further investigate why the findings were inconsistent with previous ones. It was revealed that low level of institutional trust weakened the effect of regulation tactics on integrity-based trust.

Psychological variables predicting perceived job stress among policemen in Ile-Ife, Nigeria

Femi Lhevbare Obasfen Awolowo University, Ife, Nigeria

The study examined psychological variables as predictors of perceived job stress among policemen in Ile-Ife, Nigeria. The study employed ex-post-facto research design. A total of one hundred policemen were drawn within the divisional headquarters in Moore, Ile-Ife, Osun state, comprising 64 males and 36 females within the ages of 18 to 52. Three hypotheses were drawn from the review of literature and tested with appropriate statistical tools. A 2-Way ANOVA analysis showed that self-esteem does not have a significant influence on perceived job stress among the policemen (F(1,92)=1.074, P>0.05). Also, there was no significant self-monitoring differences on perceived job stress of the policemen (F(1,92)=0.017, P>0.05). Further results revealed that locus of control does not have an influence on job stress (F(1,92)=0.235, P>0.05) among the participants. Reasons were given why the outcome of this present study negates the outcome of previous studies with emphasis on the socio-political situation experienced by policemen in Nigeria. Recommendation was made with emphasis on the importance of adopting stress-reduction strategies in organisation to improve efficiency at workplace.

The association of personality resources to workplace motivation

Tatiana Ivanova Higher School of Economics, Russian Federation; Evgeny Osin

With support of Russian scientific humanitarian fund, project #12-06-00806 “Personal resources in workplace motivation system.” Work motivation is a broad category that encompasses a number of characteristics of both work environment and personality. According to self-determination theory (Deci & Ryan), the general motivational tendencies (intrinsic or extrinsic) are reflected in any domain of activity, including work. However, the association of work motivation to personality resources, which are widely recognised as personal strengths and virtues contributing to well-being and goal achievement, is not clear. The sample included 4,700 employees of a major national electric company. Respondents were asked to participate in a study of well-being at work and completed a questionnaire that included Russian versions of the Situational Motivation Scale (Guay, Vallerand & Blanchard, 2000), Personal Views Survey II measuring hardiness (Maddi, 1997), Generalized Self-Efficacy Scale (Schwartzer & Jerusalem), Multiple Stimulus Types Ambiguity Tolerance Scale (McLain, 1993), and the Life Orientation Test (Scheier & Carver, 1985), as well as a number of variables reflecting workplace factors. The results of our study demonstrated that personality resources mediate the impact of workplace factors, such as salary, work conditions, and work achievement upon the well-being at work. Intrinsic motivation and workplace well-being were also strongly correlated. Exploratory and confirmatory factor analysis of the scales measuring personality resources (hardiness, self-efficacy, ambiguity tolerance, and optimism) formed a single factor that was labelled Personality Potential. The corresponding scores were summed up forming an integral index of Personality Potential that was shown to be a good predictor of intrinsic motivation. The results are interpreted within the framework of Personality Potential theory (Leontiev, 2011).

The coherence between organisational identity and corporate image: A case of change management in a health organisation

Davide Jabes IULM University - Milan, Italy; Cinzia Sciangula; Vincenzo Russo

This paper discusses the results of an action-research in a local health organisation in Milan. The analysis of demand led to the formulation of intervention: improve the corporate image in a time of strong structural and organisational changes. The hypotheses of the project were: a. There were shortcomings in the flow of information. b. This led to a deterioration of organisational climate and corporate image. c. Educational activities focused on internal communication could improve the attractiveness of the organisation (Thomaz, 2010; Rao, 2009; Forman, Argenti, 2005). The extant literature is full of reports detailing that care providers, such as doctors and nurses, spend a significant proportion of their time obtaining or providing information (Henrich et al., 2008; Soto et al., 2006), and detailing the deleterious effects of poor interprofessional communication (Bokhour, 2006, Burd et al., 2002; Dechairo-Marino et al., 2001; Simpson et al., 2006). The hypotheses a. and b. were confirmed by qualitative and quantitative research: 22 semi-structured interviews were conducted on employees; a questionnaire composed of two scales, the Communication Evaluation Survey (Winegarden, 2009) and 3 factors (autonomy, job involvement, dynamism) of MDQ13 (Mayer, D’Amato, 2005) distributed over a significant sample (177 subjects) of the workforce; a customer satisfaction questionnaire was distributed to 150 patients. The results helped to implement a training process and a system of internal evaluation, which involved 10 manager and 100 employees from HR and wards. This article briefly discusses the articulation of the training project and its impact on the corporate image.

Leadership for performance excellence: Looking within and around the CEO

Ajay K Jain Management Development Institute, Denmark

The basic proposition in psychological literature which has emerged is that behaviour is a function of personality and the environment (Lewin, 1936). Later, Korman (1971) proposed that leadership behaviour, in particular, should be viewed as a function of the person and the environment. As an organisational theorist, I assume that the business environment is highly complex, dynamic and globally connected. Thus, leadership effectiveness can be postulated to be an interactive function of the leader’s behavioural, organisational and environmental characteristics. The purpose of this exploratory research is to develop an integrated leadership model from the behavioural competencies of seven CEOs by adopting psychological, sociological and strategic perspectives on leadership studies. The data for this study was collected at two stages. First, I did qualitative research from the data of 118 executives to develop a 35 item leadership behaviour questionnaire. Then the quantitative data was collected from 525 senior and top executives of seven CEOs from large size organisations. The data was collected in face to face conditions. Each respondent has filled out a questionnaire about his/her CEO’s behaviour based on his/her personal interaction with him. The results of exploratory factor analysis have yielded four factors, namely, evolved self (looking within), people and culture development (looking around), strategic focus (looking beyond) and performance excellence (sustainable development) in the changed business environment context. These factors need to be aligned with each other to achieve performance excellence. The alignment (fit) is a continuously evolving process which
is largely dependent on the immediate environmental and contextual factors. Leaders need to look within, around and beyond to achieve the condition for a better fit.

Unlocking quantum value: Consciousness as a practice at the workplace

Raymond Jambaya Help University Graduate School, Malaysia

The effective utilisation of affective and cognitive dimensions of emotional intelligence within the psychosocial work space has become crucial for creating competitive advantage, in an era dominated by knowledge workers. The purpose of this study is to explore the perceptions, application and impact of workplace consciousness behaviours within a multi-cultural Malaysian Call Centre firm. The paper seeks to establish the business case of workplace consciousness against three competitive dimensions, namely peak performance, functional creativity and staff well being. Multivariate analysis will be conducted on 150 purposively sampled subjects. The relationship between workplace consciousness behaviours and performance indices and its implications for human resource development within current knowledge economies in the sector will be discussed in accordance with the results.

The effect of safety prioritisation and descriptive norms on safety compliance: An experimental study

Li Jiang Soochow University, China

Violations are the main triggers of workplace accidents. It is therefore important to improve safety behavior in the workplace. The present research investigated the effect of safety prioritisation and descriptive norms on safety compliance. A simulated safety task was realized by computers in the laboratory. With a 2×2 between-group design, 93 undergraduate students participated in this experiment. Results showed that the main effect of safety priority and descriptive norms were significant on safety compliance. The interaction effect was also significant, specifically, in the safety condition the relationship between descriptive norms and safety compliance was more positive than in the productivity condition. Implications for safety research are discussed.

Why job seekers are attracted by corporate social responsibility: Experimental and field evidence

David Jones University of Vermont, United States of America; Chelsea Williness

Using experimental and field designs, we tested three signal-based mechanisms that explain why job seekers are attracted to organizations known for their corporate social performance (CSP): Anticipated pride from the organisation’s perspective, perceived value fit, and expected treatment. In a longitudinal experiment (N=180). At Time 1 we measured individual differences including communal orientation and pro-environmental values. At Time 2 we manipulated the presence and type of CSP via company web pages and assessed participants’ attraction to this potential employer through the signal-based mechanisms. Tests of mediation through regression and Sobel tests showed support for participants’ attraction due to an organisation’s CSP through all three mechanisms. In a field study (N=171), we collected survey data from job seekers who attended job fairs and completed measures in reference to a recruiting organisation they identified as an attractive employment option. We also coded the hiring organisations’ recruitment materials (posters, handouts) for the extent they contained CSP content. Tests of multiple mediator models using bootstrap regression-based analyses provided support for job seekers’ attraction due to CSP through all three mechanisms. Thus, across two studies using three different operationalisations of CSP (manipulated CSP information, job seekers’ perceptions of CSP, and the degree of CSP content in hiring organisations’ recruitment materials), results provided consistent support for the three signal-based mechanisms. Our findings highlight theoretically interesting differences between the effects of an organisation’s community involvement versus its pro-environmental practices.

Performance management practices in public universities in Uganda: An instrument development

James Kagoori Kyambogo University, Uganda

The purpose of this paper is to develop and validate an instrument for measuring and assessing perceived performance management practices in public universities in Uganda. These performance management practices are based on metaphors derived from the agency, upper echelon, resource-based view, dynamic capability and goal setting theories. Data were collected from a sample of 474 respondents in four public universities in Uganda. Questionnaire item development was based on an intensive literature review, reliability assessment, exploratory factor analysis and confirmatory factor analysis. Results show that items related to individual members’ perceived performance management practices that are based on having appropriate employer-employee relationships (agency relations), identifying and utilising available resources and involving employees in goal setting to achieve performance in an ever-changing environment. The data used are from a single sample from a studied population though a systematic procedure of instrument development (i.e. descriptive statistics, reliability and inter-correlation analysis, exploratory and confirmatory factor analysis) that was conducted could limit generalisability of the results over the entire population. The procedure could be replicated using different samples in the same population for future instrument development in different organisations. Scores at the individual level could be used to promote performance management practices in public universities in Uganda.

The last straw: The additive effects of interpersonal stressors on service sabotage

Feng Hsia Kao National Taiwan University, Taiwan, R.O.C.; Bor-Shiuan Cheng; Tsu-Ting Lin; Min-Ping Huang

The professional service industry has become a growing and important economic sector. However, what we know about the key successful factors of such professional partnership teams is relatively limited. In this study we investigated the effect of partners’ relationship on partnership performance. We also examined the mediating effect of trust as well as the moderating effect of organizational control on such a relationship. We conducted questionnaire surveys to collect empirical data from professional law firms and accounting firms. In total, there were 51 firms (partnership teams) and 132 partners’ data were collected. Results show that, (1) the affective relationship among partners has positive effects on partnership performance, but the instrumental relationship has negative effects on partner performance; (2) trust plays a mediating variable between partners’ relationship and partner performance; (3) organizational control mechanisms have a moderating effect on partners’ relationship and trust. The theoretical and practical implications of the findings and future directions are discussed.

The relationship between mental health and job satisfaction in education personnel

Abolghasem Khoshkonesh University of Shahid Beheshti, Islamic Republic of Iran

The purpose of the present research was to investigate the relationship between mental health and job satisfaction in teachers. The statistical community of this research was the teachers of the Tarom district of Gazvin province. The sample includes 100 teachers that have been chosen via a cluster multistage sampling method. Assessment instruments were the General Health Questionnaire (GHQ) and the job satisfaction questionnaire. Data was analysed by using Pearson correlation coefficient and Stepwise multiple regression methods. Findings show that there is a positive correlation between physical health and general health with job satisfaction and there is a negative correlation between depression, anxiety and social function with job satisfaction. Stepwise regression analysis showed that depression, anxiety, social function and physical health, in four steps, could explain 70.6% of variance in job satisfaction.
Does entrepreneurship make sense for African youths? Young people’s beliefs and perceptions about entrepreneurship in Uganda

Julius Kikomo Makerere University, Uganda

The dominant view in the literature is that young people in Africa have a negative attitude towards self-employment, especially in the informal sector. It is generally argued that young Africans prefer formal employment to self-employment because of the ‘white collar’ mentality that they acquire from school. This paper argues that attitudes of young people towards self-employment vary from country to country, mainly depending on economic, social, political and historical factors and that there is a larger latent demand for a kind of entrepreneurial behaviour or self-employment among young people in Africa than is generally reported in many studies. The study sought to assess the entrepreneurial potential as well as attitudes towards entrepreneurship among students at two universities in Uganda. Findings from this study indicate that there is a strong desirability for informal sector employment among the study respondents. Results revealed that the majority of young people in the sample wanted to start their own business in the informal sector. Moreover, a relatively large proportion of respondents wanted an informal job. Of the respondents who wanted a job, more wanted a job in the informal sector than in the formal sector. Getting a job in a state institution/company was least in their plan. Students expect the organisation of additional training and introductory subjects that prepare them for setting up their own companies. For others, knowledge of preparing a business plan and performing market analysis would be of greatest use, while others expect their higher education institutions to organise additional training and meetings with employers. However, there are some significant variations in these results according to age and gender.

Self-attributions of causality to successful and unsuccessful events in the workplace, job satisfaction and general well-being.

Yashar Klipp University of Witwatersrand, South Africa; Gillian Finchilcecu University of Witwatersrand, South Africa

This paper delves into the phenomenon of attributional tendencies in the workplace, indicating how both job satisfaction and general well-being are related to certain attributional tendencies - biases in attributions of causality. As people employ these biases in attributing causes to a wide variety of significant events in their lives, it was the aim of this study to better understand how certain types of biases relate to people’s perceptions of satisfaction with their job and their life and health. A purposive sample of 74 white collar South African employees was given a modified version of the Occupational Attributional Style Questionnaire and the Overall Job Satisfaction Scale and the General Health Questionnaire to complete. Correlation and regression analyses were conducted. The results indicated significant and positive relationships between job satisfaction and the attributional dimensions of globality and controllability. Stability, globality and controllability dimensions all exhibited significantly positive relationships with general wellbeing. It has recently been found that attributional tendencies may be subject to manipulation (Proudfoot, Corr, Guest & Dunn, 2009), meaning any information on their causes or effects has implications for training and development programmes in organisations. As this study focused on relationships of job satisfaction as well as general wellbeing with attributional tendencies, the implications of the study extend beyond the domain of the workplace and into the private lives of the individual.

The relationship between attitude to retirement readiness and retirement phobia among civil servants

Susan Kolawole University of Jos, Nigeria

This research was designed to examine the relationship between civil servants’ attitude to retirement readiness and their subjective experience of retirement phobia. The sources of retirement phobia and the relation of these to their gender were equally examined. A sample of 60 civil servants: 30 males and 30 females in Jos metropolis, was used, using stratified random sampling procedures to select the subjects. The civil servants were aged between 50 and 60 years. The result confirmed the researcher’s prediction that retirement readiness will be related to retirement phobia; over all, the civil servants exhibited wholesome attitudes towards retirement planning, and these reflected in their high levels of self-reported retirement phobia. The major findings of the study were as follows: main sources of retirement phobia to civil servants were financial, lack of planning early enough for retirement, insecurity, and lack of retirement seminars. The majority of the Plateau State civil servants indicated a willingness to attend workshop/seminar in the future.

Validation of Saville Consulting Wave and Swift Analysis Aptitude in Mauritius

Rainer Kurt Saville Consulting, United Kingdom; Hennie Kriek; Nailah Moussa; Fred Guest

This study investigates the validity of the Professional Styles version of the Saville Consulting Wave personality questionnaire range and Swift Analysis Aptitude (SAA) in 14 leading companies in Mauritius. In a concurrent validation study, a mixed occupational group of 221 Managers and Professionals completed the Professional Styles questionnaire, Swift Analysis Aptitude and the Performance 360 Self-assessment. Their performance was also evaluated by at least one self-nominated external rater. Point-to-point validation of a priori hypothesised relationships of trait predictor scales with external work ratings at section level reached statistical significance for 11 of the 12 sections with an average uncorrected validity of .16. Giving Support correlated highest at .28 (uncorrected) and was also the highest (but not significant) correlate for Showing Resilience where the aligned correlation was only .03. Ability test results were only available for a small subsample (N=58) where SAA Total score correlated .38 with Global overall performance, and also significantly with Performance 360 external ratings on Evaluating Problems (.42), Creating Innovation (.32), Structuring Tasks (.32), Working with Information (.42), Driving Success (.30), Working with Things (.27), Showing Resilience (.27), Communicating Information (.25), Investigating Issues (.25) and Providing Leadership (.23). The results demonstrate empirically that the Saville Consulting personality and ability instruments predict aligned work performance criteria in a cross-cultural setting given the multi-racial nature of the workforce in Mauritius. Where Resilience is central to a role caution is warranted – possibly as expressions of this construct may vary across cultural groups.

Effects of happiness and psychological meaningfulness on support and engagement in the workplace among women

Karolina Laba University of Johannesburg, South Africa; Madelyn Geldenhuys

Stevenson and Wolfers (2009) state that the expansion in women’s opportunities has been extensively studied. However, the concurrent decline in well-being has largely gone unnoted. With more than half the world’s population being unhappy, happiness topics have received much attention within the field of psychology. The aim of the present study was to investigate the effects of happiness on the relationship between Social/Organizational Support and Work Engagement amongst women due to a lack of research regarding concepts related to well-being: Happiness, life satisfaction, engagement, etc. on women within the South African working environment. Further scientific knowledge of these important topics is needed from a South African context. This study utilised a quantitative research design. Data was gathered with the use of paper and pencil questionnaires (cross-sectional survey). A sample of n=207 women in the South African work context was gathered. The results showed significant relationships between Happiness, Work Engagement and Support (Social and Organisational). Additionally, Happiness moderated Social and Organisational Support on Work Engagement respectively. Further analysis demonstrated significant differences on Work Engagement for different age groups and race groups. An engaged person provided with social and organisational support can impact on their own as well as the company’s performance. This study highlights crucial factors that contribute to the well-being of South African women within the work context.

Stress and its subjective and objective measurements in the context of temporary agency work

Sandra Lemanski University of Greifswald, Germany; Axel Kramer; Hicham Benkhai; Manfred Bohnewasser; Harald Below

Temporary employment is connotated with a predominantly negative reputation since it demands the frequent change of the workplace, tasks or the social work environment. This leads to uncertainty and a loss of control and can result in the development of stress. In the context of the project Flex4work, two main research questions are the focus of interest. Firstly, if and what kind of differences between temporary agency and permanent workers regarding their perception of stress can be observed, is being examined. Secondly, how subjective experience of stress affects the objective stress parameters cortisol and antioxidant potential is being analyzed. The latter was determined by a new method based on urine samples. To answer the two questions, permanent and temporary agency workers were surveyed via handheld devices over a longer period of time. In addition to that, urine and saliva samples were in-
cluded. Longitudinal data were analysed with the help of multilevel analysis. The findings indicate that there are no significant differences in stress levels between the two groups of employees. However, there are interesting differences in the causes of stress and in the markedness of the dimensions. Regarding the objective stress parameters it was found that in cases of high pressure the level of cortisol increased.

The antioxidant potential and food are correlated, there are a lot of different opportunities for intervention.

Procedural justice, workplace envy, and interpersonal counterproductive work behaviour: A moderated mediation analysis
Yuhui Li Renmin University of China, China
Hongchang Li HRSO, Zhejiang University, China; Zhongming Wang

This study aims to reveal the relationships between perceived justice, envy and interpersonal counterproductive work behaviour (ICWB), and the role of gender with social comparison theory. Using K. J. Preacher, D. D. Rucker, and A. F. Hayes’ (2007) moderated mediation framework, the author tested the model with the data from Chinese 1294 employees (48% male, average age = 28.02 ± 6.73). Results showed that (a) a significant positive relationship between workplace envy and interpersonal counterproductive work behaviours \((r = -.34, p < .001)\) and a significant negative relationship between perceived justice and interpersonal counterproductive work behaviours \((r = .10, p < .001)\), (b) workplace envy mediated the influence of perceived justice to interpersonal counterproductive work behaviours \((p < .01)\), (c) male workers always show higher level of interpersonal counterproductive work behaviours than women at the same level of envy \((p < .01)\), (d) the regression coefficients of perceived justice to envy to ICWB are stronger in male workers. This means that the mediating model of perceived justice, envy and ICWB is moderated by gender. Results underscore the importance of accounting for employees’ gender role when examining the relationships between envy, perceived justice, and counterproductive work behaviors, and give us some suggestions for how to manage men and women workers with different ways.

Effects of power on change decisions following negative consequences
Hongchang Li HRSO, Zhejiang University, China; Zhongming Wang

Most organisational change decisions are decisions following negative consequences, and are typically made by people with high power. However, few researches investigated whether power would result in changing decisions or escalation of commitment to previous decisions. The present research utilised a laboratory experiment to investigate the effects of power and personal responsibility on risk decision making following negative consequences. Based on approach/inhibition theory of power, the authors predicted that power would moderate the relationship between personal responsibility and escalation of commitment, so that people with low or high power would be more prone to increase commitment to previous choices compared with people with moderate power. One hundred and thirteen undergraduate students participated in the experiment. Power was primed with the mindset priming method, and personal responsibility was manipulated by varying whether the subjects, as the CFO of a fictitious company, made the initial decision or not. Then they were asked to make the second fund allocation decision following the negative consequences resulting from the initial one. UANOVA showed a “U” shape relationship between power and escalation of commitment, so that subjects primed with low or high power investigated more money in their previous choices than those in the control group, and the effect of responsibility was not significant. This research demonstrated the metamorphic effects of power in risk decision making following negative consequences, and suggested the importance of power in similar organisational change settings.

The effect of work stress and organizational support on safety behaviours
Yongjuan Li Institute of Psychology, CAS, China; Xueyuan Liu; Li Jiang

The purpose of the current study was to explore the combined effect of work stress and organisational support on employees’ safety behaviours. Specifically, we investigated the influence of a job demand stressor and compensation – a related stressor on employees’ safety compliance and safety participation, respectively; and the possible moderating effect of organisational support on the relationship of the above. A total of 216 civil aviation air traffic controllers answered the questionnaires. Results showed that the job demand had no direct effect on employees’ safety behaviours. The relationship between a compensation – related stressor and employees’ safety behaviours were significantly positive. The higher the employees’ perceived the organisational support, the higher the probability that they would behave safely, and the effect of perceived organisational support on safety participation was stronger than that on safety compliance. Perceived organisational support moderated the relationship between a compensation – related stressor and safety compliance, while it had no significant effect on the relationship between job demand stressors and safety behaviour. Implications for safety behaviour research and safety management are discussed.

Person-job fit and burnout: The moderating effect of achievement orientation
Chaoping Li Renmin University of China, China

We examined the moderating effect of achievement orientation on the relationship of person-job and job burnout in China. Using moderated multiple regressions with data collected from 379 employee, we found that the relationship between person-job and burnout was significantly moderated by employee’s achievement orientation, suggesting that high achievement orientation will enhance the person-job fit’s negative effect on job burnout. Implications for burnout research and management practices are discussed.

Investigating the relationship between leader-member exchange (LMX) and psychological ownership: The mediating role of organisational justice
Liang-Hsuan Lin Yuan Ze University, Taiwan, R.O.C.

Since employees’ psychological ownership is an important factor to an organization, and even though scholarly interest in employees’ psychological ownership has increased, there is not much research about the psychological ownership of stuff in retail stores. To extend previous research on organisational justice and psychological ownership, this study aims to examine the relationship between leader-member exchange and psychological ownership for a store, while simultaneously examining the mediating roles of distributive, procedural and interactional justice, in order to contribute to organisational justice literature. Data was collected from 60 store managers and 300 subordinates based at food chain store in China. A structural equation modeling analysis was conducted to test the following hypotheses: the subordinate’s perception positively relates to psychological ownership; and organization justice mediates the relationship between LMX and psychological ownership.

Political skill and locus of control as moderators of the relationships between work stressors and burnout
Weipeng Lin UC Berkeley, United States of America; Wenqi Wei; Jingjing Ma; Kun Yu; Lei Wang UC Berkeley, United States of America; Jing Jiang; Lingsi Qiao

Integrating the two-dimensional model of work stressors with burnout research, the present study examined the relationships between challenge stressors, hindrance stressors and the three dimensions of job burnout (i.e. exhaustion, cynicism and inefﬁcacy), and the moderating effects of individual differences (i.e. political skill and locus of control) on the stressors-burnout relationships. A total of 299 Chinese civil servants participated in the questionnaire survey in two phases. The results showed that challenge stressors were only positively related to exhaustion, while hindrance stressors were positively related to all three dimensions of burnout. Furthermore, participants’ political skill moderated the relationships between hindrance stressors and all three dimensions of burnout, such that the relationships are weaker for individuals with high political skill. Locus of control moderated the relationships between challenge stressors and exhaustion, such that the relationships are weaker for individuals with external locus of control. These results suggest that the boundary conditions of the relationships between different type of stressors and different dimensions of burnout are divergent. Various types of individual differences (i.e. skill and personality) can act as resources to buffer stressors-burnout relationships in separate way.

Ego depletion in emotional labour: The role of sense of humor
Lin Ling Central China Normal University, China; Hongyu Ma

This research studied the effect of individual’s personality trait (sense of humour) and emotional labour on ego depletion, in the case of individuals with negative emotion before engaging in emotional labour. Research One used the Emotional Labour Scale, the Coping Humour Scale, and the Emotional Exhaustion Scale to investigate the relationship of emotional labour, sense of humour, and ego depletion in 370 salesmen and waiters. The results revealed that ego depletion was significantly positively correlated with surface acting, while it was significantly nega-
tively correlated with deep acting. Compared with surface acting, deep acting resulted in less ego depletion. Sense of humour had a significantly negative correlation with ego depletion. Compared with low sense of humour, high sense of humour resulted in less ego depletion. Sense of humour had a moderate effect between surface acting and ego depletion. Research Two verified the results in Research One and further studied the interaction of emotional labour (surface vs. deep acting) and sense of humour (high vs. low) on ego depletion. This research adopted an emotional regulation paradigm, using instructions to arouse emotional labour and using movie fragments to arouse negative emotion (sad). The results revealed that the interaction effect between emotional labour and sense of humour was significant. Under the condition of surface acting, the person with low sense of humour resulted in the highest ego depletion. Results in Research Two validated the results in Research One. This study suggested that, relative to surface acting, deep acting was a more effective emotional regulation strategy, so for staff who often faced strong emotional response at work, deep acting skill training was very useful.

The big five personality traits: Its relations with employee creative behavior and outcomes in maintenance and transitional job stages

Peng Lingjiao Peking University, China; Lingjiao Peng; Xiang Yao

Two studies were conducted to investigate the relationship between Five-Factor Model (FFM) personality and workplace creative activity (creative behavior and/or patent disclosure) in high-tech organizations during both the maintenance job stage (N=304) and the transitional job stage (probation period) (N=202) with multi-source and longitudinal data. The results showed that Openness and Conscientiousness predicted creative behavior in both maintenance and transitional stage; Openness predicted patent disclosure even after creative ability was controlled at maintenance stage; Extraversion predicted creative behavior during the maintenance stage, while Agreeableness predicted creative behavior during the transitional stage. These findings emphasized the importance of taking a dynamic model of creativity activity at different job stages.

How followers’ unethical behaviour is triggered by leader-member exchange: The mediating role of job satisfaction

Songbo Liu Renmin University of China, China; Wei Hu; Xiaoshuang Lin

Generally, scholars have found that individual characteristics should not be the only explanation for unethical behavior. Alternatively, organizational factors should be taken into account for further studies. In an organization, leaders are supposed to have tremendous control over employees’ behavior. Theoretically, the way of handling the relationship between leader and his/her subordinates is different. It is unavoidably involved in employees’ unethical behavior, according to certain research. In previous studies, LMX has been proved to be related to many positive outcomes, such as OCB and job performance. However, attention has seldom been paid to the relevance between LMX and organizational negative behavior (or unethical behavior). By investigating a big sample of Chinese managers empirically, we successfully confirmed the mediating effect of job satisfaction on the relationship between LMX and unethical behavior. Though numerous researches have shown the positive influence of job satisfaction on job performance, attention has seldom been paid to the relationship between job satisfaction and negative behaviour in an organization. So, by expounding the mechanism of LMX and unethical behavior, we complement the satisfaction theory by adding its influence to negative behavior. In terms of practical aspects, managers can reduce unethical behaviors by increasing social exchanges with their subordinates and employees’ job satisfaction.

A cross-organization comparison study of the moderated role of social dominance orientation

Chang Liu Peking University, China; Lei Wang Peking University, China

People generally believe that abusive supervision would result in employees’ perception of organizational injustice. However, this relationship is not always true. The social dominance orientation held by employees will have an impact on this relationship. The present study examined how individual social dominance orientation (a general attitudinal orientation towards intergroup relations, reflecting whether one generally prefers such relations to be equal, versus hierarchical) moderates the relationship between abusive supervision and employees’ feeling of organizational justice. Using 257 employees respectively in a Chinese state owned company and a wholly owned Italian company located in China with different managerial culture backgrounds, we found that in both companies individual social dominance orientation moderated the strength of the relationship between abusive supervision and organizational justice such that the relationship was weaker for employees who were higher in social dominance orientation. We further found that both abusive supervision and employees’ perception of organizational injustice were lower in the native state-owned company than in the foreign company. The implications for theory and practice are discussed.

How ethical leadership influences unethical behavior

Songbo Liu Renmin University of China, China; Gonghai Chen; Xiaoshuang Lin

Recently, with the exposure of many business scandals, people have realised that the behaviour of leaders influences organisational ethical climate both directly and indirectly. The relationship between ethical leadership and unethical behaviour is a hot topic, but seldom has attention been paid to the mechanism in this relationship. We investigated the random sample of 249 Chinese managers in four companies and examined the mediating effect of perception on ethical climate. The result of regression analysis shows that ethical leadership was negatively associated to employees’ unethical behaviour. In addition, the dimension of instrumentalism and dimension of law/code of ethical climate mediated the relationship between ethical leadership and unethical behaviour. The paper has the following two contributions: 1. Empirical results indicates that to cultivate an organisational ethical culture, praise or punishment is not the only tool; ethical leadership should be paid attention to. 2. We confirmed the mediating effect of ethical climate, the mechanism of ethical leadership influencing unethical behaviour. The paper gives rise to an understanding of the significance of cultivating ethical climate and leads supervisors to engage in proper behaviours.

On the nature of employability in China: Insights into the construct and a new measure

Xiaoping Liu Sun Yet-Sen University, China; Jingsong Deng

The study was carried out with three mini-studies. In study one, the connotation and dimension of employability in the Chinese context were explored based on literature review, interviews, and open-ended questionnaires. In study two, based on the results of study one, the employability scale was compiled, and the reliability and construct validity of the employability scale were tested. In study three, the differences of employability between graduates who have received offers and those who haven’t got were explored, and the relationships between employability and employment outcomes were also analysed. The results of study one indicated the employability in the Chinese context consists of nine dimensions, which were described as basic skills, transforming theory into practice skills, interpersonal and teamwork skills, self-development skills, honesty and reliability, diligence and self-motivation, adaptability and openness, self-efficacy and initiative, engagement and professional dedication. The results of study two showed that the reliability and construct validity of the employability scale were acceptable. In study three, 1282 graduates were surveyed, and the results showed that there were significant differences in all nine dimensions of employability between those who had received offers and those who had not. There were significant positive correlations between dimensions of employability and four employment outcomes, such as payment, person-job fit, person-organisation fit and job satisfaction, which indicated this employability scale had good predictive validity.
Cognitive evaluation of entrepreneurial opportunities

Martin Lukes Prague University of Economics, Czech Republic; Petz Ocko; Tomas Laboutka; Miroslav Krizek

The study reflects a growing interest in the phenomenon of entrepreneurial opportunities. Its aim is to investigate how entrepreneurs cognitively evaluate opportunities. The study is based on in-depth interviews with 30 highly-experienced entrepreneurs in the Czech Republic. As a part of the interview, entrepreneurs were introduced to a realistic scenario of a new start-up opportunity in the automotive industry, which they subsequently evaluated, while thinking aloud and thus describing their evaluation processes. What they think about the opportunity, whether they like it or not and why. They also described the steps they would take in making decisions to exploit the opportunity. Our main findings are as follows: (1) Opportunity evaluation processes are influenced by a large variety of factors - available social and financial capital, psychological and cognitive factors, and contextual factors. (2) The background of the entrepreneur is crucial for the evaluation process. Especially significant is the role of entrepreneur’s social capital and professional experience. (3) Evaluation consists of two parallel cognitive processes: (a) heuristic and intuitive, triggering emotions and effectuation, and (b) analytical and rational, focused on considering feasibility. (4) Cognitive complexity can have both positive and negative effects on opportunity evaluation. The richness of cognitive scripts enables entrepreneur to grasp an opportunity from different angles. On the other hand, cognitive biases can also prevent relevant judgmental decisions.

Industrial/Organisational/Work

The effect of quantity and quality of applicants on selectors’ behaviors

Tzyy Jiun Lung Hsuan Chuang University, Taiwan, R.O.C.

Research interest in the topic of employee recruitment has increased substantially over the last 40 years. However, most of the research has focused on the recruitment source, recruiters and realistic job previews, while no one has been interested in the relationship between recruitment and selection. Our study aims to understand the effect of the quantity and quality of applicants in recruitment objectives on selectors’ behaviors. Subjects were randomly assigned to one of four cells of a 2 X 2 factorial design. The two qualitative factors were the quality of applicants (divergence or contingency) and quantity of applicants (40 or 80 applicants). The results showed that the quantity of applicants affected the number of applicants accepted and decision time, but that the quality of applicants affected nothing. The preferences of our subjects were not all the same, but were not totally different either. The number of reasons had no relationship to the number of applicants accepted, but had a low relationship to decision time. The subjects’ behaviors were not really rational or irrational.

Research on the work-family interface of sports coaches in China

Xiaobing Luo The P.E Institute, China

The work-family interface includes conflict and facilitation. Since research on the work-family interface was put forward, scholars were constantly taking up the connotation, antecedents, outcomes, mechanism and coping strategies of work-family conflict, but the rise of research on work-family facilitation brings a new research domain for the work-family interface. Based on a literature review of the work-family interface, integrating the characteristics of the work-family interface of sports coaches, this research constructed integrated models of the work-family interface (including work-family conflict and work-family facilitation) through selecting several key variables and testing the models. Especially explored were the moderating effects of several moderators, which include family-friendly policies, individual coping styles and social support about the models. Several coaches, a family and an administrative official were interviewed in succession. Strategies for the work-family interface for coaches from four levels by the results of confirmation and interviews were put forward. 257 cases were analysed by Lisrel8.70 and Spss16.0. The major findings in this study were as follows: (1) Antecedents and outcomes of work-family conflict: job stressors and job involvement can forecast positively W→F conflict; family stressors and family involvement can forecast positively W→F conflict; W→F conflict can forecast negatively job satisfaction, can forecast positively emotional exhaustion, depersonalization; W→F conflict can forecast negatively job satisfaction, family satisfaction, depersonalization, and can forecast positively personal accomplishment. (2) Antecedents and outcomes of work-family facilitation: job involvement can forecast positively W→F facilitation; family involvement can forecast positively F→W facilitation; W→F facilitation can forecast positively family satisfaction; F→W facilitation can forecast positively job satisfaction and family satisfaction. (3) Moderator model of work-family conflict: family-friendly policies can moderate the relationship between job stressors and W→F conflict, can moderate the relationship between job involvement and W→F facilitation, can moderate the relationship between family stressors and W→F conflict, can moderate the relationship between family involvement and W→F facilitation; the 3 individual coping styles, which include direct action, advice seeking and cognitive reappraisal, can moderate the relationship between family involvement and W→F conflict; supervisor and colleagues, and social support. (4) Moderator model of work-family facilitation: advice seeking and cognitive reappraisal can moderate the relationship between family involvement and F→W facilitation. (5) The applied strategies to work-family relationships for Coaches include several perspectives: from the individual, family, organisational and social perspectives, coaches can weaken their work-family conflict and its negative outcome and enhance their work-family facilitation. The strategies for the work-family interface for sports coaches include individual action strategies and cognitive strategies such as direct action, advice-seeking and cognitive reappraisal, family support from parents, spouse and offspring, organizational support from supervisor and colleagues, and social support.

Is conscientiousness always good for employees? A moderated mediation model

Jingjing Ma Peking University, China; Lei Wang Peking University, China

Considerable previous research has demonstrated the positive impact of employees’ conscientiousness in organizations. However, in this study we surveyed 221 Chinese civil servants using longitudinal design and found that conscientiousness may exert a bad influence on employees. The results showed that employees’ conscientiousness had significant strengthened moderation effects on the full mediation relationship between challenge stressor and job burnout through perceived stress. Specifically, when dealing with more challenge stressors, compared with their colleagues who had lower conscientiousness, those high in conscientiousness perceived more severe stress, resulting in more burnout experience. Meanwhile, conscientiousness did not significantly influence the partial mediation relationship between hindrance stressor, perceived stress and burnout. Implications and future research concerning the potential dark side of conscientiousness in organizations and the differentiation between challenge stressors and hindrance stressors are discussed.

The influence of appreciation on emotion regulation and well-being of older service workers

Sabine Machowski Goethe-University Frankfurt, Germany

The demographic change forces organisations to focus more on older employees. One potential of older workers are their socio-emotional skills and positive attitudes which are very important in the service sector. First studies have shown that age is positively correlated with authentic and negatively correlated with non-Authentic emotion regulation strategies. Appreciation is an important resource and positively correlated with attitudes and well-being. We suppose that appreciation of customers and supervisor has a positive influence on the use of emotion regulation strategies, as well as on well-being. Furthermore, we hypothesise that this relationship will be moderated by age. We conducted a diary study with 203 service workers of financial institutions who completed a questionnaire each day up to five diaries, resulting in 936 recorded emotionally important interactions with customers. Results of multilevel analyses confirmed our hypotheses regarding appreciation and emotion regulation. If service workers perceived that their work was appreciated by customers, or their supervisor, then, as expected, older workers used less non-authentic strategies than younger employees. Finally, appreciation by customers moderated the relationship between age and situative exhaustion in the way that if workers experienced high appreciation of customers older workers were less exhausted after the situation than the younger employees. One practical implication is that appreciation is an important resource for older workers to show their potential and should be more encouraged. Organisations can do something to support older workers by means of human resource management.

Non-remuneration predictors of intention to quit among personal financial advisors

Johan Malan Stellenbosch University, South Africa; Ronel Van Tonder

Insurance sales organisations all over the world invest a great deal of time and money in the recruiting, training and retaining of their sales people. Currently turnover among sales people are very high within the first 36 months of employment.
which costs organisations large sums of money. Focusing on the intention to quit of currently employed sales people at a large insurance organisation in South Africa, the non-remuneration predictors of burnout and intention to quit were explored to shed some light on the turnover problem. These constructs are emotional labour, self-efficacy, time wasted on non-sales activities and supervisor support. The research approach included both quantitative and qualitative techniques. A convenience sample of 122 financial advisors with less than 36 months of service was utilised. The results indicate that significant relationships exist between time wasted on non-sales activities, burnout, and self-efficacy; self-efficacy, burnout and intention to quit, and burnout and intention to quit. The study contributes to the better understanding and managing of high turnover amongst sales people, especially those working in the insurance sales environment. The findings can be used as a tool to guide HR practitioners in the development of more effective retention strategies.

The social anxiety spectrum and work limitations among managerial level employees

Johan Malan
Stellenbosch University, South Africa;
Lindy Emsley
University of Bergen, Norway

Social anxiety symptoms are common, but unrecognised within the workplace. The aim of the study was to explore to what extent the social anxiety spectrum of symptoms influences the performance of management employees and how the disorder should be managed in the workplace. A non-experimental research design was followed and managerial level employees from two large organisations were represented (n = 118) in the sample. The results of the present study indicated that social anxiety affects all areas of work. These symptoms were associated with several areas of work limitations and performance difficulties not restricted to social interaction or presentation. It was also found that job demands increase social anxiety symptoms, work limitations and perceived performance difficulties, while job resources decrease social anxiety and perceived performance difficulties. This study offers recommendations with respect to the management of these challenges in the workplace.

The matrix of trust and personal effectiveness

Shradha Mathur
University of Delhi, India

The study was conducted to find gender differences (working males and females) and sector based differences (private and public sector banks), if any, in the level of trustworthiness and on the dimensions (self disclosure, openness to feedback and perceptiveness) and styles of personal effectiveness (effective, insensitive, egocentric, dogmatic, secretive, task obsessed, lonely, emphatic and ineffective) and to observe the relationship between them. Personal Effectiveness scale developed by Udai Pareek and Trust Quotient scale developed by Charles Green were administered to 90 employees from private and public sector banks in the city of Jaipur, Rajasthan, India. The sample size was 90 subjects and it was divided equally between the two sectors. Forty female and 50 male employees were considered for the study. No significant differences were observed in the levels of trustworthiness and on the dimensions of self disclosure and openness to feedback for the employees of the two sectors. Significant differences were observed in the level of trustworthiness of the male and female working population (t=4.42, p<0.01) and perceptiveness (t=2.26, p<0.05). A positive significant correlation was observed between the trust quotient and openness to feedback (0.33, p<0.05) and between openness to feedback and perceptiveness (0.409, p<0.1) for the employees of public sector banks. The study suggests gender differences in the level of trust and perceptiveness where female employees outscored their male counterparts.

When the seat becomes too hot: Whistleblowing and employees’ intentions to leave their jobs

Stig Berge Matthiesen
University of Bergen, Norway

Whistleblowing can be defined as the disclosure by organization members (former or current) of illegal, immoral or illegitimate practices under the control of their employees to persons or organizations that may be able to affect action. In the present study the link between whistleblowing and a possible effect of it, namely the employees’ intention to quit their jobs, are examined. 1604 respondents, randomly selected citizens of Norway, took part in a postal survey study (52% females, mean age: 45.8 years). The research questions addressed were as follows: (1) Does the whistleblower subgroup report a higher propensity to quit their job (intention to leave), as compared with the non-whistleblower group? (2) Is it possible to trace further subgroup differences, for instance that blowing the whistle after severe organisational wrongdoing/ corporate crime, more substantively leads to plans to exit the organisation? Moreover, the respondents were presented for a list of 24 possible wrongdoing acts, of which one or more of those forced them to take whistleblowing action. In line with this, the last research question will be: (3) Which link can be traced between various combinations of the wrongdoing acts being investigated, and the whistleblowers’ subsequent intention to leave their jobs? Overall, the study demonstrated a significant connection between whistleblowing and intention to leave the job, especially if organisational wrongdoing or corporate crime was the triggering event. Regarding the 24 wrongdoing acts, the picture is mixed.

The association between leadership, organizational citizenship behaviour and organisational innovativeness

Stig Berge Matthiesen
University of Bergen, Norway; John Susseg; Jose Martinez; Eva Gonzalez; Thomas Knudsen; Antonio Fuertes; Rodrigo Carcedo

A representative survey study of Norwegian leaders was conducted (n= 2910 leaders). In this study, the leaders were asked to evaluate their own leadership style, and the kind of contact they have established with their immediate subordinates. Two aspects around the leadership style were analysed: To what extent the leaders consider themselves to behave as transformational leaders, and how they evaluate the relationship with the followers in terms of social exchange (LMX; leader member exchange theory). Both of these leadership dimensions predicted perceived OCB (organisational citizen behaviour) among the employees, as well as perceived organisational innovativeness. Transformational leadership has been suggested as the most efficient kind of leadership. However, good social exchange relationships between leaders and followers predicted OCB more strongly than the transformational leadership style. OCB predicted organisational innovativeness substantially, also when it was controlled for the two leadership dimensions. It is suggested that prosocial reflections such as OCB among the employees and leader are conducted as is portrayed in LMX and transformational leadership constitute core elements in organisations aiming to become more innovative.

Male and female managerial perspectives on sense of coherence and concepts of identity: findings from a selected industrial organisation in South Africa

Claude-Helene Mayer
Rhodes University, South Africa, Germany

The sense of coherence (SOC) is a global life-orientation that influences health and well-being. It is interlinked with identity. However, only a few studies have been conducted in South Africa which connect SOC and identity. The main aim of this study is to focus on how male and female managers in an international and culturally-diverse work environment define SOC and identity and how these concepts are interlinked. The study contributes to the increase of interdisciplinary, as well as culture- and gender-related understanding of SOC and managerial identity in a South African setting. The purpose of this paper is to present selected research findings regarding the following research questions: (1) Which SOC-life-orientation do managers in the selected context display? (2) How do managers define themselves in terms of who they are? (3) How are SOC, managerial life-orientation and identity interlinked? Data was gathered by a mixed method study using qualitative and quantitative methods, such as questionnaires, in-depth interviews as well as observations within the selected international organisation. The sample included 27 managers. Findings show that managerial SOC scores vary in managers across culture and gender. High-scoring SOC managers link their life-orientation to religion and humanistic values, whilst low-scoring SOC managers connect their life-orientation to practical implications and social relationships. Identity concepts of high-scoring SOC managers are more complex and detailed in structure and show a higher complexity than low scoring SOC managers. Conclusions will be provided.

A model of critical predictors of stress and job satisfaction and well-being in hospital staff

Eunice Mccarthy
UCD, Ireland; Ian Clifford

Aim: Adopting a Systems Model of Change and Interaction this research maps critical relationships between organisational culture, job satisfaction, stress and coping, well-being and desired future change. Method: A cross-sectional random sample of 179 staff including nurses, medical and administrators was studied. Attitude scales were specifically developed and tailored to the hospital demands with a core focus on stress, coping and well-being, hospital culture and leadership, job satisfaction and change. Results: Factor and multiple
regression analyses were traced which mapped culture and leadership as core predictors of well-being and stress and job satisfaction. In-depth qualitative analyses further reinforced these findings. Conclusions: Culture and leadership change were viewed as central to future positive engagement in hospital work within the context of a national recession.

Worker relationships and aid organisation success: A mediating link
Ishbel McWha Cornell University, United States of America
In most international aid organizations workers from outside the country (expatriates) are recruited to work alongside local counterparts in developing countries. The focus of this strategy is on the transfer of skills and knowledge from the international ‘expert’ to the local ‘novice’, with the ultimate goal being local management of their own affairs. Such a strategy, however, often fails to recognise the knowledge and skills already held by local workers and automatically sets up an unequal status differential between expatriate and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers, which is further reinforced by the higher pay usually afforded to expatriates and local workers.

Perceived leadership style and employee participation in a manufacturing company in the DRC
Jeremy Mitonga-Monga University of South Africa, South Africa; Frans Clilliers; Melinde Coetzee University of South Africa, South Africa
The objective of this study is to examine (1) the relationship between the perceived leadership style (measured by the Leader Behaviour Descriptive Questionnaire) and employee participation (measured by the Employee Participation Survey), and (2) at how individuals differ with respect to these variables in terms of demographical factors such as gender, age, educational level and functional department. A cross-sectional quantitative survey was conducted with a convenience sample of 200 employed employees in a manufacturing company in the Democratic Republic of Congo, 200% males and 40% females. Descriptive statistics (means, standard deviations and Cronbach’s alpha coefficient), correlational, multiple regressions analyses and test for significant mean differences were performed to achieve the objective of the study. The internal consistency reliability of the two instruments ranged between 0.55 (medium) and 0.75 (high). The results indicated that the participants’ perceptions of a leader’s behavioral style have a significant influence on the perceptions of employee participation. Participants’ with master’s and doctoral degrees were significantly more positive about the level of employee participation than the participants with undergraduate levels qualifications. Participants in the exploitation management department were significantly more positive about their leaders’ style than those in the other functional departments. The findings add new knowledge that may be used to inform human resource practitioners in the development and coaching of leaders and employees in manufacturing companies. Future research should be conducted in different public and private organisations in the Democratic Republic of Congo.

Ethical leadership, psychological safety and employee engagement
Karen Milner Wits University, South Africa; Dina Hendler
Given the prevailing ethical crisis and subsequent collapse of a number of modern organisations, the lapse in leader ethics as a determining factor of the proliferation of corrupt practices, has come to dominate leadership discourse. Ethical leadership has been linked, not only to avoiding organisational destruction, but also to fostering healthy, productive organisations. In line with this, the current study aimed to assess the role of employee perceptions of ethical leadership in promoting employee engagement, via the mediating mechanism of perceptions of psychological safety. Furthermore, it aimed to assess the role of psychological safety in mediating the relationships between the components of ethical leadership, namely person orientation, ethical guidance, power sharing, integrity and role clarification, and employee engagement. Having distributed an email survey to administrative employees of a technological goods producer, Kalshoven et al’s (2011) Ethical leadership at Work scale, Carmeli and Gitel’s (2009) psychological safety scale, 17-item version of Utrecht’s employee engagement scale (Schaufeli & Bakker, 2003) were completed by 139 participants. Using structural equation modeling, the findings supported the linkage between ethical leadership and employee engagement, and confirmed the role of psychological safety in mediating this relationship. While power sharing was excluded due to inconsistency of the scale, employee perceptions of leader person orientation, integrity, role clarification and ethical guidance were linked to employee engagement via the mediating variable of psychological safety.

Development and validation of a multi-dimensional construct of ethical leadership under post-merger integration
Shenjiang Mo Zhejiang University, China; Zhongming Wang
Ethical leadership is a critical driver of success under post-merger integration. However, little attention has been paid on describing behavioural dimensions of the concept in specific organisational change context. Using social exchange theory as a basic theoretical framework, we designed three interlocking studies to investigate the viability and conceptualisation of ethical leadership. Specifically, in study 1, applying a social exchange frame, 12 supervisors who have experienced merger events were invited to participate in this study to investigate specific ethical leadership behaviours in post-merger integration. Three dimensions of ethical leadership were identified, i.e. integrity, justice and care for people. In study 2 (EFA), data from 168 employees within 56 teams in merged firms confirmed the three-dimension ethical leadership construct. In study 3, we collected another set of data from 183 employees within 61 teams in merged firms. CFA results demonstrated that the three-dimension construct of ethical leadership explained variance in inter-group trust under post-merger integration. To establish construct validity we related ethical leadership to other leadership styles. The expected pattern of relationship emerged, e.g. positive relationships with servant leadership and transformational leadership. Taken together, this research project (NSFC 70732001) suggested that the three-dimension scale of ethical leadership can help us to better understand the content and consequences of ethical leadership in organisational change context, particularly in the post-merger integration process.

Ethical behaviour in a multi-cultural workplace: What constitutes a reasonable person? Alwyn Moerdyk Rhodes University, South Africa
The need for ethical behaviour in all walks of life has come to the fore in recent times, none more so than in the world of work. In South Africa and many other countries in the world, the need for ethical behaviour has become paramount in the light of many recent failures in this regard. There are three basic approaches to ethics, namely teleological or consequentialist approaches (including utilitarianism), deontological approaches (morality lies in doing one’s duty, however this is defined), and the virtuous person approach (what would a virtuous person do in a particular moral situation?). Much of the literature in philosophical discourse around morality and ethical behaviour is predicated on the assumption of rationality and what a reasonable person would do under the circumstances. However, what is generally left out of this equation is the fact that the principles used to construct rationality and reasonableness are often culturally bound and also reflect developmental processes such as those identified by Kohlberg inter alia. These differences in outlook affect the development of a common ethical vision in multi-cultural, pluralistic situations. This paper looks at these issues and suggests processes of contractualism and the development of universally agreed-upon moral principles as a means of building an ethical organisation.

The perceived impact of outsourcing on the work attitudes and behaviours of contingent workers Tshegofatso Mongeke University of the Witwatersrand, South Africa; Michael Greyling
There has been a significant development of new forms of employment, which have resulted in the apparent fragmentation of the integrated organisation and the outsourcing of non-core activities and
workforce in South African organisations. This process has been highly criticised by trade unions which contend that “this phenomenon allows employers to operate outside the legal constraints that have been developed to protect working conditions and to guarantee certain minimum levels of protection for employees” (Bamu and Godfrey, 2009, p. 53). This study explored the attitudes and perceptions of workers who have experienced a shift from permanent to temporary employment as a result of outsourcing to allow for a greater understanding on how these perceptions can potentially affect work behaviours and attitudes. Four in-depth interviews were conducted with employees employed in the Johannesburg area, who had all experienced outsourcing. Thematic content analysis was used to analyse the results. The most salient themes elicited pertained to the experiences and perceptions of the change in employment, negative perceptions towards the employees’ current employers as well as inadequacies regarding working conditions and the job itself. From the results it was evident that the way employees experience and perceive the change from permanent to contingent work can change their work attitudes and behaviours to some degree.

Experience of meaning at work: Scale development and model testing

Matthew Monnet
Pacific Lutheran University, United States of America

The purpose of this study is to investigate the relationship of stress with the experience of hedonic and nonhedonic affect at work. There are several contributions of the current study to the extant literature on workplace stress. First, construct validity is established for a new affect scale labeled “hedonic well-being.” Specifically, the viability of a three factor model of subjective well-being is supported. Additionally, the results of the current study offer additional insight into the direct and moderating effect of social support.

Metaresilience - alchemy of burnout

Paul Mooney
Resilience Enterprise, South Africa

During 2011, research and intervention processes designed to understand the transformation of burnout into resilience and work engagement, took place with 80 staff from Nedbank as part of a Masters study undertaken by the author with Middlesex University’s Institute of Work Based Learning (London). During 2012, this research will deepen as part of a doctoral research programme with the undertaking of a much more rigorous process with 56 more staff which will additionally measure the impact of group resilience on organisational resilience. Data gathering modes include assessment, survey, interview, group workshop, one on one coaching, journaling, creativity and body work. The ontology is solipsistic in nature with epistemological methods ranging from empirical, rational, coherent, memetic and participatory. Triangulation will be based on quantitative, qualitative, positivist, phenomenological and reflexive processes. The main group work will be complete by June 2012 with preliminary results being available for discussion by the conference, should the abstract be chosen.

To investigate multiple relationships among workplace spirituality, perceived organisational justice and organisational citizenship behaviour

Mohammad Taghi Movaassagh
Ipsahan University, Islamic Republic of Iran; Hamid Oreyzi

The purpose of this study was to determine the relationships between workplace spirituality, perceived organisational justice and organisational citizenship behaviour (OCB). Therefore 192 subjects were randomly selected and responded to variables instruments, namely, a workplace spirituality questionnaire (WSQ), perceived organisational justice questionnaire (POJQ) and individual initiative scale (IIS). Matrix correlation and stepwise regression analysis were used for analysing data. It was hypothesised that there would be significant relationships between workplace spirituality and perceived organisational justice with OCB. Results revealed a positive and significant relationship between workplace spirituality and perceived organisational justice with OCB. The findings also suggest that procedural justice and sense of meaningful work subcales illustrate the most shared variance with OCB.

Psychological capital, social capital, work identity and employability of graduates from a leader development programme

John C. Munene
Makerere University Business School, Uganda; James Kaggaar; Joochim Buwembo

This paper is based on the premises of positivity which appear suitable to the Generation Me or, the Millennials, characterised as narcissistic and hedonistic with a distinctive concept of what is fulfilling work. It employs psychological capital and social capital to examine the employability development of young university graduates who go through a leadership programme designed to enhance their employability in Uganda. Data were collected from Leadership Development Programme Graduates sponsored by Compassion International in Uganda. Self-administered questionnaires were administered to a sample of 204, which was selected out of a population of 403 graduates using the Krejcie and Morgan’s (1970) formula of sample size determination. All respondents had gone through a minimum of 16 years of formal education where 98.5% had either a first or second degree while 1.5% had obtained a postgraduate diploma. The majority (92%) were 30 years or below. Preliminary analysis revealed that social capital, career identity and psychological capital account for 24% of variance in employability. Of this percentage, psychological capital accounts for 52% while social capital accounts for 17%. Career identity did not independently relate to employability. A limitation of this study is its cross sectional nature based on one cohort. It may not generalise to the rest of the population. Further work is required and opportunities for longitudinal work should be explored. The paper contributes to the growing body of knowledge likely to explain what fulfills the work expectations of “Generation Me” in an African country.

Frederick Taylor as a contributor to public administration

Darrell Myrick
UNISA, South Africa

Schachter (1989) wrote, “Taylor’s ghost hovers over the modern school of public administration”. Being deceased for some 75 years, a key question is whether his scientific theories of management have made a contribution to modern public administration. Taylor’s theories focused mainly on increasing productivity in industry. His concern was for a pragmatic approach to efficiency to optimise the human factor in production. The notion of pragmatism has had relevance in public administration. This paper examines how practitioners of public administration have adopted Taylor’s theories. A more direct link to public administration may be found in the work of Morris Cooke, who focused on public sector approaches to political economy. If there was any time that Taylorism was apparent in the public sector, it was in the years leading up to World War II, when the industrialisation of the public sector was necessary in the build-up to military conflict. An aim of the paper then is to examine how public administration has drawn from the field of industrial psychology, towards improving operations in public organizations. Essentially, the key question is: to what extent have industrial scientific management principles found their way into a seemingly ‘soft’ discipline such as public administration? It is a question that begs to be answered in South Africa, in light of poor service delivery, operational inefficiency and a need for greater emphasis on organisational development.

A quantitative study of organisational interventions and strain measures

Vandana Naran
University of the Witwatersrand, South Africa

Organisations and particularly individuals within organisations experience considerable amounts of stress as a result of various stressors. Organisations, as a result, provide various interventions for their employees in order to help them to deal with stress. This research was conducted within the framework of work-life balance and aimed to examine the relationship between the organisational interventions (which are measured at the company level) and strain measures which occur at the individual level. This study was conducted on existing data that was obtained from a large internet based survey with a combined sample of 13578 respondents from
101 companies who opted to participate in the study. Two stress scales were constructed - one that measured stressful work environments and the other that measured experienced stress. The results obtained through a Hierarchical Linear Model, illustrated that individuals experienced less stress and stressful work environments particularly when organisations provided facilities for this. However, this differed according to various demographic variables (gender, marital status, pregnancy, flex-time, shift-work and overtime).

**System socio-psychological reflection on the labour market development in Ukraine**

Mykhaylo Nadydonov ISPP, Ukraine; Lyubov Grigorovska; Lyubov Nadydonova

The research was devoted to determination of the status level of occupational prestige and the factors it influenced typical for Ukrainians on the background of the world finance-economic crises. Four cycles of complex representative across-country survey (n=2407, n=2394, n=2480 and n=1270) were conducted during 2008-2010. In addition, focus-group research with a variety of target audiences directed to discover occupational prestige factors was carried out. Two occupational typologies - one based on ISCO-88 and another based on the differentiation of the subjects of professional activity (man-man, man-technology, man-nature, man-symbol, man-artistic image) - were implemented for data analyses (n =1251 for adults and n =1250 adolescents). In consequence, the national standard of occupational prestige was created which was compared with the Standard International Occupational Prestige Scale. Five profiles determining their profession as prestigious were created after factor analyses. The most important factor is the idea about high earnings. Women more than men connected occupational prestige with comfortable work conditions, possibilities for rapid career, privileges, glory (fame), stability. In addition, the higher the respondent’s education level the more important are such factors as opportunity for creative self-realisation and solving difficult tasks accessible only for some people. The coexistence of the same occupations in different lists of deficit-prestige occupations is explained by both stereotypes of consciousness and stereotypes of economic system as remnants of the socialist way of life. Therefore, strategies which include such steps as fixing cycles, information during the detection of the stereotypes, the new cycle of information in collaboration with the system of vocational training is proposed.

**Power configurations, organisational support and personal well-being in a public owned company**

Elaine Neiva University of Brasilia, Brazil; Maria das Graas da Paz; Valdenis Silva University of Brasilia, Brazil

The literature on organisational behaviour emphasises the importance of studying the individual’s well-being in the organisational context and those factors that influence it. This paper focuses on power configurations in organisations, organisational support and the well-being in the organisational context. Besides, it verifies the influence of demographic variables, the impact of configurations and the organisational support on the well-being of the individuals. A cross-sectional analysis was performed by applying survey questionnaires to members of a public company. The sampling was organised to represent the company’s departments, totalling 321 respondents, of which 262 were men and 59 were women. The data were collected using three scales: Personal Well-being in Organisations; Configurations of Organisational Power; and Perceived Organisational Support. The questionnaires were answered individually. Descriptive statistic analyses was applied to evaluate the variables. Inferential statistics was used to verify the factors that influence the well-being in organisations. The analyses showed high indices of well-being among the respondents. The missionary and the instrumental power configurations were, respectively, the most perceived, while social support and management were also emphasised. The results suggest that the personal well-being in organisations is better perceived by those who are in managerial positions, the ones who stay longer in the organisation, and by those of higher ages. The data did not reveal any meaningful difference between men and women. The missionary configuration, the management style, the social support, the material support, and the possibility of being promoted in the job predict the well-being in organisations.

**Change reactions: The role of change context and attitudes toward change**

Elaine Neiva University of Brasilia, Brazil; Vanessa Nery

Studies indicate that most organisational changes fail due to human aspects. Thus, there is growing concern regarding the factors involved in reaction to organisational change, such as engagement and resistance. This study aimed to investigate the relationship between the context of organisational change, attitudes towards change, engagement behaviours and resistance. To do so, a mediation model of attitudes towards change between the context of organisational change and engagement and resistance was proposed. To test the model, a cross-sectional quantitative study in nine Brazilian states was performed. The sample consisted of 981 employees of two public organisations. Participants responded to measures of the changing context and reactions to change, developed for this work, and a scale of attitudes toward organisational change. The instruments had a 11 point agreement scale. Data were analysed by the reliability of measures, and regression analysis to test the mediation model. The result confirms that attitudes mediate the relationship between the change context and the reactions of engagement and resistance. Overall, the results support the hypothesis tested and indicate that the context of organisational change has a direct relation to reactions such as engagement and resistance. These findings allow a better understanding about the role of attitudes in reaction to organisational change.

**Organisational cynicism: Spillover effects on supervisors and performance**

Pedro Neves NOVA SBE, Portugal

Organisational cynicism has grown in contemporary Western organisations, with consequences for organisational functioning, characterised by frustration, hopelessness, and disillusionment, as well as contempt towards the organisation and the belief that the decisions made within the organisation lack sincerity. However, the mechanisms and potential moderators of the impact of organisational cynicism remain understudied. The present study addresses these gaps by: (a) Exploring the spillover effect of organisational cynicism on affective commitment to the supervisor, and (b) examining if perceived supervisor support (PSS) buffers that negative relationship. Additionally, it examines whether affective commitment to the supervisor mediates the relationship between the organisational cynicism X PSS interaction effect and performance (i.e.,mediated-moderation). Data were collected from both employees and supervisors (n=274) from 45 organisations. The results generally support our hypotheses. This study provides evidence that organisational cynicism extends its impact to other social exchange partners (i.e., supervisors) and that supervisors, through high levels of PSS, may reduce such effects, with consequences to performance. That is, organisational cynicism affects employees’ attitudes not only toward the organisation, but also toward its representatives, such as supervisors. They are particularly vulnerable due to their psychological proximity to employees. Nonetheless, supervisors themselves may actively inhibit this spillover effect by demonstrating high levels of support, thus helping to protect the organisation from the threats that cynicism poses for performance. This study opens new avenues for research on organisational cynicism and carries implications for practice.

I am stressed, ergo I perform: Stress appraisal and mechanisms linking to performance

Pedro Neves NOVA SBE, Portugal; Gloria Gonzalez-Morales

The conceptualisation of challenge and hindrance work stressors has inspired recent research on work behaviour, however this model entails an a priori determination of the type of stressor. Building on Lazarus and Folkman’s (1978) transactional model, we take into account the actual appraisal of work demands as hindrances and challenges and propose two different mediating mechanisms to study their relationship with performance. We examine the health impairment mechanism (through the mediating role of strain) and propose a second mechanism (based on social exchange and indicated by the mediating role of affective commitment to the organisation) to study the relationships between challenge and hindrance appraisal reported by employees, and extra-role and intra-role performance reported by their supervisors. In a sample of 284 employee-supervisor dyads, structural equation modeling showed that affective commitment to the organisation mediated the positive relationship between challenge appraisal and both types of performance and the negative association between hindrance appraisal and both types of performance. The negative indirect relationship between hindrance appraisal and performance through increased psychosomatic strain was significant only for extra-role performance.The findings indicate the importance of taking into account the actual appraisal of work demands for predicting performance outcomes, and reveal the key role of social exchange in explaining this relationship.
Conflict behaviour in innovation processes in the field of life sciences

Ellen O’leary Berlin Humboldt University, Germany; Annedore Schulze; Gosia Millikiewicz

Conflicts and their management play an integral part in the process of innovation. Little attention has been paid on international issues relative to creativity and innovation. The project compares conflict management and its outcomes in different cultures: Chinese, Indian, and German. This abstract presents the preliminary results of the Indian sample. Problem-centred interviews (N=35) with scientists from applied and basic research organisations within the field of Live Sciences. Qualitative content analyses are applied to the transcribed interviews. A categorisation system of conflict issues is being developed in an inductive approach. Conflicts emerge quite often in innovation processes. It can be shown that the conflict management style is decisive for successful innovation. The findings suggest the majority of researchers favour the problem-solving conflict management style. This style was also most beneficial for the innovation process—especially when used by both parties, regardless of their hierarchal relationship to one another. The dominant style of conflict resolution was most successful when used by a superior in combination with an accommodating subordinate. Our findings could not support the traditional arguments that avoiding is culturally most appropriate and useful for India. Life Science researchers in India are confronted with changing work environments and requirements at the global and organisational level. The results suggest the need for additional research on the links between conflict management styles and effectiveness within the innovation process.

Perception of organisational politics, job-related negative emotions, and violence among banks’ employees

Bolamie Ogungbamila Adekunle Ajasin University, Nigeria

Previous studies associated perception of organisational politics with negative work attitudes (Shenge, 2007) and work behaviours such as violence (Vigoda-Gadot & Kapun, 2005). Workplace violence could worsen the adverse effects of the recent financial crises in the Nigerian banking sector on the organisation, employees, and customers of a failing bank. Less research attention has been devoted to the connections among perception of organisational politics, job-related negative emotions and workplace violence, especially among employees of failing banks in Nigeria (Ogungbamila 2010). This study, therefore, investigated the extent to which perception of organisational politics (low, medium, and high) and job-related negative emotions (low versus high) influenced workplace violence. Participants were 248 employees (121 males; 127 females) of failing commercial banks in Akure, Nigeria, whose ages averaged 27.43 years (SD=9.58). Results indicated that employees who perceived high levels of organisational politics were significantly the most violent compared with those who perceived either low or medium levels of organisational politics [F(2,242) =4.93,p<.01]. Employees who reported high levels of job-related negative emotions were significantly more violent than those who reported low levels of job-related negative emotions [F(1,242)=3.94,p<.05]. Finally, employees who perceived high levels of organisational politics and experienced high levels of job-related negative emotions tended to be the most violent compared with other categories of employees [F(2,242)=3.62,p<.01]. Workplace violence was employees’ negative way of coping with self-serving behaviours and other negative work situations in the workplace. In order to reduce workplace violence, self-serving behaviours and uncertainties in the workplace must be effectively managed.

Contextual-dispositional predictors of turnover intention among employees of Nigeria’s oil industry

Olaoluwa Olufame University of Lagos, Nigeria

Whether context more or less than disposition predicts organisational outcomes have been debated in literature, but the extent to which such predict employees’ turnover intention has been evaded, whereas, this may have grave consequences for employee retention and performance strategy. Therefore, this study investigates proactive role of context (distributive procedural and interactional justice) and disposition (conscientiousness, agreeableness and emotional stability) on turnover intention of employees in Nigeria’s oil industry. Using cross-sectional survey design and multistage sampling techniques, (n =750) employees comprising 534 males (71.2%) and 216 females (28.8%) with a mean age of 35 years (S.D = 6.88), participated in the study. Data was collected using validated measures of the study variables combined into a single survey questionnaire. Coefficient alpha of the study variables are: (0.86) Turnover intention, (0.84) Distributive justice, (0.82) Interactional justice, (0.86) Conscientiousness, (0.83) Agreeableness, (0.92) and (0.82) emotional stability. Significant negative relationship was found between contextual variables and turnover intention, also, significant positive relationship was found between dispositional variables and turnover intention. Contextual variables predicted turnover intentioning better than dispositional variables (R2 =0.11; F(5, 744) = 33.42; p< .001) than dispositional variables (R2 =0.3; F(5, 744) = 53.32; p< .001), justifying the assumption of weak effects of dispositional traits in strong situations. Managerial implication of the findings was discussed.

The mediation role of perceived organisational climate between supervision climate and openness to experience among management students

Hamid Reza Orezy University of Isfahan, Islamic Republic of Iran; Hajar Massah

One of the main objectives of the in-basket test is the presentation of realistic job-related situations that elicit responses typical of on-the-job behaviour. In the current paper, original in-basket exercises of Frederiksen, Jensen and Beaton (1972) of perceived organisational climate, and supervision climate, were used to make realistic environmental perceptions. Cultural concerns for adjusting items were applied. Management students of Isfahan University (n=212) were randomly selected and responded to in-basket exercises of organisational climate (two extremes were innovation-rule climate) and supervision climate (detailed-global). Their task was to choose their role in the supervision climate. Participants responded to Openness to Experience of the Casta and McCra Neo personality scale (1992). Statistical analysis of data using Baron & Kenny procedures and Sobel Tests indicate that openness to experience mediates between the organisation climate and supervision climate. Findings show the person-situation interaction role in the organisational setting using a simulation exercise.

Co-worker and supervisor support, Islamic work ethic, conscientiousness and agreeableness on whistleblowing in two organizations

Hamid Reza Orezy University of Isfahan, Islamic Republic of Iran; Shabnam Javanmard; Shadi Dehghan

In the current paper two organizations was compared. In one organization the ethical code was supplied to employees and facilitators of that ethical code presented to them on the organisation’s code based on Islamic instructions. In another organisation, an ethical code was not yet administered. Whistleblowing behavior was measured by Bjorkelo et al (2011); co-worker and supervisor support for whistleblowing was prepared by researchers. The relation between whistleblowing and other scales indicate that Islamic work ethics and conscientiousness explain it better. To compare relations in two organizations, r was transformed to Z (Fisher Z). Findings indicate that whistleblowing and three scales of co-worker support, supervisor support and agreeableness in the organisation without an ethical code were inversely related, while the direction of relation in the other organisation is positive. While the relation between conscientiousness and Islamic work ethic is positive in both organisations. It is concluded that norms in organisation without an ethical code under the pressure of group cohesiveness may encourage corruption.

Investigation of the relationship between work-family conflict and family-work conflict with organisational justice, organisational commitment and vitality

Hamid Reza Orezy University of Isfahan, Islamic Republic of Iran; Abolghasem Nouri; Shabnam Javanmard

The aim of the current research was to investigate the relationship between work-family conflict (WFC) and family-work conflict (FWC) with organizational justice, vitality and organizational commitment in expatriate and normal work schedule of Gas Transfer Operation District two, and comparison of these two groups. Statistical population of this research was formal personnel of company in 2010. Among them 150 persons were selected randomly who completed research instruments. 75 persons from expatriate stations and 75 persons from normal work schedule were selected respectively. Findings indicate that relation among WFC with distributive, procedural, interactive and organizational justice, vitality and organizational commitment are significant. Findings in expatriate group indicate negative relation between WFC with distributive and interactive justice, vitality and organizational commitment. While in normal schedule group, WFC show significant negative relation only with procedural justice. Concluding via Fisher Z test also
indicate that WFC in expatriate group has strong relation (negative) with vitality, distributive justice, identification and exchange commitment relative to normal schedule group (p<0.05). In explaining above mentioned findings, it must be considered that work in expatriate form establish disorders between job task and family duties because their distance from their families, so make them distressed. Organizations can lower WFC level by administering training interventions and with work environment strategies contain family-friendly characteristics and maintain their personnel subjective well-being, organizational commitment and perceived justice in desirable level.

Cross-understanding dynamics in medical emergency intervention teams
Catalina Otoiu Babes Bolyai University, Romania
Cross-understanding is conceptualised as the extent to which members of a team have an accurate understanding of each other’s mental models. It is believed that by affording such understanding, group effectiveness is increased through more reliable and speedy coordination and a better decision-making process (Huber & Lewis, 2010, 2011). Cross-understanding is usually formed through repeated interaction and information exchange between team members. While this is easily obtained in classic teams where people work together for a long time, and have such information sharing opportunities, when team membership constantly changes, the emergence of cross-understanding and other emergent states relevant to team effectiveness is challenged. The present study investigates elements of cross-understanding within medical emergency intervention teams that operate in shifts with different membership. The purpose of the study was to investigate our participants’ perspectives on cross-understanding formation within their teams, and to identify which of its components they consider relevant for team effectiveness and performance in this particular setting. Individual and group interviews were conducted with 15 paramedics working for a medical emergency intervention service. All interviews were recorded; transcripts were coded and analysed using thematic analysis. Our participants were asked to describe their experience of working for this service and being part of the intervention teams, and to emphasise information and knowledge sharing and how these affect team performance. Components of cross-understanding were also identified and were associated with speed and efficiency of the intervention and preferences in team membership.

How entrepreneurs choose science parks: An experimental research
Jiayning Pan GERC, Zhejiang University, China
The objective of this study is to investigate the factors that influence Science Parks location choice of entrepreneurs. Building on an asset complementarity perspective, human capital and social capital measures are used to examine the science parks location decisions of entrepreneurs and the motivation of entering science parks is used as a mediator. The study uses an experimental method to examine the decision making mechanism. Eighty MBA students at Zhejiang University participated in the study and were randomly divided into different experiments. Experiment 1 was focused on individual entrepreneurs and Experiment 2 was focused on entrepreneur teams. The results showed that entrepreneurs’ educational and business backgrounds strongly affect the location choices, and the different properties of entrepreneur teams also had big influence. The motivation of entering science parks were constituted by technology motivation, market motivation and policy motivation. Each dimension showed different mediating effect in two experiments. The present findings indicated that individual entrepreneurs and entrepreneur teams should choose a proper science parks based on their own background and come to a park-entrepreneurs fit.

Effects of organisational climate on human resource strategy and commitment under change in Chinese family business
Jiayning Pan GERC, Zhejiang University, China; Zhongming Wang Zhejiang University, China
Family business in China is undergoing great changes. Work commitment and motivation has been a challenge, while talent management becomes a key strategy. Recent studies in family firms examined the impact of human resource practices on work commitment. However, the underlying mechanism remains unclear. This study (NSFC70232001 & NSSSF102d&dd406) developed and tested a modern model of organisational climate on human resource strategy (HRS) and work commitment. A field survey was conducted among 112 Chinese family firms (a human resource manager and three employees from each firm participated). A multilevel structural equation analysis was conducted. The results showed that commitment-based human resource practices were positively correlated to work commitment when companies had a harmonious organisational climate of trust, cooperation, shared codes and language. In turn, when the climate was not positive, human resource practices had no significant effect on work commitment. The findings suggested that under
increasingly high competition due to talent internationalisation, Chinese family businesses should carefully enhance their organisational climate in order to effectively use HRS practices to promote work commitment. Implications of this study to the family business HRS development under organisational change and talent internationalisation were discussed.

Differential effect of multi-level science parks on motives and performance of high-tech firms under change in China

Jianying Pan GERC, Zhejiang University, China; Zhongming Wang; Esbjorn Segelod; Lennart Bogg Science parks have provided an innovation and change platform, and eco-system, for high-tech firms in China. However, the mechanism of how these parks, at different levels (city, provincial, national levels), affect performance among those firms, remains unclear. This study (NSFC70232001 & MU grant) examined the differential effects of science parks on high-tech firms under organizational change and talent internationalization. Two main questions were examined in this study: (1) do different levels of science parks have different added-value to high-tech firms located in science parks? (2) do high-tech firms in different levels of science parks have different motives in terms of location and innovation strategies as well as performance? A sample of 399 high-tech firms participated in this study to test the hypotheses. The results showed that the different level of science parks had a moderating effect on motives and performance of high-tech firms. National level of science parks had a more added-value contribution to performance of high-tech firms than that from other level of science parks. National level of science parks also provided better job opportunities than that from provincial ones. The study indicated that local level of science parks played a positive effect in facilitating cooperative initiatives between enterprises and universities for technology transformation. However, provincial level parks showed weaker effects on eco-system development to other firms than that from national ones. Implications of the findings from this study to an innovative capability transfer model were discussed.

Entrepreneurial self-efficacy and entrepreneurial intention in India: a comparative study of professional students

Govind Swaroop Pathak Indian School of Mines Dhanbad, India; Ming Wang The current globalised scenario has brought in both challenges and opportunities for India. In the changed context, the researchers are increasingly interested in studying the concept of ‘Entrepreneurship’ and the phenomenon has been described from various standpoints. Given its importance, there are many unanswered questions. The present research endeavours to examine the relationship between Entrepreneurial Self-Efficacy and Entrepreneurial Intention, in India. The sample comprised 100 professional students, pursuing a Business Management degree, and 100 students pursuing an Engineering degree, in a technical institute. Standardised questionnaires to measure the variables of the study were adopted for use in the Indian context, employing the technique of de-centering (Werner & Campbell, 1970; Brislin, R.W, 1980). The findings of the study reveal interesting differences and relationship among the variables. Based on the findings of the study, theoretical and practical implications of the findings, and further research questions, are discussed.

Cumulative disadvantage explains age divergence in well-being between employed and unemployed Germans

Maria Pavlova University of Jena, Germany; Rainer Silbereisen The negative impact of unemployment on subjective well-being (SWB) is well known, but the role of age in this relationship remains unclear. We suggest that the age-related duration of current employment status contributes to greater SWB among the employed and to lower SWB among the unemployed via the life-course mechanism of cumulative advantage and disadvantage. In particular, in the context of a stable labour market with low job mobility and high unemployment rates, as in Germany in the mid 2000s, some labour market entrants quickly achieve stable employment and start to accumulate related benefits, whereas the others are channelled into long-term unemployment, whereby their resources are depleted. With age, such cumulative processes may exacerbate the well-known gap in SWB between the employed and the unemployed. To test this proposition, we used cross-sectional data on employed (n = 1382) and unemployed (n = 254) Germans (age 18–42) surveyed in 2005. By estimating a moderated mediation model, we found that, among currently employed individuals, relatively older age predicted longer employment duration (tenure), which was related to higher SWB via higher income and higher perceived occupational security. Among currently unemployed individuals, age predicted longer unemployment duration, which was associated with lower SWB via lower perceived social support. Thus, age was indirectly related to higher SWB in employed individuals and to lower SWB in unemployed individuals, which supported our expectations. Findings also shed light on the psychosocial advantages of long-term employment, which were not the polar opposites of the disadvantages of long-term unemployment.

Batswana female managers’ career experiences and perspectives on corporate mobility and success

Mpho Pheko University of Cape Town, Botswana The current study sought to investigate Batswana female managers’ strategies for entering and succeeding in managerial positions. The study also investigated challenges and consequences of success for the female managers. While gender development research elsewhere has been diverse, in Botsswana the research seems to focus mostly on the impact of socioeconomic challenges and the existing legislations on gender development. Qualitative interviews shaped by the objectives of the study, as outlined above, were conducted with 464 employees (n = 10) representing different industries and professions which was related to higher SWB via higher income and higher perceived occupational security. Among currently unemployed individuals, age predicted longer unemployment duration, which was associated with lower SWB via lower perceived social support. Thus, age was indirectly related to higher SWB in employed individuals and to lower SWB in unemployed individuals, which supported our expectations. Findings also shed light on the psychosocial advantages of long-term employment, which were not the polar opposites of the disadvantages of long-term unemployment.

Development and validation of the sensitivity towards being the targets of upward comparison scale

Mpho Pheko University of Cape Town, Botswana Two studies (i.e., Study 1 and Study 2) were designed to develop an instrument for assessing out-performers’ Sensitivity Towards being the Targets of Upward Comparison (STTUC). Similar to the fear of success research, the STTUC construct provides some insights into the ways by which personal achievements can be viewed as costly or threatening (Henagan, 2010). Study 1 is part of an ongoing PhD dissertation designed to investigate antecedents of STTUC among Botswana’s black employees. Study 2 is currently being designed to further validate the measuring instrument that was designed to assess STTUC in Study 1. For Study 1, a convenient sample of 464 employees was obtained from a variety of organizations in Botswana. Data for Study 2 will be collected from the University of Botswana students. Research on the STTUC construct and other related constructs was used to conceptualise the proposed scale which taps into three key conditions of STTUC. In Study 1, Exploratory Factor Analysis (EFA) was used before Confirmatory Factor Analysis (CFA) to first give some insight into the data set. Cronbach’s reliability coefficient alpha was thereafter calculated for each factor. Coefficient alpha ranged from .86 to .95 for all the subscales. CFA was thereafter conducted to verify the factor structures of the observed variables and to detect unidimensionality of the subscales. The results of Study 1 showed that the proposed instrument has an identifiable factor structure, and adequate levels of reliability and validity. By using a different sample for Study 2, the aim will be to further assess the proposed scale’s convergent validity and discriminant validity. Both studies make theoretical and empirical contributions. For instance, while research activities on experiences of STTUC are increasing, there is no validated and standardized instrument for assessing STTUC. Such an instrument is needed because to fully understand the impact of STTUC on employees, their performance, and their career progress, it is essential to have a valid and reliable instrument designed to assess employee’s STTUC. The study may also aid in widening the scope of research on the relatively new STTUC construct.

Talent management practices as a predictor of employee well-being

Yvette Plenaar (Wilm) University of Pretoria, South Africa; Nicolene Barkhuizen University of Pretoria, South Africa Many organisations are currently facing a scarcity of human capital competencies required for special-
ist positions in organisations. The result is that organisations have to manage their human capital in a systematic manner in an attempt to gain and sustain future competitive advantage. Employees today are more concerned about healthy workplaces where they can flourish. The challenge arguably then exists for organisations to development talent management practices that can contribute to the well-being and retention of their employees. Against this background the main objective of this research is to determine whether Talent Management Practices are a significant predictor of employee well-being. A quantitative research approach was followed. The Human Capital Instrument for Assessment of Talent Management Practices and the Shiroim - Melamed Vigour Measure (SMVM) for the measurement of the level of well-being were administered among employees and managers (N= 485) of a South African multinational organisation. The results showed overall that Talent Management is a significant predictor of employee well-being. All Talent Management Practices were significantly related to the three dimensions of employee well-being. The results of the study indicated that effective talent management practices have a significant effect on the level of well-being experienced by an employee. This is an important finding as the effective application of talent management practices can contribute to employee well-being and in turn enhance the performance of the organisation.

Predicting and driving sustainable leadership effectiveness: A case study
Sonia Pinho Accenture, South Africa

Whereas organizations and psychological practitioners have for some time focused on the measurement of leadership, many assessments have to date not yielded comprehensive and usable insight into the behaviors that make leaders effective. As a result, leadership development is often insufficiently grounded in targeted measurement and practical application. This paper will focus on how leading organizations are shaping integrated leadership development programs to ensure that they have available the leadership competencies required to deliver on their strategic business objectives. Key here is a focus on identifying not only the personality traits and states that define effective leaders, but also predicting actual leadership performance and providing detailed coaching-based developmental feedback. This will be illustrated through case studies of organizations using a tool known as the Personality and Leadership Profile (PLP) to guide the development of their leadership potential aligned to the strategic imperatives of the business. The PLP is a self-report measure which offers insight into intellectual, personality and social scales, converging to predict leadership style as well strengths and development areas according to benchmarked "best leader" research. It forms the foundation of programs that drive tangible improvement in organizational leadership performance, while at the same time establishing a culture of coaching based leadership. Through structured measurement, targeted development and immediate on-the-job action, PLP-based leadership development programs accomplish change toward "best leader" behaviors that are both evident in the short term and sustainable in the longer term.

Emotional intelligence and leadership effectiveness: Some evidence from India
Rabin德拉 Kumar Pradhan Indian Institute of Technology, India; Shantanu Mazumder

Emotional intelligence is one of the most studied subjects in the field of psychology, management and other behavioural sciences. Past research shows that emotional intelligence plays a significant role in achieving managerial success in the workplace. Despite its popularity, emotional intelligence remains an elusive construct. This can be attributed to the lack of empirical evidence and inappropriate investigations. This research was to bridge this gap to some extent by investigating the degree of relationship between emotional intelligence, and leadership effectiveness variables. Data were collected on 303 managers from Kolkata Municipal Corporation, Calcutta, India by administering the test of emotional intelligence, transformational leadership, job satisfaction, and job performance and success. Data were analysed with the help of descriptive statistics, correlations, factor analysis and structural equation modeling by using SPSS-15.0 and AMOS 4.0. The results revealed that emotional intelligence positively and significantly predicts leadership effectiveness. The study also reported the mediating role of transformational leadership in the relationship of emotional intelligence and leadership effectiveness. The theoretical and practical implications of the study are discussed in the light of empirical findings.

Justice perceptions of performance appraisal mechanisms and its effects: A study of Indian banks
Pooya Purang IIT Bombay, India; Arunima Shrivastava

The Indian banking sector is changing rapidly since the 1990s, operating in a more competitive environment, intermediating larger volumes of foreign financial inflows. The challenges faced are fast changing technology, establishing an international presence, attracting and retaining talent and overhaul HR policies and practices to enhance employee productivity essential for performance of the bank. Performance appraisals play an important role in this effect; perception of fairness of performance appraisal being an important issue as employees frequently perceive them as unfair and ineffective. However a gap remains in the literature to study perceptions of justice of performance appraisals in the fast-changing Indian banking sector. This study uses the 4-factor structure of organisational justice to study the employees’ perceptions of fairness of performance appraisal mechanisms and examines the effects of justice perceptions on the job satisfaction and organisational commitment. The study used the survey research design was used. A sample of 340 participated in the close-ended questionnaire, along with this open-ended questionnaire were used to elicit opinions towards the performance appraisal system, a total of 62 respondents participated in that. The regression analysis showed that procedural, informational and distributive justice affected job satisfaction and procedural, interactional and distributive justice affect organisational commitment of employees. The findings highlight that uses and fairness of appraisals are primary concerns of employees in Indian banks and different perceptions of justice of appraisals guide attitudes, which has implications for both managers and researchers.

Aging as a psycho-neurological construct: Implications and recommendations for social and business change
Wiehann Rademan Sanlam Personal Finance, South Africa

Possible differences in work related cognitive output and change orientation between age groups are often controversial matters. In response to a research request by a South African financial institution, the presenter considered age as a psycho-neurological structure and the implications of aging on the change orientation of managers. In two separate studies (2008 and 2011) internal organisational data regarding change related paradigms, specifically conservatism versus radicalism was collected and analysed. Psychometric assessment results suggested a correlation between work performance and conservatism in a group of advisors (“sales agents”) younger than 35 years of age. Secondly, there was no clear difference on the conservatism scale ratings between managers who completed schooling during the period 1970 to 1979 and those completing between 1980 and 1994. In conclusion there seems to be little evidence that a general change orientation in the workplace is related to aging. Organisations should value all possible contributions from different groups, be it age, origin, language, gender or work orientation. There seems to be little value in segmenting competitive markets by belief, social relationships, history, and culture. It is further suggested that researchers make use of diverse information samples when collecting data or testing responses to change, either in suggested or real change. Finally, the specific contents of a change need or project should lead skilled aligned recruitment.

Knowledge creation and servant leadership: A relational perspective
Rishabh Rai University of Delhi, India; Anand Prakash

Knowledge creation is a dynamic activity where new ideas and meaning are created through cooperative, collaborative and interactive relationships. However, too much emphasis on a competitive spirit and on labeling knowledge as only an information-processing activity holds humans as decontextualised, mechanical, and autonomous beings not influenced by belief, social relationships, history, and culture. Due to this position, organisations ignore the significance of people and relationships. The relational perspective describes how servant leaders create interdependent and cooperative systems which facilitate knowledge creation. We begin by suggesting that shared leadership is an important function of servant leaders. Servant leaders develop constructive and interactive dialogue by encouraging followers to assume leadership roles. In this way, followers and leaders alike engage in mutual influence and direction, which in turn helps in creating shared context. Next, we suggest the development of the caring relationship by leaders which leads to increased cooperative and collaborative behaviour
because followers’ views are respected, appreciated, and invited regardless of their perceived value. Shared leadership and caring relationships help to break the hierarchical boundary between leader and follower, remove followers’ underlying distrust and fear in expressing beliefs and perspectives, and create a common platform for the expression of implicit and explicit knowledge. Finally, we conclude by suggesting the need to change organisational practices that inhibit cooperation and encourage competition such as a performance appraisal system or an individual centric reward system.

Decoding employee engagement: An analysis of antecedents and consequences

Neeti Rana Goutam Buddha University, India; Neeti Chhabra

Employee engagement has been defined in many different ways and used synonymously with established constructs like organisational commitment and organisational citizenship behaviour. It has been often defined as emotional and intellectual commitment to the organisation or the amount of discretionary effort exhibited by employees in their jobs. Employee engagement has also been defined as psychological presence but it was further stated that it involves two critical components: attention and absorption. Attention refers to ‘cognitive availability and the amount of time one spends thinking about a role’ while absorption means ‘being engrossed in a role and refers to the intensity of one’s focus on a role.’ Burnout researchers define engagement as the opposite or positive antithesis of burnout. Personal disengagement refers to the ‘uncoupling of selves from work roles; in disengagement, people withdraw and defend themselves physically, cognitively, or emotionally during role performance.’ Thus, engagement means to be psychologically present when occupying and performing an organisational role. In the academic literature, engagement is said to be related to but distinct from other constructs in organisational behaviour. Given the limited research on employee engagement, there has been little in the way of model or theory development. The present paper analyses: (i) psychological conditions of personal engagement and disengagement at work; (ii) potential antecedents; and (iii) consequences of employee engagement. In sum, engagement leads to both individual outcomes (i.e. quality of people’s work and their own experiences of doing that work), as well as organisational-level outcomes (i.e. the growth and productivity of organisations).

Portuguese system of protection of children: using a taxonomy of errors for an evidence based management

Dora Redruello Faculty of Law, U Coimbra, Portugal; Sanja Ferreira

In this communication we intend to present the results of an investigation involving Child Protection Commissions in Portugal, in order to create a taxonomy of errors for the management of the Portuguese System of Promotion, and Protection, of Children and Youth. Child Protection Commissions (n=22) were chosen according to the criteria of representation from the different realities of the country’s mainland and islands. Each commission participated in one Focus Group that lasted approximately six hours and the participants discussed, in depth, their practices with reference to a set of Guidelines defined specifically to this end (e.g., relationship with law enforcement authorities, how to they evaluate and decide to refer a child for adoption). The narratives of real cases were essential to understand how real procedures and actions were developed. From the analysis of the discourse participants (content analysis using MaxQDA), three main categories of errors emerged: Process, Resources, and Relationship with Family/Significant other people. Each of these categories subdivides into several indicators that will be also presented in this communication. The participants identified the taxonomy as a useful and practical tool that will allow every professional of the Protection Commissions to identify and report an error in an accessible way.

How attitudes of dentists and dental hygienists towards task redistribution are related to gender

Jan Jaap Reinders UMCG, Netherlands; Cees van der Schans; Boudewijn Stegenga; Pieter Onclin

Dental task redistribution stagnates in some countries. In many other countries, however, this is uncultivated. Attitudes of professionals might provide clues. In turn, these attitudes could be influenced by gender. Gender influences work relations and gender distributions within dentistry and dental hygiene are observed. The purpose of this study was to provide a summary of literature regarding attitudes of both professions towards task redistribution. A secondary purpose is to verify whether gender is related to these attitudes. A systematic literature review was conducted to inventory the percentage of dentists and dental hygienists with attitudes towards task redistribution. PubMed and related citation searches resulted in nine articles after selection by two independent reviewers. Subsequently, gender distribution and cultural values related to gender equality (self-expression values) were inventoried. Compared to dental hygienists, more dentists are negative about task redistribution (82.4%, range: 24% and 49.7%, range: 42.1% respectively). Gender and self-expression values were related to the attitudes of both professions. However, self-expression values are negatively related to the attitudes of both professionals. Dental hygienists are more positive about task redistribution compared to dentists. Both professionals are less positive about task redistribution in countries with relatively more self-expression values. Probably, self-expression values do not represent gender equality, but to the need for psychological distinctiveness, which is related to professional identification. Furthermore, male dental hygienists are likely to be more committed to professional change, in contrast to male dentists.

Trust in innovation cooperation through project manager qualification

Markus Roewenstrunk Institute of Industrial Engineering, Germany; Susanne Niewoeheren; Wolfgang Herff

Innovation cooperation often combine experts from different organisations with various socialisations, adding interdisciplinarity to intra-, inter- and extra-organisational levels of cooperation. For projects with such heterogeneous constellations, developing a trustful collaboration is a challenging task but also an essential prerequisite for successful work. Therefore, a qualification concept has been developed within the research project “VERMIKO” that aims to foster trust encouraging work contexts with the inclination that actors in innovation projects value, accept, and return trust. Within this concept, trust is understood as a socio-psychological disposition and action oriented decision towards people or systems. It takes into account the complex interaction of personal and situational variables - thus follows a dynamic-transactional perspective. The full article will describe in detail the qualification concept, the field study, and the results. The main component of the qualification is a seminar, which will sensitise project managers about trust and show opportunities to promote it. The seminar addresses trust affecting factors, the relationship of trust and mistrust, the influence of relationship history, and the effect of norms and values. The impact of the seminar is analysed through a pretest-posttest-control-group design. The experimental group will participate in the seminar, the control group in a communication-training. Web-based-training modules function as preparation for the seminar and a post evaluation method. The expected results that the qualification of project managers enables them to promote trusting cooperation and make collaboration more effective, will further be evaluated through qualitative and quantitative methods (interviews, surveys) and thoroughly discussed.

A comparison between rate of entrepreneurial behaviour among males and females students in Iran

Zeinab Rostami University of Isfahan, Islamic Republic of Iran; Hamideh Abdolhoseini; Mohammad Abedi

The main purpose of this study was a comparison between rate of entrepreneurial behaviour among male and female students in Iran. The population of the study was all of the University of Isfahan students. For this purpose, 73 of the students (36 males and 37 females) were selected by simple random sampling and the Moshef entrepreneurial behaviour questionnaire was completed. For the analysis the results were used the statistical program SPSS 15 and the indicators and statistical methods, including mean, standard deviation and t-test Results. The results showed that there isn’t any difference between entrepreneurial behaviour among males and females students in Iran (P

Coaching psychology: Caring for the informal caregiver in the workplace

Elizabeth Cornelia Rudolph UNISA, South Africa; Michiel Buyts

The increasing prevalence of work/life balance challenge professionals (psychologists, human resource managers and management) to create a welcoming, safe and inclusive organisational environment, without becoming directly involved. It is natural to look after the sick, elderly, children and disabled. Those who care for these people tend to be forgotten. Working with people necessitates fundamental understanding of the uniqueness of each individual. The objective of the paper was to reconstruct the work/life journey of a respondent that care for her disabled mother. The research methodology used a multi-qual-
Managing cultural diversity at work: The effects of diversity perspectives on leadership
Gro M. Sandal University of Bergen, Norway; Per Sjøberg; Hege Bye

With globalisation and changing demographics, many European workplaces are becoming more culturally heterogeneous. The aim of this study was to determine how leaders’ approaches in managing multicultural work groups are linked to diversity perspectives at individual and organisational levels. A model of diversity management based on Berry’s acculturation framework is proposed. The model describes four leadership approaches; assimilation, multiculturalism, separation, and laissez faire. A total of 149 leaders in Norway participated in the study. Leadership approaches were assessed by the Diversity Management Scenario Questionnaire (DMQ). The leaders also completed the Benefits and Threats of Diversity Scale, and questions about whether diversity was integrated into the human resource (HR) strategies of their organisation. The results showed a strong association between separation, and leader expectations that contact between employees of different ethnicities would result in intergroup anxiety. Leaders in organisations with a HR diversity strategy were most likely to endorse multiculturalism. Separation and laissez faire leadership were associated with lack of HR diversity strategies in the organisation. In conclusion, the results suggest that HR strategies at the organisational level transcend to how leaders manage diversity in their work units.

The impact of employability skills training for young people - evaluation study of a training programme
Matthias Schmidt TU Dresden, Germany

Long-term unemployed youths need help to develop their employability. The project “Bridges to work” included training, coaching and mentoring units for the young unemployed participants and was designed to help them getting new jobs. In addition to developing practical skills, the training also took account of the physical and psychological aspects of health. The pilot project combines "modules" that offer the young unemployed the possibility to learn within the process of real work and to make progress in their professional skills. The invention and assignment of so-called Senior Coaches was of special importance. The Senior Coaches acted as personal advisors for each of the young men and women during the whole period of the program. The project has been evaluated with a summative evaluation following Kirkpatrick’s 4-Level-Model. In a two-wave panel study with a quasi-experimental research design the program was compared to the conventional program and a group of young unemployed with no intervention. Most of the participants of the "Bridges"-project experienced positive changes in their personal variables as the pre-condition for taking on self-responsibility for their lives. In addition, they experienced a remarkable improvement in their health. In total, 484 young unemployed participated in the program "Bridges" and the rate of integration in a job or a job training was 56.2% - a notable result compared to traditional programs with a rate of 20 - 30%.

Antecedents to shared leadership: Psychological empowerment and team potency
Maj Schoeler Fausing Aarhus University, Denmark; Joshua Lewandowski; Hans Jeppe Jeppesen; Michelle Bligh

The ubiquitous pursuit of innovation and knowledge sharing has led to an increased use of teams. This questions our traditional, hierarchical leadership models. Shared leadership represents an adaptation of leadership to the team-level, and it facilitates effective enactment of team member knowledge. Moreover, shared leadership describes influence and leadership as a collective, shared activity distributed among team members. Studies demonstrate positive relationships between shared leadership and performance across different contexts. However, there are few studies that focus on the antecedents of this concept. Considering that shared leadership builds on influence sharing and acceptance of influence from others, we argue that feelings of psychological empowerment combined with team potency are crucial to the development of shared leadership. The purpose of this study is therefore to investigate the predictive value of these antecedents in relation to shared leadership and performance. Toward this end, we conducted a survey among 81 teams in a Danish company (N=562). Results of the structural equation model and the correspondent fit indices indicated that psychological empowerment and team potency significantly predicted shared leadership. Moreover, we found that shared leadership was positively related to team performance based on manager ratings, output, and perceived performance. The study thus, supports the relevance of shared leadership in a team context and provides an initial understanding of antecedent conditions for its development. Particularly, the results indicate that in order for shared leadership to emerge successfully, organisations need to create conditions that empower individual team members and that allow for team potency to develop.

The negotiation of different levels of identity by leaders of a southern African youth movement
Jenna Segal University of Witwatersrand, South Africa

Psychology has defined identity as a conception of the self which is essentially self-referential and relational, that gives an answer to the question of ‘who am I?’. In areas of social science in today’s research on identity, there has been a shift in focus from the unchanging traits and essence of the production of identity, to what the awareness of identity permits and promotes and what ensues from it (rather than how it is shaped and how it became what it is). This view of identity as fluid and flexible guided the present research, which explores the identity negotiation of leaders within a youth movement. The research explored the ways that leaders made sense of the process of negotiation of individual leaders’ identities and their relationships to organizational (or sometimes programmatic) identities. A qualitative, interpretive methodology was employed, with data being collected using participant observation and in-depth interviews with five leaders of Habonim Dror Southern Africa. The analysis found two ways that participants made sense of individual versus organizational identities; The first of these by treating them as one and the same, and the second was by separating the identities and proposing the possibility or necessity of ‘switching’ between them at different times. The discussion includes consideration of the implications of the findings for identity negotiation and organizational identity.

Impact of emotional intelligence and organizational commitment in relation to turnover intention
Meera Shanker JBIMS, SNDT Women’s University, India

Emotional Intelligence has become an increasingly popular construct in diverse business environments.
Corporate social responsibility and organisational commitment - the moderating effect of treatment of employees

Rahul Sheel IIM Ahmedabad, India; Neharika Vohra

It has been observed that the Corporate Social Responsibility (CSR) practices of a firm lead to an increase in the level of organisational commitment (Brammer, Millington, & Rayton, 2007; Kim, Lee, Lee, & Kim, 2010; Peterson, 2004; Turker, 2008). This finding needs to be studied further to understand the dynamics of the relationship between the external activities of the organization and its impact on employees within the organisation. This study investigates the moderating effects of the treatment of employees measured through perceived organisational justice and perceived organisational support on the relationships between CSR and organisational commitment in the Indian context. In other words, it examines how employee’s perceptions about how they are being treated by their organisation interact with the positive effects of CSR on their commitment to the organization. The study uses a tighter definition of CSR to only include those activities that benefit external stakeholders and accrue indirect benefits to the organisation. Data was collected from 356 employees working in different Indian companies. Hierarchical multiple regression analysis was used to test the hypothesis. It was found that CSR has a significant positive relationship to organisational commitment and a perception of support and justice among employees positively moderated this relationship. The results imply that if employees perceived the organisation as being fair and supportive towards themselves the CSR activities of the organisation have an enhanced effect on employee’s affective commitment to the organisation. This paper contributes to the current pool of nascent research on the relationship of CSR and employee attitudes.

Abusive supervision and employee performance: mechanism of fsb and learning goal orientation

Chuangang Han; School of Psychology CCNU, China; Yang Jing; Hongyu Ma

The literature on abusive supervision has consistently demonstrated the negative relationship between member perception of supervisor’s abusive behavior and member performance. The process through which supervisor’s abusive behavior influences member performance, however, is still not fully understood. This study provides a mechanism for the process. Specifically, we predict that the feedback-seeking behavior (FSB) of the member mediates the relationship between abusive supervision and the member’s performance, and the learning goal orientation moderates the relationship between abusive supervision and FSB. We used a sample composed of supervisor-subordinate dyads from seven enterprises to investigate our hypotheses. 500 employees and 140 supervisors from 7 enterprises located in Hubei, Xiamen, Zhejiang and Guangzhou. The final matched sample included 306 employees and 124 direct supervisors. Two structured questionnaires were employed as the research instrument for the study. One consisted of four scales designed to measure abusive supervision, FSB, self-rated performance, and learning goal orientation. The other one consisted of one scale designed to measure supervisor-rated performance. Cronbach’s alpha coefficients for above measures were .58 to .94. The standard coefficients of abusive supervision on FSB, supervisor-rated performance were -.356(p<.01), -.314(p<.01). The findings showed that FSB played a mediated role between abusive supervision and super-rated performance, and member’s learning goal orientation moderated the relationship between abusive supervision and FSB.

Ethical climate as a moderator in the relationship between spiritual intelligence and counterproductive work behaviour

Purnima Singh IIT Delhi, India; Neha Jain

Spiritual intelligence refers to the intelligence that addresses and helps in solution of problems of meaning and value and places our actions and our lives in a wider, richer, meaningful context. Seeing its immense relevance at workplace it was thought to be an important determinant of counterproductive work behaviour. Ethical climate being another important contextual variable was tested for its moderating effects in the relationship between spiritual intelligence and counterproductive work behaviour. Data was collected from 351 employees from organisations in Delhi and NCR, India. Two private sector organisations (n = 181), and 2 public sector (n = 170) organisations were taken. Obtained results showed significant moderating effects across private sector organisations. Moderating effects were not found significant across public sector organisations. This kind of results could be due to the inherent nature of public sector organisations in India. These organisations follow a typical “baba” culture where ethical ways of functioning have not percolated in the system to that extent as they are in private sector organisations.

Motivation as related to passion: An equity perspective

Arvind Sinha Indian Institute of Technology, India

Author and associates discovered that social inequity may be perceived not only in terms of financial rewards, but anything that the person subjectively considers as rewarding, the nature of which may be related to personal values. An intense or frequent reinforcement of over-reward occurrences may lead to a strong inclination toward a self-defining activity that one likes or loves. Such an inclination has been termed in the literature as ‘passion’. Using the variables of social inequity and competence, the contribution of ‘over-rewarding’ inequity on effective organisationally relevant behaviour (with passion-nurturing outcomes as the reward) was investigated. The sample consisted of 100 senior undergraduates and 100 pass outs alumni of a technological university, and 80 professionals working in banks. Data analysis comprised interview data, exploratory factor analysis, and regression analysis. Results suggested that an ‘advantageous inequity’ arising out of a basic psychological need of relatedness to some (or a larger) cause, and a feeling of competence to make significant contributions to the profession and human-kind at large, may be related to passion. People getting a chance to nurture their passion with such perceived advantage are also likely to be better contributors to the organizationally and possibly socially relevant outcomes.

Exploring the incidents of ill-health among South African accountants

Monica Smith University of Pretoria, South Africa; Nicole Barkhuizen University of Pretoria, South Africa

Research over the past couple have years has shown that accountants are particularly prone to the adverse consequences of stressful work environments. Once an accountant is diagnosed as being burnt out their symptoms normally show as ill-health, such as depression and counterproductive work behaviour. As a result many accountants are leaving their profession to work in fields that seem to be less stressful. The main aim of this research is to determine ill-health (i.e. psychological and physical) of accountants. A quantitative research approach is followed in this study. A General Health Questionnaire is administered amongst accountants in South African organisations (N=2000). We anticipate that high levels of psychological and physical ill-health among the respondents. In addition we also expect that significant differences exist between the ill-health levels of accountants based on their demographic characteristics and lifestyle orientations. Accountants are a scarce skill in the South African context. Organisations cannot afford to lose these individuals because of a work environment that contribute to workplace stress and ill-health. Our research highlights the importance of addressing workplace stressors effectively to eliminate the adverse consequences thereof on accountants.
Job insecurity and its cross-domain effect on family satisfaction: The role of employees’ affective well-being and detachment
Beatrix Sara Open University of Catalonia, Spain; Amparo Caballer; Thomas Hoega
Labour market developments have important implications for employees’ job stability. Job insecurity is a work stressor associated with a large variety of negative outcomes. Research has dedicated a great amount of effort to examining these detrimental consequences of job insecurity. However, previous studies have mainly focused on the outcomes inside the work domain, and little attention has been paid to the spillover effects of job insecurity on variables in other life domains of employees. Likewise, little is known about the processes linking job insecurity and spillover outcomes. In the present paper, a moderated mediation model is proposed to explain the relationship between job insecurity and family satisfaction. Data were gathered from 556 employees working in different Spanish organisations from the services sector. The results showed that job insecurity was directly and negatively associated with family satisfaction and affective well-being. However, the relationship between job insecurity and affective well-being was moderated by psychological detachment. Job insecurity also affected family satisfaction indirectly via affective well-being and contingent on psychological detachment.

Impact of organisational justice and trust on organisational citizenship behaviour
Kailash Bihari Lal Srivastava Indian Institute of Technology, India
This paper examines the relationships among perceived organisational justice, trust, and the organisational citizenship behaviour (OCB) of managers in Indian organisations. The data were collected from 300 respondents from top, middle and lower managerial levels, belonging to the manufacturing and service sectors, and analysed using AMOS. It was hypothesised that the factors of organisational justice, namely procedural, distributive, and interactional justice, would be positively associated with trust in management and supervisors, which, in turn, would affect organisational citizenship behaviour, and that some of these relationships would differ across sector. The results indicate that the fit is acceptable for both the samples. The results showed the effect of distributive justice on trust (stronger in the services sector compared to the manufacturing sector), and the effect of procedural justice on trust (stronger in the manufacturing than the service sector). Interactional justice was positively associated with trust. The dimensions of organisational justice had a direct effect on OCB and trust was also positively related with OCB (stronger in the manufacturing than in the service sample), and trust also mediated the relationship between organisational justice and OCB. The results confirmed the mediating effects of the various dimensions of organisational justice on trust across sectors. These have implications for management to take appropriate action to improve trust among employees as well as interpersonal relationships, and to adopt different management policies to enhance the trust of employees in two types of organisations to foster extra-role behavior among managers.

Talent mindset of leaders in the South African aviation industry
Karel Stanz University of Pretoria, South Africa
The talent mindset of an organisation is a critical success factor which can enhance its capability in driving its strategic objectives. For some, the talent of the organisation may not yet have been defined in relation to the long term objectives whilst other organisations have defined talent but experience uncertainty around the linkage of the various talent management practices. The successful organisations are those that not only understand what core talent means to them, but how to leverage the talent in a manner that allows it to act decisively to drive competitive advantage as well as secure the future success of the organisation. These organisations generally embody a talent mindset. The main objective of this research was to determine the talent mindset of managers in the South African Aviation Industry. A quantitative research approach was followed in this research. A Talent Mindset Index was administered among a convenience sample of managers and Human Resource Management (HRM) practitioners (N= 150) in the aviation industry. The results showed that managers and HRM practitioners perceived that leaders had a low to fair leader mindset towards the application of talent management practices in the aviation industry. The determination of talent mindset will significantly influence how organisations approach the war for talent and the quest to build human capability within an organisation. Currently, there is limited research on talent mindset as a construct and this research will therefore add more to the knowledge available on the topic.

Sleep quality as a criterion of the efficacy of stress management interventions in a downsizing environment
Dominique Steiler Grenoble Ecole de Management, France; Marion Troussellier
A stress management programme using cardiac coherence was implemented in a downsizing environment. The study was conducted in nine voluntary workers in order to evaluate the programme’s efficiency. A baseline evaluation was conducted on psychological variables (anxiety, perceived stress, well-being and sleep), endocrine assessments (urinary cortisol excretion, alpha-amylase salivary concentrations), and physiological recordings (electro-encephalography for sleep quality and electro-cardiogram for heart rate variability). The same assessment was done at the end of the programme. The low number of participants was due to the intrusive approach in collecting physiological data. The results showed a decrease in perceived stress and a consequent increase in well-being. The subjective and objective sleep quality improved, namely, an increase in Rapid Eye Movement (REM) duration associated with a shift in the REM phases at the end of the night, was observed at the end of the training programme. For the entirety of the results, improvements were higher in subjects with high vs. low trait-anxiety scoring. The pattern of results for subjects prone to a high level of trait-anxiety suggested that stress and sleep are related to each other in a bi-directional way: increased anxiety is associated to poor sleep, and stress reduction improves both anxiety and sleep. On the basis of these results, we would suggest that trait-anxiety can be used as an indicator of which employees should be given priority for stress management intervention.

Optimism, self-efficacy and meaningfulness: Towards a salutogenic model of occupational well-being
Magdalena Steyn University of Stellenbosch, South Africa; Gina Gurgens-Ekermans
Set within the framework of Positive Organisational Scholarship (POS), this study conceptualised and tested a proposed structural salutogenic model of occupational well-being in order to explicate the influences of the positive psychological antecedents of optimism, self-efficacy, and meaningfulness on occupational well-being (defined by general psychological health and satisfaction with work life). A two-fold operationalisation of occupational well-being was used. First, the absence of pathology was measured with the General Health Questionnaire (GHQ-28). Secondly, a cognitive-judgmental evaluation of employees’ satisfaction with their work-life (adapted from the Satisfaction With Life Scale) was used. Optimism was measured with the Scheier and Carver (1985) Life Orientation Test (LOT), whilst self-efficacy was measured with the 17-item General Self-efficacy Scale (GSES). A two-fold conceptualisation of meaningfulness was warranted: Meaningfulness in work (defined as work engagement, measured with the Utrecht Work Engagement Scale) and meaningfulness at work (defined as organisational commitment, measured with the Organisational Commitment Questionnaire, OCQ). A non-experimental research design was used. A convenience sample of 202 individuals from three organisations across South Africa participated in the research. The goodness-of-fit results obtained for the structural model provided sufficient evidence that the model is supported by the data. The results suggested that optimism influences psychological health directly. The relationship between optimism and occupational well-being (i.e. psychological health) was further highlighted through an indirect causal effect, as mediated through a combination of work engagement and organisational commitment (i.e. meaningfulness). The structural model indicated no significant paths between self-efficacy and any of the other variables.

Psychological health of employees: Beyond concepts, the day to day management practices
France St-Hilaire Sherbrooke University, Canada; Jean-Pierre Brun
Although the influence of managers’ behaviour on employees’ psychological health at work (PHW) is widely acknowledged (eg: Westerlund et al., 2010), little is known on the specific practices involved, and their positive and negative influence on employees (Gilbreath & Benson, 2004). Despite the recent studies of Yarker et al. (2007) and Lewis et al. (2010) on management behaviors to reduce stress or the relationship between leadership and well-being (Nielsen et al., 2008), we still don’t know what is the concrete manifestation of competencies in relation to PHW. The aim of these studies
was less to identify concrete managers’ actions, the
day to day management practices, but rather to
identify which management competencies reduce
stress. Thus, the aim of the current investigation is
to identify and classify the concrete management
practices in link with PHW. Semi-structured inter-
views were conducted with 70 participants (em-
ployee and managers) in a Canadian public organi-
sation. A qualitative analysis was conducted
according to an inductive approach; the agreement
between two coders resulted in an adequate reliabil-
ity. We carried out a frequency analysis of the codes
and elaborated a taxonomy of the specific manage-
ment practices bonded with PHW. The results
showed large and varied practices (n = 55) within
which 5 were noted by more than 50% of the
participants. Seven hierarchical clusters of practices
emerged, of those, the cluster of relational practices
appeared particularly decisive. Finally, a gap was
observed between managers’ and employees’ per-
ception about the most decisive management prac-
tices. Theoretical and intervention implications will
be discussed.

**Predictors of employees’ organizational com-
mitment**

Shanti Suman Pandit Deendayal Petroleum Univ,
India

The study examines the relative effect of various
personal and organizational characteristics on
employees’ organizational commitment (OC). A
sample of 240 employees were administered the
three psychometric tools namely, the ‘Organization-
al Commitment Questionnaire’, the ‘Job Character-
istics Scale’, and the ‘Organizational Structure
Scale’. The participants’ age ranged from 23 years
to 58 years with an average of 39.35 years (SD =
9.89). The participants on average possessed the
work experience of 13.33 years (SD = 9.09). The results
obtained by using multiple linear regression (simultaneous)
analysis revealed that perceived job characteristics
was the most dominant predictor of OC followed by
perceived organizational structure, locus of control,
tenure and age. However, the contribution of age
and tenure was not found to be statistically signif-
cant. Findings of the study suggest that organiza-
tional characteristics are more important than
personal characteristics in order to predict the OC of
employees.

**Workplace incivility: Scale development and
its relationship with turnover intention**

James J-M Su Renmin University of China, China;
Jiangmin Du; Jian-Min Sun

This paper reported two studies aimed at the mea-
surement of workplace incivility and its relationship
with work attitude in Chinese organizations. We
collected workplace incivility phenomena by in-
depth interview with 25 human resource profes-
sionals and employees from manufacturing and ser-
vice industries. Combined with the items from west-
ern developed scales, a questionnaire with 40 items
was constructed. Four factors were found from exploratory
factor analysis with 250 respondents and the factors were named as work-related incivility
(Cronbach’s α = .835), supervisor/leader incivility
(α = .724), environmental incivility (α = .716), and interpersonal incivility (α = .696), respectively. The
scale has 18 items and Cronbach α is .846. Conver-
gent validity with Contina’s WIS (2001) was also
conducted. A questionnaire including the scale and
demographic information was distributed to 300
employees in four companies. 189 valid question-
naires were used for ANOVA and correlation anal-
ysis. Results demonstrated that there is no signifi-
cant difference in the perception of workplace
incivility among gender, education level, and mar-
rriage status. Respondents aged under 25 perceive
more interpersonal incivility than other age groups.
Respondents from private companies perceive more
work-related incivility and supervisor/leader incivil-
ity than those from state-owned companies.

Workplace incivility is highly correlated with turn-
over intention (r = .267, p < .01). Implications and lim-
itations of the study as well as future research
directions are discussed.

**The influence of interpersonal relationships
on job characteristics and employee well-
being**

Suresh Sundaram Annamalai University, India

Interpersonal relationships are regarded as an im-
portant component of the psychosocial working
conditions. Individuals with excellent interpersonal
relationships rise to the top in their personal effec-
tiveness and organisational growth. Interpersonal
skills enable employees to interact successfully
within the changing and challenging workplace
environment. The major objective of this study was
to investigate the influence of interpersonal relation-
ships on job characteristics and employee well-be-
ing. This study adopts a survey design. The data
was collected from the 120 employees of three
different private organizations. Results indicate that
positive relationships with others had significantly
influenced the job characteristics and employee
well-being. The results were discussed, including
directions for future research, and practical implica-
tions drawn from the research were suggested.

**The structure of counter-productive work
behaviours in Chinese organisations: Dimen-
sionality and features**

Hanying Tang Central China Norm University, China

Counterproductive work behavior (CWB) consists of
behaviors that harm or intend to harm organisa-
tional or others’ (e.g. colleague and supervisor)
legitimate interests. Research on CWB in Western
countries has a history of several decades. However,
the studies of CWB in mainland China have just
started in these recent years. The main purpose of
this study is to investigate the types and features
of CWB in the context of Chinese culture. Several
methods were adopted to collect the CWB in Chi-
inese organisations, including depth interviews, lit-
erature reviews and questionnaire surveys. After
that, item analysis, factor analysis and descriptive
statistics were used to reveal the structure of Chi-
inese employees’ CWB. The subjects were 638
Chinese employees from various professions. The
results indicated that Chinese employees’ CWB had
two high-order factors, interpersonal CWB and or-
ganizational CWB. Interpersonal CWB referred to
interpersonal destruction. Organisational CWB con-
stituted of unconsidered, hindering and idle work
behaviours. This four factor structure is similar to
the structure of Western CWB (Spector et al., 2006.)
Specifically, interpersonal destruction is sim-
ilar to abuse against others; unconcern with work
and hindrance to work are similar to production
deviance and sabotage; idle behaviour is similar
to withdrawn. Different from Western countries,
the incidence of interpersonal destruction was lower
than the other three types of CWB in Chinese
organisations. In other words, Chinese employees’
CWB showed more confrontation to their organisa-
tions, but not people. A possible reason is that
Chinese people pay more attention to interpersonal
harmony and group solidarity.

**Team coordination: Scale development and
validation**

Ningyu Tang Shanghai Jiaotong University, China;
Chen Zhuang

Coordination has become an important topic in
understanding team effectiveness (Wittenbaum,
1996; Rico et al, 2008; Kolbe et al, 2009). Howev-
er, there are very few studies on the scale develop-
ment of team coordination. This paper aims to
develop a scale to measure team coordination which
is defined as “integrating and aligning behaviours
among team members in order to accomplish team
goals.” Study 1 interviewed 15 professionals to
investigate how team members coordinated to attain
the team goal. It showed that teams used regular
meetings, face-to-face talks, and emails, as explicit
ways to work with others, and would adjust them-
selves to others’ demands and behaviour, which
revealed the implicit way. Based on the findings
of study 1, study 2 constructed the team coordina-
tion questionnaire with 15 questions and invited
101 MBA students to complete the questionnaire.
3 questions with low reliability didn’t fit the ques-
tionnaire very well and were therefore deleted. The
12-item questionnaire consists of questions for ex-
plicit and implicit information and action. Study 3
tested the construct validity of the scale developed
in study 2, 229 employees (117 male and 112 female)
from 38 teams in joint ventures in Shanghai
participated in the study. EFA showed that 4 factors
explained 67.446% of the total variance and CFA
showed that the scale had good construct validity.
(χ2 = 451.60, df = 164; NNFI = 0.95, CFI = 0.95,
RMSEA = 0.088).

**Company media publicity and quality of
website design: Effects on potential appli-
cants**

Klaus J Templer SIM University, Singapore

The aim of this study was to investigate the effects
of company media publicity and quality of company
website design on the organisational attractive-
ness perceptions of potential job applicants. One-
hundred eighty potential applicants participated in
an experiment with a 3 x 2 factorial design. Parti-
cipants were first exposed to a newspaper article
about a company that either projected a positive,
natural, or negative image of the company. Subse-
sequently, they accessed the company’s website, in-
cluding a webpage with job advertisements. The
website was either well or poorly designed. Results
showed that positive media publicity as well as
high-quality web design were related to higher
perceived organisational attractiveness. Moreover,
The development of a talent retention diagnostic tool
Marguerite Theron University of Pretoria, South Africa

It remains a reality that talented, knowledgeable and skilled employees voluntarily resign from their current employers. When these top-performing employees go, they can leave behind them a gap which is costly to fill and challenging to manage. There is currently limited organisational data available on the reasons employees choose to stay. In addition, some researchers caution that employee retention rates are not accurately measured or are assumed to be the inverse of employee retention rates. The main objective of this research is to develop a talent retention diagnostic tool that can assist organisations in the early identification of avoidable voluntary turnover. A mixed method research approach was followed in this research using a combination of qualitative and quantitative data analysis techniques. A Talent Retention questionnaire was developed based on a thorough literature review and interviews with subject matter experts. The questionnaire was further administered among a stratified random sample of employees in a large South African multi-national company. Preliminary results show that compensation, recognition, supervisor and managerial relationships are some of the main factors impacting employee’s decision to stay with the organisation. In addition, the Talent Retention Diagnostic Tool showed high validity and reliability as a measurement of talent retention. The fact that there are no definitive answers available academically implies that turnover and retention research continues to be a worthwhile academic topic to pursue and retention of key, top performing employees remains an essential, practical goal of effective organisations.

The mediation effect of PsyCap between misfit and burnout
Jiajin Tong UC Berkeley, United States of America; Lei Wang UC Berkeley, United States of America

This study explored the psychological mechanisms explaining the impact of person-environment fit on burnout. Three psychological variables (i.e., perceived role conflicts, organisation-based self-esteem, PsyCap) were examined as possible psychological mechanisms from the environmental processing, interactionist processing, and self processing meta-theories. A total of 199 employees from a Chinese organisation with a diverse of departments participated in this research. Person-organisation and person-job fit, psychological variables, and burnout were measured in Time 1 with three waves each separated by three weeks. A total of 96 employees were also investigated on burnout in Time 2 with an interval of 8 months. Results supported our hypothesised model indicating the psychological mechanisms in burnout from above three meta-theories. Different misfit intends to induce different burnout dimensions by different psychological mechanisms. It was found that high person-organisation fit helped to reduce exhaustion, which was mediated by perceived role conflicts (i.e., the environmental processing theory); high person-job fit helped to reduce exhaustion and cynicism, which was mediated by organisation-based self-esteem (i.e., the self processing theory); and high person-job fit helped to reduce cynicism and inefficacy, which was mediated by PsyCap (i.e., the interactionist processing theory). However, only the relationship between person-job fit and exhaustion and cynicism mediating by organisation-based self-esteem was found stable in terms of 8 months. It may be the most effective way to reduce job burnout by enhancing employees’ organisation-based self-esteem. The implications for theory and practice were discussed.

Feeling fair and being satisfied: Effect of organisational justice on job satisfaction and the mediation of quality of work life
Abhishek Totawar Indian Institute of Management, India; Ranjeet Nambudiri Indian Institute of Management, India

Recognizing that the perception of fairness influences the level of satisfaction, we propose that quality of work life (QWL) mediates the effect of organisational justice on job satisfaction. Extant literature describes the relationship in dyadic pairs between justice-QWL and justice-satisfaction, but no published literature talks about a combined interplay between these three variables. Delineating this lacuna, we have explored such linkages in the present study. Data was collected from 204 managerial employees employed in three different public sector units located across India. Five factors of QWL have been identified. Baron and Kenny’s (1986) causal step approach was used to check for the mediation effect. Results confirmed the role of QWL (β=0.776; p<.05) as a mediator in the relationship between organizational justice (β=−0.048; p=n.s.) and job satisfaction. Complementing this approach of mediation tests, the Sobel test also confirmed the same (Sobel test statistic=9.755; p<.05). The results are discussed in light of available literature and future directions are suggested. This study contributes to the theory by providing a more nuanced understanding of how perceptions about organizational justice, through QWL, affect job satisfaction. As a modest recommendation to managers, the study suggests that a sense of satisfaction for an employee can be brought about only when components of justice and QWL are holistically addressed.

Dynamics of knowledge management in knowledge-intensive organisations: Role of leadership, trust and culture
Nachiketa Tripathi I.I.T. Guwahati, India; Mamta Tripathi I.I.T. Guwahati, India

The past five decades have witnessed substantial scientific research on Knowledge Management (KM). Still it is a highly-debated topic with much confusion. The objective of this paper is to look into some of those gaps by providing a comprehensive view and integrate the variables. Literature review reveals that various studies in this field have been criticised for not clearly defining the concept of KM and for poor research design, so authors suggest a more methodological investigation at empirical level. Although several studies in this area have proposed information technology as the soul of KM, this paper departs from that line by focusing on other potential relevant variables like Leadership, Trust and Culture, on the premise that technology itself is one enabler, not KM per se. This paper used a survey-based study across knowledge-driven organisations. To support it, authors postulate a framework to understand the relationships between these variables as past researches have not incorporated them together. Previous researches emphasised on leadership styles only; surprisingly few studies have addressed leadership in terms of Influence Process and Social Power in the context of KM. Therefore, addressing them will yield more accurate information about leadership and KM. Literature points out that success of KM initiatives depends on knowledge sharing and certain kind of culture. Knowledge sharing is influenced by a knowledge sharing environment and trust among workers. Therefore examining trust and culture is imperative. Moreover, the present paper will emphasise the implications of present research for the knowledge-intensive organisations.

Participative decision making as a buffering resource of the daily stressor-strain relationship
Sarah Turgut University of Heidelberg, Germany; Karthein Sonntag; Alexandra Michel I.I.T. Guwahati, India; Karthein Sonntag; Alexandra Michel

A large body of research found evidence for negative effects of stress at work on employees’ well-being and organisations’ success (Semmer, McGrath, & Bech, 2005; Sonntag, Stegmaier, & Spellenberg, 2010; Taris & Schewe, 2009). Where-as the influence of stress on well-being has been predominantly examined retrospectively, to our knowledge the relationship between anticipated stress and its effect on well-being has only rarely been investigated. The aim of the present study is to scrutinise the effect of anticipated stress on well-being. Furthermore, we are extending previous research by investigating the moderating role of an organisational resource, namely participative decision making (PDM), on the daily stressor-strain relationship. Based on the Conservation of Resources Theory (Hobfoll, 1998) a negative relationship between anticipated stress in the morning and well-being in the evening was postulated. Secondly, it was hypothesised that PDM moderates the relationship of anticipated stress and well-being. To test these assumptions a diary study (N = 107) was conducted on five consecutive working days. As hypothesised, multilevel analyses supported a negative relationship between anticipated stress in the morning and well-being in the evening. Furthermore, PDM could be confirmed as a significant moderator of this relationship. The present study highlights the relevance of anticipated stress which is sufficient to negatively impact employees’ well-being. In order to improve occupational health promotion we recommend training and coaching on an
The work-family-conflict in retail: A mediation-effect between working conditions and employees’ health
Christine Unterrainer University of Innsbruck, Austria; Anna Iwanowa

The retail sector is characterised by excessively increasing competition. To be successful, it is of utmost importance to improve the working conditions (Ulrich, 2006; Lissabon Declaration of the European Commission, 2002) not only for the company’s efficacy but also for employees’ health and well-being. The presented study questions how working conditions in retail (work-related stressors and resources) impact workers’ health considering the work-to-family-conflict as a mediator. By a cross-sectional questionnaire design, we examined 760 salespersons in Austria and Italy. Working conditions (stressors and resources) were surveyed with a measure that is based on Hackman & Oldham’s redemption of work (1974) and on the “Tätigkeitsbewertungssystem” (Hacker, Iwanowa & Richter, 1983). We measured work-family-conflict with Iwanowa’s (2006) German work-to-family-conflict scale (according to Carlson, Kaemr, & Williams, 2000; Kalveram, 2006). The indicators of psychosomatic complaints (Iwanowa, 2007) were used to examine the mental and physical health. Reliabilities for multi-item scales (Cronbach’s α) ranged between .746 and .892. CFA analyses corroborate the factor-structure of the applied measures. The computed SEM analyses confirmed the hypothesised partial mediation-effect of work-to-family-conflict on the relationship between working conditions and employees’ health. Work-related stressors impair employees’ well-being directly and indirectly through a higher perceived work-family-conflict. Work-related resources lower employees’ work-family-conflict that in turn impacts their health positively. Additionally, the resources directly improve employees’ well-being.

The differential impact of job resources and organisational identification on dedication, absorption, and vigour components of work engagement
Marshall Valencia University of Nottingham, Malaysia

Work engagement has been operationalised as the Sense of Organisational Identity (SOI) (clear versus operationalised as perception of potential for career growth in the company) would lead to engagement, and this engagement will be more driven by job resources that are oriented towards personal gain. Survey data was gathered from 168 factory workers in the Philippines. Job resources identified from past studies were examined as predictors of work engagement. Regression analysis indicated that trust in management, support from supervisor, role clarity, voice, and job challenge were significant predictors of work engagement. Perception of career growth was tested as a moderator between engagement and the various job resources considered. Findings indicated that perception of career growth moderates the impact of supervisor support and trust in management on work engagement. It was concluded that work engagement of factory workers who perceive career growth are more likely driven by job resources that were potentially beneficial to their underlying striving for social mobility. The study showed how a social identity perspective could enrich the dominant job demands-resources model in understanding of work engagement.

Alleviating the apprentice skills shortage in South Africa through creating awareness and lifting standards of selection
Gerda Van Der Merwe SHL South Africa, South Africa

With South Africa facing skills scarcities in various industries, the shortage of skilled artisans is a critical issue and one that impacts on the economic growth of the country (Solidarity, 2010). In 2008 it was reported that South Africa had a 40% shortage of qualified artisans, making trade positions some of the most difficult positions to fill (Solidarity, 2008). In February 2011 the South African Government announced a target of training 50,000 artisans by 2014/15 (South African Government Information, National Skills Accord, July 2011). Initiatives planned to alleviate the shortage will include creating awareness, promoting positive attitudes towards trades, and adequate training. However, the drive to reduce the shortage of apprentices is no longer simply a government initiative; privatised organisations will have to take responsibility as well and devise strategies in order to create learnership opportunities for both young and old to gain entry into the South African employment market. A concern facing South African organisations in this is whether the calibre of candidates they attract and employ is of the right standard to alleviate this problem. This presentation will explore the quality of apprenticeship applicants to several organisations in the mining, steel and motor manufacturing industries in South Africa. By examining different selection approaches followed by organisations, benchmarking candidates against relevant South African applicant pools, and investigating how assessment tools used in the selection process relate to training success, observations and recommendations will be made concerning selection practices to help organisations produce higher calibre artisans in the future.

A measurement model for the sense of organisation identity
Christian Van Tonder Curtin University, Australia; Tadayuki Miyamoto

Since Albert and Whetten’s (1985) seminal paper, organisation identity (OI) has become a widely ‘traded’ construct in several disciplines and more recently in Organisation Psychology. While the mainstream literature recognises the importance and relevance of OI, it also acknowledges the conceptual challenges associated with an abstract and ambiguous construct – not amenable to simple definition. These challenges have been evidenced in divergent intellectual traditions about the identity of the organisation, but in particular in the paucity of empirical research on the construct. During the past decade Organisation Identity Theory (OIT – Van Tonder, 1999) served as a guiding framework for several empirical studies that explored the definitional parameters of the OI construct – most commonly operationalised as the Sense of Organisational Identity (SOI). While substantial consistency were observed in findings across studies, dissimilar foci, methodologies (quantitative, qualitative and mixed methods designs) and samples precluded comparison and robust conclusions about the SOI. The current study set about to examine the empirical validity of conceptualising the SOI as a stand-alone [context-free] formative construct. The previously-used SOI questionnaire (operationalisation of the SOI construct) was administered on two occasions to an effective sample of 491 employees from a diverse group of organisations. The derived structural model and goodness of fit indices (robust method, CFI=1.00, RMSEA=.00), provide empirical support for the operationalisation of the SOI (clear versus diffused or uncertain) as a composite of the degree of organisational uniqueness, solidarity and enduring characteristics. The implications of the findings for research and application are discussed.

Employees’ affective experience of organisational change
Christian Van Tonder Curtin University, Australia; Tadayuki Miyamoto

Organisational change remains a central managerial and organisation-psychological concern because of
the high failure rates reported (65% to 75%) and the debilitating consequences of this for organisations and employees (Van Tonder 2009). The absence of a robust measurement orientation with regard to change and its impact (cf. Burns, 2003; Hacker & Washington, 2004; Kohler et al., 2006), but also inadequate knowledge of how change is experienced and responded to at the individual level, and how this informs organisation-level change (George & Jones, 2001; Judge, Thoresen, Puck & Wimbush, 1999), significantly constrain effective intervention. Indeed, many failed change efforts can be attributed to a limited appreciation of the individual employee’s cognitive and affective experience of the change (Kavanagh & Ashkanasy, 2006). The current study consequently investigated the impact of employees’ affective experience of change on their (self-reported) psychosocial well-being and energy / fatigue levels during the change. Data were obtained from a diverse sample of 486 employees (different companies) and the relatedness of the individual employee’s affective experience of change, psychosocial well-being, and energy/fatigue levels investigated, using SEM. Findings indicate that psychosocial well-being is primarily influenced by fear and nervousness – a consequence of the nature (type) of the change. Change management effectiveness performed a minimal role, influencing negative affect (anger, sadness) and meaningfully impacting on positive affect. The latter, however, had no impact on well-being and only a marginal influence on energy levels during change. The importance of these findings and their implications are briefly considered.

Migrant adaptation and assimilation of host country culture: Initial observations from a South African cohort

Christian Van Tonder Curtin University, Australia; Werner Soontiens; Johann Groenewald

Developed economies are increasingly relying on an influx of trained and experienced migrants to achieve growth and overcome skills shortages. Usually the focus is on mature, experienced migrants in order to achieve an instant contribution (e.g. productivity) - often involving roles for migrants that may include management functions and/or roles. Employer expectations however remain largely ignorant of the daunting nature of the migration exercise, in particular the migrant’s adjustment to the host culture and challenges to their individual identity and values. As part of a comprehensive study probing the comparative antecedents and drivers of accelerated migrant adjustment (hailing from China, India, South Africa, United Kingdom and Singapore), this paper reports initial observations for the South African respondent group. Narrative obtained from semi-structured interviews with 26 South African migrants who have settled in Australia, generated rich data which were subjected to basic content analysis. Themes extracted revealed migrant employees’ perceptions, feelings and experiences of the host country culture at various stages since arriving in the host country. Apart from approximating the general adaptation syndrome the probing of the migrant experience indicate several sources (factors) of stability and adjustment that aided and constrained cultural assimilation and adjustment. Though preliminary, the observations have significant implications for the wellbeing of migrants, their pace of adjustment to the host culture, their functioning in the workplace and in terms of institutional and managerial support policies and practices.

Stories that leaders tell during organisational change: The search for meaning during large scale transformations

Dieter Veldsman University of South Africa, South Africa; Michelle May

The knowledge economy demands the re-evaluation of theentrepreneurial business practices that have dictated and sustained past organisational successes in an attempt to remain competitive in a hyper-turbulent environment. Change has become the norm as organisations aim to manage the organisational pillars of people, process and technology to build a flexible and agile business. Leadership, as the drivers of the change process, has been criticised due to a lack of change competence and the ability to manage meaningful change on behalf of their employees. The purpose of this research will be to explore leadership stories during a large-scale organisational change process as leaders aim to navigate and find meaning for their people during the change process. The research utilised a qualitative research design with the use of narrative analysis to explore multiple leadership stories collected from a single case study. Thematic network analysis was used to explore the categorical themes of significance (the why of the change), simplicity (the end-state of the change), opportunity (the people within the change) and the future (the change vision) as obtained from the leadership dialogue. The research findings provides change leaders with a frame of reference for navigating change journeys via the use of organisational stories and explores current leadership practices which contribute to the high rates of failure associated with current change navigation efforts within organisations. The study contributes to the field of IO Psychology as it explores change leadership theory and organisational storytelling as a vehicle for creating meaningful change during organisational transformation.

Imaging the living organisation: In search of a truer means to portray organisational functioning and dynamics

Theo Veldsman University of Johannesburg, South Africa

Organisational diagnosis is an essential and crucial tool in the armoury of the Work Psychologist to understand the organisational functioning and dynamics of an organisation. Insights gained through organisational diagnosis form the basis of identifying and crafting the necessary organisational interventions to enhance the efficiency and/or effectiveness of the organisation, in the present and future. It is hence critical that the organisational diagnosis methodology applied, is able to provide a true image of the real organisational functioning and dynamics in all of its richness and complexity. The intention of the paper is to argue that the widely applied, conventional organisational diagnosis falls short of portraying the real organisation. This results in oversimplified and impoverished portrayal of the true organisation. Typically conventional organisational diagnosis is based on a mechanistic (or Newtonian) or systems (or cybernetic) reality perspective of the organisation.

The paper sets out to propose a different organisational diagnosis methodology, called lattice organisational diagnosis, from a chaos/complexity reality perspective. The metaphor of a lattice is eminently suitable to portray multi-dimensional interdependencies, interactions and patterns truer to the organisation as a living entity. The following topics are covered: conventional organisational diagnosis based a mechanistic or systems reality perspective of the organisation is critiqued; the design specifications for an organisation diagnosis methodology framed within a chaos/complexity reality perspective are explicated; and a proposed chaos/complexity, referenced organisational diagnosis methodology, called lattice organisational diagnosis, is discussed.

Leading and managing innovative work behaviour: A multilevel test among international firms

Robert Verburg Delft University of Technology, Netherlands; Deanne Den Hartog

We aim to contribute to current understanding of the effects of employment practices and leadership styles on employee innovative behaviour, and to contribute to the theoretical knowledge of how employment practices affect innovativeness by testing the moderating role of work engagement, task characteristics and creative team environment. In a multi-source, multilevel survey study among 80 dyads of employees and managers of different technology firms in multiple countries, we tested how both manager rated and perceived employment practices, as well as leadership styles relate to organisationally relevant outcomes, such as task performance, innovative work behaviour and unit performance. Hierarchical linear modelling was used to test the model. Analyses show a direct relationship between manager rated employment practices and unit performance. Also, employees perceived employment practices mediated the relationship between manager rated employment practices, and innovative work behaviour. In addition, task characteristics moderated the relationship between leadership styles and innovative work behaviour. Innovation involves both the generation and implementation of ideas. As such, it requires a wide variety of behaviours on the part of individual employees. While some people might exhibit all the behaviours involved in innovation, others may exhibit only one or a few types of behaviour. The current study shows the complexity of managing individual innovation processes. The study has several strengths, including the use of different rater sources and the multi-level nature of the study. Limitations include the mixed sample of dyads and the cross-sectional nature of the design.

Taking care of older workers

Klaske Veth Hanze University Groningen, Netherlands

The aim of the study to be presented was to construct an overview of, first, the prevalence of HRM practices which are used in health care organisations to retain older workers vitality at work, second, the wishes and needs that exist with regard to these practices in three target groups: Older workers, line managers and HR professionals, and third, the assessments of existing practices by these three categories of organisation members. As an overarching model for describing the practices and the
corresponding wishes, needs and assessments, the Job Demands-Resources model (Bakker et al., 2007) was used. In this model employee vitality is linked with, on the one hand, demands associated with jobs and, on the other hand, resources available for job holders. The whole of HRM practices can, accordingly, be split up in those practices that are intended to redress job demands (maintenance practices) and those practices that are intended to create job resources (development practices). 51 interviews were conducted in 15 hospitals and care and cure organisations. The results showed that maintenance HRM practices are far more prevalent than development practices are. Wishes pertained, though, equally to maintenance and development practices. Both existing maintenance practices and existing development practices tended to be assessed as being rather successful. In the presentation of the study details of these research outcomes will be provided; a list of the deployed HRM practices that were put forward by the interviewees together with the assessments of those practices, and a list of wished practices.

Sense of coherence, self-efficacy and job performance in the recruitment industry
Rian Viviers University of South Africa, South Africa; Calum McComb

The aim of the research was to investigate the relationship of positive psychology constructs and job performance in a group of recruitment consultants. The study was conducted in the South African recruitment industry, which is currently characterised by high levels of competition and stress as a result of socio-political and economic factors. An exploratory non-experimental field study was conducted. The population from which the sample was drawn comprised 152 recruitment consultants, all from one national recruitment organisation. 132 employees responded to the questionnaire, while 15 valid sets of performance data could finally be used. Three instruments were used to collect the data. The orientation to life questionnaire (OLQ) (Antonovsky, 1987) was used to measure sense of coherence, the generalised self-efficacy scale (Schwarzer & Jerusalem, 1995) self-efficacy and a performance appraisal measuring four key performance indicators (internality developed by the organisation) to measure job performance. A biographical questionnaire was also administered. No relationships were found between sense of coherence, self-efficacy and job performance, however, the comprehensibility component of sense of coherence demonstrated a statistically significant relationship to job performance and to two of its dimensions, namely, customer service and productivity. Stepwise regression analyses indicated that comprehensibility contributed significantly to variance in total job performance scores, and the addition of meaningfulness to the model increased variance in total job performance further. Statistically significant differences between age, gender, job type and length of service groups emerged for several of the variables measured.

The appreciative core of transformational leadership
Veena Vohra SBM, NMIMS, India

The rapid rate of change worldwide has focused attention on the provision of effective leadership for sustained organisational performance. The transformational leadership model developed by Bass (1985) seems to be a more appropriate model of leadership for environments in flux, such as the Indian business scenario. Of late, a new way to look at leadership in this complex environment has emerged consisting of two common strands: what leaders actually do, and the leader’s impact on followers and their subsequent ability to perform. Studying the appreciative inquiry (AI) behaviours of leaders may be able to provide a lens to understand effective leadership in the context of dealing with change at an organisational level, as AI reflects a set of principles (Srivastva and Cooperrider, 1990) recognising the basic connect-edness of life and provides opportunities for the creation of relationally generated meaning and organisational practice. A comprehensive review of the literature from the fields of leadership and appreciative inquiry was undertaken to examine the elements of transformational leadership through the lens of the appreciative inquiry approach. The findings of the study indicate that leaders with transformational leadership behaviours may have an appreciative core which enables them to be more effective in times of managing change. Empirical testing of the findings may provide an entirely new aspect to current leadership development programs of industry. Since India is currently facing fast-paced change this study could provide a fresh look at the design and content of leadership development in similar emerging economies across the world.

The perceived impact of bullying on an individual’s well-being
Carmen Volkwyn University of the Witwatersrand, South Africa; Colleen Bernstein

Workplace bullying can be defined as a situation where one or more individuals persistently find themselves to be on the receiving end of negative behaviors over a period of time. Bullying has adverse consequences on an individual’s mental and physical health and well-being, with psychological effects including symptoms consistent with stress, anxiety, aggression and depression. Bullying thus negatively impacts the organization by producing unhappy, unproductive and inefficient employees, consequently making the organization less effective. Using a qualitative design, this study explored the perceptions and interpretations of bullying in the workplace by conducting a set of in-depth interviews with seven South African employees who have experienced first-hand bullying. Data was analyzed using thematic content analysis. Ten themes emerged within three focus areas namely, the attribution of the bullying, outcomes of the bullying and coping mechanisms. These focus areas, along with the identified themes, are discussed within the context of the literature in order to gauge the participants’ perceived individual experiences of being bullied.

Exploring psychological profiles of leaders across five major industries in South Africa
Paul Vorster Jopie Van Rooyen and Partners, South Africa; Renate Scherrer

When considering the aspects of leadership style, we often look at interpersonal behaviours and perceived patterns of decision-making that create effective leaders. But it is also necessary to consider dysfunctional workplace behaviours and the extent to which leaders have dispositions that run contrary to occupational adjustment and well-being. In addition, a leader’s values will shape their life philosophy, and influence their choice in friends, job and career. These underlying values are seen as motivators for behaviour. Values in organisations are often reflected as an organisational culture, and individuals will be attracted to organisations that appear to epitomise their values. This symposium explores the hypothesis that different types of leaders would be attracted to different industries, and would display different patterns of normal person-ality functioning, derailing behaviours and values. We used the results from the Hogan Personality Inventory (HPI), Hogan Development Survey (HDS), and Motives, Values, Preferences inventory (MVPI) to compare personality traits, values and assess the psychological profiles of leaders across five different industries (N=913 for HPI; N=732 for HDS; N=936 for MVPI), namely Information and Communication Technology, Finance, Energy, Mining, and Education. We ran one-way ANOVAs to test for mean differences across industry type and found statistically significant effects on five of the personality indicators, four of the derailers, and eight of the values. Interesting patterns in personality traits and motivators emerged when we inspected the individual contracts across industry. We will discuss the findings with the implications for different industries in mind.

The psychological contract of new health graduates
Arlene Walker Deakin University, Australia; Lisa Pang; Christie Fullarton; Melissa Yong

Psychological contracts are the perceived mutual obligations between employees and employers that determine the nature of the employment relationship. Employees form expectations about the employment relationship that lead them to believe that certain actions will be reciprocated by their employer, this comprises their psychological contract. The transition and integration experiences of health graduates have not been explored in psychological contract research. In addition, most researchers have focused on the employee perspective of the psychological contract and have largely neglected the employer perspective. The aim of this study was to qualitatively examine the psychological contract of health graduates by considering both the employee and employer perspectives. A total of 46 participants, of whom 41 were health graduates and five were organisational representatives, participated in the study. Critical incident technique was used to collect the data via interviews. Content analysis, using language markers for categories of coding, provided evidence that a psychological contract existed between the health graduates and their employer. A thematic analysis was then conducted to identify the specific employee and employers expectations and/or obligations that comprised the psychological contract between health graduates and their employer. Both relational and transactional expectations/obligations were identified. Generally, the health graduates and the organisational representatives agreed on what the expectations/obligations of each party were in relation to the
The psychological contract of women during the maternity journey

Arlene Walker, Deskin University, Australia; Lucy Zinkiewicz; Susan Nheng; Amy Cartledge; Hannah Berman

Psychological contracts are the perceived mutual obligations between employees and employers that determine the nature of the employment relationship. Employees form expectations about the employment relationship that lead them to believe that certain actions will be reciprocated by their employer, this comprises their psychological contract. While it is believed that employees can simultaneously develop multiple psychological contracts, research examining these different types of psychological contracts is scarce. The aim of this study was to qualitatively examine the psychological contract of female employees during their maternity journey by exploring the employees’ expectations/obligations of themselves and their employer using semi-structured interviews. The participant sample were 19 female employees from a regional hospital’s Allied Health Department in Victoria, Australia, who were either about to commence maternity leave, were currently on maternity leave, or who had recently returned to work from maternity leave. A content analysis provided evidence that a psychological contract existed for the women through language markers that either demonstrated explicit and implicit expectations/obligations or reciprocation between the women and their employer. A thematic analysis identified the content of the psychological contract of these women during their maternity journey in terms of employer and employee expectations/obligations. Employee expectations/obligations related to communication, responsibility, honesty and maintaining work performance, while employer expectations/obligations related to a secure job position, abiding by the award, organisational planning, flexibility and negotiation of work conditions. Implications of these findings for psychological contract research are explored.

An investigation of work values and participation in continuing learning among employees in Hong Kong

Yung Wong, Claire; Hong Kong; Winton Au; Emily Ho

In order to encourage its citizens to participate in continuing learning, the Hong Kong government established the Continuing Learning Fund (CEF) to provide financial aid for those who desire to enhance their competitiveness. Our study attempts to investigate the impact of work values on Hong Kong employees’ participation in, and attitudes towards continuing learning. Phone surveys were successfully conducted through random sampling of households to interview 1001 full-time employees aged 18 or over, which covered all major industries and occupations in Hong Kong. The survey includes three parts: (a) Perceived importance of four dimensions of work values, namely, situational factor, self-expression, behaviour control and quality of life (Hendrix & Super, 1968), (b) work value congruence between the employees and their organization on each of the four dimensions, and (c) participation in work-related and work-unrelated continued learning. Research results indicate that participation in continuing learning differed significantly among demographic groups. For example, older participants reported lower participation in continued learning in the past twelve months. There are also significant differences in the patterns of work value congruence. We also found interaction effects between work value congruence and importance. For example, employees who reported stronger work value congruence in behaviour control participated significantly more in work-unrelated continued learning if they perceived behaviour control as important. However, no significant differences were found among those with weak work value congruence. In conclusion, we found that work value congruence and importance have meaningful effects on continuing learning.

Is a destructive leader a black sheep in an organisation? Research on destructive leadership in the context of Chinese organizations

Biying Wang, Jiangxi Normal University, China; Riguang Gao, Jiangxi Normal University, China

In recent years, Western academic research had paid great attention to destructive leadership research, but only several empirical studies had occurred in Chinese academic research. In order to examine the effects of destructive leadership behaviors in the context of Chinese organisation, we collected data from an employee-supervisor matched sample (N=219) with a questionnaire survey. The results showed that the measure of destructive leadership from Western academic research was fit for the Chinese organisational context, and more significant destructive leadership behaviours occurred in China than those in Western organisations. The results of regression analysis also showed that full mediation of organisational justice existed in the effects of destructive leadership on contextual performance and affective commitment, and partial mediation of organization justice existed in the effects of destructive leadership on task performance. According to the above results, familialism culture and the dominant position of supervisors in workplace are perhaps the important influencing factors of destructive leadership behaviour, and therefore, human resource management practitioners should take measures to decrease destructive leadership behaviors in organizations so that employees’ organisational injustice are reduced and the corresponding negative effects of destructive leadership behaviors are avoided to the greatest degree. In addition, improving employees’ organisational justice could also diminish the negative effects of destructive leadership behaviour on affective commitment, task performance and contextual performance.

Servant leadership: Measurement and its effects on employee’s attitudes

Biying Wang, Jiangxi Normal University, China; Riguang Gao, Jiangxi Normal University, China

Servant leadership was the major leadership style called and practised by Chinese. The practice of servant leadership was also effective in Western countries. As far as theoretical research was concerned, servant leadership in Western countries began from the 20th century 70 years, and had produced several corresponding measures at present. Revising the Western servant leadership measure was important for enriching and developing servant leadership theory in China. This research collected data from two samples of Chinese enterprises (N(1)=250, N(2)=366) to verify one of the Western measures (Liden et al., 2008) in the context of China and explore its effects on employee’s attitudes. Exploratory and confirmatory factor analysis showed that verified servant leadership measures included 21 items and 6 factors (behaving ethically, creating value for the community, empowering, conceptual skills, putting subordinates first, emotional healing), and the measure had good construct validity. Hierarchical regression analysis indicated that servant leadership had significant effects on job satisfaction and affective commitment, which further showed the good predictive validity of the verified measure. There were four important contributions in this research: (1) The Western servant leadership measure was well verified in China, and the applicable measure was available for the following relevant research. (2) Servant leadership had significant effects on the employees’ attitudes, which showed that it had some leadership effectiveness. (3) Organizations may select suitable servant leaders according to certain selection criteria.

A research on the effectiveness of servant leadership behaviour

Biying Wang, Jiangxi Normal University, China; Riguang Gao, Jiangxi Normal University, China

The effects of servant leadership on employees’ behaviours (contextual performance, deviant behaviour, task performance) were examined with the revised servant leadership scale of Barbuto & Wheeler (2006)(N=285). Servant leadership had significant main effects on contextual performance, deviant behaviour and task performance when controlling the effects of demographic variables in regression analysis. Servant leadership had extra effects on contextual performance, deviant behavior, but not on task performance, when controlling the effects of transformational leadership and paternalistic leadership in regression analysis, which showed the good predictive validity and incremental validity of the scale. The main effects and extra effects of servant leadership on contextual performance and deviant behavior were better than those of transformational leadership, but on task performance less than those of the latter in regression analysis. The above results indicated that the two leadership behaviours had different specific effects on employee’s behaviours, which also proved the important value of the servant leadership construct and the effectiveness of servant leadership behaviour.

The effect of shared leadership on performance: A meta-analysis

Simon Werther, Ludwig-Maximilians-Universitaet, Germany; Nico Broegger; Felix Brodbeck

Leadership is a key factor of success in teams. The focus on vertical leadership, which was often clearly defined within the boundaries of one’s status or position, shifted to the concept of shared leadership in terms of distributing leadership functions and the effect on team performance. However, empirical evidence regarding the relationship of shared lead-
ership and team performance is scarce. The purpose of our research is to determine empirical evidence about the relationship between shared leadership and performance. Our meta-analysis seeks to answer the question whether shared leadership offers an opportunity to increase performance. The present meta-analysis consisting of 15 published and unpublished field studies follows Hunter and Schmidt’s approach, hence all correlations were corrected for measurement and sampling errors. The results revealed a significant positive relationship between shared leadership and performance. Based on the results limitations and necessary directions for future research will be provided by unfolding hidden and undiscovered potentials for scientists and practitioners.

How awareness, greenwashing, and public opinion influence employees’ concept of their company’s “green” practices

Chelsea Willis
University of Saskatchewan, Canada; Kaliegh Zerr; David Jones

Evidence is mounting that organizations’ pro-environmental practices can positively impact consumer behaviour (Bhattacharya & Sen, 2004), its ability to recruit talented workers (e.g., Behrend et al., 2009), and its financial performance (e.g., Orlitzky et al., 2003). Many scholars point to organizational reputation as the mediating variable that explains these relationships: “green” practices can contribute to a company’s positive reputation, which in turn favourably affects other organisational outcomes. However, little is known about how people form impressions of a company’s green practices, and in fact research shows that people’s awareness of such practices can be quite low (Sen et al., 2008). Moreover, factors external to the work environment might influence employees’ perceptions of their organization’s pro-environmental practices. For instance, public opinion and/or media could affect their beliefs and impressions, consistent with Brown and Dacin’s (1997) concept of “construed image.” Moreover, suspicions of “green-washing” (dishonest or misleading green claims; e.g., TerraChoice, 2010) might elicit backlash effects whereby green initiatives actually have negative outcomes in some cases (Yoon et al., 2006). We conducted a qualitative investigation of these issues using semi-structured interviews with employees of a similar hierarchical level in organizations in the same industry. We analyse the interviews using a grounded theory perspective, and discuss the results in terms of describing the phenomena and presenting implications for future research and practice.

Says who? Information source credibility and job seekers’ perceptions of corporate social responsibility

Chelsea Willis
University of Saskatchewan, Canada; David Jones

Research shows that organisations with positive Corporate Social Responsibility (CSR) reputations are particularly attractive to job seekers (Greening & Turban, 2000). However, much less is known - almost nothing, in fact - about how people actually form perceptions of an organisation’s CSR reputation. For instance, how do job seekers find out about CSR, and what influences how they evaluate the information they do find? Research on information source credibility (e.g., Pornpitakpan, 2004) suggests that where, and from whom, individuals learn about CSR may affect how they react to such information, yet researchers have not studied this in a recruitment context. This is unfortunate, given the prevalence of accusations of “greenwashing” and other disingenuous motives for CSR in the popular press. Therefore, we review relevant research on information source credibility from I/O, social, and consumer psychology, and present an integrative research agenda for applying this knowledge to future research on CSR and recruitment. For instance, consumer behaviour research suggests that messages about an organization’s CSR delivered from its public relations department may be seen as self-serving, even suspicious, leading people to question the credibility of the claim (Groza et al., 2011), compared to hearing about the CSR initiatives from some third party – i.e., a source that is external to the organization – such as the media or one’s peers. These findings have theoretical and practical relevance in a recruitment context.

The application of a multi-systemic coaching methodology for effective team interventions

Gail Wrogemann
GCW Consulting, South Africa

The objective of this paper is to describe team coaching interventions using an integrated model of systems psychodynamics, open systems theory and a constellations approach. Three case studies are part of this qualitative, descriptive research. Data gathering was via field notes and thematic analysis was used for data interpretation. The sample population were teams from across industries: school, consulting firm and banking, and made up of 7-9 people across management levels. Three key themes were identified: representation, defence mechanisms and depressive position. 1. Representation: certain individuals took up specific roles within their teams which served particular needs of, and defences for, those teams. Representation was also seen in how teams themselves took up roles in the wider systems within which they existed. 2. Defence mechanisms: specific defences were consistently identified: paranoid schizoid, projection, transference and counter-transference. These defences seemed to be in reaction to anxieties of individuals, of the teams and the experienced demands of the systems. 3. The depression position indicating the acknowledgement of a shared reality: an acknowledgement of the reality of the systemic interactions and the behaviours and defences employed by self and teams precipitated deep internal shifts that was key in initiating significant transformation. When teams become aware of their defences, they can develop beyond confusing and destructive dynamics. The wisdom of all aspects of the team is recognised and used constructively. This is something team coaching needs to focus on. More research and application here would be valuable.

A model for intellectual property entrepreneurship capability under organisational change in China: A multi-case and multi-level analysis

Yuanhao Xue
GERC, SOM, Zhejiang University, China; Zhongming Wang

The knowledge-based economy in the last two decades has turned intellectual property [IP], such as patents, trademarks, copyrights etc., into a critical part of firms’ strategic resources. Particularly for high-tech start-ups in the changing technological and business environment, developing and obtaining IP Entrepreneurship Capability [IPEC] is vital for their growth and success. This study proposed a three-dimension model of IPEC based on an “exploratory-transformative-exploitative” organisational learning theory and the characteristics of IP entrepreneurship process were captured through three learning phases. A multi-case and multi-level analysis was conducted with in-depth data from four Chinese high-tech ventures which were collected using interviews, observations as well as company archives. Three interrelated dimensions of IPEC were obtained based on between-case and cross-level analyses with acquiring, retaining and utilising. Acquiring reflects the IP creation process; retaining reflects the IP management process; and utilising reflects the IP commercialisation process. These findings extended the existing theories on IP and knowledge entrepreneurship, and provided a new theoretical basis for future research (NSFC70232001). The managerial implications were discussed in terms of enhancing IPEC through balancing among acquiring, retaining, and utilising activities.

Examining the relation between career decision-making self-efficacy and career maturity

Jing Yang
Institute of Psychology, China; Chuang-gang Shen

This study aimed to examine the moderating role of achievement motivation on the relation between career decision-making, self-efficacy and career maturity. A sample of 336 undergraduates (167 males and 169 females) completed three question-
naries: Achievement Motives Scale (AMS), including motive to approach success (Ms) and motive to avoid failure (Mf), Career Decision-Making Self-Efficacy Scale-Short Form (CDMSES-SF) and Career Maturity Inventory (CMI). Multiple regression results showed that CDMSE ($\beta = .406$, $p < .001$), AM ($\chi = .280$, $p < .001$) and the interaction between them ($\chi = .182$, $p < .001$) positively predicted CM after controlling gender, grade and major. Specifically, simple slopes tests showed that there was a significant positive relation between CDMSE and CM for participants with high AM ($\chi = .537$, $p < .001$), and a nonsignificant positive relation for those with low AM ($\chi = .128$, $p = .083$). Furthermore, we examined the roles of Ms and Mf, respectively. The interaction between Mf and CDMSE was significantly negative ($\chi = -156$, $p = .002$), not for Ms and CDMSE ($\chi = .086$, $p = .092$). Simple slopes tests showed that compared to participants with high Mf, there was a more significant relation between CDMSE and CM for participants with low Mf ($\chi = -225$, $p = .002$ for high Mf; $\chi = .476$, $p < .001$ for low Mf). The findings showed that AM moderated the relation between CDMSE and CM. Moreover, Af, not as in AM, played a moderator role between them.

The effects of strategic leader’s need for achievement and risk taking propensity on internationalisation
Jun Yin; Hui Wang

The paper investigates the relationship between strategic leaders’ characteristics and firm internationalisation in private firms. For the reason that a strategic leader is the one who is in full charge of an organisation, we firstly explored the factors that could have influences on firm internationalisation by detailed content analysis of four private firms’ cases. Results addressed the fact that strategic leaders’ need for achievement, risk taking propensity, political capital and overseas experience could influence the firm’s international strategy and behaviours from different perspectives. To test the cases’ results, we then interviewed 50 strategic leaders and conducted a survey on 73 strategic leaders, financial managers and 219 top managers in private firms. We expatiated on the roles of strategic leaders’ characteristics from implicit and explicit perspectives. Using the content analysis results of the interview materials, we found that leaders’ implicit need for achievement, implicit risk taking propensity are positively related to firm internationalising intention. After the regression of survey results, we further found that leaders’ explicit need for achievement, explicit risk taking propensity are positively related to the extent of firm internationalisation. Using the moderated regression analysis, we found that strategic leaders’ overseas experience, Chair/CEO duality will strengthen the relationship between leader-member exchange and positive affect predicted contextual performance. Specifically, engagement in contextual performance of those employees with low leader-member exchange was more dependent on their momentary positive affect.

Strategic human resource management and innovation performance: Measuring the mediating effect of organisational dynamic capabilities
Wei Zhang; Hangzhou Dianzi University, China; Lana Zhang

Prior studies have found a positive effect of strategic human resource management (SHRM) on firm performance. The purpose of this study is to explore the relationship of SHRM and innovation performance, and identify organisational dynamic capabilities as an intermediary role. Based on structural interview and multilevel questionnaires, we measure SHRM through four aspects of strategic human resource plan, training and development, incentive compensation, performance evaluation. We measure organisational dynamic capabilities through three aspects of the ability of cognitive environment, integrated resource and absorptive knowledge. We measure innovation performance through two aspects of technology and management innovation performance. The empirical study by means of structural equation modeling draws some conclusions as follow from a sample of 212 small and medium-sized enterprises. Firstly, SHRM has a positive impact on innovation performance. It means that innovation performance of the enterprises which own high-performance human resources portfolio is higher than the enterprises which own low-performance human resources portfolio. Secondly, organisational dynamic capabilities have a positive impact on innovation performance. It means that improving organisational dynamic capabilities can enhance innovation performance. Thirdly, organisational dynamic capabilities play an intermediary role in the relationship of SHRM and innovation performance. It means that strategic human resource practices have a positive impact on innovation performance through affecting organisational dynamic capabilities.

Emotion management and self-injury of manufacturing workers in China
Min-Qiang Zhang; South China Normal University, China; Wen-yi Zhang; Jie-ting Zhang; Bo Zhang; Ting-yao Li; Shu-Yi Liang; Ting Li; Mei-Fang Li; Ting Xu; Wei Xiao; Jing Zhong; Yanzi Wang; Jilinan Luo

This research was conducted to investigate the pressure status, emotion management and self-injury behavior of the manufacturing workers, which was fundamental to building an Employee Assistance Program (EAP) system. Scales were developed, some of which were constructed with a semi-projective technique, to collect data about workers’ performance in the above three aspects. Afterwards, ANOVA, latent profile analysis and other appropriate statistical methods were applied to analyze the workers’ mental status, based on which some suggestions were provided. Results showed that manufacturing workers had a medium level of pressure, moderate ability to manage emotion and medium inclination for self-injury. Additionally, financial pressure was prevalent among the workers. Latent profile analysis demonstrated that workers could be divided into four latent population types based on the pressure and emotion management data, and six types according to the self-injury data. Moreover, several socio-demographic characteristics were found to influence worker’s mental status: working age, overtime, salary, gender, marriage, family, and working environment. From this research, some suggestions were summarized for factory management. First, female and married people could be prioritized in recruitment if all other conditions were equal, for they have better emotion management and a lower self-injury tendency. Second, 7-14 hours of overtime per week would be appropriate for those workers. Third, training should be provided to improve the workers’ financial management ability, which would help release the major pressure from their financial situations.

Work addiction and mental health among Chinese university teachers: Effects of burnout and loneliness
Linlin Zhang; Harbin Engineering University, China; David DeJoy

In order to investigate the mediating effect of burnout and moderating effect of loneliness on the relationship between work addiction and mental health, 385 Chinese university teachers from seven representative universities were assessed by means of various measures including the Work Addiction Scale, General Health Questionnaire, Loneliness Scale, and the Maslach Burnout Inventory. Hierarchical regression analyses indicated that work addiction was a powerful predictor of adverse mental health while demographic and related variables were controlled. Further analyses discovered that job burnout mediated the relationship between work addiction and mental health among Chinese university teachers, demonstrating that the job-demand-resource model is a unique angle for explaining how work addiction related to negative outcomes. Compared to those who experienced low loneliness, Chinese university teachers with high loneliness were more likely to become burned-out. The conclusion is that work addiction has a relationship with Chinese university teachers’ mental health. Keeping the balance between job demands and resources and providing social support to Chinese university teachers will improve the level of their mental health.

Research on team creativity stimulating and transforming into team performance: A case study of pharmaceutical R&D teams
Bo Zhang; Tongji University, China; Wei Xiao; Jing Zhong; Yanzi Wang; Jilinan Luo

Through case of two R&D teams of a pharmaceutical company, Huarrun 1999, it is found that the
context of a knowledge-based economy. Drawing on the Complex Adaptive System Theory (CAS), this article asserts that full-scale interaction of heterogeneous employees/groups provides momentum for bottom-up innovation emergence in organisations. Accordingly, leaders can indirectly influence this process by means of adjusting interaction rules, which in turn impact organisational innovation performance. Our agent-based computer modelling and simulation results confirm that (1) under well-designed rules and regulations, self-organising employee/group interaction in organisations gives birth to bottom-up organisational innovation; (2) by adjusting interaction rules, leaders can affect effectively (though indirectly) employee/group interaction and eventually influence organisational innovation performance. This article provides computer simulation evidence for future CAS-based innovation-related OB research in a knowledge era.

Interactive leadership style and organisational innovation performance: a case study from Renmin Business School
Chaowei Zhu Yichun Uni; Renmin Uni of China, China; Cheng Yang; Junlan Li
This article argues that a majority of existing leadership styles are not suitable for innovation-pursuing organisations consisting mainly of knowledgeable workers in a information-based era. To better motivate informed workers to innovate, contemporary leaders need to gain a better understanding of the inner dynamics mechanism of innovation emergence in organisations. Accordingly, this article introduces the theory of Complex Adaptive System (CAS) into organisational innovation study, to analyse explicitly the process of innovation emergence from full-scale interaction of heterogeneous knowledgeable workers. Based on this rationale, the authors propose the concept of innovative leadership style (ILS) and define it as a new, informed-worker-specific, and innovation-oriented leadership style aiming at boosting bottom-up innovation emergence in organisations. Propositions concerning ILS and innovation-pursuing organisations are proposed and a case study of a famous EQUIS-accredited business school in mainland China is adopted to verify the propositions.

A randomised control study of prevention of chronic back pain in an office work setting
Bernhard Zimlong Ruhr University Bochum, Germany; Guenther Vanessa; Elke Gabriele
The study aim was to evaluate the effectiveness of a short cognitive-behavioral intervention preventing chronication of back pain in the office work setting. A group-randomised controlled trial with a waiting list control condition was conducted. Employees of nine tax offices participated voluntarily in the study. They were included if their pretest score of chronicity of back pain on the graded chronic pain scale was grade 2 or higher. Twenty groups of 111 employees in total were randomised into either the intervention or control condition. All training sessions took place at the office. A multilevel analysis was run using the lme4 package in R language. The random intercept models accounted for the clustering of the data. Dependent variables were the differences between post-test and pre-test scores. Statistical computations yielded significant effects for pain intensity, disability, depression and time for physical activities. All significant differences between treatment and control condition are in the expected direction. Effects (Cohen's d) are of medium size ranging between d = -.30 (depression) and d= .53 (time for physical activities). Self efficacy was increased and fear-avoidance beliefs were decreased in both conditions. The short cognitive-behavioral intervention proved to be effective in reducing risk factors for chronication of back pain. Cognitive-behavioral intervention in the workplace seems to prevent chronication of back pain, thereby reducing costs and individual suffering.

Work/family conflict in the hospitality industry: A diary study on working mothers
Eva Zipperle-Mirwald University of Innsbruck, Austria; Thomas Hooge
Work and family are two key domains in every employee's life that might lead to conflict. This study investigates 40 working mothers in the service sector of the hotel and restaurant industry, which is known for job stress, long and desynchronised working hours, a lack of job control, high and conflicting work demands, and frequent customer contact. We analyse the impact of work and family demands as well as work- and non-work-related control factors on daily work/family conflict. We collected data on a daily basis (7 day questionnaire) asking for work, private life and recovery details. Additionally, the mothers answered a general questionnaire about their work situation, partner and family matters along with their recovery patterns. A multi-level analysis showed that time pressure at work, the daily and weekly amount of working hours, the degree of daily decision latitude and the daily control over their time off, had a significant impact on the day-to-day work/family conflict. Social support at home and at work as well as the daily and general customer interaction did not explain additional variance. Based on these result we suggest several practical implications to reduce the work/family conflict.

Session Type: Posters

I- process evaluation of an intervention program, "successful self", designed to prevent psychosocial distress
Shinichiro Ando Okayama Citizens Hospital, Japan; Mikayo Ando
The Successful Self program, designed to prevent psychosocial distress among new health professionals focused on self understanding, coping under difficult situations, and communicating with others. The objective of this study is to evaluate the feasibility and usefulness of this program. The program included four weekly sessions consisting of group work activities: (session 1) Identifying goals, (session 2) discussing feelings of self and of others, (session 3) solving problems, (session 4) managing stress. Five physicians, fifteen nurses, and two pharmacists attended the program and completed surveys after each session in 2010. In 2011, after modification of the program, four physicians, fifteen nurses, and two pharmacists did the same. In 2010, 69.6% of the participants reported positively
after the first session, 90.0% after the second session, 85.7% after the third session, and 90.0% after the fourth session. Seventy-five percent of the total participants reported the program was useful. In 2011, the number of program facilitators was increased from one physician in 2010 to two or three (one physician and one or two nurses). Also, one scenario in session 2 was changed. In 2011, 85.7% of the participants reported positively after the first session, 78.9% after the second session, 80% after the third session, and 90.5% after the fourth session. Ninety-five percent of the participants reported the program was useful in 2011. The program was feasible and successfully modified to increase its usefulness among new health professionals.

The relationship between emotional intelligence and work-family conflict
Maede Arabzadegan University of Isfahan, Islamic Republic of Iran; Hoseyn Samawati; Shadi Dehkeshan
Emotional intelligence is considered to be an important construct in everyday life, resulting in the focus of psychologists in different areas. Emotional intelligence is proposed as an important predictor of key organisational outcomes. The aim of this research was to explore the relationship between emotional intelligence and work-family conflict. Emotional intelligence questionnaire (Petrids & Furnham, 2002) and work-family conflict questionnaire (Netemeyer, Boles, & McMurrian, 1996) were used. Statistical population consisted of workers in an industrial company in Isfahan from which 100 employees were randomly selected. Data were analysed by means of the Pearson correlation coefficient and regression analysis. The results indicated that there is a significant negative correlation between emotional intelligence and work-family conflict (r = -0.378). In addition, results showed that optimism correlated with work-family conflict. Actual emotional intelligence could affect coping, and conflict management ability, as a result higher emotional intelligence may be significantly related to lower work-family conflict. These findings could be used for better employee selection.

Italian workers in retirement: Reasons for post-retirement activities are influenced from own former job
Piermatteo Ardolin University of Verona, Italy; Massimo Bellotto; Giuseppe Favretto; Serena Cubico; Maddalena Formicuzz
Aging population is a social phenomenon in Europe characterised by a decrease in fertility and mortality rates, and a higher life expectancy among native Europeans. In Italy, in particular, a growing number of older people are encouraged to delay their retirement due to a range of economic, social and policy changes, and various other reasons to engage in post-retirement work. For this research we considered the following factors: insufficient financial resources, additional income, interesting work, the desire to remain active, valued contribution to society, flexibility, social contact and personal development. The aim of this study is to analyse the relationship between the intention to remain in work, and work satisfaction in the past career of older workers. We used quantitative (questionnaire) and qualitative (interview, focus group) methods, to collect and analyze data. Different statistic elaborations were applied to discover the relationships among different variables (i.e. descriptive, inferential, P value test and Regression Analysis). The findings show how older people in retirement want to be appreciated. Their motivation and satisfaction depends on their past carrier and these variables push them to stay at work for a longer time.

Differences between managers and students regarding the locus of responsibility for work-family issues
Jeffrey Bagraim University of Cape Town, South Africa; Andrea Fouche
The purpose of this study was to investigate the similarities and differences in the attitudes of managers and students towards work-family issues, such as the locus of responsibility for managing this interface. Using a descriptive research design, a cross-sectional self-report survey was completed by three hundred university students (N = 103) and senior managers (N = 56) at three of the top accounting organisations in Cape Town. The MANCOVA analysis evidenced a clear and significant difference between managers and students regarding the locus of responsibility for managing the work-family interface, even when controlling for age. There were significant differences between males and females but fewer differences between managers and students. The information gained from this study should be useful for employers, educators and career psychologists. Comparing the attitudes of students and managers also illustrates the gap that exists between the expectations of future employees and what the work-family interventions and policies that employers are currently making available to their managers and employees.

The relationship between commitment and absenteeism among South African community nurses
Jeffrey Bagraim University of Cape Town, South Africa; Nadine Butler
The purpose of this study is to explore the relationship between absenteeism and commitment. Multiple types of commitment (affective, continuance and normative commitment) to multiple foci of commitment (the organisation, co-workers and the nursing profession) were examined. Absenteeism was measured in multiple ways, even though no organisational records were available. Job satisfaction, job involvement and absence culture were proposed as possible moderators of the relationship between absenteeism and commitment. The sample comprised 227 public sector nurses (54% response rate) from 11 day clinics and hospitals within the Cape Town metropole. Affective, continuance and normative commitment to the organisation were not directly related to absenteeism, although interactions between these commitment components were significant predictors of absenteeism. Affective commitment to co-workers did not significantly explain absenteeism. However, affective commitment to the nursing profession explained significant variance in nurse absenteeism both directly and through the moderating effects of the absence culture of the workplace and the profession. Levels of job satisfaction and job involvement did not moderate the absenteeism-commitment relationship.

Emotionally intelligent organisations: Applying Mayer and Salovey’s model
Angela Barbieri University of Florence, Italy; Vincenzo Majer
The usefulness of emotional intelligence in organisational psychology has been linked to variables such as leadership, emotional labour, burnout and work-related stress, including non-traditional and emerging settings such as virtual teams, project management, and artificial intelligence. Beyond the differences between paradigms, operationalisation, instrumentation and preferences of researchers and practitioners, the recognition of the importance of handling emotions, has exceeded the boundaries of any individual dimension to expand into the organisational one. This seems to be the case even in settings considered purely technical, or virtual, or otherwise not traditionally characterised by emotional work. The importance of knowing how to deal with emotions has been extended up to one of the more formalised and institutionalised relationships: that is among individuals who work in an organisation and the organisation itself. Understanding individual differences with respect to the different skills in which individuals may be emotionally intelligent can provide organisations with a useful tool to guide the employment and development of resources. But it is proposed that researchers look at the organisational dimension, not only in relation to the individual, but in relation to the organisation itself, and to behaviours that the organisation puts in place. In this respect the proposal is that it can be useful to apply the developmental perspective of Mayer and Salovey’s hierarchical model of four branches of emotional intelligence, at the level of the organisation.

The impact of talent management practices on the retention of employees in an electricity supply company
Nicolene Barkhuizen North-West University, South Africa
Many leading organisations, not only in South Africa but also globally, are facing the challenging situation of talent retention. The main objective of this research was to investigate the current application of talent management practices in an electricity supply company and the impact of these practices on employee’s intention to quit the company. A quantitative, ex post facto research approach was followed. The respondents in this research were employees from a South African Electricity Supply Company (N=96). An adapted version of the Talent Management Index (Human Capital Institute) was used to measure the current application and importance of talent management practices in the organisation. The overall findings showed that Talent Management Practices were only fairly applied in the company. Findings also showed that currently there is a large gap between the current application of talent management practices in the company and the importance thereof. Findings overall showed that talent management practices are a practically significant predictor of employees’ intention to quit the company. Employees of any organisation are the heart of the company, and without them the company can’t exist. This study aimed to identify the impact of talent management practices on employees’ intention to quit the company. The study can thus be of great significance and benefit.
to corporate business at large in the retention of employees.

Construct validity of a managerial assessment centre

Ha Barnard UNISA, South Africa; Antoni Barnard; Vuyo Nako

Assessment centre (AC) research generally demonstrates high predictive validity yet poor construct validity, questioning the effectiveness of ACs to measure the dimensions they claim to measure. For AC ratings to be useful, they must be based on underlying constructs common to both test performance and job behaviour. Assessors’ judgments should accurately reflect the underlying constructs in assessed dimensions, since these ratings constitute the basis for selection and promotion decisions. Hence construct validity of AC dimensions requires investigation. To investigate the construct validity of a leadership assessment and development centre (LADC). A correlation study exploring the relationships between scores on various dimensions within and across different LADC exercises was conducted. LADC ratings from a sample of 138 were analysed using Pearson Product Moment Correlation and principal component analysis was conducted to discover main dimensions. Large correlations amongst different dimensions in same exercises showed lack of discriminant validity whilst, the PCA showed some convergent validity among various dimensions measured across exercises. PCA findings also supported a two-factor structure, indicating assessors’ ability to differentiate between interpersonal and performance-related dimensions. Standardisation in AC administration is imperative for AC utility and useful research. The number of dimensions in an AC should not exceed eight. Similar studies are required for all AC applications to ensure meaningful decision making based on AC results.

Predictors of burnout in a nursing environment

Marais Bester NWU; Potchefstroom, South Africa; Cara Jonker

The objective of this research was to determine the relationship between Emotion Work, Emotional Intelligence, Organisational factors, and Burnout among health professionals. A cross-sectional survey design was used to collect the data. A non-probability convenience sample was taken from 294 nurses in private and public hospitals. The Schutte Emotional Intelligence Scale (SEIS), Oldenburg Burnout Inventory (English Version) (OBLI), Scales from the Frankfurt Emotion Work Scales (FEWS) and Organisational Factor Scale were administered. The Pearson correlations indicated that Client Care positively correlated with Display of Positive Emotions, Emotional Management, Emotional Integration and Emotional Utilisation, while Client Care negatively correlated with Co-Worker Support and negatively correlated with Job Autonomy. A Multiple regression analysis with Diminished Interest as dependent variable, indicated that Client care, Emotional Dissonance, Emotional Integration, Emotional Awareness and Supervisor Support were the best predictors of Diminished Interest. With Disengagement as the dependent variable, it was indicated that Client Care, Emotional Integration, Emotional Perceiving, Emotional Awareness and Supervisor Support are the best predictors of Disengagement, and with Energy Depletion as the dependent variable, Emotional Dissonance, Display of Positive Emotions, Emotional Integration, Emotional Perceiving, Emotional Awareness, Co-Worker Support and Job Autonomy were the best predictors of Energy Depletion.

Counterproductive work behaviour scale for Turkish employees: A reliability and validity study

Reyhan Bilgic Middle East Technical University, Turkey; Hande Agca; Umaran Yuce

The aim of this study is to measure the reliability and validity of a counterproductive work behaviour scale which has not been conducted before. With this aim, a scale which includes 26 items was developed and applied to 435 employees working in different workplaces. Participants from different ages and different education levels were selected and the number of men and women was balanced. In the scale, besides counterproductive behaviour items, there was a performance scale including 16 items that measure employees’ performance and also some demographic questions. The result of this analysis showed that the reliability coefficient within scales is over .70. Moreover, the correlation between the total score of the counterproductive work behaviour scale and the total score of the performance scale were analyzed and it was found that the correlation was consistent with the literature in this area, as was expected. In addition, the correlation between the total score of counter-productivity and gender, and education level was consistent with other findings in literature. All the findings in this study were discussed in line with the literature and it was indicated that the study has some limitations.

The experience of organisational commitment, work engagement and meaning of work of nursing staff in hospitals

Eriele Botha NWU, South Africa; Eriele Botha; Ilka Beukes

Nursing is a noble profession but too often a terrible job (Chambless, 1996, p.1). The primary objective of this research was to investigate the relationship between organisational commitment, work engagement, and meaning of work among nursing staff at various hospitals. A survey design with a cluster sample (N = 199) was used. The Organisational Commitment Questionnaire, Utrecht Work Engagement, Work-Life Questionnaire Scale and a biographical questionnaire were administered. All the scales demonstrated acceptable reliability. Results showed that the majority of nursing staff view their work as either a job or a calling. This will have an impact on the organisation, as the results showed that viewing your work as a calling predicts 19% of the variance in organisational commitment and 30% of the variance in work engagement. This will accompany higher levels of engagement and commitment to the organisation, as nurses will feel that they make a meaningful contribution to the hospital and will, in turn, feel more inclined to stay in the organisation as the costs of leaving it would outweigh those of staying. Biographical factors such as gender, race, age, citizenship, qualification, years of service, job level and employment status were also investigated.

Increasing insight into workplace bullying among participants on a leadership development programme

Wilma Botha SSA, South Africa

Workplace bullying has become a significant problem in South Africa. Since physical violence is unacceptable, bullying manifests as aggression in covert forms. Adverse conditions in the workplace, like frequent change, insecurity, tight deadlines, unachievable objectives and autocratic leadership, contribute to bullying behaviour. Socio-economic factors, like globalisation and recession, increase competition. To remain profitable, organisations may be forced to downsize. Bullying may thrive in circumstances where some employees have to be sacrificed to ensure the survival of the organisation. Yet, bullies usually seem to be shocked when they realise the effect of their behaviour. Often they appear to be unaware that they have been disregarding the dignity of colleagues. When confronted, bullies typically deny responsibility, and often intensify their bullying. Therefore, opportunities to involve bullies in research and counselling for behavioural change are rare. Interventions to counsel bullies may well begin with supervisors and managers, since in the South African context they are often to blame. A suggested solution is to address bullying behaviour in a non-threatening situation with participants in a leadership development programme. This presentation shares learning points after inviting 12 participants to assess themselves on a rating scale with examples of bullying behaviour. Participants did not have to reveal their ratings. Examples of bullying and alternative behaviours were then described by the facilitator. Options for preventing scapegoating, valuing diversity, handling poor performance and conflict resolution were also discussed. Afterwards participants were requested to apply their learning in a role-play exercise, and give one another feedback on their performance.

Leading others in multicultural societies

Jennifer Campbell INAAOS, Netherlands

In this paper we discuss the topic of new multicultural leadership: the kind of leadership that is required to lead others in multicultural teams, organisations and in nations or societies. A lot has been said about leadership: ample management and leadership books have been written on how to develop knowledge, skills and attitudes to lead others; what it takes to make others contribute to organisations, motivate others and inspire others. What has not been written, however, is the kind of leadership it takes that values all in one group, one nation. In many societies, a high diversity of people co-exist,
sometimes peacefully, sometimes tolerating each other, sometimes fighting and at war. How does one lead others in such a context? What do we learn from current developments in countries like Egypt or situations like in the European Union? What is required of leaders who want to embrace their nations in all their multicultural aspects? By combining insights from literature and working experience on leadership, multiculturalism, value management, human needs psychology, organization and relationship systems, coaching, and International Studies, we seek answers to these questions. We will underline the importance of: * What does leadership actually mean? Aligning core values and purpose. * Inspirational leadership: leading others from the inside out. * Leading high diversity or heterogenic groups: which specific skills are required? * International studies and leadership: how to make a successful combination. In conclusion, suggestions for leadership development and implementation will be provided.

How to improve the effect of organizational change: Training systems and training intentions

Hsin-Hung Chen Dep. of BA, National Chengchi U, Taiwan, R.O.C.; Tzu-Shian Han

This study explores the conditions for how to improve the effect of organizational change for small- and medium-sized enterprises (SMES), and takes training system and employee’s training intention as moderators to examine. The study surveyed 1209 employees from small and medium size manufacturing and service organisations (less than 250 employees) by simple random sampling, and used hierarchical regression analysis to test the hypotheses. The research findings shows that: 1. Organisational change level is positive related to the effect of organisational change; 2. Employee’s training intention moderated the main effect, and let the positive relationship become stronger. And the moderating effect of training system also show marginal significant. Overall, these findings underscore the importance of complete training system and related system design to improve the effect of organisational change. Implications and direction for future research are discussed.

Factors affecting the incomes of lesbians in the United States

Robin Church Ryerson University, Canada

Studies have demonstrated that gay men earn less, and lesbians earn more, than their heterosexual counterparts. This study explores some of the factors associated with the incomes of lesbian employees in the United States and tests some of the previously suggested explanations for the income disparity. The sample comprised 100 individuals who identified as lesbian, who live in the US, and reported being employed full time. This study found that age and education were strong predictors of the incomes of lesbian employees. Controlling for age and education, lesbian employees’ incomes were inversely related to the proportion of women coworkers. Legislative protection, organisations’ policies and practices supportive of gay and lesbian employees, and perceived discrimination were not significant predictors of income after controlling for age and education.

Entrepreneurial potential for Italian undergraduates

Serena Cubico University of Verona, Italy; Maddalena Formiciuzzi; Giuseppe Favretto; Piermatteo Ardolino; Massimo Bellotto

Choosing to be an entrepreneur can be an opportunity for the young, especially since they have difficulties in finding jobs. To detect the knowledge, attitude, and aptitude towards the entrepreneurial job, understand the variables that are related with the entrepreneurial choice in young males and females, a questionnaire (50 multiple-choice items / Cronbach Alpha .449) that analyses: personal data; entrepreneurial network of acquaintances; image of future job; ideas about male and female entrepreneurs; information about bureaucracy and investments in creating enterprises; entrepreneurial aptitude; attitude toward entrepreneurship was applied to 560 Italian humanities students. The difficulties described in enterprise creation are: economic aspects, bureaucracy, partners/co-workers, and getting credit from banks. The image of the profile of male entrepreneurs is characterised by leadership and perseverance, while females show perseverance and a strong spirit of sacrifice. Students have little knowledge about start-up processes. Attitudes toward entrepreneurship/self-employment are characterised by the choice of the addjectives: wonderful, prestigious, active, energetic, satisfying, interesting, suitable, various and flexible. Networking is an important variable that has a positive and significant effect on the others: people with a family/social network with entrepreneurs have access to a lot of information; they have a more positive image of an entrepreneurial job; and they think about it, try and are able to be self-employed more than others. We consider this research a step towards helping to identify a model that integrates elements of the entrepreneurial project: gender, attitudes, aptitudes, networking, information, and social support.

Explaining individual differences in the accuracy of interviewer ratings: A social-cognitive intelligence approach

Francois De Kock University of Stellenbosch, South Africa

Raters differ in their rating accuracy, but only recently has research attention shifted to the reasons for these differences. Taking a social cognition perspective, we developed a model of individual differences that were hypothesised to distinguish raters according to their levels of judgment accuracy. The research reported here studied the effects of rater individual differences on the accuracy of ratings in simulated one-on-one video-taped recruiting interviews. The sample consisted of managerial interviewers (N = 144) who observed five videotaped interviewees acting out scripted interviews. We used a multiple regression analysis to test predictions derived from social cognition theory stating that raters who had higher levels of social cognitive intelligence cluster variables would have higher performance rating accuracy scores. The multiple regression and relative weights analyses provided evidence for these hypothesised effects. The relative importance of individual difference variables and their incremental validity for the prediction of judgment accuracy are discussed. Implications for judgment accuracy research, rater selection and training, and rating procedure design are discussed.

Effects of rater-rater personality similarity on rating of task orientated work behaviour

Francois De Kock University of Stellenbosch, South Africa; Antonette Crouse

Performance appraisal research has shifted its emphasis to the examination of rater cognitive processes and the social and contextual variables which affect performance evaluation. Research has investigated the effect of similarity between rater and ratee on subsequent performance ratings. However, these studies have mostly relied on similarity measures based on physical similarity characteristics, for example, demographic similarity. The inconclusive nature of these findings suggests that the complexity of interpersonal judgment has been oversimplified; in social-cognition literature, substantial evidence exists that rater-ratee similarity shifts the focus of similarity judgment to deeper, sometimes unobservable, characteristics, such as values, motives and attitudes. This research study investigates whether rater-rater personality similarity in the Big Five personality traits, unduly influences task-orientated performance ratings. Self-report personality data (IPIP; Goldberg, 2006), were collected from university lecturers (N = 5), and their students (N = 152). Actual lecturer performance assessment data (end-of-semester student feedback ratings) were administered simultaneously. Data were analysed through polynomial regression analysis and response surface methodology. Results indicated that rater extraversion (r = .357), conscientiousness (r = .413) and openness (r = .178) had significant main effects on average performance ratings. Also, rater-rater personality similarity in extraversion (p < .001), neuroticism (p < .01) and openness (p < .001) had a significant effect on performance ratings, with the effects of agreeableness and conscientiousness approaching significance. The results suggest that the earlier conclusions in which personality similarity does not affect performance ratings, seem to be premature, and that more research is needed to investigate why personality similarity affects ratings.

Mapping the profile of skills from professionals and students perception of nursing in Erechim

Silvia De Medeiros URI Campus de Erechim, Brazil

This study has the objective of mapping the profile of necessary nursing competences in order to identify skills, attitudes and knowledge for professional practice. Characterised as a quantitative research, and made use of a questionnaire for collecting data. The questionnaire comprised twenty closed questions, and was drawn up so that the competences were distributed in four groups: Behavioural, Focus on the Result, Emotional Balance and Management Technique. There was a total of 48 participants, being 24 professional nurses (8 from the clinical area, 8 from the social area, 8 from the teaching area) and other participants were 24 nursing students (8th and 9th semesters from URI - Campus of Erechim). The analysis of the results pointed out the following order of classification for competences: Commitment (obtained the highest score: 97.9%); Listening, Speaking and Perception and Ethics
The motivational effects of subordinates: Trust perception in teams
Jingsong Deng Business School, Sun Yat-Sen Uni, China; Xiaoping Liu
The present study explores the functions of subordinates’ perception of being trusted in teams, with special reference to the motivational effect of feeling trusted in trust relations. The data has been collected through a survey of 229 Chinese MBA students in two cities. Four competing models for examining the effects of feeling trusted are developed and tested by using Structural Equation Modelling (SEM). Based on hypothesis-testing and the comparative analysis of fit indices of the four models, it is shown that the motivational effects of subordinates’ perception of being trusted and the job satisfaction motivated by this perception, ultimately result in subordinates’ loyalty to their team-leader and improvement in their job performance. It is also found that these mediating effects are strongly associated with the characteristics of trust motivation in Chinese culture. The present study concludes with some practical implications for trust management in the real work settings.

Discrimination among foreman job categories of the Saipa Car Company (Iran)
Shadi Derakhshan Isfahan University, Islamic Republic of Iran; Hamid Reza Oreyzi
Industrial psychologists use job analysis data for different purposes. Selecting the appropriate data analysis model is very important and depends on the purpose of the job analysis. Following Cormack et al. (1979), in the current paper, researchers use data from 310 employees in the main plant of Saipa Car Company using the position analysis questionnaire of McCormic et al. (1972). Three different levels of job analysis data were used, namely: Task oriented, worker oriented and abilities oriented. Results of multiple discriminant analysis and maximum likelihood classification indicate that clusters of jobs could be statistically separated in a two-dimensional ability space. The overall hit rate for assigning a task statement to a job cluster was greater in abilities-oriented data. Findings indicate that there are different solutions regarding the number of similar jobs in the plant. So, there is not only one objective answer for each job, rather job analysis data reveals different patterns.

The study of organisation development efforts in the oil refining and distribution company in Iran
Shadi Derakhshan Isfahan University, Islamic Republic of Iran; Hamseodin Tabatabaei Nasrabad
As we know, changes in the business world are obvious almost to everyone. Sometimes these changes take place so quickly that the organisation cannot handle the results without having prepared for them. The Organisation Development helps the organisation to face new situations, even before they happen! In this research we aimed to diagnose organisational activity to adjust to environmental changes, and whether these performances were relevant to OD evidences. To do this, information about change activity was gathered from the staff of various departments of the Oil Refining and Distribution Company in Iran. The data collecting method was direct interview. After the survey, the results indicated that at about 10 years, the organisation offered and executed some changes with the support of OD operators. Changes such as: creating an HSE department, using a new management system, changing the assessment and training system, creating a lady council and so on. The following survey clarified that many of these changes have compatibility with OD evidences.

The influence of leader behaviour, psychological empowerment, job satisfaction, and organisational commitment on turnover intention
Thamsanqa Dlhalhla Stellenbosch University, South Africa
Organisations continue to lose skilled and experienced employees due to voluntary turnover. As a result, understanding the factors that affect employees’ turnover decisions is important. Although several existing studies have identified factors related to turnover, most empirical research utilises explanatory models that do not sufficiently address the intervening processes that lead to turnover intention. We used a correlational study in a sample of military personnel (n= 318) to examine the collective effects of perceived leader behaviour, psychological empowerment, satisfaction and commitment on turnover intention. The results supported a model where turnover intention was explained to result from a combination of these organisation-related and job-related attitudes. The study adds to the existing literature in two ways. First, the findings indicated that turnover intention results strongly from the combination of leader behaviour, psychological empowerment and organisational commitment. Psychological empowerment and organisational commitment play a dominant role in the development of turnover intention, both directly

(93.7%); Leadership, Planning and Organisation (89.5%); Respecting Values (83.2%); Persistance and Determination (79%); Interpersonal Relation, Analytical Capacity, Concentrated Attention (76.9%); Good Humour, Empathy and Affection, Clarity and Objectivity (74.8%); Flexibility (70.6%); Creativity, Sharing of Knowledge (62.2%); Being Persuasive (60.1%); Entrepreneurship (41.6%); Tolerance to Frustration (37.5%). This way, it’s understood that with the results you can prioritise the competences that might be best developed within projects for training of nursing students, helping and preparing them for the labour market.

Psychological empowerment, work engagement and turnover intention
Jacob De Villiers North West university, South Africa
This study investigated the relationship between leader-employee exchange, role clarity, psychological empowerment, and engagement and turnover intention within a financial institution in South Africa. A cross-sectional survey design was used. A convenience sample (N = 278) was taken (males =31%, females =60%; 88% younger than 35 years; 57% with 2 – 5 years service) from the total population (N = 889). They completed the Leader-Member Exchange Questionnaire (Liden, Wayne, & Stilwell, 1993), Role Conflict and Ambiguity Questionnaire (Rizzo, House, & Lirtzman, 1970), Measuring Empowerment Questionnaire (Spritzer, 1995), Engagement Questionnaire (May, Gilson, & Harter, 2004) and Intention-to-leave Scale (Sjobeck & Sverke, 2000). A path model was tested with SPSS to determine the relationships of the variables. Furthermore, a theoretical model was tested through the use of structural equation modelling (Arbuckle, 2008). The latent variables included LMX (consisting of two parcels), role clarity (consisting of two parcels), psychological empowerment (consisting of four variables, namely meaning, competene, impact, and self-determination), work engagement (consisting of two parcels), and turnover intention (a manifest variable). Role clarity mediated the relationship between leader-member exchange and psychological empowerment, while psychological empowerment mediated the relationship between role clarity and work engagement as well as turnover intention. Leader-member relations lead to better understanding of roles, while role clarity empowers and engages employees.

The relationship between emotional intelligence, emotion work and organisational factors with engagement in a care-giving environment
Francois De Wet NWU: Poletaafstroom, South Africa; Cara Jonker
Not only are health professionals required to offer a service which provides mental and physical expertise, but they are also required to manage their emotions as a part of their job. The objective of this research was to determine the relationship between Emotion Work, Emotional Intelligence, Organisational Factors and Engagement within a care-giving environment. A cross-sectional survey design was used, and a non-probability convenience sample was taken from 294 care-givers. The Schutte Emotional Intelligence Scale (SEIS), The Untrecht Work Engagement Scale (UWES), Scales from the Frankfurt Emotion Work Scales (FEWS) and Organisational Factor Scale were used as measuring instruments. The statistical analysis consisted of descriptive statistics, Cronbach alpha coefficients, factor-analysis (using principle component analysis). Pearson correlations indicated that Client Care positively correlated with Display of Positive Emotions, Engagement, Emotion Management, Emotional Integration and Emotional Utilisation. Emotional Dissonance negatively correlated with Engagement and Emotional Management. Display of Positive Emotions positively correlated with Emotional Utilisation. Engagement positively correlated with Emotional Management, Emotional Integration and Emotional Utilisation. Supervisory Support is positively correlated with Co-Worker Support and negatively correlated with Job Autonomy. Emotional Management positively correlated with Emotional Dissonance, Emotional Management, Emotional Integration, Emotional Perceiving, Emotional Awareness, Emotional Utilisation, Supervisory Support and Co-Worker Support were the best predictors of Engagement.
and as mediating effects. A second unique finding of the present research was the positive relationship found between psychological empowerment and turnover intention, suggesting that either turnover process models may be more organisation-specific than previously thought (e.g., Alexander, 1998), or that empowerment may increase turnover intention because of enhanced career mobility.

Organisational culture, leader-participation and shared vision are important steps toward perceived organisational effectiveness improvement

Saiedeysmey Diba; University of Isfahan, Islamic Republic of Iran; Saied Hamid Atashpour; Amin Barazandeh; Mohsen Golparvar; Hamid Reza Orzey

This research was conducted to investigate the relationship between organisational culture, leader-participation and shared vision based organisational learning with perceived organisational effectiveness. The statistical population consisted of 450 participants in a production company in Brujen, from which, 203 people were selected using simple random sampling. The research questionnaires were organisational learning components, including organisational culture, leader-participation, shared vision (organisational assessment with 48 items). Data were analysed with Pearson’s correlation coefficient and stepwise regression analysis. Results showed that there was significant positive correlation among all the research variables. Stepwise regression analysis showed that organisational culture, leader-participation and shared vision predicted all the dimensions of perceived organisational effectiveness among the steps. According to this research, organisational managers can increase organisational effectiveness via promotion of organisational commitment, use of leader-participation for conducting organisations and the creation of a shared vision.

Safety climate and involvement in safety management: A study with first-line managers

Kouaben Dongo Remi Université Grenoble 2, France; Ngueuetsa Robert Université Grenoble 2, France; Mbaye Sofetou

Because the safety climate (Zohar, 1980) reflects perceptions of the importance placed on safety in an organization and the perceived attitudes of managers towards safety issues, it is becoming one of the key variables in obtaining the best safety performance and stronger commitment to safety-related actions (Silva et al., 2004; Cooper and Phillips, 2004, Tucker et al., 2008). This study examines the effect of safety climate on involvement in safety management by first-line managers (FLM), a largely unexplored population. 63 FLMs responded to a questionnaire measuring perceived safety climate at the workplace, risk perception, and involvement in safety management. As expected, FLMs who perceived a good safety climate in their company reported getting more involved in safety management than did FLMs who perceived a poor safety climate (F(1,60) = 23.30, p < .01, PRE = .27). However, the fact that FLMs are called upon by the workers they supervise, prompts them to be more involved in safety management, thereby mediating the effects of perceived attitudes of management toward safety issues, and encouraging from immediate supervisors in communications about the safety climate. Some possible avenues for improving the involvement of FLMs in safety management are suggested.

Intention to quit among Generation Y academics at higher education institutions

Ronen Du Preez Stellenbosch University, South Africa; Anecia Robyn

Talent retention is an international challenge across industries, and especially for academic staff at higher education institutions (HEIs) in South Africa. It may be argued that HEIs are more dependent on the intellectual and creative abilities and commitment of their academic staff than most other organisations. For an HEI to maintain a long-term trajectory of excellence in research outputs and teaching, a strong focus on retaining a younger generation of skilled academics is needed. Unfortunately, HEIs have to compete with industry to retain these employees. At the same time, the academic profession has increasingly fallen behind the private sector in terms of, amongst others, remuneration, resulting in a shortage of young academics in South African HEIs. An investigation into intention to quit amongst Generation Y academics at HEIs is therefore justifiable. A mixed-method research design, including both qualitative (focus group and blog) and quantitative (questionnaire) phases, was applied. Academics (n = 189) at six HEIs in South Africa were sampled. The results indicate that job satisfaction, transformational leadership, employee engagement, remuneration, reward and recognition have a significant negative impact on intention to quit. Job satisfaction and employee engagement had the most significant impact on intention to quit. This study contributes to the body of knowledge on intention to quit among academics, and specifically the so-called Generation Y academics. The findings serve as input for the development of efficacious retention strategies and mechanisms to retain Generation Y academics at HEIs in the RSA.

How does social capital influence entrepreneurial decision-making: An empirical study

Hong Du School of Management, ZJU, China; Xinyu Du; Gaogqi Chen

The significance of entrepreneurship and its impact on each aspect of society has drawn extensive attention recently, while entrepreneurial decision-making, the most relevant concept, is becoming scholars’ main interest. Under the background of a relationship-embedded society like China, social capital plays a great influence on entrepreneurial decision-making. The purpose of this study was to investigate how social capital influences entrepreneurial decision-making. Based on “social learning theory,” this study investigated the social capital, entrepreneurial self-efficacy, and entrepreneurial decision-making linkage via a quasi-experiment involving 221 business and economics students who are expected to graduate within two years. A series of two business scenarios with embedded ambiguous data regarding two issues: technological developments and the trend toward internationalisation, were developed to measure cognitive categorisation characteristics and the decision of starting a new venture. These were adapted from Palich and Bagby’s (1995) equivocal scenarios describing a clothing retailer, which we changed to a fictitious clothing startup, ABC. The information paralleled that of the original scenarios. Results indicated that individuals with more helpful weak ties showed stronger entrepreneurial self-efficacy, therefore categorised equivocal business scenarios significantly more positively than did other subjects. Regression analysis demonstrated that these perceptual differences were consistent and significant (i.e. individuals with more helpful weak ties perceived more strengths versus weaknesses, opportunities versus threats, and potential for performance improvement versus deterioration). Positive cognitive characteristics were proved to directly lead to the decision of starting a new venture. We also found that risk propensity had a moderating effect on this relationship.

Australian award based achievement and direction in industrial and organisational psychology

Mark England Australia

This poster outlines actual achievements in Industrial and Organisational Psychology in Australia as recognised by awards in research, teaching and practice. This paper reports on and explores the interviews I conducted with three award winners for the period 2008 to 2011 as recognised by the Australian Psychological Society. The interviews consist of agreed standardised questions covering personal motivations and achievements together with suggested direction for Organisational Psychology. As a result current and emerging directions for industrial and organisational/work psychology research and practice are explained.

Self-regulation strategies buffer negative effects of goal conflicts on work satisfaction

Wiebke Edar University of Bielefeld, Germany; Elke Wild; Malte Schwinger; Julia Gorges

Junior scientists’ workplace is characterised by high autonomy, but also by numerous demands in research, teaching and administration. Qualifying in a highly competitive environment to become a senior researcher requires dealing with multiple tasks and goals. As time is a rare and limited resource, junior researchers perceive intergoal interference due to time constraints. That is, goal conflicts occur when the pursuit of one goal detracts the pursuit of another (Austin & Vancouver, 1996). Experiencing goal conflicts may have a negative impact on work satisfaction, motivation and well-being. With our study we aimed to identify and test emotional and motivational self-regulation strategies that might buffer these negative effects. In an online questionnaire, junior scientists from all over Germany (N = 695) named conflicting goals. We expected the extent to which participants reported these goal conflicts to be stressful, to negatively affect their work satisfaction and well-being. In line with our hypotheses, we found that higher levels of perceived strain of goal conflicts were associated with lower work satisfaction. However, this relation was moderated by junior scientists’ use of regulation strategies. In particular, an overall measure of self-regulation (Schwarzer, 1999) as well as the use of several motivational regulation strategies (Wolters, 2003) seems to be helpful in diminishing losses in work-
Job satisfaction is one of the most intensively studied topics in psychology, as it is not merely the absence of disease or infirmity. The purpose of the current study was to investigate the relationship between mental health and Life Orientation in hospital employments in Iran. The study was carried out so far has dealt with the impact of different types of work extending technology on time pressure. The study is based on data from 2005 and 2006 collected by means of the socioeconomic panel (SOEP), a representative repeat survey carried out on more than 20,000 people. By also taking into account influence variables such as age, job-related stress factors and autonomy, the multivariate analyses show that personality traits have a highly significant influence on job satisfaction. As expected, neuroticism has a negative influence on both satisfaction constructs. Agreeableness, extraversion and conscientiousness have a positive effect, whereas openness (to experience) only influences overall job satisfaction.

The role of power distance in internal communications, case history: Italian committee for Unicef
Zeno Filippi Comitato Italiano per l’Unicef, Italy; Massimo Bellotto; Raffaele Coruzzi
This research aim to perform a report of the internal communications within the biggest Italian not for profit organisations. The first purpose is to observe how the power distance and the expectations of role affect the organisation’s internal communications. The second purpose is to formulate a plan for internal communications through the use of participatory devices. First, the study begin with 155 surveys online, resonance of 60.3%, addressed to all staff of the Italian Committee for Unicef, 110 employees in the main structure of Rome and 45 in the Italian territory. Second, the study continues with four focus group involving 32 employees with the aim of analysing the results of the previous survey. Third, the study terms with five semi-structured interview with the top-management. The research continued with a bench-mark, in the form of semi-structured interview to the human resource managers, able to investigate the study area within the major Italian not for profit organisations: Actionaid, Greenpeace and Médecins Sans Frontières. The research identifies many critical issues in the communication flow and decision making of the Italian Committee for Unicef, together with some significant strengths. It also tracks a report of internal communication within the Italian not for profit organisations aforementioned. The research has achieved its initial objectives. First, greater power distance seems to accelerate the flow of internal information. Second, a three-year communication plan with the aim of increasing the level of employee participation in decision-making.

Satisfied with your job? Personality of the beholder
Simon Fietze Univ. of the Fed. Armed Forces, Germany
Job satisfaction is one of the most intensively studied subjects, not only in the field of organisational psychology. Whereas a major part of the research carried out so far has dealt with the influence of working conditions (situative approach), more recent studies focus on the connection between personality traits and job satisfaction (dispositional approach). The personality traits under examination tended to be chosen unsystematically, without a theoretical foundation, and on the basis of small – mostly selective – random samples. The Five-Factor-Model provides a personality psychology tool that has been recognised for 20 years and is used to record the significant aspects of individual personality (neuroticism, openness, agreeableness, extraversion, and conscientiousness). Taking as a starting point the above-mentioned criticism of the research carried out so far on the dispositional influences of job satisfaction, my study looks at the connection between the Big Five personality dimensions and two facets of job satisfaction (overall job satisfaction and satisfaction with personal income). The study is based on data from 2005 and 2006 collected by means of the socioeconomic panel (SOEP), a representative repeat survey carried out on more than 20,000 people. By also taking into account influence variables such as age, job-related stress factors and autonomy, the multivariate analyses show that personality traits have a highly significant influence on job satisfaction. As expected, neuroticism has a negative influence on both satisfaction constructs. Agreeableness, extraversion and conscientiousness have a positive effect, whereas openness (to experience) only influences overall job satisfaction.

Antecedents of work engagement among working women in South Africa
Madelyn Geldenhuys University of Johannesburg, South Africa; Karolina Laba
Positive psychology in the workplace has become an important topic of research in recent years. Research on the opportunities of women in the workplace seems to be prominent, however there is a lack of investigation into the well-being of women in the workplace. The aim of this study was to investigate work related well-being among women in the South African workplace. The roles of job demands (work load), job resources (organisational support and advancement) and work-role fit on work engagement of women were investigated. Further, the mediating role of psychological meaningfulness was determined. This study used a quantitative research design. Data were gathered with the use of paper and pencil questionnaires. The sample comprised 237 women in the South African workplace. The results of this study indicated significant main effect for workload, organisational support and work-role fit on work engagement. Psychological meaningfulness mediated the relationship between work-role fit and work engagement and partially mediated the relationship between organisational support and work engagement. This study gives insight to the important factors contributing to higher levels of work engagement for women. From a practical and managerial point, it is necessary to understand what motivates and affects the well-being of women in the workplace.

Engagement and psychological meaningfulness at work: The effects of life satisfaction and gender
Madelyn Geldenhuys University of Johannesburg, South Africa; Jillian Williamson
Scientific knowledge relating to the field of positive psychology within the South African workplace is required. The objectives of this study were (1) to investigate the relationships between work engagement, psychological meaningfulness, life satisfaction and gender and (2) to test whether life satisfaction and gender had a moderating effect on the amount of engagement and psychological meaningfulness put forth by employees. Although research on life satisfaction is abundant within the field of psychology, research within the work environment is limited. Furthermore, research is needed within South Africa to promote the wellbeing of employees. Survey designs were used to capture a sample from various South African organisations (n = 800). The Satisfaction with Life Scale, the Work Engagement Scale and the Psychological Meaningfulness Scale were administered. The results showed that life satisfaction, work engagement and psychological meaningfulness were significantly correlated, psychological meaningfulness was a significant predictor of work engagement. Life satisfaction had a significant effect on psychological meaningfulness and work engagement, gender significantly moderated psychological meaningfulness on work engagement and that gender, psychological meaningfulness and work engagement were significant predictors of life satisfaction. This research created an understanding of employee wellness at work through the combination of employee’s personal and work lives. Future research could focus on
identifying what behaviours promote such constructs to enhance individual and organisational success.

**Is an organisational trust always reliable?**

_Lech Gorniak_  
_Cracow University of Economics, Poland_

In this presentation I would like to share my opinions and assumptions, based on several years of my research on an interpersonal trust phenomenon. I am a social psychologist and I specialize— in a theoretical and practical sense— in an organisational communication issues. The problem of trust in organisations— in traditional and virtual ones— and between organizations, is raised more and more often over the last decade. Especially, it is combined with an economical effectiveness of organisations (Lane and Bachman 2002, Kramer and Cook 2004, Kramer 2006, Bachman 2006, Gradzowski et al. 2007, 2009, Hardin 2009, Matzat 2010, Colquitt et al. 2011). The reflections I will focus on are the efforts of searching for the answers to the questions fundamental for the researcher and practitioners. If the benefits of trust are not resulting from a simple linear relations— „a more trust a more benefits” (Barney and Hansen 1994, Adessio and Castlelo 2010) could it mean that: (1) Is there a convincing method of perceiving different degrees of trust between people? (2) How could we describe the difference between trust and naivety? (3) Should we (and why) trust implicitly? (4) Could control and organisational procedures regulate the need for trust? (5) Why do people engage in trusting others in spite of the fact that this phenomenon is known from an asymmetrical relation “gain–loss” (por. Deutsch 1958)?

The moderating effect of interview structure on racial similarity effects in simulated interview ratings

_Daniel Hauptfleisch_  
_University of Stellenbosch, South Africa_

Race-group similarity effects were investigated as a form of interviewer bias in selection interview ratings. Social Identity Theory predicts that interviewers would assign higher ratings to interviewees of the same social group, the so-called in-group. Past research has lent only partial support to this hypothesis. This study argues that interview structure may help to explain inconsistent research findings since structure could inhibit the functioning of the similarity-attraction mechanism. The present research pursued two objectives, namely (1) to determine the degree to which race-group similarity exerts a biasing effect on selection interview dimension ratings and (2) to determine same-group bias increases when interview structure is experimentalized diminished. This study manipulated the degree of structure in interviews and compared the degree to which race-group similarity effects were evident under each condition. Interviews were simulated by showing video-taped interview segments to a sample of participants, and asking them to rate interview dimensions on rating scales that had been compiled to reflect the degree of structure in each condition. The data were analysed using Hierarchical Linear Modelling (HLM) and multiple regression analysis. The results support the hypothesis that racial similarity effects are found under low-structured conditions, as well as the notion that interview structure moderates the influence of similarity effects. However, racial similarity effects were also found with the highly structured condition. Although these were smaller than in the low-structured condition, they still proved to be statistically significant.

**Classification of concepts of safety culture**

_Kenichi Hayase CRIEPI, Japan; Takeshi Itoh; Naoko Hasegawa; Tomoyuki Yamazaki_

Although many concepts of safety culture have been proposed, there is no agreed one. This situation sometimes causes confusion in both academic and practical area. The purpose of this study is to review and classify concepts of safety culture in order to solve such confusion. Concepts of safety culture in 14 literatures were classified based on the classification way for concepts of corporate culture (Iida, 1993). The following two aspects were effective to organise the concepts. The first one is visibility, whether safety culture includes visible thing or not. The second one is viewpoint of existence of safety culture. One is that companies could be divided into ones with safety culture or ones without it. The other is that companies could not be divided in such a way and there are only differences in its strength. The result would be helpful to solve the confusion especially in evaluation and enhancement of safety culture.

**Cognition and multi-faceted aspects of motivation**

_Roche Herbst Human Capital Solutions Inc., Canada; Maretha Prinsloo_

The objective of this study was to measure multifaceted aspects of motivation to include concepts of energy, cognition, values, consciousness and life scripts amongst senior executives working within a global context. Pressure from the recent global economic crises may have a significant impact on those factors that reflect levels of awareness, perception and motivation, related to current strategic leadership behaviour. This analysis examines how different industries and organisational variables are involved, and create a challenging new context within which global executives are required to function effectively, by considering the outcomes from individual motivational profile results. The organisational variables include leadership, culture, strategy, people and the organisation. The industry variables include the financial recession and limited market opportunities. Methodologically, a psychometric and interviewing approach were used. This type of research can be seen as quantitative action, exploratory, descriptive and non-experimental. A cross-cultural sample of 150 senior leaders within a large international manufacturing and mining organization has been investigated. In summary, a SWOT analysis of strategic challenges based on the key assessment findings was presented. Key findings were the relative strength of strategic capability, the inherent risks for organisational pathology and the impact of mergers and acquisitions on the organisational culture. Conclusions of these findings were consolidated into the implementation of strategic principles based on learning, team work and leadership.

**A comparative leadership analysis in an agricultural business**

_Marita Heyns_  
_Northwest University, South Africa_

The purpose of the study was to compare the perceptions of subordinates from two different departments with top management’s own perceptions regarding top management leadership and innovative ability to determine whether differences and/or similarities exist. The empirical study included the Multi Leadership Questionnaire (MLQ form 5X) from Avolio & Bass (2004) to measure self- and subordinates’ perceptions of leadership styles. The Situation Outlook Questionnaire (SOQ) was used next to measure leaders’ self- and subordinates’ perception on the ability to be innovative. The questionnaires were completed by 6 executive committee members (top management) and subordinates from two different departments that have a direct relationship with the executive committee members in an agricultural business. The research findings revealed that there is a significant difference between leaders’ (executive committee members) self-perceptions on their own leadership and ability to be innovative, versus the perceptions of their subordinates on their leadership and ability to be innovative. The research showed that leaders tend to assess themselves higher than their subordinates do. Both leaders and subordinates indicated that the leaders have a transformational leadership style. The results also showed that there is a weak to moderate, positively significant correlation between innovation and transformational leadership styles. Recommendations were made to further promote leadership innovative ability.

**An exploration of leadership trust orientations in an agricultural business**

_Marita Heyns_  
_Northwest University, South Africa; Albe Mouton_

In a fast-changing business environment such as that in which the agricultural sector of South Africa is operating, the competitiveness is very high and stockholders demand better financial performance every year. For an agricultural business to be successful in the end, it must have certain structures, monitoring and control systems in place to manage the internal and external risk factors. Traditional control systems are however, no longer entirely functional. This study explores the importance role of leadership trust orientations in the management of an agricultural business. The primarily goal is to determine the trust orientation profile of top- and middle-level managers. The entire management population of a specific agricultural business was used as target group. Quantitative research techniques were used to determine various dimensions of trust, e.g. leaders’ propensity to trust, willingness to take risks, etc. Statistical analyses indicated that, despite individual variance, the general level of trust was low. Implications for leadership based on outcomes, as well as its potential impact on lower reports, are highlighted. Recommendations focused on specific areas of trust that could be targeted for improvement and also highlights areas for future research.
How abusive supervision affect job satisfaction? A moderated mediation model
Chenyu Hu, Peking University, China; Lei Wang, Peking University, China
Previous research has shown that abusive supervision is negatively related to job satisfaction and this relationship is mediated by subordinates’ justice perception. In the present study, employees (N=419) from a foreign manufacturing company located in southeastern China rated their information. Data was collected in two waves (with 8 month interval) to reduce possible common method bias. While employees’ power distance orientation and their superiors’ abusive behaviours were collected at Time 1, their justice perception and job satisfaction were collected at Time 2. Adding individual power distance orientation as a moderator, we examined and extended Tepper’s (2000) research. Results showed that individual power distance orientation moderated the mediated relationships between abusive supervision and job satisfaction in an organisational justice, such that the effect of organisational justice on job satisfaction was weaker for employees who were higher in power distance orientation. The theoretical and practical implications are discussed.

Motivation for a high job performance and job satisfaction
Cristina Ionica, National Intelligence Academy, Romania; Dorina Coldea
Our study intended to assess the relationship between motivational sources (typology proposed by Leonard, Beuvaux and Scholl, 1999), achievement motivation (Schuler, Thornton and Frintrip, 2000) and job satisfaction (Spector and Lamond, 2002) in order to identify those motivation factors that can help to improve job performance and job satisfaction in an organisational environment affected by nowadays economic crisis. There are some general rules which apply to everyone, but most people are usually motivated by what they perceive as rewards and there are different ways to get them committed and motivated. An evolving socio-economic context creates prerequisites for continuous readjustments of strategies to motivate employees in order to obtain job performance and job satisfaction. The question arises: “what are the best motivation factors and how they can be developed in the context of our present socio-economic reality?” The results of this study, based on data collected from 100 subjects who work in the Romanian public institution allowed us to approach motivation as a process and to diagnose and plan a new organisational strategy for improving job performance, job satisfaction and commitment in this particular organisational sector.

Attitudes towards multiple role planning amongst South African engineering students
Ameeta Jaga University of Cape Town, South Africa; Ilde Marais; Jeffrey Bagrain, University of Cape Town, South Africa
Young adults develop expectations about the future that includes the management of multiple work and family roles. The objective of this study was to test a multidimensional model of attitudes towards multiple role planning (ATMRP) amongst young adults studying towards a professional career with known high work demands. ATMRP is a young adults’ set of attitude, or orientation, toward planning for future involvement with work and family roles. Those with a realistic attitude toward multiple role involvement are more likely to successfully manage a multiple role lifestyle. A survey questionnaire was completed by engineering students (N = 146). Exploratory factor analysis evidenced the multidimensionality of the ATMRP scale. The five dimensions found were knowledge/certainty, commitment, independence, involvement and flexibility/compromise. Multiple regression analysis was used to examine the effects of individual cultural values (gender role ideology, allocentrism and ideocentrism) on attitudes toward planning for future work and family roles. Allocentrism, a collectivistic personality attribute, explained a significant proportion of the variance in the ATMRP dimensions of commitment, independence and flexibility. Ideocentrism (an individualistic personality attribute) and gender role ideology (beliefs about the suitability of particular roles for a particular gender) were not significantly correlated with any of the ATMRP dimensions. Contrary to expectations, there were no differences between male and female students regarding their expectations about managing multiple roles. The findings are discussed with suggestions for those interested in further research to develop the ATMRP construct and for those concerned about helping young adults develop a better planned orientation for managing multiple work and family roles.

Does personal resilience moderate the relationship between work-family conflict and turnover intention amongst blue collar workers?
Ameeta Jaga University of Cape Town, South Africa; Yashfa Mohamed-Kohler; Jeffrey Bagrain, University of Cape Town, South Africa
The object of this study was to investigate the nature and effects of work-family conflict amongst an under-researched group in the work-family literature, blue collar workers. Blue collar workers often face different work-family challenges from those of white collar workers. They are less able to afford domestic help, rarely enjoy access to the benefits of flexible work programmes and are more likely to hold traditional stereotypical gender beliefs. A survey questionnaire comprising established scales with good psychometric properties was completed by blue collar workers employed by a chemical company in Cape Town (N = 136). Exploratory factor analysis on each scale showed that the scales measuring work-family conflict, resilience and turnover intentions were unidimensional. The unidimensionality of the work-family scale was contrary to expectations and extensive previous research showing a distinction between time-based and strain-based work-family conflict. Hierarchical multiple regression analysis showed that the work-family conflict variable explained a significant proportion of the variance in turnover intention over and above that explained by demographic and contextual variables. No support was found for the moderating effect of personal resilience on the relationship between work-family conflict and turnover intention. The results indicate the need for further research on the nature and outcomes of work-family conflict amongst blue collar workers and signals the possibility that current models of work-family conflict require revision for future research on blue collar workers.

Personality, organisational identification, and their relationships to performance of college teachers
Hong Jiang, Capital Univ. of Econ. and Busi., China
Based on a sample of 865 college teachers from 13 universities, the study used a correlation analysis and a regression analysis to test the relationship between personality and the performance for the college teachers, and also the moderating effect of the organisational identification on the relationship above. The results showed that (1) the five dimensions of the big-five personalities have positive relationships with Organisational Citizenship Behaviour; (2) The extraversion dimension, the neuroticism dimension and the conscientiousness dimension of the big-five personalities were positively correlated with the college teachers’ research performance; (3) Organisational identification had a moderating effect on the relationship between extraversion and teaching performance. This effect of also existed between conscientiousness and Organisational Citizenship Behaviour; (4) The simple five dimensions of the big-five personalities had no relationship with teaching performance, but the interaction effect of conscientiousness and agreeableness was positively related to the teaching performance. So it is possible to improve the faculty’s performance by improving their Organizational Identification with faculty, even with different personalities.

What kinds of job seekers are attracted to socially responsible employers?
David Jones, University of Vermont, United States of America; Chelsea Williness
Recent studies have illuminated three signal-based mechanisms that explain why job seekers are attracted to companies with reputations for corporate social responsibility (CSR); CSR provides signals that inform their perceptions of value fit, expectations about how they will be treated, and beliefs about the organization’s prestige. However, little is known about the kinds of people who are attracted by CSR. We drew upon these reasons, why job seekers are attracted by CSR, to understand who is attracted by CSR. We used upon these reasons, why job seekers are attracted by CSR, to understand who is attracted by CSR. Specifically, we tested the effects of individual difference variables relating to CSR and each signal-based mechanism in two studies (Ns = 76 and 116) using longitudinal experimental designs. At Time 1, participants completed individual differences measures. At Time 2 they reviewed web pages of three companies, including a target company whose pages contained a manipulation of the type of CSR activity (community involvement versus pro-environmental practices). Results showed that several individual difference variables were positively associated with the target employer’s attractiveness and the signal-based mechanisms. These relationships tended to be stronger when the CSR was about community involvement, which we expected in some cases (e.g., for communal orientation) but not in others (e.g., for social-identity consciousness). We also found that individuals who were more conscientious were particularly attracted by CSR relating to community involvement, suggesting that these CSR activities may help organizations attract high performing...
employees. We discuss the implications of these results for theory, research, and recruitment practice.

The role of psychological empowerment and organizational commitment in teachers' job burnout

Mahdieh Sadat Khoshouei University of Isfahan, Islamic Republic of Iran; Maryam Bahrami

This research was conducted with the aim of investigating the role of psychological empowerment and organizational commitment in teachers' job burnout. From among the teachers in Shahreza schools as the statistical population, 110 teachers were selected using random sampling. Data was collected through administration of scales of Psychological Empowerment Scale (Spritzer, 1995), Organization Commitment Questionnaire (Allen & Meyer, 1990) and Maslach Burnout Inventory. Three dimensions were considered, including emotional exhaustion, depersonalization, and personal accomplishment (Maslach & Jackson, 1981). Data were analysed with the use of Pearson’s correlation coefficient and hierarchical regression analysis. Results showed that psychological empowerment has a significant negative correlation with emotional exhaustion and depersonalization (dimensions of job burnout) and a significant positive correlation with personal accomplishment (another dimension of job burnout). Organizational commitment also has a significant negative correlation with emotional exhaustion and depersonalization. However, hierarchical regression analysis shows that psychological empowerment predicts emotional exhaustion and personal accomplishment, and organizational commitment predicts emotional exhaustion.

Optimising knowledge-management and team climate by management cockpit tools

Gerald P. Kolar University of Applied Sciences, Austria; Unterrainer Christine University of Applied Sciences, Austria; Kasar Armin; Winkler Peter

Effective knowledge management (KM) is an important competitive factor for successful companies. As Zarraga and Bonache (2005) point out, team atmosphere has important consequences on KM. Thus, in our empirical study we focus on the relationship between KM and team atmosphere in the context of a market research institution. Results reveal that the categories of knowledge-sharing and knowledge application are particularly strongly associated with a team climate. Management-cockpit tools may be adapted to support transparency and efficiency of these categories. Thereby, we can build on existing data warehouses and management information systems, highlighting some important key indicators of management cockpits. The specific benefit of these indicators consists in the representation of relevant information for each team as well as the corresponding division according to their respective requirements. This specific focus strongly encourages knowledge application as relevant competitive factor.

A game-theoretical framework for work motivation theories

Ludek Kolman Czech Univ. of Life Science, Czech Republic; Pavla Rymesova Czech Univ. of Life Science, Czech Republic; Lucie Gralton

The presentation concerns results of a motivational survey in which two groups of respondents differ only slightly in their characteristics, or in ways seemingly superficial. Even so, their answers differ significantly in several cases. A possible way to understand this result might be explained by an assumption, as follows: The stimuli which commencing the motivational processes are learned (in difference to the processes and contents of the motivation as such), some individuals might differ in their answers to events and situations according to their diverse life experiences and previous learning. This assumption could be used to implement a theoretical model wherein the individual motivations responses will be defined as strategies in the sense of game theory. The results of the survey will be presented. The data were analyzed by means of SPSS software. The theoretical model will be introduced, and its main implications discussed. The paper was prepared thanks to the support of the Czech Science Foundation grant #P407/10/1262.

Occupational stress, mental health and coping among IT professionals

Chandraiah Kotta Sri Venkateswara University, India

The study was aimed at investigating occupational stress, mental health, and coping among professionals working in the information technology industry. The sample for the study consisted of 150 Information Technology (IT) professionals working in Lucknow and Allahabad cities of UP of India. The Job Satisfaction scale, Occupational Stress Index coping behaviour of Pressure Management Indicator (PMI) developed by Cooper et al was used to measure the level of job satisfaction, occupational stress and coping behaviour of both junior and senior professionals. The sample was drawn based on simple random sampling procedures. The results showed that stress is very common in the IT industry due to the nature of the work and is unavoidable. The available studies in the literature reveal that various factors are responsible for experiencing occupational stress in this industry. Due to an uncertain economy, increased demands for overtime due to staff cutbacks, act as negative stressors. The relentless requirement to work at optimum performance, takes its toll in job dissatisfaction and employee turnover. ‘Mental Illness’ being a shorthand term for a variety of illnesses that affect mental well-being.

Emotional labour scale: Development of an Indian measure

Sandeep Kumar Banaras Hindu University, India; Binayak Shankar; Ashok Singh

The display of emotion of employees in customer service is at central stage, in order to create the perception of quality of service. This concern has led service employees to engage in performing emotional labour. The four major conceptualizations of emotional labor are: (a) Strategic model (Hochschild, 1983); (b) Behavioural model (Ashforth & Humphrey, 1993); (c) Interactionist model (Morris & Feldman, 1996); (d) Emotion regulation model (Grandey, 2000). These measurement models have limited their coverage to the main theme of their definitions while overlooking the other components contributing to emotional labour. This limit in horizon in measuring emotional labour necessitated the need for a new tool to measure emotional labour. We have attempted to rise above the limitations of various definitions and integrate all of these measures to provide a comprehensive characterisation of emotional labour, covering all domains of organisational life. The proposed model covers individual (strategies), job characteristics, and emotional deviation produced in the process. We propose five dimensions of emotional labour on the basis of extensive review: deep acting, surface acting, frequency, attentiveness, and emotional dissonance. Ten items for each dimension were formulated. A total of 300 employees of public as well as private banks were administered this questionnaire, out of which 250 returned. These data were used for analysis. The Cronbach’s alpha reliability of various dimensions ranges from .65 to .85, and reliability of complete scale was found to be .81. The validation of the scale on a sample of university teachers is in progress.

Personality as a moderator variable in the relationship between stress state and job attitudes

Sandeep Kumar Banaras Hindu University, India

Stress is subjective in nature; it varies from person to person and situation to situation. Sometimes people feel good and sometimes bad; it depends on their subjective state. A ‘subjective state’ is defined as a relatively transient quality permeating conscious awareness whose representation is distributed across a variety of mental processes or structures, and which has the potential to generalise across activities, and contexts. It is vital to understand how the stress state affects job attitudes and how personality moderates the relationship between stress state and job attitudes. The aim of the investigation was to study the relationship of stress state and job attitudes, and to examine whether personality moderates the relationship between stress state and job attitudes. The current study was conducted on 175 employees working in coal mines situated at Dhanbad (India). The Stress State Questionnaire, S-D Employees Inventory and Job Involvement Scale; and Eysenck Personality Questionnaire-R were used to measure stress state, job attitude and personality respectively. The results were analysed using correlation analysis and moderated regression analysis. The results of the investigation revealed that the task engagement dimension of stress state positively correlated with job attitude (job satisfaction and job involvement) and the distress dimension of stress state negatively correlated with job attitudes. The different dimensions of personality (extraversion, neuroticism and psychoticism) significantly moderate the relationship of stress state and job attitudes. The findings support the notion that the person appraises and regulates their own stress state.

Emotional intelligence and (d)stress in the South African Police Service

Despina Learmonth University of Cape Town, South Africa; Danny Papier

This study aimed to determine how levels of Emotional Intelligence (EI) were related to overall levels of stress, anxiety and depression amongst members of the South African Police Service (SAPS). South Africa has some of the highest reported rates of violent crimes worldwide. Members of SAPS, as a result of their vocational positions, are often ex-
posed to these violent crimes. High levels of stress, anxiety and/or depression can adversely affect work performance with resulting absenteeism, low morale and sub-standard work output and outcomes. This in turn, can negatively impact on work colleagues. The study’s participants were 40 police officers (13 female and 27 male) 20 officers from Khayelitsha and 20 officers from Delft police stations (mean age 38.6 years). Both these police stations are located in informal settlements on the periphery of the city of Cape Town. Police officials were randomly selected to complete two study questionnaires. A correlation analysis was carried out between the DASS-21 and the Schutte’s Emotional Intelligence Scale scores to determine whether a relationship existed between EI and psychological (di)stress, depression and anxiety. The results revealed that EI significantly correlated with stress (p=0.057) and anxiety (p=0.026), but not depression. Inverse relationships between EI and stress, and EI and anxiety, were found. Interventions to increase levels of EI amongst members of SAPS may be hugely beneficial in preventing the negative outcomes so frequently associated with psychological (di)stress.

Transformational leadership in relation to organisational culture within the South African national defence force
Ophilia Ledimo University of South Africa, South Africa; Ophilia Ledimo

Political and legislative changes in South Africa have led to the transformation of the new South African National Defence (SANDF), through integration of different forces. This created a diverse workforce with new leadership, strategic intent, processes and systems. This article poses the question: What is the relationship between transformational leadership and organisational culture within SANDF? The main objective was to explore the relationship between transformational leadership (Leadership Practice Inventory) and organisational culture (Organisational Culture Inventory) within SANDF. An empirical study was conducted using a quantitative survey on a random sample of N=238 ASGP employees within SANDF. Results indicate a significant positive relationship between transformational leadership and organisational culture, and that demographic groups differ significantly in their perceptions of variables. Organisational development practitioners proposing interventions for leadership development and culture change need to take into consideration the relationship between transformational leadership and organisational culture. Results contribute to current organisational development literature and provide valuable information that is useful in proposing leadership and organisational development interventions that are vital for organisational survival.

Social support can reduce job stress: A moderating role of other orientation
Dan Li Peking University, China; Lei Wang Peking University, China; Si Yu

Perceived social support can conditionally reduce the stress of one’s work, however, there is no agreement on the levels and patterns of influence. Some theories, such as stress theory model and transactional model, suggested that personal characteristics play an important role in generation of stress. Other theories, such as the Buffeting Model, mentioned that the social support as a group-level moderator can impact a person’s physical and mental health. According to these models, we conducted a two-stage quantitative study by three questionnaires. Participants completed questionnaires on perceived social support, other-orientation, and job stress on Time 1, and they were also asked to complete the questionnaire of job stress 3 months later. The results revealed that social support in fact reduces one’s job stress, however, the reducing effect was stable and significantly moderated by participants’ other orientation. Specifically, the social support can reduce more job stress on the individuals with higher other orientation than the individuals with lower other orientation. This finding suggests that the perceived social support would not always account for one’s job stress effectively, while moderated by factors such as other orientation. Additionally, the result extends not only the research areas of job stress and social support, but also provides many practical implications on human resource management.

How shared leadership influences individual learning behaviour: The mediating effect of psychological safety
Songbo Liu Renmin University of China, China; Zhen Wang; Feng Liu; Xiaoshuang Lin

Edmondson’s “Leader behavior-psychological safety-learning behavior” model has been established for more than a decade. We wanted to enrich this classic model by: (1) Adding one more specific type of leadership, shared leadership, into this field, (2) extending the research level from only team level to team-individual level; shared leadership is an emergent team property that results from the distribution of leadership influence across multiple team members, which is totally different from the traditional leadership perspective. We put forward that shared leadership is helpful for psychological safety (team level), and then leads to individual behaviour positively. By investigating 56 work teams in a big Chinese company, we confirmed the mediating effect of psychological safety on the relationship between shared leadership and individual learning behaviour through hierarchical data analysis. Our study is also a step forward to explain the “black box” of leader behaviour - individual learning behaviour. In the shared leadership field, we answered 2 important theoretical questions: (1) Is shared leadership really good for team members? (2) How does shared leadership function?

The relationship between servant leadership, affective team commitment and team effectiveness
Bright Mahembe Stellenbosch University, South Africa; Ames Engelbrecht

Effective teamwork is one of the core components of high-performance organisations. Value-based leadership practices play a critical role in team effectiveness. The primary goal of the study was to design and conduct an analysis of the relationships between servant leadership, affective team commitment and team effectiveness. The aim of the study was to validate a theoretical model explicating the structural relationships between these variables in the South African education sector. A convenient and multi-cultural sample consisting of 202 primary and secondary school teachers was drawn from 32 schools in the Western Cape Province of South Africa. High levels of reliability were found for the sub-scales of the latent variables. Unidimensionality of the sub-scales was also demonstrated through exploratory factor analyses (EFA). Good fit with the data was found for the measurement models of the specific latent variables through confirmatory factor analyses (CFA). Structural equation modelling (SEM) showed a good fit for the structural model. A positive relationship was found between servant leadership and team effectiveness. Furthermore, multiple regression analysis showed that affective team commitment moderated the relationship between servant leadership and team effectiveness. The findings emphasise the central role played by servant leadership and affective team commitment in understanding employees’ behaviour in teams. Servant leadership fosters team effectiveness if employees feel committed to their work team. Future studies should expand the theoretical model by incorporating additional latent variables that may influence team effectiveness.

How I integrate the principles of Logotherapy (meaning/purpose in life) in my work environment
Solomon Makora Central University of Technology, South Africa

The purpose of this study was to investigate whether Viktor Frankl’s theory of finding meaning in life can be taught to all people, including members of the management team in my institution. The participants are 14 members of the Welkom Campus Management Committee (WCMC) at the Central University of Technology, Free State. For the quantitative data, a pre-experimental design, one group pre-test-posttest design, has been used to evaluate the influence of the workshop on the participants’ Purpose in Life Test (PIL) scores and Minnesota Satisfaction Questionnaire (MSQ) scores. T-tests for paired samples were computed on the 28 complete sets of pre- and post-test PIL and MSQ scales to test the significance of the outcomes. In the qualitative section, a participatory action research design has been used. On average, the group displayed a high purpose in life before the workshop, with a mean score of 121.50. However, the workshop brought about a significant increase of 6.21 in the participants’ PIL scores. For general work adjustment, the group displayed a high degree of satisfaction before the workshop (MSQ M= 82.29; after the workshop, their mean MSQ score increased to 85.21. Thus, teaching Logotherapy to the management team resulted in significant improvement in their levels of meaning, as well as job satisfaction. As a result, the higher the participants’ levels of meaning, the better adjusted they were at work. The results were confirmed by the qualitative part of the action research.

Interpersonal relations in six departments of a university: A comparative analysis
John Marasigan Kwantlen Polytechnic University, Canada

The study aimed at demonstrating positive relationship between various aspects of interpersonal rela-
A comparative study of stress and anxiety before and after Ramadan

Tayebeh Mehrabi Isfahan University Of Medical Sciences, Islamic Republic of Iran

Managers of institutions have a very tensive job. Studies show that people without religious bonds cannot fight satisfactorily their daily desires and their frequent changes. One of the regular praysings and principles of Islam is fasting which is approved for providing spiritual health and increasing patience and tolerance in individuals. This study wants to find out how fasting may effect the experienced tension of managers. Data were collected using the Katel’s standard questionnaire of anxiety and stress symptoms. The questionnaire was filled out by managers one month before Ramadan and one week after Ramadan. Data were analysed using T-test, Pearson and Spearman correlation coefficient and ANOVA. Findings showed that the mean of anxiety in managers was 68.25±14.1 before Ramadan and 75.19±29.1 after Ramadan. T-test showed a significant difference (p=0.001). Also, the mean of stress in managers was 25.68±1.14 before and 19.75±1.29 after Ramadan (p=0.001). In addition, the results showed a significant difference between age with stress and anxiety among the managers (p=0.018). Fasting is the most effective way to reduce the stress effects and as the results of this study show, it brings calmness, sincerity, patience and tolerance. We hope that fasting as the focus of a lively constant culture in the society pave the way to eloquence.

Differential experiences of emotional labour and burnout among Indian professionals

Sasmita Mishra School of Management, KIIT Univ, India; Dibyendu Choudhury

An online survey was conducted on 209 Indian professionals to know the extent of emotional labour they put forth and burnout they experience. Eta tests were conducted to find out the mean difference of emotional labour and burnout across a range of precept variables. Results revealed that those professionals differed in the level of emotional labour across age, education level, total years of experience, organisation type and industry type. However, there was no gender difference with respect to experience of emotional labour. When their experience of burnout was compared across these variables, they did not differ with respect to age, organisation type and total years of experience. But, males and females differed with respect to their burnout experience. Females were found to be experiencing more burnout than males though they were seen to be exerting equal emotional labour at workplace. Findings were discussed with reference to socio-cultural context and gender role.

Stress, burnout and ways of coping among professionals

Jitendra Mohan Panjab University, India

Stress and burnout are major factors which professionals often have to deal with in their work environment. The present research was aimed at investigating the stress, burnout, type A behaviour, and ways of coping among different professionals. For this purpose, 250 professionals were purposely selected as respondents. The total sample of 250 professionals was further sub-divided into 5 groups. The sample comprised the following professions: Police, IT professionals, Medicine, Engineering and Education. The following standardised tools were used: 1. Organizational Role Stress Scale, (Pareek, 1982), 2. Maslach Burnout Inventory (Maslach & Jackson, 1981), 3. Type A behaviour Questionnaire (Cooper, 1988), and 4. Ways of Coping Questionnaire ( Folkman & Lazarus). Inter-correlation method was applied to find the relationship of Stress, Burnout, Type A, and ways of coping. Analysis of variances was also applied to find the mean differences in these groups. Results revealed that there was a significant relationship between these dimensions. Group differences were also found. It can be concluded that stress and burnout plays a very important role for professionals. Efforts should be made to manage stress and burnout effectively.

The role of academic resources on student engagement

Kelebogile Mokgele Northwest University, South Africa; Sebastian Rothmann

In order for students to enjoy and succeed in their studies, they need to dedicate their energy and time, while being both enthusiastic towards and responsible for their studies. Research done on engagement, indicates that job resources have an impact on whether an individual experiences engagement or not. Study resources should for the students, therefore, also have an influence on student engagement. Work engagement is characterised by a high level of energy and high identification with one’s work (Salmela-Aro, Tolvanen and Nurmi, 2009). The importance of job resources as positive predictions of work engagement, while job demands are not significantly related to work engagement, is highlighted by Schaufeli and Bakker’s (2004) definition of “job resources”. A quantitative research approach is followed in this study. Student Resources Questionnaire and the Oldenberg Inventory are used in the study to determine the support given in the form of academic assistance. The extent of such study resources should be able to determine student engagement. It is predicted that positive relationships will exist between student resources and student engagement. This research makes an important contribution with regard to engagement research on university students. In addition, practical interventions for increasing student engagement, as well as consequences thereof, will be suggested.

Social network and workers’ welfare

Elaine Neiva University of Brasilia, Brazil; Daniel Barbosa University of Brasilia, Brazil

The objective of this study was to investigate the relationship between workplace welfare, and the characteristics of friendship and communication networks in labour courts. This study was developed in light of the Work Psychodynamics approach, which postulates about dynamic relations involving labour organisations and individual processes. It becomes important to assess the relationship between individual processes, and the social networks that workers develop, seeing that individuals develop social networks which, configured in a formal or informal way, allows the transition of varied contents which interfere in the workings of labour organisations. Thirty public servants chosen from four labour courts participated of this study. The Work and Risk Disease Inventory (ITRA) was applied with a questionnaire for mapping and, consequently, measuring the Social Networks, making it possible to verify the relationship between the data of both instruments. One of the results found was a positive relationship between the human cost in the physical, cognitive and emotional spheres, and the positional measures of the networks. A higher impact on human cost for the public servants who assume central roles in the networks was also found. One of the conclusions is that, as the workers broaden their social networks, it becomes more demanding to maintain the bonds within the network.

Explaining the role of perfectionism and occupational stress in job burnout

Shekoufeh Nikneshan Payame Noor University, Islamic Republic of Iran; Narges Mohamadi; Mina Mazaheri

This study examined the relationship of job burnout with occupational stress and perfectionism. The aim of this study was to explain job burnout according to negative and positive perfectionism and occupational stress among a group of staff. The research design constituted a descriptive correlation. The statistical population comprised the staff of an organisation of the municipality in Isfahan in 1387 s. The total statistical population consisted of sixy individuals, therefore no sample was selected. All participants were asked to complete a Cooper occupational stress inventory (OSI-22), Geldard burnout inventory (BI-40), and Perfectionism inventory (PI-40). Pearson’s correlation coefficient and step-by-step regression analyses were used to analyse the data. The results of Pearson’s correlation coefficient indicated that there is positive significant relation between occupational stress and negative perfectionism with job burnout. Also, the results of step-by-step regression analyses indicated that negative perfectionism, positive perfectionism and occupational stress are capable of predicting job burnout. There was no significant difference between male and female. In conclusion, occupational stress and negative perfectionism increase levels of job burnout.
The influence of employees’ self-efficacy on their quality of work life

Abigail Opoku Mensah University of Cape Coast, Ghana; Lebboeus Asamani

Many employees today are spending more time in the workplace in response to job insecurity, workplace demands and financial pressures. Self-efficacy and Quality of Work life (QWL) remain relatively unexplored and unexplained, especially, in Ghana. This study seeks to find out the current status of employees’ self-efficacy and QWL, and the extent to which self-efficacy of employees influence their QWL. The study measured self-efficacy relative to employees’ quality of work life to improve performance. The study was a descriptive survey. It used frequencies, averages and other statistical methods to analyse the data. The sample consisted of 200 employees, 70 from service institutions, 50 from financial institutions and 80 from educational institutions. Organisations and respondents were randomly selected. Descriptive statistics, Pearson’s correlation and the One-Way Analysis of variance (ANOVA) were used to analyse the data using the SPSS for Windows. The results indicated that, there was a significant positive correlation between self-efficacy and QWL of employees ($r = .225$, $p < .01$). There were no significant influences of employees’ age and tenure on their self-efficacy. The results revealed that employees’ educational level significantly affected their QWL ($F = 2.92$, $p < .05$). A post hoc (LSD) analysis was conducted to ascertain which levels significantly differ.

Authentic leadership and safety climate in shipping

Olav Kjellevolld Olsen Royal Norwegian Naval Academy, Norway; Gerry Larsson; Jolje Eid; Hanne Borger; Sigurd Hystad

Due to many critical accidents in the shipping industry over the past decades, safety performance (safety compliance and participation) on ships has received increased attention from industry and research. Safety climate, defined as safety perceptions, attitudes and beliefs, is a factor that has been shown to promote safety performance in such safety-critical organisations. The study investigated how leadership influences the safety climate on board and more specifically if authentic leadership can explain a positive safety climate. Questionnaires were distributed to 499 Filipino seafarers working on Norwegian-owned cargo vessels. The results show that the level of the masters’ authentic leadership predicts level of safety climate, but only the facet of relational transparency proved to be a significant predictor on facet level. The results indicate that the authentic leadership model could represent processes that foster a positive safety climate in shipping, and that authentic leadership development may be a fruitful avenue for enhancing safety performance on ships.

The relationship between work-family conflict and job stress considering the mediating role of psychological hardiness. A sample of 250 persons from the Iran Polyacril Company were randomly selected. Measures were the Work-family Conflict Scale, Job stress scale, and Hardiness scale. Findings indicate that work-family conflict and family-work conflict are related to job stress. The mediation role of hardiness was also confirmed, using hierarchical regression analysis. To explain the results, we must notice that individuals high in hardiness are protected from job stress, because they consider changes as challenging in their lives and interpret them as unfolding and self-actualization processes. Their access to effective coping strategies, makes them capable of encountering external conditions as proactive and not passive persons; namely they plan for their own life, not relying on external conditions. These characteristics help them to manage the responsibilities of work and family life in a good manner and therefore decrease the stress resulting from work-family conflict.

Relationship among five forms of work commitment, desire to remain and turnover

Hamid Reza Oreyzi University of Isfahan, Islamic Republic of Iran; Maryam Akhbari

There is a body of research that has investigated different forms of work commitment and its relation with each other as well as its effect with exit behaviours like desire to remain and turnover intention. In this study the relation between five forms of work commitment with each other and exit behaviours have been explored based on the Randall and Cote (1991) model and Balfour and Wechsler (1996). These forms of work commitment are: work involvement and job involvement (Kanungo, 1982), identification commitment, affiliation commitment, and exchange commitment (Balfour & Wechsler, 1996). Variables which are studied as exit behavoiurs are the desire to remain (Balfour & Wechsler, 1996) and turnover intention (Porter, Crampin & Smith, 1976). The samples of this study are 272 employees of a public organisation which were selected randomly. Data were analysed based on structural equation modelling. Absolute, Comparative & Parsimonious fit indices of the presented model showed an acceptable level that indicates support for the presented model. Based on the result, work involvement has a direct effect on job involvement and an indirect effect on other variables. Also job involvement has been found to have a direct effect on all three dimensions of organisational commitment and, moreover, with the mediation role of different dimensions of organisational commitment would result in higher levels of desire to remain and lower levels of turnover intention. The result shows by changing dimensions of organisational commitment, changes in turnover intention indirectly would precede changes in desire to remain.

The Oriki as a tool for leadership development

Judith Okonkwo British Airways, United Kingdom; Vivian Adum

This study stemmed from two perspectives, the first was the exploration of cross-cultural influences in the workplace, seeking to find a route for businesses to, not only navigate the complexities that a multi-cultural workforce in a global organisation can pose, but also provide them with tools for leverage on this diversity, and build up authentic core competencies that benefit from individual experience. The second, a review of scholars poring over trend data and conceding that leadership and management are skills gaps that need to be breached in Africa in particular, with multi-nationals from NGOs to large corporates echoing this view. The author considers this an uninformed position that stems from the consideration of leadership as a Western derivative infused with a few Asian principles (predominantly Chinese). However the ability to lead people, to get the best out of them, has existed globally for several years, and there is much to be learnt from all cultures. The result has been the development of a leadership coaching methodology that has roots in Yoruba mythology but transcends cultures and is currently being trialed by individuals in various organisations. The development and practice of this method is discussed along with new insights from ongoing work.

Globalisation and healthcare delivery: The experiences of Nigerian expatriate doctors

Judith Okonkwo British Airways, United Kingdom; Vivian Adum

This presentation showcases a study that focused on the experiences of Nigerian expatriate medical professionals practicing in the United States and the United Kingdom. A survey was administered to a sample and further data gathered through a series of in-depth interviews, which focused on their experiences as expatriate professionals and the impact that this has had on their productivity. Results and conclusions are discussed.

Investigation of positive affect and emotional intelligence effect on job satisfaction among oil refinery personnel

Hamid Reza Oreyzi University of Isfahan, Islamic Republic of Iran; Narjes Fashihzadeh

Research has shown a relationship between personality and job satisfaction in two domains namely;
core self theory and genetic theories related to personality. The aim of the current research was to investigate the relation of emotional intelligence and positive affect with job satisfaction and then respond to the question of which variable has the greatest contribution to job satisfaction. The statistical population was total personnel, formal or informal persons in the Isfahan Oil Distribution and Refinery Company including 1429 persons who were working in 2009 (1338 s. c.). A simple random sample of 230 personnel was chosen. The Job Satisfaction Questionnaire of Judge and Bono (2000) Emotional Intelligence Questionnaire of Human and Health Capabilities Institution (2006), and Positive Affects in Job Questionnaire of Fox and Spector (1999) were used as instruments to measure the variables. Results indicate that affect and emotion play role in job satisfaction.

An investigation of the content of police professional identity: An internal perspective
Catalina Otoiu Babes Bolyai University, Romania; Lucia Ratiu; Daniela Andrei; Claudia Rus; Gabriel Vonas
To date, there is no commonly accepted definition of the concepts of "identity" in general, and "professional identity" in particular. Our research question was driven by the lack of a unified framework to conceptualize professional identity and by the fact that, while most of the studies in this field focus on the construction of professional identity, very few look at and discuss its content. Thus, the aim of this study was to examine the way in which Romanian border police perceive their professional identity. More specifically, this study focuses on identifying both the core and the peripheral aspects of police professional identity. The sample is comprised of 26 border police, located in different regions of Romania and working in different structures and on different organizational levels within the Romanian Border Police Force. The 21-statements test, a modified version of the 20-statements test (Kuhn & McPartland, 1954) was used to collect information about the primary characteristics of the police professional identity. Following the procedures used in Q-sort techniques, the mentioned characteristics were arranged on a +4 (least important feature) to +4 (most important feature) Q-sort distribution format, according to the degree of importance to the profession of police. Our results give a general overview of these core content of police professional identity and the main values that are comprised within it.

Social responsibility in universities: A systematic review
Catalina Otoiu Babes Bolyai University, Romania; Sofia Chirica; Daniela Andrei; Claudia Rus
The aim of this study was to systematically integrate the literature on university social responsibility in order to identify its definition and its links with professional education and with professional development within universities. The analysis was conducted on 191 papers identified through a computerized search on Sage, Wiley, Emerald, InformaWorld, ScienceDirect and SpringerLink. Using content analysis, the results revealed that social responsibility in universities was studied from different theoretical perspectives. There are no empirical studies that have examined, within the same study, multiple aspects and facets of this concept, or the interaction between these aspects, and we found no apparent trends in its theoretical development. It was frequently examined from the perspective of corporate social responsibility, and less examined in academic settings. The results of the review show that social responsibility in universities can be considered as the impact of the university on society, through professional communities, and in terms of the way in which society, through communities of practice, influences the way in which universities continuously redefine their objectives and operating mode in their efforts to become more efficient on the educational market. The main dimensions of social responsibility identified through this analysis consisted in strategic orientation, active citizenship, ethics, reflection, critical thinking and autonomy. These results reflect the multidimensionality of social responsibility in universities and the need to extend the empirical research on this topic.

The relationship between stress, workload and burnout
Seyed Reza Poorseyed University Esfahan, Islamic Republic of Iran; Hadi Emami Daramrood
The purpose of this study was to determine the relationship stress, workload and burnout in nurses. Subjects were 150 students (76 male and 74 female). The instruments, were workload Scale (WLS), stress Check list (SCL) and burnout Questionnaire (BQ). The results showed that there were significant correlations between all of the stress, workload and burnout scores (P<0.05). The result of analysis of regression show that stress, and workload together explain 5 percent of variance in burnout (P<0.01).

The relationship between self-esteem and employability attributes of postgraduate business management students
Ingrid Potgieter UNISA, South Africa
The impact of challenges such as decreased employment opportunities, increased personal responsibility to keep up with the changes, current skill shortages and demands for retaining talented and skilled staff have led to emphasis on career meta-competencies to enhance an individuals’ employability attributes. The objectives of the study were: (1) to determine the relationship between self-esteem (as measured by the Culture Free Self-esteem Inventory) and employability attributes (as measured by the Employability Attributes Scale), (2) to determine whether individuals’ biographical details significantly predict their self-esteem and employability attributes, and (3) whether males and females differ significantly regarding self-esteem and employability attributes. There seems to be a paucity of how individuals’ self-esteem relates to their employability attributes in South Africa’s multicultural organisational context. A quantitative survey was conducted on a convenience sample of N equals 304 employed adults enrolled for an honours degree in business management in a higher education institution. Correlational statistics, multiple regression analyses, categorical regressions and independent t-tests were used to analyse the data. A number of significant relationships between the participants’ self-esteem and employability were found. The results showed that biographical details significantly predicted participants’ employability attributes. Career counsellors and human resource practitioners need to recognise how people’s self-esteem and their biographical details influence their employability attributes. The findings add to existing career literature on the skills and competencies and biographical information that influence employability and provide valuable information that can be used during career development support practices and career counselling practices in the contemporary world of work.

One organisation, different minds: Agency model of hospital workers
Ariel Quezada Universidad Adolfo Ibáñez, Chile; Macarena Sanchez; Pedro Cabrera; Javiav Espinosa
In a hospital, workers are exposed to different sources of risk, e.g. infections, trauma, contagion, radiation, etc. However, risks could be higher if a worker perceives whether accidents are preventable or not. In this sense, mental models about agency are central to prevent negative actions. Culture psychology describes different information processing, promoted by different cultural contexts. Markus and Kitayama (1991) indicated that collectivism is typical in eastern cultures while individualism is typical of western cultures. Recent investigations reveal that social class is also an important cultural context, with a strong influence on cognitive agency models of individuals (Stephens, Markus and Townsend, 2007; Stephens, Markus and Fryberg, 2011). This can have an expression in the agency model of professional and non-professional workers in the same organisation. To measure implicit cognitions about agency models of participants (Fazio and Olson, 2003), we used a procedure described by Savani, Markus, Naidu, Kumar and Berl (2010)

Industrial/Organisational/Work
showing a 6 minute video and asking participants how many decisions taken by the actor, were observed in this film. We compared the number of decisions reported by professionals and non-professional participants. Collected data showed a significant difference of decisions observed by each group of workers $F(1, 59) = 46.903 \ p < 0.001$. Results reveal different agency models on different actions. This can explain diverse attributions of risky behaviour. Indeed, this finding could be used to design training in a safety culture, integrating the particular mental model of workers, focused on the cultural context of each social group.

Transformational leadership: The role of psychology in leadership development and change
Wiehann Rademan Sanlam Personal Finance, South Africa

The purpose of the paper is to introduce the concept of transformational leadership and the required competencies in the current macro environment. Research supports a transformational leadership style given the changing social and business landscape and the need for operations in multicultural environments. As such, transformational leaders aim to motivate others to achieve beyond what was originally thought possible. Ways of developing leadership are explored. As a manager of a group of psychologists, the author links current general leadership knowledge and collective professional experiences with process suggestions for other practitioners. Core to transformational leadership are the elements of innovation, collaboration and practical teamwork. Psychological change processes like consciousness rising, choosing, and conditioning, form the platform for the development of these core leadership competencies. Psychological process work, and dynamics, featured during the discussions between psychologists who coach senior managers and act as development facilitators are illustrated. Themes like strategic planning, leading others, empowerment, interactional leadership practices and personal leadership development are amongst these critical topics for discussion. Furthermore, the leadership needs of a group of South African mass middle market financial advisers are mentioned and essentials like interactive, visible and visionary leadership are briefly described. The leadership expectations within the group of advisers were identified during trend analyses after national focus groups in a financial institution were conducted. Finally, the paper concludes that transformational challenges are central to all sectors of the South African context and psychological process work can help in the selecting and moulding of leaders capable of leading change.

Quality of work life and psychological well-being of police employees: A relationship study
Rekha Rani Indian Institute of Technology, India; Pooya Garg

This study examined the effect of quality of work life (QWL) on psychological well-being (PWB) of police employees. Measuring psychological well-being of police employees is worth investigating, not only because understanding the “optimal functioning” is likely beneficial to police organisation, but also because fostering the employees’ entire health, contentment and experience fully functional person in life spheres. Quality of Work Life Scale (QWLS) developed by Angus S. McDonals and Psychological Well-Being Scale (PWBs) developed by Carol Ryff were used for data collection. The participants were chosen using purposive convenient sampling. The results from Pearson’s R and Multiple Stepwise Regression Analysis indicated that the dimensions of QWL (support from manager/supervisor; freedom from work related stress; job satisfaction; challenge, use of skills and autonomy; salary and additional benefits; relationship with work colleagues; involvement and responsibility at work, and communication, decision-making and job security) have significant and positive contribution in maintaining PWB (autonomy, environmental mastery, personal growth, positive relations with others, purpose in life and self-acceptance). The findings suggested that experiencing high QWL in the workplace dramatically leads to psychological well-being, that in turn leads to life satisfaction of police employees. In fact, QWL can definitely boost the energy, optimal functioning and positive behaviours in personal and professional life. The study provides valuable implications for the police practitioners, researchers and management body to better understand the workplace requirements and psychological needs of police employees where they can experience themselves to be fulfilling, and develop as global citizens with true human potentials.

A consideration of the role of culture and/or sub-culture as contributors to national profiles of entrepreneurial activity
Hazel Rosin York University, Canada

Differences in national levels of entrepreneurship have been observed by scholars. There is an ongoing effort to understand the reasons for this, and to identify and examine variables that appear relevant to these differences. Interest in this phenomenon is driven by the existence of a substantial body of research evidence showing that a vibrant entrepreneurial sector is an important source of a country’s economic and employment growth (Birley, 1987; Schumpeter, 1934; Thomas & Mueller, 2000). Among the variables believed to contribute to national differences in entrepreneurship is culture. Ongoing cross-national research facilitated by the Global Entrepreneurship Monitor consortium (GEM) has identified culture and social norms as one of nine “entrepreneurship framework conditions”, i.e. variables that “influence individuals’ decisions to pursue entrepreneurial initiatives” (GEM, 2009). In a review of research in this domain, Hayton, George, & Zahra (2002) concluded that culture may act as a moderator of the relationship between the economic and institutional context and entrepreneurship indicators. However, they observed that systematic and in-depth research into culture’s role is at an early stage. This paper will draw on empirical and theoretical approaches to date to develop a model of the relationship of culture (or, within diverse societies, sub-culture) to entrepreneurial cognitions and behaviour.

Safety, health and quality of life in personal and organisational level in the manufacturing industry
Jose G. Salazar Estrada Universidad de Guadalara, Mexico; Norma Ruvaluaca Romero Universidad de Guadalara, Mexico; Raquel Gonzalez Baltazar

The research aims to examine working conditions of workers in manufacturing industries. Several factors were identified as safety factors, organisational risk and perception of workers about their working relationship and about the organisational factors. A descriptive cross-sectional study was conducted, through a questionnaire applied in 24 small, medium and large industrial facilities. A second questionnaire was applied to a sample of 392 workers who had at least six months working in the same 24 facilities. Only in 25% of small industries identified health services for the personnel. In 8.3% of these industries, committees for health and safety were identified, and only 8.3% had administrative control measures. No more than 25% of workers used protective equipment in small industries, as opposed to in 100% of workers in intensive industries. The perception of risk varies depending on the hazard by up to 93% and by gender. The lack of motivation, more than dissatisfaction, is the personal factor that showed a higher significant association with organizational factors. We conclude that the main problems of occupational health and industrial safety are present in industries classified as small and medium. It is required that industries include quality programmes of working life, health and safety.

The worker’s psychosocial factors of the manufacturing industry in Mexico
Jose G. Salazar Estrada Universidad de Guadalara, Mexico; Norma Ruvaluaca Romero; Eva Nunez

This paper seeks to identify the relationship between mental health, Sense of Coherence (SOC)
Employees’ graduate and employability attributes in relation to their emotional intelligence and career anchors

Dries Schreuder UNISA, South Africa; Melinde Coetzee UNISA, South Africa

The objective of this study is to determine the relationship between the graduate attributes (measured by the Graduateness Scale), employability attributes (measured by the Employability Attributes Scale), emotional intelligence (measured by the Assessing Emotions Scale), and career anchors (measured by the Career Orientations Inventory) of a convenience sample of 67 adults employed in the South African service industry: 85% blacks, 86% females, (72%) in the early adulthood phase and (70%) at staff level, 84% in their final year of undergraduate studies at a distance learning institution in the economic and management sciences field. A quantitative web-survey approach was followed in collecting primary data. Descriptive statistics (means, standard deviations and Cronbach’s Alpha coefficients), correlation and multiple regression analyses were performed to achieve the objective of the study. The internal consistency reliabilities of the four instruments ranged between 0.75 and 0.90 (high). Significant relationships were observed between the participants’ graduate and employability attributes and their emotional intelligence and career anchors. The career anchors and emotional intelligence of the participants significantly predicted their graduate and employability attributes respectively. The findings contribute new knowledge that may be used to inform human resource career development practices concerned with optimising person-job fit and the employability of particularly young black females in the service industry. Future research should replicate the study with a broader, demographically more representative sample.

Relation of personality characteristics with job satisfaction in Iran

Mohammadreza Seirafi Islamic Azad University, Karaj, Islamic Republic of Iran

The present study has been planned and executed with two objectives: (1) Study of Relation of Personality Characteristics with Job Satisfaction. (2) Relation between Gender and Job Satisfaction. The main part of the present study is of correlation type. For this reason, a number of 60 men and women (ranging from 25 to 60 years) of staff and manpower of consulting engineering companies were selected with cluster sampling method. Research tools were JBI (Job Satisfaction Test) and NEO (five broad domains of personality). Correlation and T test were used for analysis of data. The results of the study show that there is a positive meaningful correlation between factors of "openness, agreeableness, consciousness and extraversion" with job satisfaction among men and women but a meaningful relation in the factor of "neuroticism" was not observed. From among personality factors, "openness" showed higher correlation (57%) with job satisfaction. Also, there is not a meaningful difference between gender and job satisfaction. Job satisfaction depends on various factors like work attractiveness, rate of salary, equity, colleagues and workplace. The results of the present study show that specifications of the personality of individuals can be considered as one of determining factors of job satisfaction.

Dissemination of knowledge in organisations: preparation of training instructors

Janaina Silva Universidade Federal Fluminense, Brazil; Julio Figueiredo; Claudia Mattos; Mariana Mesquita; Juliana Mello; Hayланde Nascimento; Alice Pinho; Fernanda Ribeiro; Raquel Ramos; Juliana Souza; Aimee Ferreira

To attend to organisations’ demands and to prepare training professionals to act as multiplier agents of knowledge among workers, the Supervised Internship in Labour Psychology, from Universidade Federal Fluminense (Brazil), offers a Preparatory Course for Training Instructors. The course aims to provide the participants an opportunity to learn, to study and to review key concepts, methods and instructional resources present in the practice of professional training. The activities emphasise the planning, implementation and evaluation of the syllabus. Elements related to the preparation of lesson plan, instructional objectives, content, methodology, resources, evaluation, dynamics and structured exercises stand out. The methodology is based on the reality of the participants and participatory education, which invites students to discuss the topics presented. During the course, recordings are made of each participant acting like a training instructor, followed by evaluation. The results and demand for the course reaffirm the importance of offering it as a way to integrate the main activities of the Brazilian public universities: teaching, research and extension.

The work of service providers in a Brazilian public university

Janaina Silva Universidade Federal Fluminense, Brazil; Julio Figueiredo; Claudia Mattos; Mariana Mesquita; Thayla Nascimento; Alice Pinho; Haylande Nascimento; Fernanda Ribeiro; Aimee Ferreira; Carolina Cohen; Tais Carmo

This summary presents the main results of the project: Development of the employees of the Center for General Studies UFF (Brazil). The project includes a survey of users of the service department that compose the study centre, and an organisational climate survey, in order to identify the key elements that would interfere in the quality of services, in view of technical and administrative staff. It questions the hegemonic speech, related to the quality in service provision as a key factor in the of systems today. The information collected and analysed are presented and discussed in meetings with the workers, and the direction of the unit, and are then defined as subprojects to be implemented. So far, the results obtained, in the units surveyed, confirm the hypothesis of good acceptance of services and reveal issues to be developed. The main conclusions of the study results do not differ substantially from the problems identified in the provision of services in the private sector. The theoretical premises and methodological project aimed at improving the provision of services in government agencies.

Emotional dissonance and social support in services sector

Beatriz Sara Open University of Catalonia, Spain; Maria Vera

The purpose of this study was twofold. Firstly, to analyse the detrimental effect that emotional dissonance may produce in service workers, more specifically, we have tested job satisfaction, intention to leave organisation and organisational deviance to be related to emotional dissonance. Secondly, to test that both types of social support (i.e., co-workers and organizational support) and also its combination modulate the relationships listed above. Using Hierarchical Multiple Regression Analyses we have confirmed our hypothesis, which basically are: (1) Emotion work was related to lower levels of job satisfaction, and higher levels of organisational deviance and intention to leave organisation, (2) Both types of social support (i.e., co-workers and organizational support) and also its combination modulate the relationship between emotion work on one hand and job satisfaction, organisational deviance, and intention to leave organisation on the other hand.

Recovery as a buffer of job insecurity: Can it ameliorate the effect of job insecurity on both work and non-work outcomes?

Beatriz Sara Open University of Catalonia, Spain; Thomas Hoeve

Currently, job insecurity has presented as one of most harmful stressors in employees’ work life. Accordingly, an outstanding amount of detrimental work and non-work outcomes are associated to this stressor. An outstanding amount of research has focused on its study, but without congruent results. Sverke et al (2002) and Chen and Chang (2008) have pointed out that this variability can be due to other intervening factors on relationship between job insecurity and its consequences. Accordingly, the aim of this study is to examine the moderator role of recovery on relationship between job insecurity and employees’ work and non-work outcomes (i.e job satisfaction, intention to leave the organisation, family cohesion and family adaptability). This study was carried out with 556 employees from Spanish services sector. The results showed that recovery modulated the job insecurity-outcomes relation. More specifically, psychological detachment and mastery ameliorated the levels of employees’ work outcomes (job satisfaction and intention to leave the organisation); whereas relaxation ameliorated the work outcomes (family cohesion and family adaptability).

The relationship between talent management and the psychological contract

Karel Stanz University of Pretoria, South Africa; Lizel Prinsloo

The world of work and the psychological contract are continuously changing. Employees today value career development and the improvement of their knowledge and skills more than being loyal to an
organisations. All of these might be expectations that employees have as part of the psychological contract. Organisations therefore need to develop and apply effective talent management practices to meet the psychological contract needs of talented employees. Against this background the main objective of this research is to determine the relationship between talent management and the psychological contract. A quantitative research approach was followed in this research. The Assessment of Talent Management Practices Inventory and the Psychological Contract Inventory were administered among employees (N=102) working in the service industry in Gauteng in SA. The results showed that significant positive relationships exist between the dimensions of talent management and the employer obligations of the psychological contract. The results of the study indicated that effective talent management practices can strengthen the psychological contract between employers and employees. The effective application of talent management practices in the organisation can therefore result in a more stable workforce and reduce employee turnover. Implications for future research are suggested.

**Relationships among cognitive style, person-organization fit and innovative behaviour**

*James J-M Sun* Remnin University of China, China; *Zhen Wang; Jian-Min Sun*

It has been widely reported that cognitive style is positively related with individual creativity, while its relationship with innovative behavior has been less studied. Lots of researchers have conceptualized that creativity differs from innovation because innovation is a two-component construct, encompassing both generalization and implementation of ideas, whereas creativity is at the most the idea generalization. This study aims at exploring the latter relationship. Two different versions of questionnaires were selected. Research instruments consisted of the short form of innovative cognitive style was positively related to idea implementation, (2) job demands-employee abilities fit moderated this relationship, but supplementary and employee needs-job supplies fit had no moderating effect, and (3) idea generalization mediated the relationship between cognitive style and idea implementation, and between cognitive style-demands-abilities fit moderated this relationship, but supplement and employee needs-job supplies fit had no moderating effect, and (3) idea generalization mediated the relationship between cognitive style and idea implementation. The study extended our acquaintance with determinants and mechanism of innovative behaviour in the workplace, suggesting that individual innovation is a complicated process in which each step has its own particular feature. Implications and future study agendas are discussed.

**The relationship between commitment-based human resource management, job engagement and individual innovative behaviour**

*James J-M Sun* Remnin University of China, China; *Zhen Wang; Jian-Min Sun; Ruijuan Zhang*

Individual innovative behaviour in organizations has been recognised as one of the determinants that enhance the competitiveness of enterprises. Some researchers have posited that the human resource management practices have a positive relationship to innovative behaviour, while very little empirical research has specifically examined these relationships. Based on social exchange theory, we established a theoretical framework and examined with empirical data the relationship among commitment-based human resource management practices, job engagement and individual innovative behaviour from a cross-level perspective. Questionnaires were distributed to more than 800 employees in 110 companies in different types of industries. 635 usable questionnaires from 100 companies were obtained, with 3-6 respondents from each company. Employees reported their job engagement and innovative behaviour while HRM managers from each company reported commitment-based human resource management practices. Correlations, hierarchical regression, and hierarchical linear modeling were conducted to test the hypotheses. Results showed that commitment-based HRM practices were highly correlated with employees’ innovative behavior and this relationship was mediated by the job engagement of employees. By bridging the macro and micro perspectives of strategic HRM studies, our study disentangled the implicated association of HRM practices with employee behaviour. Implications and limitations of the study were discussed and future research directions were pointed out.

**The relationship between the big five personality traits and job involvement**

*Mahnaz Talebzadeh* University of Isfahan, Islamic Republic of Iran; *Aboulghasem Nouri*

The purpose of this study was to investigate the relationship between the big five personality traits and job involvement in Isfahan Water and Wastewater Company, Iran, in 2009. In order to achieve this aim, a random sample of 125 persons were selected. Research instruments consisted of the following three questionnaires: (1) Short form of five personality questionnaire (NEO-FFI), with the reliability coefficients of 0.8 for Agreeableness to 0.87 for Openness, (2) Kanungo involvement questionnaire, with reliability coefficient of 0.8, and (3) a demographic questionnaire. The results of correlation coefficient analysis showed a significant positive relation between extraversion, openness, conscientiousness and job involvement (p<0.05). The results of multiple regression analysis indicated that Neuroticism and Conscientiousness had more impact on the prediction of job involvement compared to other variables. Although the difference between men and women was not significant in job involvement, the difference was significant between the mean of Neuroticism and Extroversion components. Considering gender, neuroticism was higher for women but Extroversion was higher for men. The relationships were negative and significant between Neuroticism and education, Conscientiousness and age, job involvement and education. Based on the best knowledge of the authors, there is no similar study in Iran or other countries. Organisational climate and demographic variables were not controlled, and the results may have been affected by these limitations.

**Psychological career resources in relation to work engagement and organisational commitment foci**

*Rebecca Tladinyane* University of South Africa, South Africa; *Melinde Coetsee*

To determine the relationship between employees’ psychological career resources (measured by the Psychological Career Resources Inventory), work engagement (measured by the UTRECHT Work Engagement Scale) and organisational commitment foci (measured by the Organisation-related Commitment Questionnaire) of a convenience sample of 318 adults employed in the South African Service industry: 76% blacks; 77% females; 59% single; 39% at staff level; enrolled for further education studies at a distance learning institution in the Economic and Management Sciences field. A quantitative survey approach was followed in collecting primary data. Descriptive statistics (means, standard deviations and Cronbach’s Alpha coefficients) and canonical correlation analyses were performed to achieve the objective of the study. The internal consistency reliabilities of the three instruments ranged between 0.75 and 0.99 (high). Significant relationships were observed between the participants’ psychological career resources, work engagement and organisational commitment foci. The findings contribute new knowledge that may be
used to inform human resource career development practices concerned with optimising person-job fit and the retention of particularly young black females in the South African service industry. Future research should replicate the study with a broader, demographically more representative sample.

Employee experiences of performance management appraisals: A qualitative study

Tshepo Tsiu South Africa; Michelle May

Existing literature about employees’ experiences of performance appraisals seemed to indicate a strong management bias in that research seemed to be written for managers. This and the researchers’ own negative and positive experiences on performance management appraisals at different organisations have also propelled interest in this area. The objectives of the research project was to explore employees’ experiences of performance management appraisals. The qualitative approach was chosen in order to obtain a deep and sensitive understanding and appreciation of employee experiences of performance appraisal sessions. This was an exploratory study because the researcher began work in a little researched area. The research setting was the Sales Division of one of the big banks in South Africa. Using the purposive, non-probability sampling method, a sample of five participants in varying employment levels was selected. A semi-structured interview was conducted with the participants. The data was analysed using the discourse analysis method. The findings indicate that those performance appraisals are conducted mechanistically by line managers; there is loss of control over key performance areas that employees are assessed on. There is, however, managerial support with regard to Action plans and Personal Development Plans. What can be concluded from this qualitative study is in keeping with the current literature debates around performance management and appraisals. It is recommended that future research studies be undertaken about challenges with performance management; objectivity and performance standards; coaching and collecting information on employee performance; and career development and training needs identification arising from performance appraisals.

Employees’ organisational commitment, subjective well-being and team work

Leonard Ugwu University of Nigeria, Nsukka, Nigeria; Regina Okwosa

Many reforms have taken place in the Nigerian banking sector. Some of these reforms were the recapitalisation and restructuring policy of the Central Bank of Nigeria (CBN) and the granting of license to private operators, which empowered them to establish new banks, (“New generation banks”). Unlike the traditional commercial banks, the new generation banks adopted a “imposed targets” strategy. Imposed target refers to the unrealistic goals set by the management requiring employees to meet certain financial benchmarks in a giving period. The question is: What are the effects of the imposed targets on the employees’ organisational commitment, subjective well-being, and team work? Three hundred and twenty-five employees (171 employees of “New generation banks”) participated in the study. Three instruments used for data collection were: Organisational commitment, subjective well-being, and team work questionnaires. Data were analysed using t-test statistics. Result showed that employees of new generation banks reported less commitment to their organisation than their counterparts in traditional commercial banks. Employees of traditional banks reported a higher level of subjective well-being than their counterparts in new generation banks. Result also showed that new generation bank employees engage in less team work than their counterparts in the traditional commercial banks.

The relationship between organisational commitment, retention factors and perceived job embeddedness

Jeannette Van Dyk UNISA, South Africa; Melinde Coetzee

The objective of this study is to determine the relationship between organisational commitment (measured by the Organisational Commitment Scale), retention factors (measured by the Retention Factor Scale) and perceived job embeddedness (measured by the Job Embeddedness Questionnaire), and to determine whether employees from different gender, age, race, marital status, tenure and job level groups differ significantly in their levels of organisational commitment, retention factors and perceived job embeddedness. A quantitative survey was conducted on a purposive sample of 206 employees in the South African medical and IT service industries: 73% females, 30 to 39 years (40%); 53% white, 59% married, at operational level (69%). The results show that the internal consistency reliabilities of the three instruments ranged between 0.67 and 0.90 (median to high). Correlational statistics revealed significant relationships between the participants’ organisational commitment, retention factors and perceived job embeddedness. Multiple regression analyses showed that the organisational commitment and perceived job embeddedness of the participants significantly predicted their intention to stay (retention factors). It follows that HR practitioners need to recognise how retention factors influence job embeddedness and commitment to the organisation in the design of talent retention strategies for employees from various biographical groups. The study contributed valuable new insights and knowledge to the field of Career Psychology that can be applied in the retention of employees in the medical and IT industries. Future research should replicate the study with a broader, demographically more representative sample.

A framework to assist senior managers in the development of middle manager integrity

Annelize Van Niekert University of South Africa, South Africa; Michelle May

A framework was developed to gain insight into senior manager’s impact on middle managers experience of integrity. The aim of this research was therefore to obtain insights from practitioners about the application and potential value-add of this framework in organisations. This study was conducted within the interpretive research paradigm and therefore qualitative data was most appropriate. Sampling was directed by criterion-based guidelines, focusing on practitioners (Industrial Psychologists and Consultants) working with management development, in different industries. A listening post was conducted. The primary task of the listening post was stated as: In your role experience explore the application and potential value-add of the framework in organisations. The data obtained were analysed using a grounded theory method. The findings of this study suggest that organisations can utilise the framework effectively by customising it according to their specific needs and in line with the organisation’s strategy, vision and mission. Such a framework can assist senior management with decreasing unethical behaviour and increasing integrity in the organisation. The framework will furthermore assist middle managers to gain a better understanding of the impact of senior management on their experience of integrity. On an organisational level, this study highlighted the important role organisations play towards creating and establishing an ethical work climate that will ensure corporate integrity. This, in turn, will enable organisations to provide value to their corporate stakeholders and society at large.

Intrapersonal, interpersonal and intra-group conflict management from a psychological perspective within a university

Adriana Mn Van Niekert University of South Africa, South Africa

This presentation is based on twelve years in-the-workplace experience and ethnographic research for my D.Litt & Phil studies (still in progress) within the University where I work as a Counselling Psychologist. I discuss why I accepted the theoretical and practical stance of some conflict management interventions, psychotherapeutic approaches and brief psychotherapies, and how I came to use specific psychometric tests. I indicate the outcomes of my conflict management interventions accordingly. My focus is on workplace conflict as a state of unresolved differences between individual(s); between individual(s); and within group(s). These differences impact negatively on the sound functioning and work performance of the employees involved. Intrapersonal conflict occurs within the employee (e.g. a person who easily gets angry or agitated). Interpersonal conflict takes place among two or more employees (e.g. serious arguments between colleagues). Intra-group conflict takes place within a group (e.g. between employees working on the same task). These conflicts happen in the context of interpersonal workplace relationships which are associations between two or more people that may range from fleeting to enduring, according to university structures and procedures. They are not mutually exclusive and employees may be involved in more than one at a time.

Organisational design as a critical organisational discipline

Theo Veldsman University of Johannesburg, South Africa

It is widely recognised that the way organisations are designed has a profound effect not only on an
organisation’s strategy, mode of working, culture and dynamics, but also on its performance, and ultimately its success. Organisational design as the Operating Model for the organisation is one of the key executive leadership tasks making up the portfolio of Executive Tasks in the organisation. Organisational design thus can only be ignored at the peril of the effectiveness and efficiency of an organisation. One can indeed compete by design. The purpose of this paper is to provide a high level overview of organisational design as a key executive leadership task: The what, why, how, who, where of design. The overview is based on personal lessons learnt from over 50 design consulting assignments over about 15 years across multiple industries, nationally and internationally; the global sourcing of leading organisational design practices, as well as the thinking of organisational design thought leaders. The following topics will be covered illustrated through case studies: Organisational design as a key executive task, defining organisational design, positioning organisational design appropriately within the organisational landscape, the levels and dimensions of organisational design, the basic building blocks of organisational design, the organisational design process, organisational design logics, key design questions to quality assure the crafted organisational design, and the key benefits of an effective design.

Organisational commitment, job satisfaction and motivation of employees working in a manufacturing industry Raghunath Vijaya S.D.M College, India; M.Y Manjula S.D.M College, India

This paper attempts to study the level of organisational commitment, job satisfaction and motivation of employees working in a garment manufacturing industry in Bangalore, India. The sample consisted of 200 male and female blue and white collar employees. The Job Satisfaction scale (Singh & Sharma, 1971), Intrinsic and Extrinsic Motivation: What you look for in a job (Udai Pareek, 2002), and the Organisational Commitment scale (Dhar, Mishra & Srivastava, 2001) were used for data collection. The obtained data was subjected to statistical analysis using two-way analysis of variance, Pearson’s correlations and T tests. Some of the important findings are that blue collar employees have significantly higher concern for the organisation compared to white collar employees. Blue collar employees have significantly higher extrinsic motivation, which shows that aspects like security, adequate earnings, sound company policies and practices, and comfortable working conditions, motivate them to perform their job. White collar employees have significantly higher intrinsic motivation, factors like interesting work, advancement, a technically competent supervisor, respect and recognition, responsibility, independence and achievement, are some of the aspects that motivate them to perform well in their jobs. Job satisfaction and organisational commitment are significantly related to each other, which shows that as job satisfaction increases, organisational commitment increases and vice-versa. Job satisfaction and intrinsic motivation are significantly positively correlated to each other, and job satisfaction and extrinsic motivation are significantly negatively correlated to each other.

Human capital return-on-investment in South African companies listed on the Johannesburg Stock Exchange Helene Viljoen University of Stellenbosch, South Africa; Francois De Cock University of Stellenbosch, South Africa

Existing human capital effectiveness measures, such as Human Capital Return on Investment (HCROI), allow human resource managers to quantify the bottom-line impact of human capital expenditure, but little is known about how HCROI varies within listed firms. As a result, users of these metrics rarely know how they ‘measure up’ against their competitors in the absence of normative information. The present study provides a set of benchmarks for human capital effectiveness measures across industry and company size categories (years 2006 – 2010) in the population of listed firms (N = 319) on the Johannesburg Stock Exchange (JSE). The results showed that, even though South Africa is considered to have a very low labour force productivity level compared to other countries, the grand mean HCROI ratio for South African listed companies was higher (M = 3.03) than those from published figures from the USA, EU and UK (PwC Saratoga, 2011). This descriptive research also explored the influence of company size (small, medium or large) and company industry (N = 42) on human capital effectiveness. No statistically significant differences (p > .05) between the median HCROI ratios across company size categories were found, although notable differences in medians of HCROI across company industry categories were observed. HCROI also showed temporal fluctuations over the study period, reflecting economic cycle influences, but year-on-year changes were bigger when the mean HCROI was used instead of the median — median HCROI remained relatively stable year-on-year.

The difference of decision to voluntary turnover toward to equity sensitivity Laila Wardhani University Kebangsaan Malaysia, Indonesia

The objective of this research was to study the interaction effect of equity sensitivity and the decision to voluntary turnover among specialist expatriate workers in an oil company. To see the relationship between equity sensitivity and the decision to voluntary turnover the level difference of decision to voluntary turnover by equity sensitivity must be tested. A total of 184 Indonesian specialist expatriate workers in Malaysia oil companies were selected to fill out the questionnaires. The instruments used in this study were a set of questionnaires containing Equity Sensitivity Instrument (ESI) and Turnover Intention Questionnaire (TIQ). The data were analysed by one way ANOVA and Regression analysis using IBM Statistical Package for Social Science (SPSS) version 19.0. Result of one way ANOVA supported the hypotheses of this study. This study found significant differences in the decision to voluntary turnover according to the equity sensitivity among specialist expatriate workers in oil companies.

Shared leadership: Who is motivated to share? Simon Werther Ludwig-Maximilians-Universität, Germany; Felix C. Bradbeck; Mareike Schneider

The focus on vertical leadership, which was often clearly defined within the boundaries of one’s status or position, shifted to the concept of shared leadership in terms of distributing leadership functions and the effect on team performance. However, empirical evidence mainly examines the relationship of shared leadership and team performance, and its potential for moderators and mediators. This explorative study examines the emergence of shared leadership considering power and affiliation motives. Following McClelland’s theory, we expect leaders with high affiliation motive and low power motive to be more open-minded towards the emergence and practice of shared leadership in their team. We used the Multi-Motive Grid to assess the motive values of 34 leaders (average age = 44.7 years, average leadership experience = 13.2 years, average company size = 50.306). The results indicate that the affiliation motive correlates significantly positive with a positive attitude towards shared leadership. Furthermore, the affiliation motive correlates slightly negatively with a negative attitude towards shared leadership. However, the correlations between the power motive and shared leadership show no significant results contrary to our hypothesis. Our paper ends with the discussion of limitations and implications for future research and practitioners.

The application of the Gestalt approach in coaching supervision for a consulting team Gail Wrogemann GCW Consulting, South Africa

The objective of this paper is to describe how a supervision process, based on a Gestalt approach, could be used to understand and resolve difficult interactions between a client and the consulting team. Research was qualitative and descriptive. One consulting team of 8 people was part of this study. Session notes were used to collect the data. Interpretation was according to thematic analysis based on the constellation methodology. The supervision process focused on processes and interruptions of contact, paradoxical theory of shared leadership. Further, the destructive impact and disturbances from unfinished business were investigated and worked with from the team’s cycle of experience. Critical parts of the process were the here-and-now experimentation and awareness of the wider field and reciprocal impacts. (Stevenson, 2004) Findings indicated a significant reduction in anxiety levels leading to increased clarity about project next steps, an increase in confidence of delivery and improved contact with the client. Re-evaluation of certain processes led to more effective project structure. Principles specific to the Gestalt approach provided key insights in understanding complex dynamics and interactions between the consulting team and client. The Gestalt approach is a holistic, process-oriented, phenomenological, existential, and field centred approach. It sees individuals and teams, as integrated wholes who strive for positive change and growth. The Gestalt approach is a powerful supervision tool which could be used far more effectively in coaching supervision.

Workplace ostracism and problem drinking: The roles of depression and need for affiliation Longzeng Wu ShU of Finance and Economics, China; Guiyao Tang; Hong Zhu

Drawing on the belonging theory, this study examined the link between workplace ostracism and
problem drinking by focusing on the mediating role of depression and the moderating role of the need for affiliation. Based on a sample of 330 blue-collar employees from two manufacturing companies in China, we found that: (1) Workplace ostracism was positively related to problem drinking, (2) depression mediated the relationship between workplace ostracism and problem drinking, and (3) need for affiliation strengthened the direct effect of workplace ostracism on depression and its indirect effect on problem drinking. We discuss the implications of these findings for theories and research, as well as for management practice.

Psychological backgrounds for formation of innovation economics in the Russian federation
Lyudmila Zakharova Nizhny Novgorod State Uni-
versity, Russian Federation; Elena Korobeynikova
The aim of the study is to develop value and motivational determinants of psychological readiness of persons in the educational and labor spheres to accept innovations. Kameron-Quinn method of OC diagnosis, method of specific situations possessing value contradictions, motivation structure diagnostics method. 520 teachers, 125 college lecturers, 250 instructors, 950 managers, 1600 executive workers, 600 students took part in the research during the period from 1999 to 2010. It is proved that innovation acceptance processes are very slow both in educational institutes and at enterprises. During 12 years innovation values in the OC stay poor: Growth is 10.5% in 1999 up to 20% in 2010, though managers consider the optimum growth to 34-37%. More often than not innovation value goes together not with result values but with relationship values (up to 25%) and stability values (up to 35%). The following had been detected: (1) Four types of innovation motivation: Innovation expectation, search, creation, acceptance and support of innovation. (2) A set of social and psychological factors which restrain search and acceptance of innovations: ethno cultural orientation, stereotypes in decision making, dominance of an amorphous OC and of an OC with expressed clannish and hierarchical components, topically unconscious value contradictions of the personnel, innovation motivation deficit. (3) A series of favourable factors which make it possible to forecast positive development: Conscious distinct innovation development orientation of management, reduction of susceptibility to stereotypes and exercise of archaic behaviour repertoire in the market and the market-adherency types of OC.

Combination modes and competency model of entrepreneurial teams in small and medium high-tech entrepreneurial firms
Wei Zhang Hangzhou Dianzi University, China
Previous studies show that technical experience or high-tech entrepreneurship has a positive impact on new venture performance. The purpose of this study is to explore combination type and characteristics of competence of entrepreneurial teams in the high-tech entrepreneurial firms. Based on experts in group and behavioural events interview from a sample of 22 entrepreneurial teams in small and medium high-tech start-ups firms, the study identifies four combination modes of entrepreneurial teams from the perspective of human resources features. There are knowledge-based expertise of the entrepreneurial team, efficient combination of the entrepreneurial team, technical resources of the entrepreneurial team, and risk opportunities of the entrepreneurial team. Simultaneously, the study proposes a competency perception model of high-tech entrepreneurial teams on the basis of Chinese cultural context, and then tests the construct model of competency characteristics of high-tech entrepreneurial teams by a competency modeling approach.

Succession plans of family business in China on the basis of dynamic psychological contract theory
Wei Zhang Hangzhou Dianzi University, China; Xiao-
iu Yuan
Previous studies show that there is a negative relationship between irregular succession phenomena and firm performance. In this study, psychological contract of family business succession is defined. It refers to an invisible and informal relationship of tacit expectations and understanding between family business owners and potential successors. Based on experts in group and case study, the study found that there are three types of psychological contract of family business succession, namely, relational psychological contract, balanced psychological contract and transactional psychological contract. Most family business owners prefer their children as potential successors based on relational psychological contract, followed by their close and distant relatives based on balanced psychological contract, and thereafter followed by professional managers based on transactional psychological contract. The recursive difference pattern under traditional culture is very clear - it is from inside to outside and layer upon layer. This result suggests that a dynamic matching of psychological contracts between internal successor or external successor and family business owners can be reached, which is very important. Transactional psychological contracts can be converted to balanced psychological contracts and relational psychological contracts. The success of professional manager in family business depends on its gradual matching process from transactional psychological contracts to relational psychological contracts. It will directly affect the transfer of implicit knowledge and social network in the family business, and it will further affect the success and efficiency of family business succession.

Job insecurity in Chinese context: A critical review
Hailin Zhao The Hong Kong Polytechnic University, Hong Kong; Chun Hui; Cynthia Lee; Guo-hua Huang; George Chen
Job insecurity has become a widespread managerial concern over the last five decades. It reflects the degree to which employees perceive their jobs, or important features of their jobs, to be threatened and to which they perceive themselves to be powerless to do anything about it. Job insecurity research has so far been conducted mostly in Western settings such as the US, Australia, and Finland. However, our understanding about job insecurity in the Chinese context is very limited. In the current paper, we noted that China is an important and interesting context for job insecurity research because of its unique social, economic, and cultural environment. In the first part of the paper, we reviewed the theoretical underpinnings, research findings and measurement issues in job insecurity research. In the second part of the paper, we reviewed the limited research on job insecurity in the Chinese context and then provided a critical review about the Chinese context-specific characteristics that may affect job insecurity and its effect. In particular, we discussed the impact of the series of economic reforms that China has gone through in recent decades and some specific culture dimensions on how people perceive and cope with job insecurity in China and its management implications. We conclude with a discussion on the new developments in job insecurity research and future research directions.

Moderator between job search intention and job search behaviour of unemployed people in China: perceived behaviour control
Jiuhua Zheng East China Normal University, China; Shuhua Zhang; Lulu Gan
The moderator between job search intention and job search behaviour has been a controversial topic in the field of unemployment, yet warrants further study as it plays an important role in succeeding in re-employment. Based on Ajzen’s Theory of Planned Behaviour (TPB), the study aims to explore the mechanism between job search intention and job search behaviour of unemployed people in China. 272 unemployed people with a mean age of 42.7 years (SD=8.33) participated in our research. A series of analysis methods, such as description analysis, correlation, and regression were used for analysis of these data. The regression analysis results indicate: (1) Job search intention has positive influence on job search behaviour, people with stronger job search intention are found to take more job search behaviours; (2) Results of hierarchical multiple regression support that perceived behaviour control plays as a moderator between job search intention and job search behaviour; (3) Age negatively affects job search behaviour. The older an individual is, the more difficulties he has in finding a job, thus fewer job search behaviours.

The influence of cognitive style and perceived climate factors on employee creativity
Jing Zhong Tongji University, China
Organizations encourage employees to take initiatives or innovate in their work so as to achieve competitive advantages. This study investigates the role of cognitive style and perceived climate on employee creativity. Cognitive styles was measured with the Kirton Adaptation-Innovation Instrument (KAI) and climate factors came from Work Environment Inventory (WEI). Based on a survey of employees from multiple industries in diversified industries of China and the corresponding creativity evaluation from their supervisors, this study found (1) that cognitive style, creativity requirements involved with a task, and supervisor support were positively related to creativity, (2) a negative relationship between resource abundance and employee creativity, and (3) that both creativity requirements involved with a task and supervisor support had negatively moderating effects on the relationship.
between cognitive style and creativity. The implication of the study is that an organization needs to identify employees’ cognitive styles and creative climate stimulants, and pay attention to the impact of perceived climate on creativity of employees with different cognitive styles.

**Session Type: Invited Addresses**

**Work-life balance: Cross-cultural, cross-domain, and crossover effects**

**Zeynep Aycan** Koc University, Turkey

The presentation will feature findings of several recent studies that would contribute to the growing literature on work-life balance (e.g., Allen, 2012 for a review). In studies focusing on cross-domain effect, the interface among 3 life domains are investigated: work, family, self. The Life Balance Model proposed by Aycan, Eskin, and Yavuz (2007) suggests that working people (esp. Gen Y) seeks to satisfy demands of work and family, while trying to ‘do something for themselves’. In studies focusing on cross-over effect, the impact of work-family conflict on spouse’s and children’s well-being is investigated. Finally, the cross-cultural effects in work-family conflict is investigated through a recently completed 10-country study.

**Burnout in the workplace: A global problem in need of solution**

**Christina Maslach** University of California, Berkeley, United States of America

Burnout research over the past thirty years has yielded both knowledge, and tools, to apply to interventions at unit and organisational levels. Innovative partnerships between researchers and practitioners point to the importance of multi-level approaches in generating relevant and effective solutions to the burnout problem.

**What has a decade of research on work engagement brought us?**

**Wilmar Schauffel** Dept. of Psychology, Netherlands

Since the turn of the century a so-called ‘positive occupational psychology’ has emerged that supplements the traditional negative approach by focusing on human strength and optimal functioning in organisations. In this presentation the recent positive turn of occupational health psychology is illustrated by using the concept of work engagement. Based on a definition of work engagement as a positive state of fulfillment that is characterised by vigour, dedication, and absorption, an international research programme was initiated over ten years ago. This address discusses the concept and the measurement of work engagement - also in relation to burnout and workaholism - and presents a state-of-the-art overview of the most important research findings. For instance, several drivers and consequences of work engagement have been identified, as well as concomitant personality factors. These findings are integrated into a model that explains the psychological processes that are involved in work engagement (and burnout) - the so-called Job Demands-Resources (JD-R) Model. This model conceives engagement and burnout as central elements in two related processes: a motivational process that starts with job resources and leads via employee engagement to positive organizational outcomes, and an energy-draining process that starts with job stressors and leads via burnout to health impairment. Attention is also paid to research on strategies that can be used to improve work engagement, both at the individual level as well as at the organisational level. The address concludes with a future research agenda.

**Session Type: Invited Symposia**

**Symposium title: Are characteristics still being a variable in psychological study?**

**Convenor: Ubolwanna Pavakanun**

**Business environment effect on human capital, entrepreneurial orientation, and business success for Thai free hotel entrepreneurs**

Ubolwanna Pavakanun Psychology Department, Thammasa, Thailand

This study aims to compare the difference of Business Environment that effect Human Capital, Entrepreneurial Orientation, and Entrepreneurial Success. Data are collected by individually structured interviews and rating scale questionnaires. Subjects are SME Independent Hotel Entrepreneurs in the highest successful provinces from 6 parts of tourism in Thailand. Statistical analysis methods include descriptive statistics. The findings are as follows: 1. Entrepreneurial success was found to be positively correlation with the Environment of business, Human capital- Experience in Management, and Skill, and Entrepreneurial Orientation with Autonomy, Innovativeness, Risk Taking, Stability and Learning and Achievement. 2. Results of comparison in difference of environment were as follows: Easy and Difficult, it showed a difference in Human Capital, except in Education Year, and with Entrepreneurial Orientation, except in Stability and Learning Orientation and Business Success. 3. Results of comparison in each part of Thailand regarding the difficult environment, showed the differences in perceiving Business environment, Human capital, and Entrepreneurial Orientation. In Autonomy, Innovativeness, Risk Taking, Stability and Learning, Achievement, and Business Success.

**Symposium title: Health psychology**

**Convenor: Vito Tummino**

**Evaluation of work related stress risks in organisations**

Pierluigi Pollicastro HSA, Italy; Aimee Ferreira

The process of evaluation of work-related stress risks represents an opportunity to implement interventions and development plans to improve the results of the organisation. Italian law has stated, December 31, 2010, as the date from which evaluation has to start. It is possible to figure out a first balance of the data resulting from the application of the law. Objective Work psychology can contribute to making work-related stress risk evaluation an opportunity. This is particularly evident with regard to improvement actions which complete the process. Interventions and instruments adopted will be illustrated, with the description of cases, research results and publications. Multidisciplinarity and communication negotiation competences are central to characterise the psychologist specialised in work-related stress risk evaluation. He will have to work with the work safety team in the working contexts and will be responsible for safety education within obligatory work safety modules. The presence of a specialised psychologist inside the process of work-related stress risk evaluation enhances the quality of the process itself, and improve the organisation results.* Antonia Ballottin, psychologist, psychotherapist Spisal (Servizio Preventivo Igiene Ambienti dei Lavoro), Uss 20 Verona (Italia) ** Pierluigi Pollicastro, psychologist, psychotherapist, Psychiatric Service 2° Uss 16 Padova, Counsellor of the Order of psychologists Veneto (Italia) *** Andrea Petromilli psychologist, Consultant in formation and development human resources. Counsellor of Order of psychologists Veneto (Italia)

**Symposium title: The combined emic-etic approach in indigenous personality assessment**

**Convenor: Fanny M. Cheung**

**The combined emic-etic approach in indigenous personality assessment**

Fanny M. Cheung Chinese University of Hong Kong, China

The etic approach to study personality cross-culturally involved exporting Western measures to other cultures. Even when high standards of test translation and adaptation have been adopted, this etic approach provided an incomplete and/or distorted picture of personality in local contexts. The early emic approach to develop indigenous measures emphasized cultural uniqueness at the expense of cross-cultural comparability. The papers in this symposium demonstrate the combined emic-etic approach to develop personality measures that are relevant to the local culture on the one hand, and facilitate cross-cultural comparison on the other. Recent studies on the Cross-cultural (Chinese) Personality Assessment Inventory (CPIA) and the South African Personality Inventory (SAPI) are reported. Cross-cultural studies using the CPIA to assess students’ vocational development in Hong Kong, China and the US show the added value of indigenous personality traits in predicting vocational outcomes beyond universal traits. An overview of SAPI, which is at an earlier stage of test construction, is presented. The procedure and outcomes of the qualitative stage of the SAPI project are introduced, in which persons from the official 11 South African languages provided descriptions of themselves and others. In addition, findings are presented on a locally derived social desirability scale developed for SAPI. These studies illustrate the rigorous research programs that support the development of indigenous personality assessment using the combined emic-etic approach.

**Emic and etic scales of the cross-cultural personality assessment inventory (CPIA): Recent research findings on career development of Chinese students**

Weiqiao Fan Shanghai Normal University, China; Fanny Cheung; Shu Fai Cheung

The Cross-cultural Personality Assessment Inventory (CPIA) consists of both etic (universal) per-
sonality scales as well as emic scales that are particularly relevant to Chinese culture. Earlier research on the CPAI showed that the relationship-oriented emic Interpersonal Relatedness factor contributed added value in predicting a wide range of social behaviours and outcomes in work as well as clinical settings. Recent studies on the career development of college and secondary schools students with the adult and adolescent versions of the CPAI confirm that harmony, Renqing (reciprocity in social exchange) and family orientation are significant correlates of career choice, career decision self-efficacy and vocational identity. The emic Interpersonal Relatedness factor supplement the universal personality factors such as Dependability and Social Potency in providing a more comprehensive assessment of personality in the context of culture.

Exploring the collective dimension of personality in South Africa using the SAPI and CPAI-2
Sumaya Laher; University of the Witwatersrand, South Africa; Leah Silva; Leah Branco
Research on personality theory and assessment in the South African context has much to contribute to local and international literature by virtue of the country’s diverse mix of cultures. The use of etic or emic instruments is at the forefront of this research, more so since South African culture represents a combination of both individualist and collectivist dimensions. There is also a growing recognition of the need for more indigenous approaches to personality theory and assessment amongst researchers and practitioners in South Africa. In keeping with these trends, this study explored the collective dimension of personality using the South African Personality Inventory (SAPI) and the Cross-cultural Personality Assessment Inventory-2 (CPAI-2) in a sample of South African first year Psychology students from the University of the Witwatersrand. Internal consistency reliability, construct validity, construct bias and item bias of the two instruments were investigated. Additionally, two focus groups were conducted exploring issues around personality, personality assessment, the two instruments and the collective dimension of personality. These results are discussed in relation to the debates on the use of etic and emic approaches to personality with a specific focus on the utility of indigenous personality instruments. The discussion will also focus on exploring the nature of the collective dimension of personality in South Africa.

The South African personality inventory: Background and current status
Fons Van De Vijver; Tilburg University, Netherlands; Velichko Valchev; Carin Marais
We describe the current status of the South African Personality Inventory, which is a personality measure that combines emic and etic procedures following an approach akin to psychosocial studies. A content analysis of interviews with speakers of each of the 11 official South African languages who were asked to describe the personality of persons they knew well yielded nine clusters (Conscientiousness, Emotional Stability, Extraversion, Facilitating, Integrity, Intellect, Openness, Relationship Harmony, and Soft-Heartedness). An inventory was then compiled for each cluster. Results of these pilots and the ensuing item elimination process are described. The project is presented as a prototype for test development in South Africa, as it attempts to comply with the strict national legislation regarding psychological assessment and tries to strike a balance between more universal and more culture-specific aspects of personality.

Social desirability among blacks and whites in South Africa
Fons Van De Vijver; Tilburg University, Netherlands; Deon Meiring; Velichko Valchev
There is a renewed interest in the cross-cultural study of social desirability. These studies can shed a new light on the old discussion about the meaning of social desirability as either self- or other-deception (impression management). A short, English version of the Marlowe-Crowne scale was administered as part of the project to develop the South African Personality Inventory to samples of 2,899 Blacks and 811 Whites in South Africa. A three-factorial structure emerged (self-deception, negative impression management, and positive impression management) that was equivalent across the groups. Blacks scored higher on negative impression management, Whites scored higher on self-deception, and no differences were found in positive impression management. Associations with personality aspects, as measured by a pilot version of the South African Personality Inventory are described. Implications for the cross-cultural assessment of social desirability and its relevance for cross-cultural psychology are described.

Predicting job performance with etic and emic scales of the cross-cultural personality assessment inventory
Mingjie Zhou; Chinese Academy of Sciences, China; JianXin Zhang; ShanShan Zhang
The results of a growing number of studies suggest that personality measurement is useful for understanding job performance. The Cross-cultural (Chinese) Personality Assessment Inventory (CPAI) which was developed using a combined emic-etic approach, which includes universal and culturally relevant personality constructs. We assume that both emic and etic personality constructs of CPAI can predict job performance well. In the current research, we combined the etic and emic personality traits together to explore the linear and/or curvilinear effects on job performance in the Chinese working setting using the CPAI. The results show that a number of the emic scales of the CPAI contributed to significantly predicting job performance, including that harmony and job performance has a positive linear relationship, face and job performance has a reversed-U curve relationship, learning and job performance has a letter-U curve relationship. Meanwhile, the Dependability (etic) factor contributed incremental linear validity in performance prediction over the Conscientiousness of big five. The results give us some insight into the relationship between personality and performance.

Retention strategies of academics in a competitive higher education context
David Makgala; North-West University, South Africa; Yvonne Du Plessis; Nicolene Barkhuizen; North-West University, South Africa
The retention of key and competent academic staff has become a central management challenge for South African Higher Education Institutions in the 21st century. Recent years have seen much of the academic intellectual capital base of HEIs been eroded to such an extent that it has an adverse impact on the quality of teaching, research and the sustainability of HEIs. The main purpose of this research is to determine the factors that contribute to the turnover of academics in South African HEIs with the aim of developing academic talent retention strategies. A mixed method research approach will be employed in this research using a combination of quantitative and qualitative data gathering methods. First, document analyses of the exit interviews of academic staff will be conducted to identify the factors that contribute to staff retention. Second, focus groups will be conducted with identified academic staff groups to verify these factors. Finally, academic staff retention strategies will be developed based on the findings.
We anticipate that significant differences will exist between the different academic demographic groups based on their perceptions of the factors that contribute to the retention of academics. South African HEIs need well qualified and committed academic staff to ensure sustainability and quality over the long term. It is therefore important to identify the factors that contribute to academic staff turnover, but also to develop effective talent retention strategies to eliminate these factors.

The relationship between the talent mindset and organisational commitment of academic heads of departments

Shelly-Anne Malherbe Univ Pretoria, South Africa; Karel Stanz

Objectives: Academic Talent Management is a concept increasingly on the mind of Higher Education Leaders as it becomes more difficult to attract, develop and retain highly skilled and competent academics. Though it seems that talent management practices are not a strategic or operational priority in many HEIs despite recognising the existing situation, Talent management is a construct that evolves around the concept of leadership mindset and involves the application of effective talent management practices to meet current and future business needs. The main objective of this research is to determine the talent mindset of academics heads of departments (HOD’s) in South African HEIs. Secondly this research sets out to determine whether a positive relationship exists between the talent mindset and organisational commitment of HOD. Methods: A quantitative research approach is followed in this research. An adapted version of the Human Capital Index for Assessment of Talent Management Practices and Organisation Commitment Questionnaire are administered among a purposive convenience sample of HOD’s in South African HEIs. Results: We anticipate that talent management practices will only be fairly applied by leadership in HEIs. In addition we predict that a positive relationship will exist between the talent mindset and organisational commitment of HOD. Conclusions: Higher Education Leaders play an important role in the career success of academic staff members. This requires that the talent mindset of leaders should focus on acquiring and developing and retention of academic staff talent.

Exploring talent management practices in south african higher education institutions

Leonie Nagel Univ Pretoria, South Africa; Nicolene Barkhuizen Univ Pretoria, South Africa

Objectives: Talent Management has become an important topic of discussion in South African Higher Education Institutions (HEIs) as it becomes more difficult to attract and retain highly qualified, skilled and talented academics. This study aims to identify to current state of academic talent management practices in South African HEIs and the importance thereof for academic staff members. Method: A cross-sectional quantitative research approach is followed in this study. An adapted version of the Human Capital Index of Talent Management Practices will be administered amongst a stratified random sample of academics in identified South African HEIs. Results: We anticipate that significant differences will exist between the perceived current state of talent management in South African HEIs and the importance thereof for academic staff. In addition we also anticipate that significant differences will exist in the perceptions of talent management practices of academic staff based on their demographic characteristics. Conclusions: Despite a continuous proliferation of research on talent management and its practices in the organisational context, little research could be found relating to the talent management practices in the Higher Education Institutions in South Africa. This research makes an important contribution towards increasing the current knowledge regarding current talent management practices and their perceived importance in South African higher education institutions.

Symposium title: Advancing dignity and safety at work
Convenor: Julian Barling

Safety behaviours and injury under-reporting among young workers in Canada
Julian Barling Queen’s School of Business, Canada

Current understandings of young workers’ experiences of workplace safety is mostly limited to the results of studies of small, convenience samples of young people (usually less than 300 participants per study). Through a partnership with Passport to Safety, a Canadian based organisation that has developed a popular online occupational safety test for high school students, we were able to survey a relatively large sample of employed students during the 2011-12 school year. The aims of the study were two fold. First we sought to measure the self-reported prevalence of different safety behaviors (specifically, safety-related voice, compliance and neglect behaviours). Related to this, we wanted to examine whether young males and females report different levels of these safety behaviours. Second, we investigated the prevalence of work-related lost time injury under-reporting as well as the reasons for injury under-reporting. Implications for safety management, occupational safety education and public policy will be discussed.

Job characteristic inventory and quality work life of Thai pharmacists
Gorsaran Sarun Siam University, Thailand

Over a decade, the jobs of Thai hospital pharmacists have been changed dramatically. Therefore, this study was conducted to survey the job characteristic inventory and the quality work life of Thai hospital pharmacists. The questionnaire was developed from the job characteristics inventory concept of Sims H., Szilagyi A. and Keller R., 1979 and the quality work life of Walton RE., 1974 and presented to 190 hospital pharmacists. The results showed that the most prominent job characteristic for Thai hospital pharmacists was dealing with others (4.11) following by observers’ reactions of abusive supervision towards perpetrators and targets. Observer reactions have implications for how third parties interact with members of the aggression dyad. Drawing on affective events theory (Weiss & Cropanzano,1996), we posit that observers of abusive supervision will experience anger towards the perpetrator, which will lead to negative attitudes, deviant intentions, and fewer helping intentions toward the perpetrator, and positive attitudes, fewer deviant intentions, and helping intentions toward the target. We conducted an experiment in which participants witnessed either a neutral or an aggressive interaction between a supervisor and subordinate. Hired actors played the role of the supervisor (perpetrator) and subordinate (target). We filmed 2 versions (neutral versus abusive supervision) of a 3 minute video depicting a supervisor and subordinate discussing a project. The only difference between videos was actor intonation, body language, and facial expressions (e.g., the abusive video included derogatory tone and body language, the neutral video did not). Participants were 225 part-time employees. We used Hayes and Preacher’s (2011) mediation macro to test our hypotheses, all of which were supported. The indirect effect of perpetrator anger (B = .16) in the abusive supervision to perpetrator attitude relationship exceeded zero in the 95% bootstrap confidence interval (.06, .29). Similarly, the indirect effect of perpetrator negative affect (B = -.15) in the relationship abusive supervision and target attitude relationship exceeded zero (-.28, -.05). Results and implications are discussed.

Symposium title: Are characteristics still being a power variable in psychological study?

Coaching psychology in South Africa: State of play and future to come

**Aletta Odendaal South Africa**

The international coaching psychology community is preparing itself for unprecedented growth as a professional discipline. Both its relation to the broader coaching industry, as well as its celebration of its psychological roots are key positioning questions that necessitate reflection from within and in conversation with the role players that shapes the development thereof. The identity of coaching psychology and its associated value proposition to the industry as well as other stakeholders are emergent and being defined. Various professional bodies representing a diversity of coaches, application domains, methodologies, training and continuous professional development are participating in the debate and formulating diverse recommendations regarding the professionalisation of the industry.

Emerging trends and challenges in professionalisation of the coaching industry: Coaching psychology

**Aletta Odendaal South Africa; Anna-Rosa Le Roux**

This paper draws from various perceptions of stakeholders in the coaching industry and builds on current knowledge, practices and positioning statements in the field. Data were collated utilising the results of surveys, focus groups, demographic analysis and reflective conversation among professional bodies, coaches, providers of coaching services and teachers within the coaching (psychology) domain. Specific research objectives were: Provide observations of emerging trends and challenges in the coaching (psychology) discipline internationally. Reflect on data obtained from stakeholders in the coaching industry in SA for further utilisation towards the professional development thereof. Create a SA perspective and roadmap for the development of Coaching Psychology as a professional discipline within the context of global trends. The coaching industry in South Africa, and globally, is rapidly moving towards a position that requires an active approach towards professionalisation. There appears to be a high degree of interdependence between psychology and coaching, it is therefore imperative to develop a clear knowledge base and shared framework of practice, education and professional standards. Professional bodies have a strategic role to play to further the movement towards professionalisation of coaching. An inclusive, interdisciplinary, participative and engaging approach among professional coaching bodies is necessary to address challenges specifically around i) Professional registration vs accreditation, ii) An enforceable code of Ethics, iii) Developing competence around the variety of approaches and application domains, iv) Minimum standards of practice and v) Boundaries based on qualification, experience and competence in coaching.

Towards a definition of coaching psychology for South Africa

**Aletta Odendaal South Africa; Anna-Rosa Le Roux**

In line with the emerging nature of Coaching Psychology internationally, the need to reflect on the constructs at a grass root level has become customary. Internationally the definitions of the British Psychological Society Special Group in Coaching Psychology (SGCP), as well as the Australian Psychological Society’s Interest Group for Coaching Psychology (IGCP) are widely used. The Society for Industrial and Organisational Psychology of South Africa’s Interest Group in Coaching and Consulting Psychology (IGCCP) developed a South African definition. Two data gathering techniques were used, namely focus groups and the Delphi technique. A total of 55 participants were used across the two phases of data gathering, and content analysis was utilised as a means of interpreting the data. The recurring themes as experienced by coaching psychologists and obtained through the focus groups were incorporated into a South African definition.

Exploring the contemporary ethical challenges in coaching psychology

**Claire Simon UI, South Africa; Xenia Goosen; Aletta Odendaal**

The purpose is to share an exploratory framework of ethical challenges faced by coaching psychologists in South Africa. The framework is based on a qualitatively study that explored contemporary ethical challenges faced by coaching psychologists when dealing with both organisations and their coaching clients. Two data gathering techniques were used, namely semi-structured interviews and the Delphi technique. A total of 16 participants were used across the two phases of data gathering, and content analysis was utilised as a means of interpreting the data. The recurring themes in terms of the ethical challenges as experienced by coaching psychologists, obtained through the interviews were incorporated into a framework of ethical challenges. The Delphi technique allowed for the validation of the exploratory framework. The findings pointed to a number of frequently experienced ethical challenges, as well as the typical ethical principles used by psychologists who coach as a guide to best ethical practice. The exploratory framework represents the broad systemic outline of the factors that contribute to ethical challenges, and depicts the non-linear, multiple interactions between these factors. The framework articulates ethical challenges from the coach’s, the coach’s, and the organisation’s perspectives. The framework can be applied by professionals and coaching clients, and can be utilised pro-actively in identifying the potential ethical challenges present in the coaching relationship. Furthermore the framework identifies ethical principles that could be used as the foundation for a code of ethics in coaching psychology.

Outcomes of effective supervision processes for coaching psychologists

**Gail Wrogemann SCW Consulting, South Africa**

Supervision is a key and ethical component in managing the quality of a coaching or consulting offering. Considering the complexities of the systems within which coaching psychologists operate, supervision is a critical component for successful interventions. However, it seems that supervision is widely advocated, but poorly practised, (Hawkins & Smith, 2010), yet without supervision, quality and sustainability decreases rapidly. This study looks at the outcomes and benefits of team supervision processes on client projects and deeper learning that becomes available to the coaches and to the client. Often coaches (or consultants) are caught unawares in processes of projection, projective identification and transference and are not aware of how this limits the growth of their clients. Coaching often happens in traumatised environments where emotional resolution has not taken place and coping mechanisms as an outcome of trauma can be experienced in subtle and confusing ways. Recognition of these themes is essential to enable coaches to become aware of their own internal process and recognise their own learning so that they can take the client through a process of resolution - one which was not available before.

Career orientations of academic staff in higher education institutions

**Dorcas Lesenyeho North-West University, South Africa; Nicolele Barkhuizen North-West University, South Africa; Yvonne Du Plessis**

Objectives The transformation of the South African Higher Education Environment since 1994 has forced academics to reposition themselves in terms of their careers. As the work environment changed and careers become increasingly fragmented in contemporary society, academic staff needs to ensure that they remain attractive hires to current and future employers. The career advancement and the development of the ‘new’ academic career are thus individually determined. Consequently academics need to adopt certain career orientations to survive in the changing work environment. The main purpose of this research is to determine the career orientations of academics in South African Higher Education Institutions. Method A mixed method approach will be followed in this research using a combination of quantitative and qualitative data gathering methods. The Protean Career Orientation Measure, Boundaryless Career Attitude Measure will be administered amongst a stratified random sample of academics in identified South African HEIs. In addition, focus group sessions will be conducted with identified academics to verify the results. Results In general we predict that academics will differ in terms of the type of career orientation that they adopt. We anticipate that there will be significant differences in the career orientations of academics based on their demographic characteristics. Conclusions: Changes in the academic work environment have implications for how academic staff enact their career. It is important to identify the career orientations of academic staff as it will have implications for their development and retention to HEIs.

Gender differences of factors affecting the career advancement of female academics in South Africa

**Lyons Sophia University of Pretoria, South Africa; Nicolele Barkhuizen University of Pretoria, South Africa**

Objectives: Despite a significant improvement in the number of females entering the South African workforce since the first democratic elections, gender differences in career advancement in South Africa; Anna-Rosa Le Roux
African Higher Education Institutions (HEIs) still exist. The main objective of this research is to determine the gender differences relating to factors that affect the career advancement of female academics in South African HEIs. More specifically, we aim to investigate whether there are any significant differences between the perceptions of males and females regarding the factors that facilitate and constrain females’ career advancement in HEIs.

Methods: A cross-sectional quantitative research approach is followed in this study. A revised version of a questionnaire by Zhong (2006) will be used to measure the facilitating and constraining factors that have an impact relating to female academics’ careers. Participants will include both male and female academics of identified South African HEIs. Results: We anticipate that significant differences will exist between the perceptions of male and female academics regarding the factors that facilitate and constrain female’s career advancement in South African HEIs.

Attraction and retention of academic knowledge workers in higher education institutions in south africa

Sharon Victor Univ Pretoria, South Africa; Yvonne Du Plessis Univ Pretoria, South Africa

Objectives: Higher education institutions are positioned within the knowledge economy to foster the development of a much needed type of worker. There are, however, identifiable challenges associated with the sustainability and quality of their service and product if they themselves cannot attract and retain highly talented academic knowledge workers. This research intends to examine how the academic knowledge worker is unique in their contribution to the knowledge economy. In addition, the systemic nature of the attraction and retention of these academic knowledge workers will be examined, highlighting the psychological contract as a conduit organisations can use to enhance their effectiveness in this area.

Method: A mixed method approach will be followed in this study. Initial focus groups will be used to further develop the construct of the academic knowledge worker and their practices. Following this a questionnaire will be designed to highlight the organisational practices.

Results: We predict the academic knowledge workers are unique in their contribution to the knowledge economy. In addition, how they are attracted and retained will depend largely on how higher education institutions meet their personal and professional needs. Contributions: This research will enable higher education institutions to more actively attract and retain their talent, or face losing them to other sectors of the market.

Towards the conceptualisation of emotional labour in the postgraduate supervision process

Stefan Vorster Univ Pretoria, South Africa; Yvonne Du Plessis Univ Pretoria, South Africa

Objectives: Emotional labour (EL) has been researched in various sectors, but is still unexplored in the academic sector. This study firstly aims to explore and conceptualize the term “emotional labour” in the postgraduate research supervisory process. Secondly, to what extent emotional labour is present and experienced by the supervisor and more specifically where in the postgraduate supervision process. Method: The study employs a qualitative research approach seeking deeper understanding of emotional labour. A phenomenological view is followed exploring supervisors’ understanding and experience of the phenomena of emotional labour within the postgraduate supervision process. Convenience and purposive sampling is used. The sample size will depend on data saturation during data collection based on semi-structured interviews, narratives and possible focus groups. Data analysis will be done by Atlas Ti.

Results: The study predicts that emotional strain is present during all phases of the postgraduate supervision process. The relationship between supervisor and student for the purpose of reaching the end goal of a dissertation is not a simple process in terms of emotions and feelings. Conclusions: The outcome is to see whether there is emotional strain on supervisors during the postgraduate supervision process in the current escalated demand for delivering successful postgraduate students in a shorter time. The value of this study is knowledge expansion and understanding of EL in the Higher Education Industry. The proposition is that if EL is experienced as emotional strain it could affect the attraction and retention of academic talent.

The psychology of decent work: Promoting decent civil service salaries and exploring the dual-salary system

Lori Foster Thompson North Carolina State University, United States of America

This presentation integrates and synthesises two studies that explore the psychology of decent work. Decent Work is one of the cornerstones in the poverty reduction strategies of the International Labour Organisation and the United Nations’ Millennium Development Goals. Launched in 2007, a campaign called Decent Work Decent Life stresses the importance, for poverty reduction, of decent working conditions - including decent pay. A recent systematic review of wages in the health and education sectors of low- and middle-income countries revealed that they are often inadequate and demotivating, and that even when they have been bolstered to decent levels, their effect has not been methodically evaluated. This means that it may be premature, as some have done, to call for radical pay-for-performance systems, which the evidence suggests can bring problems of their own into the sector. Pay-for-performance may have a more constructive role to play in other settings, however. For instance, pay-for-performance might help redress the institution of “dual salaries” where expatriates are paid more than locals even when doing similar
or identical jobs within international aid projects and joint enterprises. A recent systematic study of dual salaries in Africa, Asia and Oceania revealed that dual-salaries are de-motivating, unjust and unaligned with local aspirations. Taken together, these studies reveal (i) that poverty reduction work is not necessarily itself decent, and (ii) that psychological evidence can be used to improve its effectiveness at poverty reduction.

Humanitarian work psychologists from lower-income countries: Their work, challenges, and how technology can help

Lori Foster Thompson North Carolina State University, United States of America

The Global Task Force for Humanitarian Work Psychology (GTF) is a group that seeks not only to apply organisational psychology to humanitarian concerns, but also to help transform the discipline of psychology by promoting diverse perspectives outside mainstream and high-income settings. International psychological conferences are some of the venues with the best chance of promoting diverse voices. However, due to economic and logistical considerations, those from lower-income countries are often not able to attend. This symposium is devoted to presenting the innovative work of several humanitarian work psychologists from lower-income countries around the world who were unable to travel to Cape Town. Where possible, electronic presentations from these academics and researchers will be presented and discussed. For example, the work of Leo Marai – professor of psychology at the University of Papua New Guinea and co-chair of the GTF – will discuss via videotape his research in Papua New Guinea. Dr. Thompson – an expert on technology’s role in the workplace – will also discuss the importance of internet technology in assisting the GTF’s efforts to promote greater alignment to the priorities and perspectives of lower-income countries. This presentation will be a unique opportunity for the audience to consider the importance of ‘who is not in the room’ and the role that socioeconomic inequality plays in the determination of research agendas and priorities.

Leadership and organisational justice: Propositions for strengthening human resources for health in sub-Saharan Africa

Lori Foster Thompson North Carolina State University, United States of America

Africa has the worst health outcomes per dollar spent in the developing world, and the International Monetary Fund rates the efficiency of African health spending as the lowest in the world (Gupta, 2001). One of the explanatory factors being offered as an explanation is leadership (WHO Africa Monitor, 2007). Using Uganda as a case study, the study will examine the construct validity of transactional, transformational, and servant leadership models, and investigate the effects of these types of leadership on organisational justice perceptions, public service motivation, turnover intention, and organisational citizenship behaviour (OCB). Finally, the study will assess these models of leadership in the context of public, faith-based, and private-for-profit health sectors. A cross-sectional survey design will be used with a sample of 720 nurses and doctors in hospitals from the above sectors using disproportionate stratified sampling. The research instrument will be a structured self-administered questionnaire. Factor analysis will be undertaken to check whether the dataset segregates the constructs into the same dimensions as previous studies. Correlation coefficients will be generated and linear regression will be performed with the leadership models as predictors of organisational justice, public service motivation, turnover intention and OCB. Finally the t-test for independent samples will be used to examine variation along the various constructs of the study across the health sectors studied. Recent progress on this study will be presented and that progress will be used to illustrate the importance, and some of the dynamics of research on leadership in health sectors in lower-income countries.

The BPS division of occupational psychology: OP-FIRST project

Dave Bartram SHL Group Ltd, United Kingdom

The ‘OP-FIRST’ project ran from 2004 through 2006. Its aim was to establish the identity of contemporary occupational psychology in a rapidly changing organisational and academic context and to define the knowledge, skills and competences that underpin the profession. The main questions the project set out to answer were: 1) Future. What are the main challenges OP needs to meet? 2) Identity. What are the unique skills and knowledge bases that make OP what it is? 3) Recognition. How can OP continue to be recognised as a field that can offer unique insights, understanding and solutions to organisations and the individuals within them? 4) Standards. How can we ensure that standards are kept rigorous, current, and in line with international developments in the profession? 5) Talent. How can we ensure that talent is managed most effectively? The focus of the presentation will be on the work done on ‘Identity’. The main emphasis of the project was placed on the rigorous, scientific gathering of data, using a wide variety of qualitative and quantitative techniques, to provide a multi-method corroboration of findings and recommendations. Some of the key findings and their implications will be discussed.

Practice of IO psychologists in South Africa: SIOPSA Future Fit project

Fred Guest TTS-Top Talent Solutions, South Africa

In 2008 the Society for Industrial and Organisational Psychology of South Africa (SIOPSA) identified a need for a long-term project to critically evaluate how Industrial Psychologists (IP) add value to their clients and communities. The Future Fit project highlighted the need for research in 11 action domains. The areas of ethics and scope of practice were the most important of these. Building on the work of the BPS OP-FIRST project and the work of Bartram & Roe (2005) on the Definition and Assessment of Competences in the Context of the European Diploma in Psychology, the scope of practice action domain initiated a research project to sample the views of IP professionals in South Africa. A survey was distributed to approximately 2346 individuals on the SIOPSA membership database and 240 completed surveys were received. The survey was followed by a range of discussion session at SIOPSA regional branches. This presentation will focus on the results from this survey and discussion groups. Areas that will be addressed include: The main areas of practice and work roles of IPs in South Africa; the perceived importance of various primary, secondary and behavioural competency areas for success; comments on how the role of the IP might change in the future. Further research and the implications for future training and development of IPs will be discussed.

Affirming psychology in industrial psychology

Mary Schaerer Saville Consulting, South Africa

Industrial psychology is an applied sub-discipline of psychology, and industrial psychologists are trained to be behavioural specialists in the workplace. As such, industrial psychologists approach workplace problems or enhance organisational functioning from a behavioural perspective. Industrial psychologists also operate as human resource management practitioners within organisations. An investigation was conducted on how behavioural science could be applied by industrial psychologists in the human resource management domains. The importance of investigating this research question was to enable or enhance the practice of industrial psychologists in the human resource management domains. The aim of this study was to create a socially constructed futuristic framework that could inform industrial psychologists on how they could practically apply psychology in human resource management domains. Relevant stakeholders that have an influence on the industrial psychology profession were also identified and included in this study in order to provide a holistic perspective on all the organisations that may support the use of psychology in the human resource management domains. A qualitative research approach was utilised to explore the research question. The main contribution of this study is that industrial psychologists may be better able to position themselves in order to embed behavioural science in the human resource management domains.

Leadership for innovation: Looking within, around and beyond

Convenor: Ajay K. Jain

Leadership for performance excellence: An Indian experience

Ajay K. Jain Management Development Institute, Denmark

The basic proposition in psychological literature which has emerged, is that behaviour is the function of personality and environment (Lewin, 1936; Sanjose, Morf, & Panter, 2003). Korman (1971) proposed that leadership behaviour should be viewed in Lewinian terms as a function of the person and the environment. As an organisational theorist, I assume that the business environment is highly complex, dynamic and globally connected. Thus, leadership effectiveness can be postulated to be an interactive function of the leader’s behavioural competencies and organisational and environmental characteristics. The purpose this study is to develop an integrated leadership model from the study of seven CEOs’ behaviour by adopting psychological,
The study applies Bandura’s concepts of efficacy beliefs to an organisational context in order to investigate the relations to employee influence. We are also applying Bandura’s proxy efficacy concept, i.e. beliefs about another agent’s capacity to safeguard interests. We identified Health & Safety Committee (HSC), Work Council (WC), and management as such proxy agents operating at distal levels and they constituted the organisational agents together with oneself and the team. The study was accomplished in a green tech company with 568 participants. Reply rate 74%. The results of the regression analyses with control of gender, age, work function and seniority show that employee efficacy influence is positive related to the different forms of efficacy. Main results: individual influence to self-efficacy (p<0.001), team efficacy (p<0.05), HSC (p<0.001), WC (p<0.001) and Management (p<0.001). Team influence to team efficacy (p<0.001). The results indicate that if an employee experiences influence at distal issues the employees also experience a greater efficacy to proxy agents, and overall where an employee experiences influence he also experiences a higher efficacy to the given agents at that level. In conclusion it can be said that to the extent that efficacy means more successful organisational agency, the results point to the potentials of granting employees autonomy and influence and thereby include employees in the management of work and organisational issues.

Experienced influence (in organisations) and efficacy beliefs to organisational agents

Hans Jeppe Jeppesen Aarhus University, Denmark
Maj Schoeler Fausing; Thomas Joensson

The study applies Bandura’s concepts of efficacy beliefs to an organisational context in order to investigate the relations to employee influence. The results of exploratory factor analysis have yielded four factors which are named as people and culture development (looking around), strategic focus (looking beyond), evolved self (looking within) and performance excellence (sustainable development). An integrated leadership model is developed to suggest a need to align highly evolved self leadership competencies with the business strategy, and cultural and people aspects in the organisation for achieving excellence in the changed business environment.

The improvement of cultural intelligence amongst leaders: An African focus

Ebbben Van Zyl University of the Free State, South Africa

The aim of this qualitative literature discussion, is to discuss ways by which leaders can improve their cultural intelligence levels within the African organisational context. The world is characterised by political, social and economic environmental changes. Internationalisation and globalisation, for instance, have brought about world competition and require leaders/managers to interact with and manage people who are culturally diverse. The power of Africa and its long-term impact on global markets and economies are only beginning to surface and to be understood by the world, which will increase the pressure on leaders, as well as the complexity of leading businesses in the years to come. Cross-cultural people skills are important because managing people effectively is critical to organisational efficacy. Ways to improve the cultural intelligence amongst leaders in the African working context, should therefore be investigated. Important concepts will be defined, with the focus on cultural intelligence and the significance thereof to the leader/manager in the African organisational context. Cultural intelligence can be improved by, inter alia, obtaining knowledge of current leadership and management practices in Africa. Thus, this presentation will discuss leadership and management in Africa (focusing on the changing African context, cross-cultural challenges and the African cultural value system), followed by a description of a cultural intelligence implementation model of leadership. Last, servant leadership as a tool to implement the cultural intelligence implementation model, will be discussed.

Symposium title: Long Life Learning for Leaders: The ontopsychological contribution

Convenor: Pamela Bernabei

Creativity in business leaders

Pamela Bernabei FOIL, Italy, Italy

The real problem and the most significant challenge for enterprises in the developed world is that of finding a model to foster creativity. How do we know how to invest our efforts in a way that will bring progress, growth and prosperity? The application of ontopsychological consulting to leadership and business consists mainly to: a) Analyze the position of the leader as an efficient cause; The leader is the brain of the whole business; 2) lead the subject to recover full awareness of her/his potential and intelligence. Just as the living cell already carries the capacity to sustain and evolve its identity, human being is naturally endowed with creative intelligence, enabling her to establish advantageous interaction with the environment. Yet many historical and social factors could generate fixed stereotypes and non-functional thought. Overcoming non-functionality and recovering this integrity may empower the person to gain knowledge of everything concerning her/his interests and success. Method and application in Europe, China, Brazil and Russia will be presented.

Intuition and results: The dual concept for the leader

Fabrizio Brazzolotto Foil Germany, Germany

Intuition provides a new and additional instrument, a new pivotal type of information which can be assembled and compared to the other information that one already has. It enables us to reach the best solution, reduce the margin of risk. The key questions: What is intuition? Is it innate? How should we define intuition? Can we learn to exploit this capacity? By taking up this challenge the author will describe the application of the ontopsychological approach - a contemporary current that, based on its own original discoveries, implemented a basic operational rationale that makes it possible to isolate deviant complexes and gratifying drives - and its methodology to the topic. One of the characteristics of the approach is that it can facilitate, individuate, and help to actualise the leader’s intuition. Being a direct and exclusive emanation of the ontic In-itself, intuition is the formal projection of the point of optimal functionality, in the mediation of one or more contexts in relation to the subject. Results will be discussed, in particular the author will highlight: a) How in a given context of actions and reactions related to an inner or outer player, intuition pinpoints the optimal choice in the concurrence of several problems or several solutions; b) how to analyse intuition through images, impressions, conceptions, systemic thinking, experiences, semantic fields.

The quid of economics: The subject object relation function

Gabriella Palumbo AEO and ISS, Italy; Saraia Schutel AEO and ISS, Italy

What is exactly the focus of economics as a science? Generally speaking, value is anything that increases being, anything that causes and brings to life more being. Economic value, in particular, is the relationship between object and subject whereby the subject (a man, a bank, an institution) is the operator and the object is the quantum; matter exists not in and itself but because of the specific function in the relationship within the synergy between that subject and that object. The key determinant in this relationship is the subject: the owner injects existence, defines the object legally and institutionally. The function may be ontological or ideological. Within the relationship between subject and object, ontological is that function that benefits the subject’s identity of nature (where identity of nature is understood to mean that which is specific to the subject’s being In-itself). On the other hand, this function is ideological if it is functional to the subject’s ideological identity, representing only what the operator thinks or believes. In the light of this new perspective the rationale and contradictions of the homo aeconomics will be discussed.

Long life learning by ontopsychology for leaders in times of globalisation

Tatiana Veretinova FOIL, Russia, Russian Federation; Pamela Bernabei

One of the objectives that ontopsychology proposes is the fostering of responsible operators in the global context. According to the finality and specific goal foreseen by the leader, the method focuses on teaching the ability to analyse the social context in a functional, integral and humanistic perspective: 1) Globalisation of the current and potential market; 2) digital technology; 3) human capital. The paper will describe how to detect the criterion of conformity to the operative functionality of the leader in this context, allowing the reaching of the success: 1) For the operator, 2) for the company, 3) for the global functionality of the context. The ontopsychological fostering is aimed at the leader, understood as any individual who operates movement, transference of means and
growth in and for the service of social context to improve quality of life and psychological well being. It is not only a matter of personalities deservedly known, but also entrepreneurs from small companies, constructors, artisans, agents of the commerce, artists, consultants, producers, young entrepreneurs. Results and application carried out at international level will be showed.

Symposium title: Online assessment and candidate performance  
Convenor: Andreas Lohff

Impact of language proficiency on psychometric properties of online personality assessment  
Hennie Kriek  TTS Top Talent Solutions/UNISA, United States of America; Maike Wehrmaker; Katharina Lochner; Achim Preuss

Intelligence tests are often criticised for being biased against certain groups. For this reason, so-called culture fair or culture free tests were developed (e.g. Cattell & Cattell, 1963). But even these tests have minimum language requirements in that the test taker has to understand the instructions. In our study, N = 107 South African job applicants who were non-native English speakers completed a personality questionnaire and a test battery. The test battery comprised tests measuring English language proficiency as well as numerical and verbal abilities, mechanical-technical understanding, calculating skills, multi-tasking ability, and perception. Most of the tests only require very basic language skills. However, participants’ performance was significantly worse than the norm group’s performance on all the tests. The effect mitigates when controlling for language proficiency. However, the impact of language proficiency on the reliabilities of the personality scales is highly significant: The lower the language proficiency the lower the reliabilities. Findings suggest that selection tests should be controlled for language proficiency if test takers can’t complete the tests in their mother tongue and/or general language proficiency is low. Practical implications will be discussed.

Introduction and overview  
Andreas Lohff cut e Group, Germany; Maike Wehrmaker; Katharina Lochner; Achim Preuss; Hennie Kriek

New technology allows for completely new methods and structures of unsupervised online testing. It requires quality aspects that go beyond classical psychometric criteria. One vital aspect of these extended quality criteria is the determinants that affect the fairness of unsupervised online testing. Latest empirical findings suggest that other factors apart from ability can influence a participant’s performance on psychometric tests. Such factors are for example certain personality traits and language proficiency. Furthermore, while taking a test, instant feedback seems to alter test takers’ performance. Finally, impression management impacts the results applicants gain when taking personality tests. Therefore, being able to predict the degree of impression management in personality testing is important for ensuring the quality of the data and for providing adequate feedback.

Symposium title: Psychological services and humanity approach in the process of transition from state to private sectors in East Europe  
Milošlav Solc

Work and organisational psychology and services in the Czech Republic  
Milošlav Solc  Capa a. s., Czech Republic

Work and organisational psychology (WOP) has a rich history in Czech lands; it changed the mission and methods during various periods (1918-1948, 1949-1955, 1956-1970, 1971-1989, 1990-1993). Some historical psychological laboratories in industry are still up-to-date and fully functional (e.g., Vitkovice Steel laboratory from 1923). A significant milestone was the transition from the state to private sectors (1994-2010), as well as influence and involvement of the European Union, multinational organisations and influences of the new entrepreneurial strategies in Central Europe. Recent developments and current status of WOP has to be analysed from the perspective of a) specific sectors: industry (e.g., stress assessment in chemical industry), transport (especially traffic psychology, railway and air traffic), army, finance, interior, health, work and social affairs, education (careers improvement), municipality; and b) with respect to concrete case studies (including private practice of WOP in small and medium enterprises). Trends in WOP and psychological services: Increase in complexity and interdisciplinarity of services and research (economic psychology, human engineering, personnel psychology, psychology of market and PR, psychology of entrepreneurship, cross-cultural psychology). Continuing transition from state to private services (opportunity and threat); and increase of WOP practice in small and medium enterprises (SME). Addressing of topical problems (recession, unemployment), and global challenges (psychology of entrepreneurship, global economy, psychology of environment). Trends of WOP in the framework of European Union 2020 strategy (headline targets).

Psychological services and a humanist approach in the process of transitioning from state to private sectors in Eastern Europe  
Milošlav Solc  Capa a. s., Czech Republic

The symposium addresses the theme from various angles, in wide contexts and by in-depth empirical probes: Initial presentations will be devoted to Psychology of Democracy, to a scrutiny of social psychological prerequisites of democracy, different understanding of democracy across various social groups, and research of political mentalities across Eastern Europe and beyond. Findings lead to a discussion of post-totalitarian non-democratic mental heritage evident in some citizens of post-communist countries. This is a possible source of frustration and paternalism which hinders democratic initiatives, and can cause apathy or political extremism. The academic research presentations are complemented by empirical reports from various applied fields, mainly by testimony from the area of social care for handicapped children (illustrating a dramatic improvement in comparison with the pre-democratic era) and by evidence of activity in an extensive array of fields of "work and organization-
ceived leader support, which lessened work satisfaction, (ii) agreeableness, openness and conscientiousness moderated the relationship between perceived leader support and work satisfaction, thereby yielding a pattern of moderated mediation. Specifically, for those low in agreeableness, the influence of organisational justice on work satisfaction through perceived leader support was weakened, whereas people high in agreeableness did not. The same patterns were discovered for openness and conscientiousness. Theoretical and practical implications of the results were discussed.

Social support can reduce job stress: A moderating role of other orientation
Dan Li Peking University, China; Lei Wang Peking University, China
Perceived social support can conditionally reduce the stress of one’s work. However, the levels and the pattern of the influence process have not reached an agreement. Whereas some theories, such as stress theory model and transactional model, suggested that personal characteristics play an important role in generation of stress, other theory, such as the Buffeting Model, mentions that the social support as a group-level moderator can impact a person’s physical and mental health. According to these models, we conducted a two-stage quantitative study by three questionnaires. The results revealed that social support indeed reduces one’s job stress; however, the reducing effect was stably and significantly moderated by participants’ other orientation. Specifically, the social support can reduce more job stress on the individuals with higher other orientation than the individuals with lower other orientation. This finding suggests that the perceived social support would not always account for one’s job stress effectively, while moderated by personalities such as other orientation. Additionally, the result extends not only the research areas of job stress and social support, but also provides many practical implications on human resource management.

Political skills and locus of control as moderators: Work stressors and burnout
Weipeng Lin UC Berkeley, United States of America; Lei Wang UC Berkeley, United States of America
Integrating the two-dimensional model of work stressors with burnout research, the present study examined the relationships between challenge stressors, hindrance stressors and the three dimensions of job burnout (i.e. exhaustion, cynicism and inefficacy), as well as the moderating effects of individual differences (i.e. political skills and locus of control) on the stressors-burnout relationships. A total of 299 Chinese civil servants participated in the questionnaire survey in two phases. The results showed that challenge stressors were only positively related to exhaustion, while hindrance stressors were positively related to all three dimensions of burnout. Furthermore, participants’ political skills moderated the relationships between hindrance stressors and all three dimensions of burnout, such that the relationships are weaker for individuals with higher political skills. Locus of control moderated the relationships between challenge stressors and exhaustion, such that the relationships are weaker for individuals with external locus of control. These results suggest that the boundary conditions of the relationships between different type of stressors and different dimensions of burnout are divergent. Various types of individual differences (i.e. skill and personality) can act as resources to buffer stressors-burnout relationships in separate ways.

Is conscientiousness always good for employees? A moderated mediation model
Jingjing Ma Peking University, China; Lei Wang Peking University, China
Considerable previous research has demonstrated the positive impact of employees’ conscientiousness in organisations. However, in this study we surveyed 221 Chinese civil servants using longitudinal design and found that conscientiousness may exert bad influence on employees. The results showed that employees’ conscientiousness had significant strengthened moderation effect on the full mediation relationship between challenge stressor and job burnout through perceived stress. Specifically, when dealing with more challenge stressors, compared with their colleagues who had lower conscientiousness, those high in conscientiousness perceived more severe stress, resulting in more experienced burnout. Meanwhile, conscientiousness did not significantly influence the partial mediation relationship between hindrance stressor, perceived stress and burnout. Implication and future research concerning the potential dark side of conscientiousness in organisations and the differentiation between challenge stressors and hindrance stressors are discussed.

Virtual self-choice enhances resistance towards illusory stress
Kun Yu Peking University, China; Lei Wang Peking University, China
The current research aimed to examine how resistance towards stress is affected by mere imagined choice (virtual choice) about the work or task. In Study 1 we held a real choice task on computer to identify that participants could bear more stress in a task they choose than in a task selected by computer. Fifty graduate and undergraduate students were randomly assigned to self-choice condition or computer-choice condition. Results showed that participants in self-choice condition could persist longer in the arithmetic task than computer-choice condition, even though tasks in two conditions were actually all the same. In experiment 2 we introduce virtual choiceship, that the choice was unreal but just being informed. Three types of job choices were offered to 137 employees, who were then told to imagine they are engaging one of them. Results revealed that subjects in self-choice condition reported higher level of willingness to bear stress than other two conditions. With another sample of 107 employees, we held experiment 3 and replicated findings of experiment 2 without information about alternatives job choices presented. These findings demonstrate that virtual self-choice existing only in the mind could enhance people’s resistance towards illusory stress on an imaginary task or a job, even though people never do it and even never know about it. Theoretical and practical implications of these findings are discussed.

Symposium title: The application of evidence-based approaches in coaching psychology
Convenor: Aletta Odendaal

The authentic-intention model: Using explicit intention to decipher the interface between interpersonal behaviour and authentic leadership
Steven Bregel DynamicDIALOGUE, South Africa
The Authentic-Intention Model (AIM) provides a framework for practitioners to understand the behavioural dynamics of individuals and teams, in order to transform un-articulated intentions, ‘the agenda’, to authentic dialogue. The AIM integrates evidence-based research and adopts an a posteriori, action-learning approach that includes the following theoretical grounding: role theory; cognitive-behaviour therapy; social constructionism; dialogue; systems psychodynamics; neuroscience; emotional intelligence. Behavioural dynamics can be determined by accessing the following: Context; systemic setting; expectations and individual roles within the interaction. Content: individual’s word-phrase choices, attributed meaning. Syntax: structure/logic arising Pre-suppositions: assumptions, expectations. Intention: psycho-emotional [un/conscious] subtext and non-verbal, spatial-directional-tonal characteristics. The emerging patterns provide information for diagnosing behavioural dynamics and deepening relationships. The benefits being: congruence, credibility, authenticity, trustworthiness and meaningful collaboration. The AIM is a diagnostic and leadership-mastery tool for coaching, facilitation, transformation, and training and development contexts – to transform working relationships. It provides a practical tool to articulate that which often remains unacknowledged and unarticulated at the interface of emotion, language, irrational and rational intention.

A branding approach to coaching
Frederik Crous University of Johannesburg, South Africa
According to the embodied cognition thesis, all aspects of the mind (including high level mental constructs and tasks) are shaped by the experience and perception of bodily movements. A basic bodily movement in space may therefore serve as root metaphor/image schema for a highly complex concept. With this paper it will be shown how embodied cognition may provide for an approach to coaching. This will be done by: 1. identifying the root metaphor for optimal experience/performance, 2. indicating how this metaphor may be interpreted as a logo (image schema) for optimality/positivity, 3. suggesting that this is a valid logo ‘we work optimally by’, 4. explaining how this may serve as a method for ‘branding’ optimality/positivity in the mind of the coachee, providing the coachee with a tool for making sense of the coaching process and sustaining its outcomes. A case will be presented on how coaching as a branding process of optimality/positivity was applied.

The application of evidence-based approaches in coaching psychology
Aletta Odendaal South Africa
Coaching psychology is a rapidly expanding sub-discipline of applied psychology in both research
and practice domains. Psychology brings to coaching a solid understanding of the psychology of human change and the ability to develop coaching interventions based on theoretically grounded case conceptualisations using evidence-based processes and techniques that are applied in specific contexts. Coaching psychologists (or psychologists as coaches) should be able to draw on a range of theoretical frameworks, using client-congruent, theoretically grounded techniques in order to assist the client in reaching their coaching goals. Surveys conducted in the UK, Australia and South Africa (2003-2011) clearly established in excess of 28 different psychological models and approaches used by coaching psychologists. This symposium explores four approaches to coaching, chosen to illustrate the variety of influences on coaching psychology practice and its knowledge base. Recognising the multi-disciplinary nature of coaching and that coaching psychologists may come from multi-theoretical backgrounds, survey results on the different approaches utilized in coaching psychology as well as case conceptualisation will be utilised as the basis for the discussion. A framework for using formulation in coaching psychology is outlined through consideration of purpose, perspective and process (Lane & Corrie, 2009). It is argued that greater attention to formulation will contribute to the development of systematic approaches to practice in a highly diverse context.

Coaching Africa: A strength based systems approach towards coaching in a multicultural society
Llewellyn Van Zyl University of South Africa, South Africa; Marius Stander

Traditionally, helping professions aimed to address psychopathology (Seligman, 2011). Wellbeing was defined by the absence of distress and pathology (Seligman & Csikszentmihalyi, 2000), where no emphasis was placed on optimal development. Focusing on and re-emphasising pathology reinforces low expectations, creates dependency on outside resources and discourages individuals to develop optimally (Peterson, & Seligman, 2004; Seligman, 2011). Psychologists interested in promoting human potential need to move away from this disease model towards facilitating development through focusing on individual strengths (Park & Peterson, 2006). The purpose of this paper was to develop an analytical strengths based coaching model conducive to a multicultural society. A meta-theoretical literature review was used in order to develop the model. The model is comprised of ten phases: (a) clarifying expectations and establishing rapport, (b) identifying and marrying conscious and unconscious strengths, (c) identifying coaching themes, (d) encouraging, deriving meaning and instilling hope, (e) framing solutions, (f) building strengths and competencies, (g) empowerment, (h) changing, (i) building resilience and (j) evaluating and terminating the relationship. The focus lays on determining key concepts of the theory, the coaching process and the application of the model within a multicultural environment.

Symposium title: The state of psychology in Zimbabwe
Convenor: Gwatirera Javangwe

In the eyes of the Zimbabwean occupational psychologist
Gwatirera Javangwe University of Zimbabwe, Zimbabwe

The presentation focuses on the current trends, patterns and pathways for occupational psychology in Zimbabwe. I will illustrate how occupational psychology is taught, practised and also demonstrate the gaps inherent in both teaching and practice of occupational psychology.
The importance of students’ perception of health communication in instructional design

Clarissa Dias Universidade de Brasilia, Brazil; Elizabeth Queiroz

Health psychology enables behavioural change to enhance health and prevent illness. It plays a pivotal role in health communication, a key element of the health professional-patient relationship. Thus, clearly understanding health communication is central to dealing with health needs and education programs. It is fundamental to collect data on students’ perception of health communication to design curricula. However, several studies have indicated that this is a major problem in professionals’ day-to-day activities. Therefore, we used a purposeful sample of 139 low-income Brazilian undergraduate students majoring in health professions was taken to analyze their perceptions of health communication prior to formal instruction. They viewed this concept as consisting of the transmission of health-related information, including the communication means to carry out health promotion and disease prevention, through the interaction of health professionals, patients and health teams. They perceived it as a means to understand needs, especially patient needs - which should be listened to and respected. The key conclusions of this study are that: (1) the importance of non-verbal communication is a substantial part of the communication process, therefore one should be more attentive to this aspect during professional education; (2) insufficient attention is given to humanization awareness, needed in integrated professional practice; (3) it is indispensable to include these concerns to adequately deal with health needs; (4) public policies and education programs should be guided and service delivery effectiveness evaluated. A challenge to instructional design for higher education learning in the health field is to strengthen the understanding of health communication.

The effects of seductive illustrations on multimedia learning: Evidence from an eye movement study

Ting Duan Central China Normal University, China; Fuxing Wang; Jiawei Li Central China Normal University, China; Shaoying Gong

The current study aimed to explore the influence of seductive pictures on performance and cognitive processes in multimedia learning. Sixty undergraduates were recruited to learn the principle of lighting forming including 5 pages of slides with or without seductive illustrations and then completed a quiz. The performance data before and after the learning was collected. Eye-tracking methodology was also used to evaluate the reading patterns of individuals. Compared to the base condition (the learning content including text and cognitive interest illustrations, but without seductive illustrations), participants in the seductive illustration condition (the learning content including text, cognitive interest illustrations and seductive illustrations) (1) recalled significantly less important information and generated significantly fewer problem-solving solutions, (2) allocated fewer fixations in text and also fewer transitions between text and cognitive interest illustrations. Moreover, in the seductive illustration condition, the individuals with good learning outcomes had more fixations in text and more transitions between text and cognitive interest illustrations than the poor ones. They also reported fewer distractions by decorative pictures. The present study indicates that seductive illustrations interfere with learning by distracting the students’ attention and disrupting the coherence of the material.

The relationship between parent goals, classroom goal structures, personal achievement goal orientations and academic performance

Shaoying Gong Central China Normal University, China; Cen Chen

This study aimed to explore the relationship between parent goals, classroom goal structures, personal achievement goal orientations and academic performance. Participants were 930 junior and senior high school students from grade 7 to 12 in Jiangsu Province in China. All students were measured with the revised Perceived Parent Goal Emphasis Questionnaire, Perceived Mathematics Classroom Goal Structures Questionnaire, and Achievement Goal Orientations Questionnaire. The results showed that the achievement performance was positively predicted by personal mastery-approach orientation and performance-approach orientation, and negatively predicted by performance-avoidance orientation. Parental goals students perceived and classroom goal structures affected students’ performance primarily by the mediation of their individual goal orientation. Perceived parent goals and classroom goal structures had a significant influence on academic performance through personal goal orientations. Specifically, perceived classroom mastery goal structure positively predicted performance through personal mastery-approach orientation, while classroom performance goal structure predicted performance through personal performance-avoidance orientation negatively. Perceived parental mastery goals positively predicted performance through personal mastery-approach and performance-approach orientations, and parental performance goals negatively predicted performance both directly and indirectly through personal performance-avoidance orientations. These findings demonstrated that goals from environmental influence individual’s goals, and therefore influence individuals’ achievement.

Digital technologies in learning

Roche Herbst Human Capital Solutions Inc., Canada

The aim of this study was to examine how digital technologies assist individual learning difficulties in mastering constructs and processes through designing, thinking and learning. The transformative potential of technology and educational software programs have become increasingly significant for teaching/learning experiences. The term “learning difficulties” and “learning disabilities” are used interchangeably. This analysis explored how technology plays a role...
in learning difficulties related to 'delayed' sensory processing because of developmental or learned aspects or language impairment. Methodologically, interviews, tests and questionnaires were used to determine cognitive abilities and perceptual processes when dealing with verbal and visual information. The rationale for using different technology or educational software programs based on the assessment results are discussed. The population considered individuals with learning difficulties. A sample of 45 cases were reviewed. This type of research can be seen as problematic, exploratory, descriptive and non-experimental. It examined learning goals enabled through technology in academic and workplace settings. In summarising the results, implications for understanding the positive potential which digital technology plays in assisting those with learning difficulties are described. Conclusions based on the findings reveal various recommendations and helpful interventions in managing some aspects of atypical cognitive development or inconsistent cognitive functioning.

A strategy to overcome learning difficulties among students with different cognitive styles

**Olga Kasatkina**
Moscow State University of Psychology & Education, Russian Federation

The results of a study on self-organisation of students enrolled in the Bachelor of Psychology program at the Faculty of Distance Learning at Moscow State University of Psychology and Education are presented. The sample consisted of 66 students from first to seventh semester between the ages of 18 and 50 years. The aim of this study was to determine the preferred strategy used to overcome learning difficulties depending on the cognitive style. The basis for the typology of strategy to overcome learning difficulties, are indicators of high or low "activity in finding solutions to problems" and communication strategy "Consulting/Isolation". The combination of these indicators allowed us to distinguish four groups of students. Next, we tried to answer a question connected to whether there is a relationship between coping strategies in learning and cognitive styles. To establish the connection between the indices we used the Spearman rank correlation coefficient. The following variables were studied: main index of Field dependence/Field independence (Witkin, H.A), the main indicator of impulsivity/reflexivity (Kagan, J). According to our records, the main figure of field independence associated with active problem solving strategy, as well as with isolated communication strategy rs ≤ 0.01. The main indicator of reflexivity associated with the communication strategy was .01 ≤ rs < 0.05. Reflective students are significantly more likely than impulsive students to prefer communications strategy U= 383, at p<0.05.

The effect of physical exercises on mathematical achievement and attitude in middle school students

**Zohre Nouri**
Shahid Beheshty University, Islamic Republic of Iran; **Masood Sharifi**

In this research we study the effect of physical exercises on learning mathematics and attitude toward math in middle school students in Tehran, Iran. In order to carry out this study we selected 129 male and female students in a stratified random sampling method in two groups including an experimental group and a control group. First they did pre-test, and then the experimental group students, before every math class, did 15 minute aerobic exercises and 15 minute juggling in the middle of training as a break time. The control group did not do any exercises, only trained. After 15 sessions all groups were tested. Learning mathematics was measured by an achievement test made by the researcher. Student attitudes about mathematics were measured by a researcher made questionnaire. By use of the t-test, the results show a significant relationship between physical exercise and learning mathematics. Also, physical exercises before and during training mathematics affected students' attitudes toward mathematics. Furthermore, the experimental groups got higher scores in attitude toward mathematics and the difference was significant. There was a significant difference in pre-test and post-test attitude in the experimental groups. It seems that physical exercises have some effect on learning mathematics and students' attitude towards it: maybe it is better to do some physical exercises before math classes to learn better.

A metacomprension approach to enhancing older people's self-regulated learning

**Christian Stanov Rossnagel**
Jacobs University, Germany

The self-monitoring approach posits that improving the metacognitive monitoring of learning enhances performance. Given the importance of meta-cognitive control for real-world learning (e.g., workplace learning), the self-monitoring approach may be a promising platform for self-regulated learning trainings. Two issues need dealing with, however, on the way to such a platform. First, self-monitoring significantly predicts learning performance, but accuracy is often low. Second, accuracy is affected by features of the materials. In two experiments, I therefore tested whether accuracy depends on the self-monitoring criterion (Exp. I) and how context effects bias learning judgments (Exp. II). In Exp. I, 80 older (51–65 years old) participants read expository texts and took a knowledge test. Texts were divided into segments of 2–3 sentences each. In a 2x2 design, half the participants made judgments of learning (JOL) after each segment (local monitoring) or after reading the entire text (global monitoring). Half the participants in each monitoring condition either judged the likelihood of recalling the keyword (matched JOL) or of answering a test question (standard JOL). Local JOL yielded higher accuracy than global ones. This local effect was most pronounced for matched JOL. In the second experiment, I manipulated the sequence of easy and difficult segments as measured by propositional density. 40 new participants read different difficulty sequences (e.g., EDEDED, DDDEEE) and made global or local matched JOL. The latter type of JOL covaried with the difficulty sequence and yielded superior accuracy to global JOL, showing how judgments can be systematically biased.

Relationship between self-esteem, learning motivation and academic achievement in Chinese high school students

**Yuehua Tong**
University of Jinan, China; **Lucia Rossi**; **Eduardo Keegan**

The current study was to investigate the relationship between self-esteem, learning motivation and academic achievement in the context of China. The Rosenberg Self-esteem Scale and Learning Motivation Inventory were administered to 179 first year high school students (82 males and 97 females). Their academic achievement scores and demographic information were collected at the same time. The results were as follows: (1) In terms of gender difference, achievement motivation and self-responsibility in learning motivation differed significantly. Achievement motivation and self-responsibility of girls were higher than that of boys (t=-2.282, p<0.05; t=-2.900, p<0.01). (2) There were significant positive correlations between self-esteem, learning motivation (achievement motivation, test anxiety and self-responsibility) and academic achievement (r=0.160-0.793). (3) Achievement motivation, test anxiety and self-responsibility were the mediators between self-esteem and academic achievement. Achievement motivation, test anxiety and self-responsibility fully mediated the relationship between self-esteem and academic achievement. Implications for counseling high school students are discussed.

Academic discourse socialisation: Enslave- ment versus emancipation

**Vasi Van Deventer**
University of South Africa, South Africa; **Jean Hagen**

Traditionally, students are socialised into academic discourse by learning, and abiding by, the discourse community’s local discursive practices, in a sense becoming enslaved by, and into, academic discourse particular to their field of study, for example the discipline of psychology. However, research relating to academic discourse socialisation frames this process as a bi-directional social construction that is constantly evolving through students’ and teachers’ interactions and their social and cognitive experiences towards the goal of developing academic literacy. However, participant roles define students as novices lacking in the necessary knowledge, and teachers as experts, who provide scaffolded learning environments with which students need to engage. Thus, despite advances in teaching and learning, agency still lies with the experts, and students remain docile recipients of pre-established knowledge. This is a model of enslavement rather than emancipation and does not accommodate the shifting perspectives of the university in the information age. What signs, if any, are there then of shifting perspectives? The present paper reports on the findings of a discoursal analytical study involving psychology students from two universities. Although students readily buy into academic enslavement, they do constitute and negotiate their identities in an attempt to counter traditional academic discourse, and to push the boundaries of the university.

The impact of active navigation on the transfer of spatial learning from virtual to real environments according to the effect of viewpoint displacement

**Gregory Wallet**
Université Victor Segalen Bordeaux II, France; **Helene Sauzeon**; **Florian Larrue**; **Pra- shant Arvind-Pala**; **Bernard N’kaoua**

The purpose of this study was to examine the effect of navigation mode (passive vs. active) on the virtual-real transfer of spatial learning, according
The mediating role of metacognitive ability in mathematics between mathematics anxiety and mathematic academic achievement

Shuangzhou Zhou Beijing Normal University, China; Congcong Han; Yinghe Chen

The present study was designed to explore the mechanism among mathematics anxiety, pupils’ metacognitive ability in math and math academic achievement. A prospective study with 100 school students were investigated by the revised Questionnaires of Pupils’ Metacognitive Ability in Mathematics and Mathematics Anxiety Scale for Children. The results showed that: (1) Mathematics anxiety was negatively correlated with math academic anxiety; (2) The math academic achievement and metacognitive ability in math of high mathematics anxiety group was significant lower than that of low mathematics anxiety group; (3) Pupils’ metacognitive ability in math mediates the relationship between mathematics anxiety and math academic achievement.

Session Type: Posters

The humanities at Wits: The meaning of 'self' and 'identity'

Amanda Ballen University of Witwatersand, South Africa

This research was an investigation into the meaning eight postgraduate students made of their studies in the Humanities at the University of the Witwatersrand (Wits). The research defined Humanistic study as that which has as its end, moral development and self-reflexivity as constitutive of self growth, investigating how this occurred. It bridged theory and narrative in a psychological discussion about the consequences of the activities of interpretation and criticism. Given the current devaluing in South Africa of education for its own sake, the research revealed that the Humanities could also contribute to social awareness and provide human resource. This showed that in addition to developing the ‘self’, Humanities studies counted as ‘knowledge’ and ‘skills’ that could be considered as ‘cultural capital’ that constructed identity. Although it was expected that the Humanities student’s academic enculturation would have alienated him from students who had not been through the same process, the poignant finding in this research was that if it had, it was not that this was related to a sense of superiority. Rather, the challenge of the Humanities instilled the particular virtue of intellectual humility. This grounded the Humanities student in an embracing of all kinds of persons, even those who were not products of the Humanistic process.

Experiential learning via group relations conferences

Jennifer Campbell INASA0, Netherlands

In this paper we examine the definition, value and impact of experiential learning in general and specifically the method of group relations conferences. A group relations conference is a "real time" learning laboratory where participants can analyse their leadership styles and experiment creatively in expanding their repertoire of leadership skills. Together with conference staff, they critically examine different models of organisational functioning and appraise their leadership performance. A group relations conference is an accelerated learning experience. It is designed to enable participants to understand in greater depth the factors behind the exercise of effective leadership and to develop further their own leadership capacities and the leadership potential of others, by generating management goodwill and employee "buy-in", and understanding and working with their own and their organisation’s resistance to change. By means of interviews with participants we examine the impact and value of experiential learning via group relations conferences. Also we discover the contra indications for this learning method and criteria for both those who want to learn and those who want to create a group relations conference setting.

Action and object naming in Hindi-speaking patients with PSP and PD

Poopa Chaudhery Jawaharlal Nehru University, India

Progressive Supranuclear Palsy (PSP) is a rare brain disorder that causes action-object naming deficit. Parkinson’s disease (PD) is also associated with word-finding and grammatical difficulties. However, little is known about such language impairments in Hindi-speaking PD and PSP patients. The principle aim is to find if action-object naming is affected in Hindi-speaking PSP and PD patients. In addition to this, the study will focus on abstract nouns and verbs. 10 Hindi-speaking patients each with PSP and PD will be studied. The data will be elicited through picture identification, word recognition, manual action representation and frontal assessment battery. In PD the action and object naming is intact. However, in PSP while the object naming is intact, action naming is to a larger extent impaired. In PSP higher frequency words are more easily recalled in comparison to lower frequency words. The present study reveals that nouns and verbs are localised in separate areas of the brain. It will be interesting to study how abstract nouns and verbs are placed in the brain.

The effects of metacognition and epistemological beliefs on second language learning

Moises Kirk De Carvalho Filho Kyoto Univ. Foreign Studies, Brazil

Educators agree that beliefs related to knowledge and to the process of learning (i.e., epistemological beliefs) may affect students’ experiences, attitudes, expectations, and even the strategies they use to learn a second language. The main objective of this study was to assess what beliefs about second language learning Japanese students of Portuguese hold, how these beliefs are organised and how they relate to students’ metacognitive skills and their academic performances. Freshman students majoring in Portuguese language at Kyoto University of Foreign Studies in Japan answered a modified version of Carvalho and Kusumi’s (2006) epistemological beliefs questionnaire, which also included items especially developed to assess beliefs about second language learning. The results showed that the beliefs held by the Japanese students regarding second language learning are systematically organised and that they could be categorized into five different factors: (1) Beliefs about a traditional approach to the study of Portuguese; (2) Beliefs about a communicative approach to the study of Portuguese; (3) Beliefs about the quality and sufficiency of resources to the study of the second language; (4) Beliefs about the efforts needed to master the second language; and (5) Beliefs about individual behaviours that promote the learning of Portuguese. In addition, the results revealed that the beliefs about second language learning are related to students’ metacognitive skills and that they significantly predict students’ academic performance in Portuguese. The study concludes with an analysis of the educational implications of the results.

Personal epistemology of Thai university students and their past learning experiences

Takayoshi Fujiwara Mahidol University, Thailand

The purpose of the study was to explore the relationships between individuals’ personal epistemology and their past learning experiences. This study investigated the dimensional structure of the beliefs about knowledge and knowledge acquisition held by Thai university students. It further examined whether their epistemic beliefs were significantly different among the groups of the Thai students with different educational experiences. The participants of this study (N = 608) completed the 32-item Epistemic Belief Inventory (Shraw, Benzie, & Dunkle, 2002), by indicating how they agreed or disagreed with the statements about domain-general epistemic beliefs. The participants were undergraduate students studying in a Thai university, and they were all Thai native speakers and of Thai nationality. A five-factor structure was identified for the epistemic beliefs through a principal component analysis of the participants’ responses to the 32 items in the questionnaire. MANOVA identified a significant difference among the groups of students educated in different systems of secondary education in terms of three of the five identified factors. 

Learning
The results indicate an increased learning performance with a shaded line drawing and a realistic image, in contrast to a simple line image, although, no significant difference between a shaded line drawing and a realistic image was found. The results are discussed in terms of their relevance for image learning and education science.

Two effects, one explanation: A study on the effects of intended and actual enactment
Victor Kubik Department of Psychology, Sweden; Fredrik Jonsson; Lars-Garan Nilsson; Monika Knopf
Motor-function encoding action phrases, facilitates recollection more than verbal encoding (enactment effect, c.f. Nilsson, 2000). Further, if the phrases are intended to be recalled via motor-function encoding it also leads to higher memory accessibility, referred to as the intention-superiority effect (Goschke & Kuhl, 1993) or the intended enactment effect (Freeman & Ellis, 2003), depending on whether the same process or different processes are assumed to underlie both effects. In three experiments, both effects were studied as a function of list length (18, 30, 60, or 90 items), retrieval expectancy (free recall, recognition) and different retrieval measures (free recall, cued recall and recognition). Additionally, different moderator variables for these effects were investigated (familiarity, degree of motor involvement of the action phrases, individual differences in action orientation). Similar effects of intended and actual enactment were found for memory accuracy and accessibility (i.e., response latencies), but the effects were moderated by the nature of the action phrase and action orientation. State-oriented individuals and highly motoric action phrases showed a pronounced (intended) enactment effect. The results, at least partially, support a common explanation for both effects.

Exploring the association between visual perception abilities and musical notation reading
Hong-Yih Lee School of Psychology, Taiwan, R.O.C.
In reading music, the acquisition of pitch information depends mostly on the spatial position of notes as well as on spatial processing ability. This study explored the visual perception abilities of individuals with poor music reading ability. Two groups were differentiated based on different musical notation naming abilities and then assessed according to their visual perception abilities, including spatial processing and object recognition ability. It was found that that a high correlation seemed to exist between note-reading ability and visual-spatial processing ability. This study depends mostly on the spatial position of notes as well as on spatial processing ability. This study explored the visual perception abilities of individuals with poor music reading ability. Two groups were differentiated based on different musical notation naming abilities and then assessed according to their visual perception abilities, including spatial processing and object recognition ability. It was found that that a high correlation seemed to exist between note-reading ability and visual-spatial processing ability. The results indicate an increased learning performance with a shaded line drawing and a realistic image, in contrast to a simple line image, although, no significant difference between a shaded line drawing and a realistic image was found. The results are discussed in terms of their relevance for image learning and education science.

The effects of learning transfer with different methods
Zhang Qi Psychology Department of Liaonin, China; Xiaoxiao Zhang; Kejia Qv
The pupils and middle school students could learn the mathematical operations rules by the worked examples in past studies. But the learning effects were obviously restricted by key-steps, that mines "difficult learned steps" in the operation of worked examples. In order to reduce the degree of difficulty to learn the key-steps, we respectively used three methods that "decomposed key-step simply", the methods of designing the "process-oriented" and "product-oriented" worked examples to design the key-steps in extraction operation worked examples. We adopted a "gap-filling" method to discriminate the key-steps in the extraction operation on worked examples, and selected 90 7th grade students, randomly divided to three groups that respectively
learned different extraction operation worked examples. Finally, they were all examined using the transfer test. The results showed: (1) There were key-steps in the extraction operation worked examples for 7th grade students, (2) the transfer test achievements of the "decomposed key-step simply" and "process-oriented" groups were significantly higher than the "product-oriented" group. The far transfer test achievements of the "process-oriented" group were significantly higher than the "decomposed key-step simply" group.

Dyslexia in higher education
Duncan Yates Wits, South Africa; Cheryl Malek

This paper aims to discuss issues around dyslexia in the context of South African higher education. All too often dyslexia is undiagnosed, especially in students from historically disadvantaged backgrounds. As a result these students often underperform. Student difficulties are further complicated by the multilingual environment in South Africa as many students are undertaking academic studies in a language other than their home language. This brings an additional challenged to the diagnosis of dyslexia. Support services at many Universities aim to identify learner difficulties so as to provide the appropriate resources. In order not to waste limited resources, screening and appropriate referral is an important part of any student support unit. The use of a computerised screener can help to improve accessibility to support for students with dyslexia and generate more opportunities for assistance. The Lucid Adults Dyslexia Screener (LADS) for adults is a useful screening tool and provides a number of benefits in terms of time, resources and cost-efficiency. This screener is currently being used at the Disability Unit at Wits University. A comparison of the LADS screener results and Occupational Therapist assessment results is presented. The importance of the development of a dyslexia screener with South African norms is also discussed. For students that have been identified as having specific learning disabilities assistance in the form of study skills, time management, mind mapping software, speech recognition software and reading programs can be offered to support students. The benefits of these services are explained in further detail within this paper.

The different learning behaviours between high and low ADOG learners
Lili Zhang Nanjing University, China

Academic delay of gratification (ADOG) refers to "students' postponement of immediately available opportunities to satisfy impulses in favour of pursuing academic rewards or goals that are temporarily remote but ostensibly more valuable." ADOG is important because if a learner succumbs to temptation, he could not continue the long term learning process. A correlation was found between ADOG and motivation, cognitive strategy, metacognitive strategy, resource management, and grades of students. High ADOG students have higher motivation and use more self-regulated learning strategy when pursuing a long-term academic goal. The present study examined the behavioural differences between high and low ADOG students from four aspects, planning, time management, corresponding to distraction and actual learning behaviour by using daily reports, interview and questionnaire. As a result, high ADOG students distributed more time on study than playing from the beginning, but low ADOG students distributed more time on playing at first three weeks and became to use more time on study only at the last week right before the final examination. High ADOG students can correspond to distraction rationally and effectively, as well as use more self-regulated learning strategies than low ADOG students during the actual learning process.

Capable learners: Characteristics and needs of the upper 15 percent
Elsbeth Stern ETH Zurich, Switzerland

The distribution of most cognitive capabilities follows the bell curve. Thus, 70% are within one standard deviation of the mean, while 15% score higher than one standard deviation above mean. In principle, this group of people is especially well-prepared for taking advantage of learning environments provided by schools during childhood and adolescence. There is also growing evidence that the prosperity of modern information-intense societies depends considerably on the contributions made by the most cognitively able part of the workforce. Amazingly enough, however, research on human learning has only rarely focused on the upper 15% as a group of capable learners. Rather, the majority of research has concentrated on giftedness, which, by definition, only involves the top 1–2%. This line of research has demystified the concepts of giftedness and genius, because it has been shown that, although top scores on intelligence tests clearly increase the probability of aca...
For qualitative differences in cognitive processing between the top 2% classified as gifted and those scoring somewhat lower. At the same time, however, there is evidence for the existence of qualitative differences in learning and thinking between average scoring learners and capable learners. Scientists focusing on how to exploit high cognitive capabilities through education should therefore broaden the scope of cognitive capabilities in their research. In my talk I will present findings from behavioural learning research as well as from neuroscience which indicate characteristics of cognitive processing in the group of capable learners. Educational implications will be discussed.
Results indicated that the intervention program was successful for adults with TBI.

Dimensions of executive functions in school-age children: A developmental study regarding construct dimensions

Vanessa Aran Filippetti CIIPME - CONICET, Argentina

The present work aims to analyze the factor structure of executive functions in school-age children, in order to identify whether the nature of executive functions (EF) is unitary or diverse in the childhood population and to examine if, in the case of it being diverse, these processes follow a different evolutionary course. We worked with a sample of 125 children between 7 and 12 years old. To analyze the effect of age on each factor, the sample was divided into three groups of age (7-8 years, 9-10 years and 11-12 years). We applied a neuropsychological battery composed of different executive function tasks sensitive to prefrontal cortex functioning. Exploratory Factor Analysis (EFA) indicated a four factor solution which explains a high percentage of the variance. These factors were: (1) Cognitive flexibility which explained 21.3% of the variance, (2) working memory/verbal fluency (19.36%), (3) planning/autoregulation (15.05%) and (4) interference control (12.67%). Regarding the development of each EF component, MANOVA results revealed a significant effect of age on all four dimensions. However, univariate analysis indicated no significant effect of age on the number of complete categories of the Wisconsin Card Sorting Test (WCST) and on planning. These results raise key questions about the dimensional nature and the development of EF in school-age children and could therefore be particularly useful in the clinical assessment of executive dysfunction in developmental disorders.

The landscape of normal cognitive change with aging

Linas Bieliniauskas Ann Arbor VA/US of Michigan, United States of America

This address will focus on the neuropsychological changes associated with normal vs. abnormal aging and its practical implications, the relationship to affective changes, and the differences in the style of cognitive functioning in the elderly vs. in young adults. Recent findings concerning alterations in the organisation of cognition with age will be highlighted, as well as current knowledge regarding activities which may potentially affect cognitive health.

ADHD and EF deficits in relation to socio-emotional functions: Developmental perspectives

Gunilla Bohlin Department of Psychology, Sweden

Two longitudinal studies are presented with children followed from preschool to middle school age. Behavioural ratings of ADHD, ODD and internalising problems were obtained in the first data wave. Tasks tapping working memory and inhibition were also given and repeated later. Several data waves to obtain follow-up information were performed, with the last one at ages of 12 to 14 years. Using a developmental perspective, results will be presented for predictive relations: between EF and ADHD symptoms with attention and hyperactivity separated, EF in relation to socio-emotional functioning, and EF and ADHD symptoms in relation to school performance. Similarly a developmental perspective will be taken for EF and the interrelations of EF components in the development from preschool to school age will be presented. Finally, some efforts at studying EF development during the first years will be discussed.

Clinical evidence for the continuities within working memory

Cesare Cornoldi University of Padova, Italy; Rossana De Beni

Robust evidence has supported the assumption that working memory is not an unitary system. However, also models hypothesising the articulation of working memory in a limited number of subsystems meet a series of problems, especially in explaining the specific failures which can be found in working memory tasks. The presentation will show why models assuming the continuity between different aspects of working memory better explain the specific failures which can be found in developmental disabilities and in aging. In particular, data collected with groups of dyslexics, poor comprehenders, non-verbal learning disabled children, and elderly people will be presented. Results show that: (a) Verbal and visuospatial working memory must be distinguished, (b) the distinction decreases in correspondence with increases in the degree of required control, (c) further distinctions can be found within the visuospatial processes, but with a lower degree
of separation, (d) failures in controlled verbal processes do not necessarily imply failures in controlled visuospatial processes and vice versa, (e) the relationship between working memory and intelligence is related to increases in working memory control, (f) the relationship in the elderly is mediated by experience, culture and metacognition.

**Normative data of the Rey Auditory Verbal Learning Test for the Venezuelan population: Assessing the implications of demographic variables**

**Aline Ferreira Correia** 
**Witwatersrand University, South Africa; Ilva Campagna**

The Rey Auditory Verbal Learning Test (RAVLT) is a neuropsychological tool widely used to assess cognitive functions such as attention, memory and learning ability in the auditory-verbal domain. Norms have been developed in many different languages and cultural contexts. These demonstrate different relationships between the performance on the RAVLT and several demographic variables. The main objective of this research was to develop specific norms for the Venezuelan population studying the influences of age, education, gender and socio-economic status in the sample. A Spanish version of the test was administered to a stratified sample of 629 healthy adults. Participants included both genders, ranged between 20 to 79 years of age, between 0 to 13 years of schooling and represented all socio-economical levels. Pearson’s Correlation analyses showed a significant association between RAVLT performance and age (r=-.401, p<.05). According to the strength of the correlations, only age and education where considered in the final norms. The development of appropriate ranks to split these two significant demographic variables was achieved through the analysis of variance (ANOVA) with Bonferroni’s adjustment. Additional Pearson’s Correlation analysis and multiple regression and ANOVA were made to better understand the structure of the test and to assess the contribution of each item to the total score. This study reveals the influence that age and number of years of education have on the total score of the CDT and also have established the development of a specific ranking system for these variables for use in the Venezuelan population.

The **Wisconsin Card Sorting Test in the South African Setswana-speaking university population**

**Christi Gadd** University of Limpopo - Medunsa, South Africa; **Warwick Phipps**

In South Africa there is a dire shortage of neuropsychological tests standardised for use with its multi-cultural population. This study, therefore, aimed to conduct a preliminary standardisation of the Wisconsin Card Sorting Test (WCST) – an established neuropsychological test measuring executive functions - for Setswana-speaking university students. Specifically, a descriptive, cross-sectional, non-experimental research design, testing 93 participants on a computerised version of the WCST, with instructions translated into Setswana, was performed. Regression analysis showed which demographic variables should be considered in the standardisation. Neither gender, age, nor level of education influenced WCST performance for all sub-scores, except trials to complete first category, which was influenced by age. One normative table was thus constructed for the entire 18- to 29-year age group for all sub-scores except trials to complete first category, which required separate norm tables for the 18- to 19-year and 20- to 29-year groups. Finally, in investigating the psychometric properties, the WCST displayed adequate internal consistency in the study population. This study thus effectively developed a methodological framework on which a full standardisation of the WCST for the South African population can be undertaken and also yielded relevant preliminary normative data and psychometric properties. Finally, special issues pertaining to the standardisation of the WCST in South Africa were reviewed, including that of race and ethnicity in the standardisation sample; the construct equivalence of executive function - as measured by the WCST; and alternative measures of reliability for the WCST.

**The role of the amygdala in subjective experiences of anger and fear**

**Yvonne Gartner University of Cape Town, South Africa**

The role of the amygdala in the processing of subjective basic emotions is still debated in neuropsychological research. The question of whether amygdala lesions result in a decrease of intensity of all affective states, or whether this decrease is limited to anger and fear, remains unanswered due to inconsistent findings from empirical studies. Past studies have tended to focus on individuals with either a healthy or damaged amygdala. The current study, however, has taken a new approach by comparing the retrospective descriptions of subjective emotional experiences of individuals before and after amygdala damage, and between these individuals and participants with a healthy amygdala. Patients suffering from Urtiach-Wicthe Disease (UWD) lose their amygdala by puberty as a natural consequence of the disease. Eight UWD and eight matched control group participants, aged 23 to 69, were interviewed, using semi-structured interviews, and asked specific questions about past and current emotional experiences in their lives. Participants were matched on age, race, gender, socio-economic status, home language, level of education, and geographical location. As predicted, the subjective experience of anger and fear as dominant emotions in a population with damage to the amygdala was lower when compared to the controls. Furthermore, UWD participants, but not controls, experienced anger and fear with less intensity in adulthood when compared to childhood. The implications of amygdala damage on subjective emotional experiences are discussed.

**Differential response to early adversity: Evidence from gene-environment interaction on cognitive plasticity**

**Ximena Goldberg** Universitat de Barcelona, Spain

While childhood maltreatment has been identified as causing lasting disturbances on several aspects of adult development, it has been proposed that individual response to adverse experiences may vary widely (Seligman, 2000, 2011). In the present study, we used a twin-based design to explore the effect of childhood adversity on adult cognition, and its putative interaction with socioeconomic context and genetic variants of genes involved in prefrontal functioning (COMT). In an initial sample of 234 healthy adult subjects (117 twin pairs) we fitted a general regression model that allowed the effect of early individual experiences (Adverse Childhood Experiences Questionnaire; Felitti, 1998) to be tested among genetically identical subjects. We used memory performance (Wechsler, 1997) and cognitive adaptability (the Wisconsin Card Sorting Test, Heaton, 1993) as outcome variables. We found differential effects of individual early adversity on memory only in the high socio-economic status group (β=-1.81, p<.05). These findings suggest that individual competences are a result of the interaction between genetic and environmental influences, and further support a model of differential susceptibility to distressing experiences. Supported by a Marie Curie Early Stage Researcher grant to XG (MRTN-CT-2006-035987).

**Group differences in neuropsychological, psychosocial and emotional functioning in children with epilepsy and chronic renal problems**

**Saraswathi Govender University of Limpopo, South Africa**

The aim of the study was to predict group membership by comparing the epilepsy groups and children with chronic renal problems from a non-Western rural background on various psychological measures. The sample comprised 100 children with tonic-clonic seizures and 100 children with simple partial seizures between the ages of eight to twelve years. A third group of 100 children with chronic renal problems was used as a comparison to control for the effects of having a chronic condition. The findings of the study indicate that epilepsy presents...
This research aimed to explore and contextualise South Africa's particular reference to race, gender and the South African climate. Previous research added to our understanding of the cultural and social factors that influence lying behavior in South Africa. The study was conducted in a sample of students from various racial and gender groups in South Africa. The fMRI design, we used an aversive conditioning procedure. Over 40 unmedicated patients with BPD and dissociative symptoms and 20 healthy controls took part. In order to manipulate dissociation, 20 patients were exposed to a script describing a personalised dissociation-inducing situation (BPD-disso). Whereas the other 20 patients (BPD-neutral) and the healthy controls (HC) were exposed to a personalised script describing a neutral situation. We hypothesized that BPD-disso show diminished acquisition of differential averse delay conditioning compared with BPD-neutral and HC. Specifically, we expect increase in valence to the conditioned stimulus (CS+) and different skin conductance responses to the conditioned stimuli (CS+ versus CS-) in the acquisition phase for the BPD-neutral and HC subgroups. In contrast, we expect no increase in valence to CS+ and no differential response regarding skin conductance for the BPD-disso subgroup. Neurobiological hypotheses refer to specific activation of the limbic system, but are exploratory. Results with respect to valence ratings of the conditioned stimuli (CS+ versus CS-), skin conductance responses as well as neurobiological findings during acquisition will be presented.

Which sex is better when it comes to lying matter: An fMRI study of deception
Anna Grabowska Nencki Institute, SWPS, Poland; Wojciech Szczkowski; Marcel Falkiewicz; Artur Machewka; Katarzyna Jednorog; Iwona Sztatkowska
Deception is considered a social behaviour in which one person attempts to persuade another to accept as true what the deceiver believes to be untrue. From the neural perspective, lying is a complex cognitive process. We studied the effect of sex on deceptive behaviours and their neural correlates using functional magnetic resonance imaging methodology. Fifteen female and 14 male volunteers participated in the study. They were told either to lie or to tell the truth while answering questions from a questionnaire focusing on their personal information. Both men and women committed more errors and had longer RT when they were told to lie (inhibit truthful response) than to tell the truth. The “lie > truth” direct contrast comparison of the BOLD signal revealed activation in a number of structures, including areas of the inferior frontal cortex, insula, precuneus, thalamus, caudate nucleus, and cerebellum, supporting the complex cognitive structure of deception. Males showed much broader activations in the prefrontal regions. Direct contrasts of activations in male and female subjects revealed higher signal intensities in males compared to females in the area of the left middle frontal gyrus (MFG). Based on the idea that the amount of neural activity depends on the computational demand imposed by the task, greater intensity of the left MFG activation in men can be considered as indicative of a greater effort and may suggest that men require more "neural resources" than women in monitoring and inhibition of truthful responses and selecting the false response.

EEG Biofeedback training of executive functions in a case of attention deficit hyperactivity disorder
Morayo Jimoh University of South Africa, Nigeria
A number of different treatments have been proposed to treat attention deficit hyperactivity disorder (ADHD), yet little material has been published in the literature to improve the performance of the mechanisms behind attention, inhibitory control, cognitive flexibility and working memory in these children. Therefore, the objective of this study is to ascertain improvement in the aforementioned executive functions in an ADHD pupil following neurofeedback training. The population for this study comprises of all primary school pupils in Lagos state diagnosed with ADHD. The subject for the study was a previously diagnosed 10 year old ADHD boy. Assessment was done using the Thought Technology equipment and Test of Variables of Attention (T.O.V.A.). The subject participated in a twice weekly intensive neurofeedback training for 6 months. Feedback presentations were contingent on the production of Beta (16–20 Hz) and the inhibition of Theta activity (8–12Hz). Results from the study revealed that the subject based on operant conditioning was able to decrease theta activity successfully in the prefrontal (PF) and frontal (F) aspects of the brain and as such there was a noticeable improvement in T.O.V.A. performance and Attention Deficit Disorder Evaluation Scale (ADDES). It is therefore concluded the EEG Biofeedback may improve executive functions in ADHD. Findings further suggest that EEG Biofeedback may be explored as an alternative treatment to ADHD among children. There may be a need to replicate this study in future.

Influence of acute dissociation on learning processes in borderline patients
Friederike Hinrichs; Zl Manneheim, Germany; Christian Schmah; Elisabeth Pfeiffer
Stress-induced dissociative states are a common feature of borderline personality disorder (BPD). By definition, dissociation is characterised by a disintegration of perception, consciousness, identity and memory. Neurobiological findings and clinical data suggest that dissociative experience inhibits conditioning processes, but experimental studies are lacking. The aim of the study was to determine whether high states of dissociative experience would specifically alter emotional learning. In an MRi design, we used an aversive conditioning procedure. Over 40 unmedicated patients with BPD and dissociative symptoms and 20 healthy controls took part. In order to manipulate dissociation, 20 patients were exposed to a script describing a personalised dissociation-inducing situation (BPD-disso). Whereas the other 20 patients (BPD-neutral) and the healthy controls (HC) were exposed to a personalised script describing a neutral situation. We hypothesized that BPD-disso show diminished acquisition of differential averse delay conditioning compared with BPD-neutral and HC. Specifically, we expect increase in valence to the conditioned stimulus (CS+) and different skin conductance responses to the conditioned stimuli (CS+ versus CS-) in the acquisition phase for the BPD-neutral and HC subgroups. Neurobiological hypotheses refer to specific activation of the limbic system, but are exploratory. Results with respect to valence ratings of the conditioned stimuli (CS+ versus CS-), skin conductance responses as well as neurobiological findings during acquisition will be presented.
Association of CCR5 polymorphisms with HIV-1 related neuropsychological impairment in Asian Indians
Moathu Khullar; Chandigarh, India; Sunil Sharma; Sudesh Prabhakar; Ritu Nehra; Mahender Kumar; Rajni Sharma; Amit Kumar
Chemokine receptors are thought to be involved in HIV infection, and disease progression. The chemokine receptor gene, CCR5 molecule, serves as a major cell surface co-receptor for the entry of HIV into the host cell. We examined whether CCR5 promoter polymorphisms may affect the development of neuropsychological impairment in Asian Indian HIV-1 patients. We recruited 50 HIV-1 seropositive individuals out of which 18 were typical progressors (TPs) and 32 were non progressors (NPs) of over 2 years duration. CCR5 A9092G and CCR5 59653T polymorphisms were genotyped using direct sequencing. Neurocognitive status was assessed using comprehensive neuropsychological (NP) testing. CCR5 A9092G and C59653T genotypes did not show any significant association with progression of HIV infection. On studying association of HIV infection progression with neuropsychological impairment, no significant difference was observed in different neuropsychological domains such as learning, memory, executive function and information processing speed among TPs and NPs. Furthermore, none of these neuropsychological domains were found to be associated with CCR5 9029 and CCR5 59653 polymorphisms in our cohort. Our preliminary results do not suggest an association of CCR5 polymorphisms with HIV infection related neuropsychological impairment in our population; however, further studies in larger cohorts are required to confirm this observation.

Comparison of cognitive abilities between epileptic and normal children in Wechsler Intelligence Scale for Children
Mazdheh Leoipour Isfahan University, Islamic Republic of Iran; Ahmad Abedi; Leila Esmaeili Isfahan University, Islamic Republic of Iran; Mohammad Reza Abedi
The aim of the present study was to compare the cognitive abilities profile between epileptic and normal children in the Wechsler Intelligence Scale for Children, fourth edition (WISC-IV). The statistical population of the study included normal and epileptic children between 6-16 years old. The samples were 30 normal and 30 epileptic children who were selected by available sampling method. The method of study was causal-comparative. Wechsler Intelligence Scale fourth edition was performed on children. The collected data was analyzed by statistical method of MANOVA (multi-variable variance). Results showed that there was a significant difference between normal and epileptic children in verbal comprehension IQ, perceptual reasoning IQ, working memory IQ, processing speed IQ, full scale IQ and subscale of Wechsler Intelligence Scale fourth edition (P<0.05).

Neuropsychological peculiarities of 7-10 year old children with different school performance
Sundagush Kudaibergenova Kazakh National University, Kazakhstan; Anara Kassymzhanaova
The aim of this study is comparative analysis of neuropsychological profiles in 6-10 year-old children with high and low school performance on basic subjects. 90 children were examined in total, forming two groups equalised by gender and ethnic-nicity: 46 pupils with low school performance refer to experimental group, while other 46 children with high performance to control group. A modified version of A.R.Luria’s neuropsychological tests, methods of nonparametric statistics and statistical analysis SPSS 11.5 were used for analysis. Groups were compared using the following parameters: forebrain, hindbrain, right-hemisphere, left-hemisphere of brain indices and the following indicators: programming and monitoring of activity, serial organisation of movements, kinaesthetic functions, auditory function, visual gnosis, visual-spatial functions. The key results were: (1) Children with low school performance show lower measures of neuropsychological indices while other peers show higher performance. This gives evidence of qualitative specificity of neuropsychological institutions and maturation speed of morphofunctional basis of psychical processes in children with different school performances; (2) Right-hemisphere brain indices in girls, regardless of their school performance, are higher than in boys; (3) Major differences between students with high and low performance rate refer to the development of hindbrain and right-hemisphere parts of the brain in 7-8 year old children. In the 3-form (9 years old) excalation of left-hemisphere parts of the brain takes the priority in remedial students, while neuropsychological profiles of students with poor and advanced performances almost line up.

Congenital hypothyroidism (CH) globally affects 1 in 4500 children (Rovet & Hepworth, 2001). Left untreated, the disorder leads to metabolic disorders, culminating in serious mental retardation and physical disability. The current study explored whether the deficits reported in the literature were consistently present in a CH sample group in South Africa and if a pattern would emerge specific to learning. A battery of tests which included the Similarities subtest, the Number Problems subtest, the Missing Parts subtest and the Block Design subtest from the Senior South African Intelligence Scale-Revised (SSAIS-R) was used to obtain overall intellectual performance, while the Story Memory subtest, the Memory for Digits subtest, the Symbol-Digit Coding subtest (all from the SSAIS-R), the Rey Osterreith Complex Figure task, the Rey Auditory Verbal Learning task and the Stroop Colour Word test was used to gauge cognitive performance. The data was collected from five English speaking CH children between nine and 16 years of age and followed a mixed methods analytical approach. The results indicated that mild cognitive deficits were associated with intraterrine deficiencies of the hormone; diagnosis within the critical window period and l-thyroxine control. In terms of learning, declarative learning was found to be adversely affected. Deficits were also observed for visuospatial and auditory verbal memory with poor organization and plan-
Using a prosthetic limb to elicit body ownership
Saleha Mahomed University of the Witwatersrand, South Africa; Marilyn Lucas

Vision, touch and proprioception are part of daily life, a fundamental aspect forming multisensory perception that creates a sense of body-part ownership which is often taken for granted by the healthy individual. However, this phenomenon of ownership can be disrupted even in healthy individuals. Previous research has shown that this feeling of possession can be produced at the sight of brushing an artificial limb at the same time as brushing the persons own hand when the artificial limb is aligned with the subject’s own shoulder. This research has questioned whether vision and proprioception together with the pre-requisite sensory modality of touch, are necessary to generate a feeling of body ownership. A mannequin arm was used on a sample of 30 participants to create a feeling of body ownership allowing one of two sensory modalities to dominate over the other. Two open ended questionnaires were used during the different conditions. Using a mixed models analysis, results indicated significant findings in the vision and proprioception conditions independently. However, non significant findings for the interaction effect between vision and proprioception were found. The results of this study are discussed in order to broaden theory and practice in the area of body part ownership.

The mnestic block syndrome revisited: Repression or motivated forgetting?
Hans Markowitsch University of Bielefeld, Germany; Angelica Staniloiu

Memory is a dynamic process that comprises remembering and forgetting. Remembering the past is a core feature of humans that enables them to preserve a robust sense of personal identity and helps them to prepare for future demands. Forgetting operates in a dynamic neural connection with remembering, by allowing the elimination of irrelevant information and reducing interferences. Stress and traumatic experiences could affect this connection by inducing brain structural and/or functional changes. This might subsequently lead to various memory disturbances. The stress-induced (psychogenic) amnesic conditions primarily affect the patient’s own biography by either blocking the retrieval of old memories – leading to retrograde amnesia, or by impairing the acquisition of new memories for long term storage, leading to anterograde amnesia. We have studied several dozen patients with either form of stress-related amnesia both neuropsychologically and with structural and functional neuroimaging methods, with the primary aim to unravel the neural correlates of environmentally-induced (stress-related) amnesic conditions. Several mechanisms may contribute to the psychogenic memory "loss", such as retrieval impairments, consolidating defects, motivated forgetting and/or deficits in binding and reassembling details of the past. Our own research data from using comprehensive neuropsychological testing and combined functional and structural neuroimaging emphasise as a primary mechanism a so called mnemonic block that is posited to result from a stress hormone-mediated desynchronisation during retrieval between processing of affect– laden events (that is assumed to preferentially engage the right hemisphere) and fact-processing (engaging the left hemisphere).

A neuropsychological functional profile of the professional boxer
Daniel Martínez Carlos Albizu University, Puerto Rico; Amarilis Ramos

Boxing is an international sport with a long and complicated history. Unfortunately, boxing has placed more emphasis on the physical aspect of the boxer while neglecting the neuropsychological and mental health effects of the sport. The neuropsychology of a boxer includes the following comprehensive features. The capability to focus on appropriate stimuli during the competition, the relative psychomotor skills relating to the techniques necessary in the boxing ring, the level of motivation during the competition and his/her quality of life, in general. The boxer must perceive and process information, think and analyse productively, react timeously to the changes in the ring, and control his/her movements. The current research studied male professional and amateur boxers, including 8 world champions. Results of the research in the following areas will be presented and discussed: Short and long term memory, IQ, cognitive flexibility, comprehension, emotional status, and processing skills. The following neuropsychological battery was administered: WAIS-3, Wechsler Memory Scale 4, Tracing Test A and B, Rey Auditory Verbal Learning Test, Animal Naming Test, Center of Epidemiological Scale of Depression. In addition, relevant and pertinent recommendations will be shared with the audience regarding preventative and relevant health issues with specific attention to the analysis and protection of the boxer’s neuropsychological skills.

Neuropsychological deficits in Tshividza speaking children with attention-deficit hyperactivity disorder
Mudzunga Mathivha University of Limpopo, South Africa

The aim of the study was to establish whether children with Attention Deficit/Hyperactivity show deficits in cognitive impulsiveness and motor functions, caused by a hypofunctioning dopamine system. A group of 84 primary school children, classified as ADHD and 42 controls, matched for age, gender and socio-economic status, with children without ADHD symptomatology, were compared on their performance on neuropsychological assessment tools which tests the functions of the cortical areas supplied by two dopamine branches. The battery consisted of the Wisconsin Card Sorting Test, the Grooved Pegboard, and the Maze Coördination Task. The results of the tests were analysed as a function of Gender and ADHD subtypes. In the majority of tests the clinical groups performed worse than the control groups. This was the case for both genders. The Hyperactive/Impulsive and Combined subtypes consistently performed poorer than the other groups. The results indicate that children with ADHD are more impulsive (deficient executive functions) and have poorer motor control than their control counterparts which may be an indication of dopamine dysfunction. Early intervention can help to prevent the devastating effects of underachievement, poor self-image, and in the long term, possible delinquent behaviour.

New tests for the evaluation of topographic disorientation following brain lesions
Roland Maurer Université de Genève, Switzerland; Brit Erni; Virginie Descloux

People suffering from posterior right hemispheric lesions very often show impairments in wayfinding (they feel ‘lost’, and are unable to identify their whereabouts or to find the way to specific places). The symptoms vary quantitatively but also qualitatively from patient to patient and across time, making the impairment difficult to assess. In everyday life, orientation is a critical ability, and rehabilitation and follow-up of patients require appropriate evaluative tools; so far, few of them exist, if any. We have developed three original tests which will be described here, along with results from clinical patients and from a control population. As we wanted the tests to be applicable in standard clinical practice, they are essentially tabletop tests. Studies in normal participants have shown that perspective taking (the possibility to mentally anticipate how the world appears from another location, which is heavily involved in wayfinding) is processed differently for rotations and translations. Based on Piaget’s “three-mountain” experiment on children, we developed one test to assess mental self-rotation; and another, a variant of the former, to assess mental translation. Orienting and finding one’s way additionally requires computations on the mental, or “cognitive”, map of the environment. The third test assesses to what extent the patient can still query his/her cognitive map, that is, whether the patient can compute the spatial relations between known landmarks in his/her everyday environment, which he learned prior to being hospitalised.

Cumulative mild head injury in schoolboy rugby players
Kathryn Nel University of Limpopo, South Africa; Christopher Nel

Sport participation as a form of exercise is considered essential for adolescent boys and encouraging involvement in sport or physical activity is important both physically and socially. However, participation in sport brings the risk of sports related injuries particularly in contact sports such as rugby. In South Africa, rugby is a traditional team sport played by many of the schools in the country. Traditionally the game is seen as one that promotes teamwork and teaches discipline and it is associated with peer group bonding, or a rite of passage, amongst adolescents. The knowledge that cognitive damage can occur in contact sports is problematic as adolescent boys have to achieve in both academic and sporting arenas. A quasi-experimental survey design was utilised for the study. A final sample of 26 schoolboy rugby players and 14 non-contact sport controls (schoolboy hockey players) was utilised. The age of the sample ranged from fifteen to eighteen years, SD = 2.6. A computerised assess-
Apathy and executive functioning following damage involving the anterior cingulate cortex
Progress Njombara University of Cape Town, South Africa

Neurological models of apathy implicates anterior cingulate cortex (ACC) dysfunction in the disorder’s symptom profile (e.g., Cohen et al., 1999; Thobois et al., 2010). Apathetic patients with lesions to this brain area offer an opportunity not only for understanding the psychiatric features of the disorder, which are still a subject of debate, but also for investigating its associated neurocognitive phenotype. Understanding the disorder’s neurocognitive correlates is paramount in informing patient-centred rehabilitative interventions. In this study, two male patients (SP and GA) with bilateral lesions involving the ACC were assessed for levels of apathy and depression, and executive functioning. 20 neurologically intact controls also provided normative scores on the Iowa Gambling Task. Results indicated that SP and GA had high levels of apathy and low scores for depressive symptoms. SP showed relatively intact executive functioning on the standard executive function tests, but GA had significant impairments. Both patients were significantly impaired on the Iowa Gambling Task. SP’s intact executive function performance suggests that deficits in this cognitive domain are not crucial for the presence of apathy symptoms. We discuss these findings and how they shed light on the relationship among apathy symptoms and executive function deficits, as well as their implications for rehabilitation and patient care.

The nature of music
Isabelle Peretz University of Montreal, Canada

The last decade of research has provided compelling evidence that the ability to engage with music is a fundamental human trait. Yet the biological basis of music remains largely unknown. Recent findings indicate that a small number of individuals have severe musical problems and that these deficiencies have neuro-genetic underpinnings. Such a musical disorder is termed congenital amusia, an umbrella term for lifelong musical disabilities that cannot be attributed to mental retardation, deafness, lack of exposure, or brain damage after birth. Congenital amusia provides a natural experiment; a rare misfortune which results in cumulative mild head injury (TBI) and behaviour.

Misconceptions about traumatic brain injuries among university students
Chrisma Pretorius Stellenbosch University, South Africa; Mandi Broodryk

The purpose of this study was to investigate the incidence and type of misconceptions about traumatic brain injuries (TBI’s) amongst university students. Misconceptions of individuals with prior experience with TBI’s were also compared to individuals with no prior experience. A convenience sample of 705 university students was recruited. Data were collected by using an electronic survey. The link to the survey was sent via email to all the registered students at Stellenbosch University. The participants had to complete the Common Misconceptions about Traumatic Brain Injury Questionnaire (CM-TBI; Pappadis et al., 2010). The findings of this study suggest misconceptions in each of the 7 categories of misconceptions about TBI’s. Categories related to amnesia and unconsciousness showed the most misconceptions while the brain damage category showed the least misconceptions. The findings also seem to suggest a significant difference between the misconceptions about TBI’s between individuals with prior experience with TBI’s and individuals without prior experience. Generally, these findings appear to be in keeping with previous literature, which suggest that misconceptions about TBI’s are common amongst the general population. The findings also seem to suggest that misconceptions about TBI’s are more common in individuals with personal experience with a TBI.

Associated factors to secondary alterations of the attentional control system in aphasic patients
Aymara Reyes Oriente University, Cuba; Erislandy Omar Martinez; Aymara Reyes Saboře

Aphasia is the most common primary neuropsychological disorder. It is a neuro-cognitive syndrome, frequently associated with secondary alterations of the Attentional Control System (ACS). Such attention disorders, when processing language in aphasia patients intensify the deficit which maybe associated with multiple factors related to the injury or the patient. The aim of the study is to describe the secondary neuropsychological alterations of ACS in aphasic patients, and to determine the factors of injury (etiology, location, time of recovery of the damage, age, grade level), and how these are associated to such secondary alterations of the ACS. The study was carried out in 68 aphasic patients of both sexes, aged between 15 and 60 years. The tests used where: the Trail Making Test, Porteus Labyrinth Test and the Series of Loops. Statistical processing was carried out by frequency distribution and a Multiple Ordinal Regression. Statistical analysis showed that the secondary neuropsychological alterations of ACS in aphasic patients are associated with the location and the time of recovery of the damage, and are independent of age, education and the etiology of the injury.

Frontal EEG asymmetry and z score changes in brain waves following cognitive behavioural therapy
Krishnan Saradadevi Meston College of Education, India

Although previous studies have shown that anxious individuals exhibit greater relative right frontal electroencephalogram (EEG) activity at rest, no studies have investigated whether improvements in symptoms as a result of treatment are associated with concomitant changes in resting brain activity. Regional EEG activity was measured at rest in 16 higher secondary students with higher levels of test anxiety, before and after cognitive behavioural therapy (CBT). Results indicated that patients shifted significantly from greater relative right to greater relative left, resting frontal brain activity from pre- to post treatment. Greater left frontal EEG activity at pre-treatment predicted greater reduction in test anxiety from pre- to post treatment and lower post treatment test anxiety after accounting for pre-treatment symptoms. There are significant changes in the Z scores of alpha, beta, theta and delta waves. These relations were specific to the frontal alpha EEG asymmetry metric. These preliminary findings suggest that resting frontal EEG asymmetry may be a predictor of symptom change and end state functioning in test anxious students who undergo efficacious cognitive behaviour therapy.

Changes in EEG during cognitive behavioural therapy for test anxious students
Krishnan Saradadevi Meston College of Education, India

Coupling between EEG delta and beta oscillations is enhanced among anxious individuals during test situations. EEG coupling patterns associated with CBT have not yet been quantified in test anxious individuals. In this study, we used repeated measures design, in which 16 students from an adolescent group with a principal diagnosis of test anxiety completed 3 week, daily sessions of cognitive behavioural therapy and two EEG assessments: One at pre-treatment, and one at post-treatment. Treatment was associated with reductions in symptom severity across multiple measures and informants, as well as reductions in delta-beta coupling at rest. Moreover, the clinical group exhibited greater coupling at pretreatment than did post hoc control participants with low test anxiety. The EEG cross-frequency profiles in the clinical group normalised by the post treatment assessment. These findings provide evidence of concomitant improvement in neural and behavioural functioning among test anxious students undergoing cognitive behaviour therapy.

EEG correlates of affective coherence in sentences describing social interactions
Gesche Schauenburg Freie Universität Berlin, Germany

Affect Control Theory (ACT; Heise, 1979; 2007) proposes, based on a large body of empirical findings, that emotions are systematically associated with specific social actions. It further emphasises that the knowledge of the relation between social actions and emotions is acquired in socialisation through learning language. According to ACT, people use the affective meaning of words as a source of information to infer whether a given social event corresponds to cultural norms. Thus normativity of social interactions is being judged by the degree of perceived affective coherence which is implied by emotional connotations of the words used to describe social events. Affective coherence can be modeled mathematically using impression-formation equations, obtained in empirical studies by regressing the ratings of the evaluation, activity and potency (cf. Osgood, Suci, & Tannenbaum, 1957) of words in the context of a sample of given events on out-of-context semantic differential ratings of the same words. Validity of those equations has been shown in behavioural and simulation studies.
Addressing the question of influence of affective meaning on social information processing, we will present the first data from an EEG-experiment investigating neurophysiological correlates of affective meanings in visually presented sentences describing social actions using a classic N400-paradigm. The degree of affective coherence was systematically manipulated using above mentioned regression equations for generating our stimuli. Across conditions, we control for variables potentially influencing sentence processing, e.g., ocurrences of subject-object and verb-object relationships and close probabilities.

**Hypnotherapy and hypnosis can be defined in psychological, physiological and neurological terms**

Jacobus Schalk Scholtmeyer South Africa

The territory of the hypnotherapist, namely the pre- and unconscious mind can be described in psychological terms by the processes of repression and dissociation. The secretion of endorphins is the origin of the unconscious mind on a physiological level, where they act as the bedrock of evolution and the backbone of civilization. If trauma is excessively intense, the result is losing touch with the internal reality, because if a person is subjected to emotional- or physical trauma from pre-birth, the information messengers or peptides spread the information regarding this trauma throughout the body which is stored psycho-neuro-endocrinologically. It is commonly accepted that the vehicle used to explore the unconscious mind is hypnotherapy and that all hypnotherapeutic work should be done in a light to medium trance (hypnosis) and that deep trance should be reserved mainly to recover deeply repressed material. In terms of neurofeedback, light trance can be described neurologically as the dominance of sensorimotor rhythm (SMR) across the sensor-motor strip. Medium trance may be referred to as the dominance of high alpha with its origin in the thalamus, and deep trance as the dominance of theta rhythm, with its origin in the septal area of the limbic system and in the thalamus. Hypnotherapy can be effectively utilized as a powerful vehicle to explore trauma in the unconscious mind and to reframe (change) it where the associated symptoms are cured as a result.

**The implementation and evaluation of an attention-training programme following pediatric traumatic brain injury**

Leigh Schrief University of Cape Town, South Africa; Genevieve During; Ju-Reyn Ockhuizen; Kevin Thomas

Traumatic brain injury (TBI) is a global public health problem. It has been recognised as a leading cause of mortality and morbidity in children and adolescents. In South Africa, however, neuropsychological rehabilitation interventions following pediatric TBI has been lacking. This paper describes our early efforts at implementing an attention-training intervention for children following moderate to severe TBI. This study is a case-controlled trial. It involved the evaluation of a ten-week neuropsychological intervention (Pay Attention!) for children following TBI. The study included an intervention group and three matched control groups. The program was also further evaluated through case studies (N = 2). Results showed some positive outcomes of the intervention, which varied among the participants. However, they did not generalise across all functional domains. Our findings provide a snapshot of the process of implementing neuropsychological interventions in a developing-world context where this is needed but is not standard practice and sheds light on the challenges in this process as well as the gaps in such service delivery. Continued research of this nature is needed on a larger scale in order to further identify those factors that promote and / or hinder the implementation of rehabilitation interventions for pediatric TBI in our developing-world context. This will inform and facilitate future interventions of this nature.

**The spike-time-dependent plasticity model of retrieval induced forgetting**

Sverker Skälenkran Sweden; Gerd Walhausen; Mikael Johansson

Retrieval-induced forgetting (RIF) is the empirical phenomenon that the retrieval of a desired memory representation can impair the recall of related, but currently irrelevant memories. We present a theory suggesting that Spike-Time-Dependent Plasticity (STDP) plays an essential role for this phenomenon. According to this STDP-RIF theory, the neural representations of items receive a stronger and faster input, which according to STDP leads to Long-Term Potentiation (LTP). Non-retrieved, related items receive a relatively weaker and slower input to the neural representation, leading to Long-Term Depression (LTD). Finally, unrelated items do not provide sufficient input for spike synchronisation leading to no changes in plasticity. The theory thus accounts for why selective retrieval induces forgetting of related memories, while mere item repetition does not, as well as other empirical phenomena characterizing RIF. In addition, it provides a framework of how neural spike synchronisation relates to memory.

**Clinical utility of the Colour Trails Test in Polish validation studies**

Joanna Stanczak Psychological Test Laboratory, Poland; Emilia Lojek

Despite the growing usage of the Colour Trails Test (CTT) the data on its diagnostic value compared with the Trail Making Test are still scanty. The aim of our research project was to investigate the qualities of the CTT as a measure of attention and executive function disorders in various clinical populations in Poland. Basic psychometric characteristics of the CTT (i.e. temporal stability and the influence of demographic variables on CTT performance) indicated by D’Elia et al. (1996) were confirmed on 400 healthy Polish adults. Clinical investigations were further performed on 259 subjects including patients with brain damages (N=99), subjects with mild cognitive disorders (N=28), dementia (N=11), depression (N=29), schizophrenia (N=30), and alcohol abuse (N=31), and elderly subjects (N=31). The results showed significant differences on the CTT measures between all clinical groups and healthy controls, patients with frontal versus posterior cortical lesions, and patients with left versus right hemisphere injuries. Significant correlations between CTT scores and the results on other executive measures such as the Verbal Fluency Test and the Verbal Concept Attainment Test were also observed. Additionally, our research indicated clear cutoff scores distinguishing normal and pathological CTT performance. Such cutoff scores for the CTT have not yet been presented by other researchers. The results showed that the CTT is a highly valuable neuropsychological measure of attention and executive disorders. The cutoff scores for CTT performance obtained in the present study require further confirmation.

**Dual-tasking: Neural correlates of decision-making with simultaneous executive load**

Bettina Staschikiewicz University of Duisburg-Essen, Germany; Frank Schulte; Mirko Pawlikowski; Katrin Starcke; Lena Schaefer; Matthias Brand; Tobias Schoeler; Stefan Moderwald

In everyday life, persons often have to perform different tasks simultaneously. In a recent study, Starcke et al. (2011) demonstrated that the ability to make advantageous decisions in risky situations (using the computerised Game of Dice Task, GDT) diminishes when a secondary executive task (a 2-back working memory task) has to be performed simultaneously. The current fMRI-study investigates the underlying neural correlates of performing this dual-task paradigm (GDT+2-back). 18 healthy participants performed the standard GDT and the GDT+2-back task in a high field 7-Tesla MR scanner. Indeed, on the neural level differences were found between performing the GDT compared to performing the dual-task paradigm: performing the GDT+2-back evoked more activation in the frontal lobe, the parietal lobe and in premotor areas in comparison to the brain activity when performing the GDT only. The results indicate that making advantageous decisions under risky conditions during a situation with secondary executive load needs more neural activation in brain areas linked to executive functioning as in an identical situation without additional load. In more detail, the brain areas involved are associated with the performance of mathematical operations (e.g. number processing and comparison) as well as with attentional and executive processes, which are all important ingredients in decision making under risk.

**Neuropsychological assessment in patients with intractable temporal lobe epilepsy**

Mahgol Tavakkoli University of Isfahan, Islamic Republic of Iran; Hamid Taher Neshatdoost; Majid Barekatain

Cognitive impairment associated with Temporal Lobe Epilepsy (TLE) have been recognized in multiple studies. We designed this study to find a specific cognitive profile in patients with TLE who were candidates for epilepsy surgery. We also sought to establish whether neuropsychological assessment could differentiate left TLE, right TLE, and normal subjects. The sample of this study consisted of 29 patients with right TLE, 31 with left TLE, and 32 subjects without history of seizure as controls. For all recruited patients and controls, a demographic questionnaire, the Wechsler Memory Scale-III (WMS-III), Color Trail Making Test (CTT) and Wechsler Adult Intelligence Scale-R (WAIS-R) were administered. Multivariate analysis of variance was carried out to reveal differences in
Effect of cortical activity neuromodulation on language recovery: A case study
Jasmina Vukasovic; The State University of Novi Pazar, Serbia and Montenegro; Natalija Radivojevic; Sladjan Milanovic; Lubica Konstantinovic; Irena Avramovic Illic; Ivana Avramovic; Aleksandra Dragin; Sasa Filipovic; Milan Jelic; Aleksandar Jeremic

Aphasia is a common consequence of a stroke. Results show that two kinds of changes in neural activity may be of the most importance for aphasia recovery. First, a number of studies have shown that transcription of lesions left hemispheres is associated with language recovery. Second, the activation of the right hemisphere was observed in aphasia patients while performing language tasks. Although the effect of that type of activation remains unclear, a growing number of recent reports suggest that right hemisphere activation does not lead to better language performance in stroke patients. For the purpose of clarifying the mechanisms of language recovery, transcranial magnetic stimulation (TMS) has been increasingly used in recent years. TMS is a safe, noninvasive method that can be used to enhance neuroplastic changes in brain activity. In this paper we present a right-handed patient with chronic post-stroke nonfluent aphasia, who was investigated as a part of a project of TMS cortical neuromodulation effects on cognitive functions recovery. The sessions consisted of the application of a continuous theta burst (cTBS) protocol over right hemisphere followed by intermittent TBS (iTBS) protocol over left hemisphere. For iTBS, which should have facilitatory after-effect, the TMS coil was positioned over Broca’s area, while for cTBS, supposed to have an inhibitory after-effect, the coil was positioned over Broca’s area analogue on the right. Results show improvement in spontaneous speech, repetition performance and auditory comprehension. The most prominent improvement was observed in spontaneous speech.

Organisational strategies and memory performance in children treated with radiation therapy for acute lymphoblastic leukaemia
Sarah-Jane Whittaker; University of the Witwatersrand, South Africa

In the treatment of acute lymphoblastic leukaemia (ALL), cranial radiation therapy causes damage to the deep white matter structures in the brain and associated cortical atrophy (Chu et al., 2003). Given the greater proportion of white matter in the right hemisphere than in the left, cognitive deficits relating to right hemisphere abnormalities were expected. This study assessed the nature and scope of memory impairment associated with radiation injury in 8 South African ALL children. Verbal memory was assessed using the Rey Auditory Verbal Learning Test and the Digit Span subtest of the Senior South African Individual Scale – Revised (SSAIS-R). Visuospatial memory was assessed using the Rey-Osterrieth Complex Figure Test and the Coding subtest of the SSAIS-R. Z-scores were used to answer questions of comparison between the ALL sample and a healthy asymptomatic sample matched on the demographic variables in the study. Results showed important differences in working memory performance and cognitive organisational strategies related to right hemispheric differences. These are discussed in relation to the subsequent learning and academic development of ALL children.

A new cognitive therapeutic programme of aphasic impairments in plurilingual cases
Nacira Zellal; Labo Cognit Neurosc Alg Univ, Algeria; Bouazzouzi Ali; Benmoussa Lamia; Lamara Mohammed Smal; Zellal Nacira; Tribache Rabia; Izemane Abdellatif; Haciame Mohamed

The main challenge in the neuropsychological field, since 1915, has been the creation of theoretical models. In this proposal, we synthesise our 30 year experience in neuropsychological clinical-theoretical approach. We began our research in neuropsychology in 1977 (Paris VI, Faculty of Medicine). We have worked in description, then classification (N. Z., Glossa, 23,1991), then interpretation (N. Z., IALP, Septembre 1998), then rehabilitation (N. Z., I.A.L.P., Cairo, 1995) of aphasic syndromes. We have used a programme - the first of an Algerian neuropsychological battery plurilingual tasks: the “MTA” 2002, the elaboration and technical realisation were financed in the frame of a French-Algerian agreement project (CMEP - Algiers and Toulouse Le Mirail Universities - 91MDU 177). Starting from our neuropsychological typology and cognitive interpretation of aphasic impairments, we will present a cognitive theoretical model of aphasia based upon temporospatial structuration concepts. A therapeutic programme deduced from this model gives positive results, promising new perspectives in neuropsychoses (N. Z., ANAE, 111, 2011). We have directed a research team with Sciences of Language and Cognitive Neurosciences of Algiers 2 University Laboratory experience during these two last years. The team proposed two case studies based on the results: a motor and a sensory case followed by group work, using the said model. Patients are trilingual: arabo-phone, berbero-phone and francophone, which means that our therapeutic programme can be applied whatever the aphasic language.

Neurological soft signs in Chinese adolescents
Xiongzhao Zhu; Medical Psychological Institute, China

The aim of this study is to investigate the prevalence and features of Neurological Soft Signs (NSS) in Chinese adolescents. A total of 3689 mainstream school students were recruited in the present study. The soft sign subscales of the Cambridge Neurological Inventory were administered to all participants. Among them, 499 subjects also finished the Arrow task and the Color-word Stroop Test. The prevalences of various neurological soft signs in adolescents ranged from 0.4% to 24.9%. The most common neurological soft signs in adolescents were finger agnosia of left hand (24.9%), finger agnosia of right hand (23.7%), rhythm tapping (22.6%), left-right orientation (16.8%) and graphesthesias of left hand (13.1%). Boys obtained higher scores on the motor coordination subscale, sensory integration subscale, disinhibition subscale and total neurological soft signs than those of girls. Scores in the motor coordination subscale, sensory integration subscale, disinhibition subscale and tota neurological soft signs showed significant age differences. The logistic regression analyses found that sex and
age were both predictors of NSS. The total score of NSS had significant correlations with reaction times and accuracies in the Arrow task and the Color-Word Stroop Test. Chinese adolescents show some degrees of neurological soft signs, and boys have significantly more neurological soft signs than girls. Neurological soft signs are decreased with age.

Validity of a South African adaptation of the Boston naming test
Lauren Boerecke University of Cape Town, South Africa; Helen Ferret; Kevin Thomas
The purpose of this study was to examine the validity of a modified short form of the Boston Naming Test (BNT), and so to contribute to a larger research program aiming to modify, translate, and norm commonly used neuro-psychological tests in South Africa. The modified BNT included 15 items, all drawn from the pool of 60 items on the original test, judged more culturally appropriate for the South African population than those on other commonly used short forms. First, we demonstrated the cultural bias inherent in the original 60-item BNT by investigating the performance of a sample of undergraduate students (n = 30) who were fluent in English, emerged from high socioeconomic status (SES) backgrounds, and had experienced a high quality of education. Comparisons to North American norms for a similar age group showed that even these highly-educated English-speaking South Africans scored significantly lower than their North American counterparts. Secondly, we conducted a preliminary examination of the cross-cultural validity of the modified short form by comparing the performance of two groups of healthy community-dwelling older adults. Results showed that low-SES isiXhosa-speaking individuals (n=30) performed significantly more poorly than high-SES English-speaking individuals (n=30). Regression analysis confirmed that SES and education differences, rather than age and sex differences, accounted for the between-group differences. This research is another step in the ongoing attempt to provide culturally appropriate neuro-psychological tests and norms for clinical and research purposes in South Africa.

Active living impacts executive functions: Comparisons across cognitive status
Cindy De Frias University of Texas at Dallas, United States of America; Roger Dixon
In a recent report from the Victoria Longitudinal Study (VLS), we observed a multidimensional (3-factor) structure for six executive function (EF) tests in cognitively elite (CE) older adults, a unidimensional structure for cognitively impaired (CI) older adults, and mixed structure for the cognitively normal (CN) older adults (de Frias, Dixon, & Strauss, 2009). The three EF constructs were “Shift- ing” (Color Trails, Brixton), “Inhibition” (Stroop, Hayling), and “Updating” (Reading and Computational Span). In this study, we examine whether (a) there are cognitive status (CE, CN, CI) differences in the kind and degree of everyday lifestyle activities, and (b) whether an engaged lifestyle moderates or mediates the effects of cognitive status on EF. Level of cognitive, social, and physical engagement was assessed using the VLS-Activity Lifestyle Questionnaire (VLS-ALQ: Hultsch et al., 1999). Participants (N=501, 53 to 90 years) stemmed from the VLS (Sample 3, Wave 1). MANOVAs indicated that CE adults more frequently seek cognitive engagement relative to CN and CI adults. Moderator analyses (hierarchical regressions) indicated that CI adults who are engaged in social activities have better EF than those who are less socially engaged. CI adults with high social engagement perform similarly on EF to CN adults. In fact, CI adults with low social engagement do not display this pattern. The association between cognitive status (CI, CN, CE) and executive function is partially mediated by lifestyle engagement (especially cog- nitive engagement). Studies of EF and aging will benefit from considering concurrent cognitive status and everyday lifestyle engagement.

Cortisol/dehydropiandrosterone ratio and executive performance in intimate partner violence victims
Veronica Juanes Nova Southeastern University, United States of America
Intimate partner violence (IPV) has become a major health issue among women. Victims of IPV may display several sequelae including physical and psychological outcomes. Research has demonstrated that female victims of IPV display a neuroendocrine system dysfunction. Furthermore, women victims of IPV display cortisol and/or dehydroepiandrosterone (DHEA) level disturbances with negative consequences for women’s health and cognitive functioning. In addition to IPV, perceived discrimination can also elicit both physical and psychological stress in individuals. The presence of race-related stressors and perceived discrimination may contribute to the increase in cortisol/ DHEA ratio in ethnic minority IPV victims. It is hypothesised that African American female victims of IPV will report significantly higher rates of perceived discrimination, race-related stressors, and cortisol/DHEA ratios in comparison with Caucasian female victims of IPV. Furthermore, African American female victims will display poorer performances on executive functioning tests. Instruments will include the Discrimination Stress Scale to assess perceived discrimination, and the Race-Related Events Scale to evaluate exposure to race-related stressful events. Neuropsychological tests will be administered to assess executive functioning and will consist of Complex Figure Test, Trail Making Test, and The Verbal Fluency Test. Statistical analysis may show higher rates of both perceived discrimination and race-related stressors in African American female IPV victims compared to Caucasian victims. Additionally, the African American women may display higher levels of cortisol/DHEA ratio, predicting poorer neuropsychological performance. This study can give support to multicultural therapy, and bring a neuropsychological perspective to IPV research.

Emotional competence as related to perceived parenting of physically and visually-impaired adolescents
Shyam Juyal Gurukul Kangri University, India
This paper aims to: 1. Identify the differences believed to exist between perceived parenting of physically and visually impaired adolescents; 2. To assess the emotional competence of both the groups; 3. To explore the relationship between perceived parenting and emotional competence of physically
and visually impaired adolescents. We investigated 140 adolescents, 70 physically and 70 visually impaired adolescents. They were selected randomly. Further, males and females were equally distributed from each group of above. A significant difference was found between physically and visually impaired adolescents on adequate expression and control of emotions and encouragement of positive emotional aspects of emotional competence. Girls in the physically handicapped group possessed lower mean scores on the perceived parenting dimensions of rejection vs. acceptance and neglect vs. indulgence. Visually-impaired girls perceived more positive parenting on freedom vs. discipline and faulty role expectation vs. realistic role expectation dimension of parenting. Visually-impaired boys showed more competence emotionally on the encouragement of positive emotions. Regarding the relationship between the two variables, visually impaired adolescents were shown as having significantly positive relationships between most of the dimensions and aspects of emotional competence, whereas, adolescents with physical handicaps showed significant positive correlations between two variables in only one of the set of variables. Visually impaired adolescents therefore were found to be more competent than their counterparts. Boys of both groups were shown to have higher competence than girls. Visually impaired adolescents showed significant positive relationships between both the variables on most of the dimensions and aspects of emotional competence than the physically handicapped adolescents.

Relation between functional brain asymmetry differences among the Kazakh and Russian ethnic groups.

Il'mihanova Lyatzat Kazakh National University, Kazakhstan; Mukhtar Pernenbetov; Jakoop Satybaldy; Lyazzat Il'mihanova; Musaikieva Al'miya; Lyazzat Komekboayeva; Gaizle Teleboayev; Satybaldy Dzhakupov

In a study of the dynamics of the maximum amplitude of the alpha rhythm of the electroencephalogram (EEG) of the students of the Kazakh and Russian ethnic groups, in the performance of the cognitive operations of the EEG parameters were recorded: (counting down, the table of Pythagoras) for the left brain, and when the spatial task (mental rotation of the cube, driving a nail), aimed to the left brain, and when the spatial task (mental rotation of the cube, driving a nail) aimed to the right brain. It was established that when the mathematical task is observed, depression of alpha rhythm parameters decrease is mainly in the left hemisphere, while making extensive assignments, in the right hemisphere. These findings are largely consistent with results obtained by other scientists, dedicated to functional brain asymmetry. Studying the features of the dynamics of the maximum amplitude of the alpha rhythm of EEG in students of the Kazakh and Russian ethnic groups in Kazakhstan, in the performance of the above cognitive tasks, significant differences were found. Our findings are consistent with those studies in Russia, indicating a lack of inter-ethnic characteristics of the EEG of young Khakas and Russian ethnic groups. Our data show that the dynamics of the maximum amplitude of the alpha rhythm of the electroencephalogram (EEG) of the students of the Kazakh and Russian ethnic groups in Kazakhstan and the Khakas and Russian ethnic groups in Russia have no differences in the performance of cognitive tasks.

Neuropsychological correlates of risky alcohol use by young adults

Michael Lyvers Bond University, Australia; Monique Bakhuijzen-Pons; Juliette Tobias-Webb; Charlotte den Butter; Andrea Grauvogel; Susan van Hooren; Wim Waterink Bond University, Australia

Traits of impulsivity, reward sensitivity, and disinhibition have been linked to risky alcohol use in young adults, suggesting that inherent deficiencies in frontal lobe function increase alcohol-related risk. A community sample of young adult social drinkers (n = 47) was divided into low risk, hazardous, and harmful drinkers based on the Alcohol Use Disorders Identification Test (AUDIT) scores. MANCOVA controlling for age and gender revealed a significant effect of the AUDIT group on three well-known neuropsychological tests of frontal lobe functioning: the Wisconsin Card Sorting Test (WCST), the Iowa Gambling Task (IGT) and the Tower Test, F(8, 32) = 2.72, p = .02, observed power = .86. Individual effects were significant for IGT, F(2, 18) = 4.21, p = .03, and for the Tower Test, F(2, 18) = 5.15, p = .02. WCST perseverative errors approached significance (p < .10). These neuropsychological tests can distinguish patients with focal lesions of the frontal lobes from those with lesions of posterior regions as well as from controls, thus our results in a non-clinical sample are striking. As participants were social drinkers who reported never being treated for any alcohol or drug related problem, with no history of head injury or neuropsychological or psychological disorder, findings are consistent with our hypothesis that some of the executive function deficits reported in alcoholic samples may reflect premorbid traits rather than sequelae of chronic alcoholism. Such premorbid deficits are likely to predispose to risky alcohol use via mediating traits such as impulsiveness, disinhibition and reward sensitivity.

Ayurvedic approach on memory stimulation in the French West Indies

Yenкамala Mina Centre Hospitalier de CBE, Guadeloupe; Joelycine De Rotrou; Mina Yenкамala; Atreya Smith

The purposes of our study is to estimate the efficiency of cognitive stimulation and to consider the possible influence of three constitutional types of Ayurvedic medicine, called tridoshas, on the efficiency of the program with healthy persons, over the period of three months. We intend to meet thirty elderly people from 50 to 70 years old during twelve weekly sessions according to the methodology of the program Neuropsip, stemming from works of J. de Rotrou. These sessions consist of exercises and techniques to prevent the cerebral ageing. During the first session (T1), there is an evaluation of the constitutional types Vata, Pitta or Kapha by means of several questionnaires, such as the questionnaire of Prakriti, Memory Impairment Screen (MIS) and the test of associative memory. These tests cover the lifestyle and various other domains of life and are concerned with the manner in which the memory is made. In the second session of the program (T2), a revaluation of the MIS and the associative memory is made. Our first results allow us to show that the cognitive stimulation is effective for the healthy elderly. By implementing the characteristics of tridoshas, we expect that the program will be more effective for the Kapha type, followed by the Pitta type with the expectation that the program would be less effective at the Vata type. This program of memory stimulation presents the possibility of giving cognitive skills directly to the person, thus allowing participation in their own health.

Sexuality following traumatic brain injury

Ihorn Moreno University of Montreal, Canada; Michelle McKerrall

Traumatic brain injury (TBI) is a major cause of morbidity and mortality in both developing and developed countries. In the United States, a national estimate indicates that approximately 1893 in 100000 people sustain a TBI with residual disability, impairment, or handicap as a result. In Canada, it is estimated that there are 120000 TBIs each year. TBI can lead to neuropsychological, behavioural, emotional, and physical changes. As a whole, these consequences are associated with sexual changes in survivors ranging from 50 to 60% post-injury. A critical review of the literature shows that studies of sexuality following TBI address mainly the patients’ sex-related (64%) and patient-partner’s perspectives (22%), while the professionals’ (7%) and the non-injured spouse’s perspectives (7%) have received less attention. However, the most important methodological difficulties correspond to the underrepresentation of women and the loss of insight that may limit the patient’s self-perception of deficits and may be an obstacle when trying to get reliable information concerning sexuality issues.

Time orientation assessment of institutionalised patients with Alzheimer’s Disease

Cornelia-Eugenia Munteanu CMDT, Romania

This paper aims at presenting the influence of global warming effects and changes of seasonal climatic conditions upon time orientation of institutionalized patients with Alzheimer’s disease (AD). Time orientation assessment focuses on five items: year, season, month, day and date. Romania’s temperate continental climate has autumn months (September, October, November) with moderate temperatures and precipitations, and winter months (December, January, February) with frost, snow and blizzards. Time orientation items used to assess cognitive functions were tested on 171 patients (M = 72.66 years) diagnosed with different stages of AD severity. Data collected between September 2011 and January 2012, evaluated 94 patients (September - November 2011) and 77 patients (December 2011 - January 2012). During examination, institutionalized AD patients identify the season according to outer weather signs. The results reveal an important aspect: 8 out of 94 patients (8%) mistook autumn for spring or summer, whereas 27 out of the remaining 77 patients (35%) mistook winter for autumn or spring. This difference of 27% may be significant, as the assessment was conducted in an abnormally warm period, and the patients used sun orientation. It is therefore appropriate that time orientation assessment of institutionalised patients with AD be scored depending on climatic conditions. In order to check if patient misorientation is due to cognitive
decline, further questions can be asked after correct month identification, e.g., “Which holiday do we celebrate in December?” In conclusion, time orientation assessment of institutionalised AD patients must take into account both context and climate.

Effects of erythropoietin in the executive control in Parkinson disease
Vanessa Perez-Boscourt University of Havana, Cuba
The Parkinson disease produces a dysfunction in the prefronto-striate circuitry that is hypothesised to play an important role in the executive control. The aim of the investigation is to evaluate the protective effects of the human recombinant erythropoietin (EPOrh) in the executive control in PD recording the ERPs while the subjects respond to the Ericson flanker task. 18 PD patients (I-II Hoehn and Yahr stage, medicated, 41-65 years) and 9 healthy controls, matched in age, sex and education level participated in the study. Patients were slower and committed more mistakes than controls, creating a response selection that requires extra time and greater effort, due to the dysfunction in the dopaminergic system produced by PD. Behavioural results showed no effect of the EPOrh medication in patients in the executive control, according to the worse performance of the EPOrh group in precision and reaction time. However, non medicated patients show a possible dissociation in the neural answer mechanism in the incongruent condition. The ERPs show maximum amplitude of the N2 component at Cz with a significant difference between patients and controls. Patients with EPOrh medication have the minor N2 amplitude, being absent a component modulation by the effect of the new medication. N2 latency does not show significant difference by groups or by conditions. The EPOrh medication could have an effect in the early visual processing or the perceptual integration of tasks, given that the amplitude of the complex N1-P1 was greater in patients with EPOrh than in not medicated patients.

Processing of emotional information in schizophrenia: Relation to olfactory deficits
Krystyna Rymarczyk Warsaw School of Social Science, Poland; Iwona Makowska
Deficits in odour identification, as well as impaired emotional perception have been often described in schizophrenia (SZ). However, it is not clear whether these impairments are linked. The aim of this study was to examine the relationship between olfactory deficits and ratings intensity of emotional images selected from International Affective Picture System (IAPS) in patients with schizophrenia. Fifty patients with SZ and 27 normal controls were tested by the PST (Pocket Smell Test). Clinical rating scales included the Positive and Negative Syndrome Scale (PANSS) and the Negative Symptom Assessment (NSA-16) scale. Additionally, subjects provided ratings intensity of their emotional response to the images (IAPS). We found significantly lower PST scores in SZ patients compared to healthy controls, which are consistent with the majority of published reports. Furthermore, both healthy and schizophrenic patients report very similar emotional ratings when viewing IAPS images, however patients with negative symptoms show a heightened sensitivity to emotionally negative pictures. Additionally, it has been shown that negative symptoms are also specifically correlated with poor olfactory identification. In summary, this study provides further support for the observation that many people with schizophrenia have deficits in olfactory identification. These findings also extend the work of previous studies indicating that negative symptoms are associated with poor olfactory identification. Finally, an important practical implication of our findings is that IAPS visual emotional stimuli seem suitable to elicit emotional reactions in psychophysiological or functional imaging studies of the neural substrate for emotional experience in schizophrenia.

Executive function deficits in autistic individuals in Ghana
Joana Salifu Stellenbosch University, South Africa
The study examined executive function deficits among autistic individuals in Ghana. Fifty-nine participants, comprising 28 autistic individuals and 31 healthy controls, were recruited from the Autism Awareness Care and Training Centre in Accra and Tema in Ghana. They were administered tests assessing executive function and quality of life. The results indicated that autistic individuals in the study displayed deficits in executive function in comparison to the healthy control individuals. Overall, autistic individuals presented with significant deficits irrespective of their age and functional level when compared with healthy controls. Significant relationships were found among executive function deficits and deficits in communication as well as self-care and socialisation aspects of adaptive functional skill among autistic individuals, even when their age and functional levels were controlled for. The results suggest that autistic individuals in this study may benefit from training in executive function skills, which may subsequently enhance their quality of life. Implications of the findings are reviewed.

Qualitative parameters of neuropsychological assessment of children with ADD
Yulia Solovieva Autonomous University of Puebla, Mexico; Luis Quintanar
The end of pre-school age and beginning of school learning is an important period for cognitive development. One of the most frequent clinic difficulties at this age are known as Attention Deficit Disorder (ADD). Historical-cultural neuropsychology offers the functional analysis of brain mechanisms that determine the clinical features of the syndrome of ADD. Such information can be obtained through qualitative analysis of errors and particular features observed during the implementation of brief neuro-psychological assessment (Solovieva & Quintanar, 2010). This assessment provides the tasks for evaluation of programming and control, phonematic and kinesthetic integration, motor sequential organisation, spatial functions and retention in visual and verbal modality. Qualitative parameters and features of cognitive activity of Mexican pre-school and school children are presented in the study. Results of execution of neuropsychological tests by children with ADD and children without any disorder are compared. The results reveal significant differences in favour of children without ADD, while children with ADHD show a neuropsychological profile characterised by a severe functional deficit in the programming and control mechanisms, motor sequential organisation, spatial analysis and synthesis and nonspecific brain activation. The ADD is, therefore, a complex neuropsychological syndrome in which different mechanisms are involved. Various psychological processes and brain mechanisms should be taken into account in order to guarantee effective methods and strategies for correction.

Body mass index does not affect grooved pegboard performance in healthy South African adults
Charles Van Wijk South Africa
Obesity has been associated with poorer performance on the Grooved Pegboard (GP) among healthy older adults. The GP is widely used in South Africa, among others for the assessment of HIV Associated Neurocognitive Disorders. Obesity is growing among the younger adult population in South Africa, which is the group also most at risk for HIV. It is not clear whether the interaction between body mass and GP performance would be among a group of healthy youngsters. This study investigated whether body mass might affect fine psychomotor skills. A sample of 800 healthy adults (20-49 years) completed the GP and had their Body Mass Index (BMI) calculated. The sample consisted of 32% women and 68% men, and came from all the South African language groups and provinces of origin. The relationship between GP and BMI was examined using ANOVA and correlation coefficients. The expected gender differences in GP performance found elsewhere were demonstrated in this sample. No significant interactions between BMI categories and GP times were found, and no significant correlations between BMI continuous scores and GP times were found either. In spite of the presence of a wide weight spectrum among the participants and the absence of any history of known medical disease, the lack of significant BMI-GP interactions suggest that the effects of BMI may be generally discounted when interpreting GP results.

Session Type: Invited Addresses

What are the neurocognitive consequences of benzodiazepine exposure?
Simon Crowe La Trobe University, Australia
Most investigations into the effects of the long-term use of benzodiazepines focus only on a limited range of neuropsychological domains making it unclear whether the effects of the drug are specific. This paper presents the results of three meta-analyses and one empirical study which addressed the following questions: (1) Are there cognitive effects of long-term benzodiazepine use? (2) Does the cognitive function of long-term benzodiazepine users improve following withdrawal? (3) Are previous long-term benzodiazepine users still impaired at follow-up compared to controls or normative data? (4) Can the long-term cognitive effects of these drugs be attributed to the underlying cause for their use, anxiety disorder? Taken together, the results provide strong support for the hypothesis that long-term benzodiazepine use does lead to global cognitive deficit. While the results indicate that long-term benzodiazepine users do show recovery of func-
Short and long-term effects of sports concussions on cerebral functions
Maryse Lassonde
University of Montreal, Canada
Traumatic brain injury (TBI) constitutes a significant public health problem with an incidence between 180 and 500 per 100,000 population per year. Among the various degrees of TBI, concussions or mild traumatic brain injury (mTBI), resulting either from a direct blow to the head or from an impulsive force transmitted to the head, constitute a serious problem in sports. On an annual basis, about 20% of all high school football players suffer a concussion, and this is likely an underestimation given that many athletes and coaches often fail to recognize them, especially when there is no loss of consciousness. Because concussions in sports are a problem of such magnitude, they are considered an epidemic and greater public attention is finally being paid to the problems of athletes with persistent problems secondary to TBI. There has been a large amount of research investigating the effects of TBI, but little is known about the pervasiveness of the effects. The majority of neuropsychological studies report recovery from the effects of a concussion between 2 and 10 days after the incident. However, there is a growing body of evidence suggesting that there are cumulative effects of concussions that manifest as increased susceptibility to subsequent concussions as well as an increase in their severity. This paper will present electrophysiological, cognitive and anatomical studies, that show evidence of persistent and long-term deficits following sports concussions. Event related potentials reveal a significant reduction in the amplitude of the electrophysiological measure (i.e., the P3 waveform) associated with attention and working memory updating. Moreover, athletes with a history of multiple concussions, but not the ones who sustained a single concussion, continue to show abnormal P3 responses up to 3 years following their last concussion. Using MR spectroscopy, we have also shown that, 48 hours after their concussion, young athletes have abnormal neurometabolite levels suggesting early degenerative processes that persist at least 6 months after the concussion. More importantly, we have recently compared a group of healthy former athletes in late adulthood (60 years old) who sustained their last sport-related concussion more than 30 years ago with healthy former athletes with no history of concussion. Relative to controls, former athletes with a history of concussion had a lower performance on neuropsychological tests of episodic memory and frontal lobe function (response inhibition) and a significantly delayed and attenuated P3 component. Moreover, the memory and response inhibition deficits correlated with the reduction in P3 amplitude. These results are important because they show a progression in clinical symptoms: whereas young asymptomatic athletes display abnormal electrophysiological responses with normal neuropsychological scores, older athletes, while continuing to show abnormal ERP results, start showing cognitive deficits akin to those seen in MCI, a condition characterized by early memory impairments that convert at a rate of about 10-20% annually into dementia. These findings raise serious concerns. Indeed, they indicate that concussions may constitute a risk factor in the development of Alzheimer’s disease. Finally, these results should make us reconsider the presence of violence in sports such as hockey, football and other contact sports.

The evolving role of neuropsychology in the management of concussion in sports: An international perspective
Mark Lovell
University of Pittsburgh, United States of America
Over the past ten years, the neuropsychologist has come to play a critical role in diagnosis and treatment of concussion in athletes. Currently, in the USA, all professional sports leagues require neuropsychological assessment as part of their management protocols and this is becoming increasingly common at the collegiate and High School level as well. This presentation will provide a historical perspective on the development of neuropsychological assessment procedures for use with athletes and will focus specifically on the expansion of the role of neuropsychology outside of the United States. In addition, the latest international guidelines for returning concussed athletes to sports will be discussed with a specific focus on the use of currently available neuropsychological test batteries that have been designed specifically for use in sports. Finally, cross-cultural data will be presented to highlight the potential use of neuropsychological assessment tools in countries and cultures that are currently underserved.

Facial expressions of emotion: A neuro-cultural perspective
Manas Mandal
DIPR, India
The face is considered to be the most important channel of communication of emotions. Research in the study of human emotions has predominantly focused on the face as the medium for expressions of emotion. While some researchers propose that facial expressions have an evolutionary-biological root, others believe that these are largely moderated by prevailing socio-cultural constructions. Unarguably, facial expressions serve the adaptive functions of conveying emotional reactions to the external world, and this process of adaptation takes place either through a biological or social evolution or both, with a high degree of simultaneity. In this paper, a neuro-cultural perspective is adopted to explain the biological and social influences in facial expressions of emotion. Support is drawn from studies that utilised hami-facial composites of emotion. These studies reveal that the two sides of the human face are highly asymmetrical in expression. For example, the left of the face responds more often to a biological trigger (innate facial affect program), while the right of the face reflects social expressions in general (culture-specific display rules). Findings of these studies are reviewed with a view to developing a neuro-cultural theory of facial expressions of emotion.

Emotion, intuition, and the neuroscience of false beliefs
Oliver Turnbull
University of Wales, South Africa
There is a diverse body of recent evidence, much of it from modern neuroscience, on the role of emotion in human mental life. Much of this literature suggests that emotion is of central importance in many (perhaps all) aspects of the mind, including domains such as higher cognition that have long been regarded as operating (or at least optimally operating) independent of emotional influences. Most notably, when carrying out complex decision-making tasks, people seem to gain substantial advantages from using emotionally-mediated learning systems. These appear to operate outside full conscious awareness, which humans commonly describe as a reliance on gut-feelings, hunches and intuition. We now know a great deal about the neurobiology of such emotion-based psychological processes founded in large part on evidence from patients with focal frontal brain lesions. For example, one strand of our data investigate neurological patients with amnesia, suggesting that such emotion-based learning can occur independently of episodic memory. A further strand has investigated the effects of over-reliance on emotion in neurological patients, which appear to result in false beliefs. Our data suggest that these delusion-like opinions might be motivated by emotional factors, and shaped by cognitive defences, as has long been contended by the field of psychodynamic psychotherapy.

Cutting-edge developments in neurorehabilitation and future directions
Barbara Wilson
Oliver Zangwill Centre, United Kingdom
Neuropsychological rehabilitation is concerned with the amelioration of cognitive, emotional, psychosocial and behavioural deficits caused by an insult to the brain. Major changes have occurred over the past decade or so. In this presentation, I select what I consider to be some of the most important changes in the rehabilitation of adults with brain injury over the past five years. Included are new assessment procedures, new treatment strategies for cognitive, emotional and psychosocial problems, new theoretical models to improve our understanding of the consequences of brain injury, and recognition of the need to find new ways to evaluate the efficacy of rehabilitation. The final part of the presentation considers possible future developments in rehabilitation. We consider stronger links with basic neuroscience, better use of imaging procedures, collaboration with pharmaceutical companies, better evaluation of our programmes and look at the possibility of brain-computer interaction methods.
Seeing’ with the ears and hands and bionic eyes: From basic research to visual rehabilitation

Amir Amedi Hebrew University of Jerusalem, Israel

The exciting view of our brain as meta-modal or as axonal myelinisation or reduced through cell death. Throughout life, and particularly during infancy, high inter-neuronal connectivity present at birth. Recent advances in rehabilitation approaches, both noninvasive, like sensory substitution devices (SSDs) which provide visual information using sound or touch, and invasive, like visual prosthesis, may potentially be used to achieve this goal, each alone, but preferably together. Visual impairments and said solutions are being used as a model for answering fundamental questions ranging from basic cognitive neuroscience, showing that several key visual brain areas are actually highly flexible, modality-independent and, as was recently shown, even visual experience-independent task machines, to technological and behavioural developments, allowing blind persons to ‘see’ using SSDs and other approaches. I will present evidence that SSDs can be potentially used as a research tool for assessing the brain’s functional organisation as an aid for the blind in daily visual tasks, to visually train the brain prior to invasive procedures, by taking advantage of the ‘visual’ cortex’s flexibility and task specialisation even in the absence of vision, and to augment post-surgery functional vision using a unique SSD-prostheses hybrid. Taken together the reviewed results suggest a brighter future for visual neuro-rehabilitation.

Brain plasticity following sensory loss: Effects on performance, cortical reorganisation and rehabilitation strategies

Franco Lepore Université de Montréal, Canada

The brain is a highly organised structure, with well-defined areas sub-serving specific functions, and high inter-neuronal connectivity present at birth. Throughout life, and particularly during infancy, the structures and connexions are either reinforced against architectural constraints (e.g. memory limitations) independent of content. In contrast, the evidence from understanding perspective points to links across domains along conceptual relations among domains.

Functional MRI study of Piaget’s conservation-of-number task in preschool and school-age children: A neo-Piagetian approach

Olivier Houde Descartes Sorbonne University, France

Jean Piaget’s theory is a central reference point in the study of logico-mathematical development in children. One of the most famous Piagetian tasks is number conservation. Failures and successes in this task reveal two fundamental stages in children’s thinking and judgment, shifting at approximately 7 or 8 years of age from visuospatial intuition to number conservation. In the present study, preschool (non-conservers) and school-age (conservers) children aged 5-6 years and 9-10 years, respectively, were presented with Piaget’s conservation-of-number task and monitored by functional magnetic resonance imaging (fMRI). The cognitive change allowing children to access conservation is related to the neural contribution of a bilateral parietofrontal network involved in numerical and executive functions (i.e. inhibitory control). These new fMRI results highlight how behavioural and cognitive stages as defined by Piaget in the twentieth century progressively unfold in the brain during children’s development.

What constitutes a domain? Piagetian implications of perspective-taking in development and the brain

Josef Perner University of Salzburg, Austria

There is a large body of evidence that children master a variety of perspective-taking tasks at the same age and these tasks tend to correlate strongly. Also evidence is emerging that these perspective tasks share parietal brain regions. I will draw out some general implications for development and the structure of the mind. The data speak against strict domain specificity for any evolutionarily sensible conception of domain. The changes we observe can also not be captured by the usual notion of domain generality, which typically refers to architectural constraints (e.g. memory limitations) independent of content. In contrast, the evidence from understanding perspective points to links across domains along conceptual relations among domains.

Inhibitory control in number-conservation and class-inclusion tasks: Neo-Piagetian inter-tasks priming studies and brain imaging data

Gregoire Borst Descartes Sorbonne University, France

In this set of studies, we investigated whether success in number-conservation and class-inclusion tasks relies on a general ability to inhibit misleading strategies. The experimental design was such that in one group of participants, the class-inclusion task served as a prime and the number-conservation task as a probe and vice versa in the other group. Children’s response times were shorter in the number-conservation task when performed after the class-inclusion task (and vice versa in the other group) than in control prime-probe sequences in which the primes did not require the inhibition of a misleading strategy. A control experiment revealed that these inter-task priming effects did not simply reflect that class inclusion and number conservation rely on the reversibility of concrete operations as Piaget would have hypothesised. Taken together the results provide additional evidence that cognitive development is rooted in both the acquisition of knowledge of incremental complexity and on inhibitory ability. Critically, the present findings suggest that this ability is not domain- or strategy-specific. New brain imaging data suggest that the inferior frontal gyrus/insula might be the critical structure for the type of inhibition process engaged in Piagetian tasks.

Jean Piaget’s theory and new discoveries from developmental neuro-imaging

Olivier Houde Descartes Sorbonne University, France

Tracing the connection from brain functions to children’s cognitive development and education, is a major goal of modern human neuroscience. In the mid-twentieth century, the Swiss psychologist Jean Piaget described a Circle of the Sciences (opposed to Augustine Comtes Scale of the Sciences), in which developmental psychology provides the foundations for logic and mathematics, and is itself grounded in biology, biochemistry, chemistry and physics. But it was not until after Piaget’s death (1980), with the advent of brain imaging techniques, that it became possible to study the biological foundations of cognitive development. What have we learned?

Symposium title: Brain plasticity following sensory loss: effects on performance, cortical reorganisation and rehabilitation strategies
Convenor: Franco Lepore

Symposium title: Jean Piaget’s theory and new discoveries from developmental neuro-imaging
Convenor: Olivier Houde
approach, has stimulated the advancement of learning environments in the domains of science and mathematics that focus on knowledge building and conceptual restructuring. I will present longitudinal data from elementary school children on learning science and mathematics, which, in fact, show long-term head starts for students with advanced specific conceptual knowledge at the beginning of elementary school. How these results can be interpreted in the light of more recent theoretical frameworks influenced by cognitive neuroscience, such as executive functions, will be discussed.

Symposium title: Mental health, neuropsychiatric assessment and integrated health services
Convenor: Michela Colombu

The infancy and adolescence neuropsychiatric operative unity: Interdisciplinary activities in Italy
Simona Siani HSA, Italy
The Infancy and Adolescence Neuropsychiatric Operative Unity (UONPIA) is part of the Neurosciences Department and operates in the territory with the aim of safeguarding and promoting health within infant and adolescent groups (subjects are aged 0-18) and parents’ support. UONPIA collaborates and integrates with the other operating units of Azienda Ospedaliera Fatebenefratelli and Oftalmico, which guarantees very good coping with problems connected with neuropsychiatric disorders in children and adolescents, offering highly specialised support to families with regard to both diagnostic and rehabilitation aspects. UONPIA activities, devoted to the evaluation and rehabilitation of neuropsychiatric pathologies in Infancy and Adolescence, are inspired by a multidisciplinary approach which integrates the clinical competences of Infancy neuropsychiatrists and psychologists with expertise in rehabilitation therapies (physiotherapists, speech therapists and psychomotoric therapists). Complex cases and cases of adolescent deviant behaviour are dealt with in collaboration with law institutions, with units operating for the protection of the adolescents and primary care social services. In recent years the Italian reality has entered the second phase of the migration cycle, witnessing the presence of an increasing number of foreign adolescents and an increase in the demand for assistance, with the consequence that it is necessary to activate different approaches in line with the different cultures and the complexity of problems.

Symposium title: The rationality of human reasoning
Convenor: Jean-Francois Bonnefon

Reasoning about emotional events
Isabelle Blanchette UQTR, Canada
The study of reasoning has traditionally focused on comparing participants’ reasoning responses to prescriptions of normative logic, with implications for debates about rationality. Recent experimental research has shown that reasoning about emotional stimuli may be associated with increased departures from normative prescriptions. Furthermore, different studies suggest that highly emotional events as well as stress also increase reasoning “errors”. These studies however typically examine incidental emotions that are unrelated to the semantics of the reasoning stimuli. I will present our recent work examining participants’ reasoning about highly emotional and personally meaningful experiences showing strikingly different patterns of results, with evidence of “improved” logicality when reasoning about emotional topics. These quasi-experimental studies have been conducted with groups such as combat veterans and victims of sexual abuse, and has led to hypotheses concerning relevance and emotion that we have also tested experimentally.

The rationality of human reasoning
Jean-Francois Bonnefon CNRS and Université de Toulouse, France
During the last decade, the psychology of reasoning has undergone a profound transformation, which has led to the instalment of what some have called a new paradigm. This new paradigm gives central importance to individual differences and uncertain information, as well as decision-theoretic considerations. In the wake of this transformation, and in line with the overarching theme of ICP 2012, the time is ripe for leading figures of the new paradigm psycheology of reasoning to consider how it will translate into the knowledge, skills and tools that can enrich and improve human life.

Reasoning in an imperfect world
Jean-Francois Bonnefon CNRS and Université de Toulouse, France
In a perfect world, people would only ever have to reason from accurate, sound, consistent information. In the real world, information is vague, uncertain, contradictory, and biased. Because the psychology of reasoning long focused on a model of the ideal reasoner in a perfect world, its relevance to daily life was limited. With the advent of a new paradigm psychology of reasoning, which pays heed to the imperfect nature of information, and the diversity of reasoners, opportunity are created for the field to impact on the well-being of the everyday reasoner.

Grounded rationality and weakness of will
Shira Elqayam De Montfort University, United Kingdom
Instrumental or pragmatic rationality is defined as thinking in a way that helps achieve one’s goals. However, people usually hold more than one goal simultaneously, goals can be in conflict with each other, and goal preferences are notoriously unstable. The quintessential demonstration of all this is akrasia, or weakness of will when agents behave, freely and intentionally, against their own better judgement. Weakness of will has been extensively discussed both in philosophy and psychology, but discussions typically assumed, implicitly or explicitly, a normative evaluation of goals. In contrast, this talk will aim to explore a descriptivist approach to weakness of will, based on grounded rationality—a theoretical framework combining descriptivism with moderate epistemic relativism. Grounded rationality argues that human thought should be evaluated relative to an agents particular epistemic context, taking into account both within- and between-individual variability as well as any cognitive universalities. However, this is not a Panglossian approach as individuals can still fail to be rational by their own lights with weakness of will again as the prototypical case.

Rational argument, rational inference
Ulrike Hahn Cardiff University, United Kingdom
Argumentation is a central part of our lives, and one of the main contexts in which our reasoning skills are brought to bear. However, reasoning research in the past has connected only poorly with argumentation due to its preoccupation with classical logic. The recent probabilistic turn in the psychology of reasoning, however, affords the opportunity to assess argumentative skills in a much broader range of setting, with clear relevance to the types of arguments we encounter in day to day life.

Psychology of reasoning
David Over Durham University, United Kingdom
New paradigm psychology of reasoning and real-world decision making. The older binary paradigm in the psychology of reasoning cannot be properly integrated with the study of actual decision making. This older paradigm is best represented by mental model theory, which holds (most recently Byrne & Johnson-Laird, 2009) that the natural language conditional is either true or false at every possibility and that its probability, P(if p then q), should be the probability of the material conditional, P(not-p or q). We will illustrate how this position is incompatible with an adequate account of real-world decision making. We will argue that a new paradigm approach to conditional reasoning based on de Finetti’s conditional event and the Ramsey test is in a much better position to explain the natural language conditional and its use in actual decision making. Results will be presented that support our approach.

Cross-modal cortical reorganisation and behaviour in the blind and the deaf
Franco Lepore Université de Montréal, Canada; Patrice Voss; Francois Champoux; Natasha Lepore; Maryse Lassonde; Olivier Collignon
Numerous results obtained in our laboratory on blind individuals consistently indicate that when tested on behavioural tasks, such as tone discrimination, sound localisation in far and near space, navigation on a tactile labyrinth or in angle discrimination using touch, they generally outperform the sighted. At the cortical level, it appears that this supersperformance rests on the recruitment of visual areas. Of particular interest is the fact that the recruited areas respect the functional specificity of the colonised visual system: The dorsal or where stream is recruited to localise the sounds whereas
the ventral or what stream is activated when the sound has to be recognised. Similar rules do not seem to hold for deaf individuals. The latter show somewhat poorer visual abilities for even low level functions, such as spatial frequency discrimination and contrast sensitivity. Higher level face discriminations are also not better carried out. Although recruitment of auditory areas by visual stimuli does occur, visual stimuli that normally activate the two systems in visual areas do not show a similar dissociation in recruited auditory cortex. Moreover, the cortical recruitment by vision is detrimental to the re-establishment of auditory function with a cochlear implant.

Adaptive cortical neuroplasticity following deafness
Stephen Lomber University of Western Ontario, Canada; Andrej Kral; Alex Meredith

Plasticity is the neural mechanism by which complex nervous systems adjust themselves to their environment. Adaptive, or compensatory plasticity is a part of this overall process resulting from the loss of a given modality that is accompanied by the corresponding expansion of the remaining systems. The experiments to be presented are designed not only to elucidate the effects of early deafness on the brain, but also reveal the basic principles governing the phenomenon. Cross-modal plasticity was examined in congenitally deaf cats. We examined the behavioural significance of reorganised auditory cortex following deafness. We hypothesised that areas which physiologically reorganised in response to deafness will be involved in behaviours that are similar to those of hearing animals, but are mediat ed by the replacement modality (vision). Behavioural tests combined with reversible cooling-deactivation of the selected cortical regions were used to examine the relationship between cross-modally reorganised cortices and corresponding alterations in behaviour/perception. In deaf cats, reversible deactivation of posterior auditory cortex selectively eliminated superior visual localisation abilities while deactivation of dorsal auditory cortex eliminated superior visual motion detection. These results demonstrate that enhanced visual performance in the deaf is caused by cross-modal reorganisation of deaf auditory cortex and it is possible to localise individual visual functions within discrete portions of reorganised auditory cortex. Collective ly, these results provide new insights into the specific brain changes induced by early deafness.

Experiential, genetic and epigenetic effects on human neurocognitive development
Helen Neville University of Oregon, United States of America

For several years we have employed psychophysics, electrophysiological (ERP) and magnetic resonance imaging (MRI) techniques to study the development and plasticity of the human brain. We have studied deaf and blind individuals, people who learned their first or second spoken or signed language at different ages, and children of different ages and of different cognitive capabilities. Over the course of this research we have observed that different brain systems and related functions display markedly different degrees or "profiles" of neuroplasticity. Some systems appear quite strongly de-

ImPACT (English administration) plus the Trail Making Test and Digit Symbol Backwards on English university groups (N = 45). Across all studies the ImPACT Visual Motor Speed Composite revealed failure to benefit from practice to the extent that was in evidence for the control groups, a finding that was replicated in the University cohort for Trails A and B, and Digit Span Backwards. The implication is that rugby playing scholars show vulnerability on speeded tracking abilities in association with participation in rugby due to repeated subconcussive and/or concussive insults, at a time when they are embarking on their final end-of-year examinations. It is suggested that: (i) Return to baseline levels for rugby players on tests that typically show a practice effect may not indicate full recovery from a concussive episode; and (ii) Careful neurocognitive monitoring of individuals involved in these sports may facilitate timely identification of those with clinically relevant fall-off warranting discontinuation of the sport.

Neuropsychological profiles of rugby players diagnosed with concussion over one rugby season
Susan Clark South Africa; Ann Shuttleworth-Edwards; Emil Rodolfo

The neuropsychological profiles of adult provincial Rugby Union players (n = 17) were compared at baseline, and at four post concussion (PC) follow-up intervals (averaging 4, 10, 16 & 24 days), with the profiles of demographically matched Non-contact Sports Controls (n = 17) tested at equivalent intervals. Measures included the ImPACT neurocognitive and symptom composites, and the WMS-III Visual Reproduction and Verbal Paired Associates subtests. Cross-sectional analyses for Rugby versus Controls revealed a significantly poorer score on Verbal Paired Associates at PC4, and significantly higher symptom reports at pre-season, PC1, PC2 suggestive of incomplete recovery. Prospective analyses revealed significant improvements on several measures at follow-up versus pre-season for each group but with less benefit from practice for rugby than controls on the ImPACT Visual Motor Speed and the Visual Reproduction measures. Overall symptoms reduced for each group post baseline evaluation, apart from Rugby at PC1, where symptoms of headache and feeling slowed down were significantly elevated. In conclusion it is apparent that (i) there are additive effects of acute postconcussive sequelae in association with chronic neuropsychological consequences of cumulative MTBI, and (ii) the findings implicate prolonged recovery from concussion of up to 24 days for Verbal Paired Associates compared with the frequently cited 7-10 day recovery.

Preliminary normative data on Xhosa-speaking high school learners on impact programme
Thandi Salman-Godlo Rhodes University, South Africa; S. Radloff; Clifford van Ommen; Ann Shuttleworth-Edwards

Concussion is a common form of brain injury, especially among sports players of all age groups. ImPACT is a valid and reliable measure of a variety of cognitive functions commonly affected by such injuries, which allows for objective return-to-play

Symposium title: Current research outcomes on computerized neurocognitive screening within the South African sports concussion arena
Convenor: Ann Shuttleworth-Edwards

Practice effects reveal visuo-motor vulnerability in school/university rugby playing scholars
Vicoria Alexander Rhodes University, South Africa; Ian Smith; Mark Horsman; Ann Shuttleworth-Edwards; Sarah Radloff

The purpose of the present paper was to report on the pre-and post-season analysis of speeded attention abilities for three separate studies on Rugby Union in which South African rugby players were compared with IQ, education and age equivalent noncontact sports controls. Study 1 used the ImPACT test (English administration) and Digit Symbol Substitution on 17-19-year-old English high school groups (N = 150); Study 2 used ImPACT (Afrikaans administration) on 16-18-year-old Afrikaans high school groups (N = 68); Study 3 used
decision making. However, studies show that the transfer of such tests from one ethnic group to another without appropriate standardisation is highly problematic and accordingly the relative absence of South African normative data for the ImPACT programme is an issue for concern. The objective of this study therefore was to establish normative indications for semi-rural Xhosa-speaking schoolboys (N = 70) with a relatively advantaged education (ages 14, 16 and 18) for the ImPACT 3.0 programme administered in English. Administrative and linguistic difficulties that were experienced by individuals during completion of the battery were also identified. The study included a comparison of the percentile scores of this sample to the USA norms for boys of a similar age group. The comparison of the USA and SA percentiles supports the need for local norms for this population in that the South African Xhosa-speaking cohort consistently scored lower than the USA sample. Finally, it is recommended that symptom self-reports should be verbally investigated with each boy after testing, given indications of comprehension problems. In closing, limitations of the study and future possible studies are discussed.

Outcomes on computerised neurocognitive screening within the South African sports concussion arena
Ann Shuttleworth-Edwards Rhodes University, South Africa

The purpose of the present symposium is to provide an overview of research outputs derived from a national research initiative on the use of the ImPACT computerised neurocognitive screening test to facilitate medical management within the sports concussion arena. The ImPACT test, now in its fourth updated version, was developed by neuropsychologists in the USA, and is registered with the Health Professions Council of South Africa (HPCSA) for use in this country. The test is rapidly growing in its use worldwide in response to concern that a significant proportion of individuals that participate in the contact sports will sustain a permanent reduction in brain function. Accordingly, there is an international consensus of opinion supporting the implementation of (i) careful identification of the sports concussion, followed by (ii) medical management of the injury on an individualised basis in a process that ideally includes computerised neurocognitive evaluation to facilitate accurate diagnosis and safe return-to-play (Aubry et al., 2002; McCrory et al., 2009). Three of the studies for presentation in this symposium add to the growing body of evidence for the presence of neurocognitive vulnerability in players of Rugby Union when compared with demographically equivalent noncontact sports controls, at high school, university, club and professional levels of play. Two additional studies present normative indications for South African non-English speaking individuals with relatively disadvantaged education compared with the USA standardisation samples. These norms are crucial to ensure the valid implementation of the ImPACT neurocognitive screening process within the local sports concussion management context, with broader implications for the applicability of this tool for culturally disadvantaged groups elsewhere.

Normative data for adolescent rugby players: Afrikaans version of impact neurocognitive screening
Ann Shuttleworth-Edwards Rhodes University, South Africa; Ian Smith; Mark Horsman

A number of computerised tests have been especially developed to facilitate the medical management of sports-related concussion. The most widely used of these programmes is the ImPACT test that was developed in the USA, and the only one to date that is registered with the HPCSA for use in the South African context. A recent Afrikaans version of the test has been developed although to date there have been no normative indications established on this translated version of the test. Accordingly, the objective of the present study was to provide preliminary normative for the ImPACT neurocognitive composite scores (Afrikaans administration) on a cohort of Afrikaans first language adolescent rugby players in the age range 14 to 21 (N = 48) with Model C education. The data were compared with existing normative data for South African English first language adolescents and players with Private/Model C schooling in two age categories (14-16 years and 17-21 years). The results demonstrate broadly commensurate outcome between the two groups (p > 0.05 in most instances), and no area of consistent disparity for any of the composites across the two age groups, thereby providing validation for this translated version of the test. However, there was an overall poorer performance in respect of the Afrikaans cohort across most composites, explicit in terms of the less advanced quality of education that pertained for the particular group of Afrikaans speaking adolescents.

Deleterious neurocognitive effects in association with participation in club level rugby
Diana Zoccola Rhodes University, South Africa; Ann Shuttleworth-Edwards; Rodolfa Emil

In a cross-sectional analysis the neurocognitive profiles of adult club Rugby Union players were compared with demographically matched Non-Contact Sport controls at baseline (rugby n = 33; controls n = 32), mid-season (rugby n = 24; controls n = 24) and post-season (rugby n = 20; controls n = 22). Further, in a prospective analysis the neurocognitive profiles of Rugby Union players and Non-Contact Sport controls who participated throughout the season (n = 20 and n = 22, respectively) were examined at baseline versus mid- and post-season. Measures included the ImPACT neurocognitive composites and the Purdue Pegboard. Cross-sectional analyses for Rugby Union versus Non-Contact Sport controls revealed a significantly poorer score on the ImPACT Visuo-motor speed and Reaction Time composites and the Purdue Pegboard, with a predominant trend in the direction of the rugby group performing worse than the non-contact sport control group on all the motor speed measures. Prospective analyses revealed significant improvements on measures at mid- and post-season versus pre-season for each group but initially with less benefit from practice for the rugby group. In respect of all measures, there was a consistent trend for improved performance from the pre-to mid-season assessment intervals, and a more gradual tendency for improvement at the post-season assessment interval. In conclusion, the research implicates: (i) chronic deleterious neurocognitive consequences of cumulative MTBI in association with long term participation in rugby, and (ii) value in utilising tests of speeded hand motor performance diagnostically immediately postconcussion.

Symposium title: Emotion and adaptive social function
Convener: Melike Foulie

The role of the right hemisphere in affective social bonding and negative mood
Jill Mordell United States of America; Susan Malcolm-Smith

There is a link between depression and loss of social bonds, which may be mediated by the opioid system (Panksepp, 2005; Zubieta, 2003). Here, we investigate the higher cortical elaboration of this subcortical attachment system. While left-hemisphere (LH) lesions are associated with depression and despair, right-hemisphere (RH) lesions are linked with emotional indifference and even euphoria. Our research investigated the link between sadness/depression and this aspect of social attachment by studying 20 RH patients in whom these feelings of connectedness and sadness are abnormal. LH (n=20) and neurologically intact controls (n=20) served as comparison groups. RH patients appeared to demonstrate less interest in social bonding than controls or LH patients. They appeared to become more egocentric with weak performances on Theory of Mind tasks. Our research explored the different attachment styles between LH, RH, and control groups. We found reduced attachment scores due to increased levels of egozentricity in the RH group. The Beck Depression Inventory and Panksepp’s Affective Neuroscience Personality Scale were also administered to explore emotion-related personality traits and mood. Initial results from this study shed light on the role of the healthy right hemisphere in mediating social attachment and negative mood.

Symposium title: Luria’s romantic neuro-psycho-logy in the XXI century
Convener: Boris Velichkovsky

The contribution of frontal lobes to social cognition
Tatia Lee University of Hong Kong, China

Social cognition’ is the term that refers to the scope of cognitive affective processes underpinning satisfaction and rewarding social interaction and relations with others. Understanding the neuropsychological foundation of social cognition will shed light on intervention for promoting prosocial behaviour, which is essential to social harmony as well as successful social integration of people suffering from various clinical conditions. The important roles played by frontal lobes in regulating optimum social cognitive functioning, e.g. mentalising (the awareness of the mental states of self and others), emotion recognition (the decoding of emotional cues delivered via facial expression and prosody), and emotion regulation, have been widely investigated starting with pioneering work by A. R. Luria. In this presentation, the contribution of frontal lobes to mentalising and emotion regulation will be reviewed and discussed on the basis of our clinical research.
Symposium’s abstract
Boris Velichkovsky Technische Universitaet Dresden, Russian Federation; Ann Watts; Elkhonon Goldberg

Alexandr Romanovich Luria (1902-1977) was one of the towering figures of psychology and neuroscience in the past century. This invited symposium reviews the many facets of his global legacy from the perspective of contemporary research and neuropsychological practices. There are different reasons for an enduring interest to Luria’s work in the whole area of contemporary mind, brain and behavioural sciences. These are, first of all, his empirical discoveries such as the demonstration of the cultural-historical nature of higher-psychological processes, and the studies of the verbal control and their development in ontogenesis. Luria also was among the first to grasp the central role of the frontal lobes in normal human cognition, as well as the potentially catastrophic consequences of frontal-lobe damage. This pioneering research into frontal-lobe function and dysfunction foreshadowed what today is referred to as “executive functions” and “meta-cognition”. On a more abstract level, Luria developed an original clinical-theoretical approach to brain-mind-behaviour relationships thus offering an important alternative to the existing physicalist and mentalist approaches. Luria himself referred to his favourite version of psychology as “romantic science”. The present status and future perspective of broad integrative approaches in psychological science and application will also be discussed at this symposium.

Neuropsychology in South Africa in the 21st century: Luria’s influence
Ann Watts Entabeni Hospital, South Africa

South Africa is a multi-cultural and multi-lingual country in a rapid state of evolution and transition. However, most prevailing models of neuropsychological assessment have been quantitative in nature and rooted in a Euro-American orientation. The latter is also true of rehabilitation procedures. Their application within the South African context reflects the legacy of colonialism and apartheid with which our discipline is still grappling. As such, South African neuropsychologists have historically had few assessment and rehabilitation tools which are relevant for, and take cognisance of, the rich cultural and linguistic diversity of our population. Alexandr Luria developed a clinical-theoretical approach to brain-behaviour relationships within a Marxist-Pavlovian materialistic framework and his work has offered South African neuropsychologists important alternatives to existing approaches. This paper will examine the role that Luria’s work has played in the development of neuropsychology in South Africa. It will also discuss adaptations that have been made to Luria’s qualitative and individualised investigative method for assessing neuropsychological status and his rehabilitation procedures to render them appropriate for use in the South African context.

Symposium title: Treating cognitive disorders: Challenges and advances (British Psychological Society session)
Convenor: Susan Gathercole

Cognitive impairments and rehabilitation
Barbara Wilson Oliver Zangwill Centre, United Kingdom

Neuropsychological rehabilitation is concerned with the amelioration of cognitive, emotional, psychosocial and behavioural deficits caused by an injury to the brain. Major changes have occurred in cognitive rehabilitation over the past decade or so. It is now a partnership between patients, families and health care staff and is focused on the achievement of meaningful and personally-relevant goals. There is widespread recognition that cognitive, emotional and psychosocial functioning are interlinked and all should be targeted in rehabilitation. This is the basis of the holistic approach. There is increasing use of technology to compensate for cognitive deficits and some of these aids are discussed. It is also acknowledged that we need to draw on a number of different theories, models and frameworks to plan our rehabilitation. Some of these models are described together with evidence for effective rehabilitation and guidelines for good practice.

Human genetic variation and education: An evolutionary perspective
Juko Ando Keio University, Japan

Tens of thousands of human behavioural genetic studies reveal that all human psychological and behavioural traits are substantially heritable. Heritability estimates of major psychological traits (e.g., cognitive abilities, personality and psychopathological traits) are around 30-60% which are comparable to common biological features of flora and fauna. These psychological traits are multidimensional and their combination is literally infinite. This means that our society should and does adapt to huge and unpredictable genetic variations. One of the major evolutionary strategies to achieve this requirement is learning by teaching (LBT), a foundation of education, which is defined as learning by a triadic (teacher-learner-learning materials) social interaction. As an extremely social animal, human beings should live altruistic and cooperative lives while they meet their individual bio-social conditions. Minimal educational situations such as hunter-gatherer society and traditional apprenticeships systems, in which knowledge and skills to survive are transparent, depend mainly on individualistic observational and participation learning which implicitly embeds LBT in social contexts of local and cooperative communities. The WEIRD (western, educated, industrialised, rich, and democratic by Lancy (2010)), societies are too complex and opaque for individual learners to learn necessary knowledge and skills to live with explicitly, and to systematically organise LBT functions in varieties of educational institutes and systems. Both implicit and explicit educational systems might make genetic variations apparent and, in some situations, exaggerate by gene x environment interaction. Validity and implication of the above arguments will be discussed.

The visual system under challenge: Insights from normal and impaired face processing
Marlene Behrmann Carnegie Mellon University, United States of America

Understanding the psychological and neural mechanisms that underlie face recognition is of great importance, not only because these functions have distinctive evolutionary and social significance, but also because face perception is probably the most developed visual perceptual skill in humans. To shed light on the mechanisms subserving face recognition, we conducted a series of behavioral studies with normal individuals and with individuals with prosopagnosia, either acquired or congenital in nature. We also employed high resolution structural and functional imaging methods to explore the distributed cortical circuitry that supports face processing, including multiple regions of ventral occipital cortex and the anterior temporal lobe, and their cooperative structure and function, as well as the relationship of these structures to the frontal cortex. We find, for example, that whereas the core, posterior nodes of the face network appear to be intact in individuals with congenital prosopagnosia, there appears to be a disconnection between these regions and more anterior, extended regions. Structural imaging studies reveal that the white matter tracts that connect the core and extended regions are compromised in these individuals and recent findings obtained from resting-state fMRI investigations support the absence of a coherent functional network in the same individuals. These findings not only shed light on the systems mediating face processing but also have implications for visual cognition, more generally. Moreover, the studies of impaired face processing may have an impact on other neuropsychological disorders and may guide the development of intervention studies with better efficacy.

Decoding of perceptual decisions from early EEG signals
Stefan Bode The University of Melbourne, Australia; Jason Forte; Simon Lilburn; David Sewell; Philip Smith; Jutta Stahl

Perceptual decision making is believed to be driven by the accumulation of sensory evidence following stimulus encoding. More controversially, some studies report that neural signals preceding the stimulus also affect the decision process. In this study, we used a multivariate pattern classification approach for the analysis of the human electroencephalogram (EEG) to decode choice outcomes in a perceptual decision task from spatially and temporally distributed patterns of brain signals. Our findings demonstrate that neural signals preceding a stimulus can be predictive for choices when the stimulus does not provide sensory evidence. Moreover, participants’ recent choice history was found to prime choice behaviour in subsequent trials. A diffusion model of decision making, when fit to the behavioural data, revealed a systematic starting point bias by showing dependencies of choices on choice outcomes from the preceding trials. Within an accumulator model framework of perceptual decision making, these results strongly support the hypothesis that basic choice priming can systematically bias the starting point of a diffusion process towards a decision criterion. This bias is reflected in pre-stimulus brain signals, which, in turn, become informative for future decisions. Thus, our findings provide a model for how non-stimulus driven decision making could be accomplished on a neural level.

The serotonin transporter in the human brain has a role in attentional processes: PET study with [11C]MADAM
Jacqueline Borg Karolinska Institutet, Sweden; Johan Lundberg; Anna-Lena Nordstrom; Isabelle Klazing; Hristina Jovanovic; Lars Farde; Christer Halldin

The serotonin transporter (5-HTT) is the primary mechanism for regulation of synaptic serotonin concentration and may thus provide a marker for global serotonergic neurotransmission activity in the brain. Experimental animal studies, studies of 5-HTT gene polymorphisms, and pharmacological manipulations in healthy volunteers, have implicated that 5-HT is important for cognitive functioning. In this molecular brain imaging study, our aim was to confirm the suggested role for the 5-HTT in cognitive functioning. Twenty-nine volunteers were examined with positron emission tomography (PET) and the radioligand [11C]MADAM. The binding potential (BP) of [11C]MADAM to available 5-HTT was calculated for the dorsal raphe nuclei, hippocampus, anterior cingulate, insula, temporal cortex and frontal cortex. Cognitive functions were assessed with a battery of neuropsychological tests. BP of [11C]MADAM in all projection areas, but not the raphe, correlated significantly with scores in Rapid Visual Information Processing (RVIP), a procedure measuring sustained attention. Controlling for age, level of education and global IQ, we also found significant correlations between performance in Spatial Working Memory Test and BP of [11C]MADAM in raphe, anterior cingulate and hippocampus. Thus, our results support a role for the serotonin system in the biological underpinning of cognitive functions in man. The observed relationship between 5-HTT availability and attention and working memory performance, also require particular interest in future studies on the patophysiology of psychiatric disorder involving impairment in these cognitive functions.

Role of stimulus complexity variations in the context of subliminal priming
Dennis Dal Mas CITEC, Bielefeld University, Germany; Sabine Thomsen; Benjamin Reichelt CITEC, Bielefeld University, Germany; Hans Markowitsch CITEC, Bielefeld University, Germany; Sina Kuhnle

In neuroscientific research on priming it remains unclear how switching from complex to simple stimuli and vice versa affects subliminal priming mechanisms on the behavioral and on the neurophysiological level. Some experiments suggest that complex stimuli facilitate the processing of simple representations of the same stimuli within the field of priming. However, there are also indications that priming is impervious to stimulus complexity alterations. In the present study, the role of these complexity variations in natural visual stimuli is investigated by using a double masked priming paradigm in conjunction with functional magnetic resonance imaging (fMRI). A stimulus is subliminally presented while being sandwiched by forward and backward pattern masks. One group of participants is presented with a series of complex stimuli (i.e. photos) as primes and a range of simple stimuli (i.e. drawings) as targets. For a second group the order is reversed. We expect stronger priming effects for the first group in relation to the second group. The effects should be observable in terms of shorter reaction times, lower error rates, and differences in the hemodynamic response for the first group in comparison to the second group. Furthermore, neural representations of complexity variations will be obtained. These findings would indicate that complex visual information can enhance memory performance – even subliminally. Importantly, these findings may be used to help improve aspects of everyday life by focusing on the use of complex realistic material in various fields as infrastructure, transportation, teaching, and robotics.

Neuroscientific approach to development of creativity
Liudmila Dikaya Southern Federal University, Russian Federation

The objective of our research was to examine the dynamics of creativity and of brain cortical activity
in high school seniors developing own creativity. 68 participants were divided into two groups – control and experimental (33 and 35 high school seniors accordingly). Participants of the experimental group, unlike of controls, were taught for 2 years with the help of a special program of creativity development, which included the psychological training of creative thinking and EEG alpha feedback training. We tested the level of creativity and EEG power in participants of both groups at the beginning and at the end (at the age of 15 and 17) of longitudinal research. EEG signals for assessment were recorded at divergent task solving from 21 scalp electrodes according to the International 10-20 System. EEG power in 6 frequency bands (from 4 to 35 Hz) was statistically analyzed by 4-way ANOVA and post hoc analysis. Highly significant creativity increase in the experimental group suggests that it may be possible for a wide range of people to become more creative. Divergent task solving in participants of the experimental group compared to controls at the end of the longitudinal study was accompanied by more alpha activity in anteriomental and centrofrontal brain regions, by a higher level of theta power in frontal and central cortical regions and by a high cortical activation in right temporal area (p≤0.05). So the training of creative thinking is reflected at the brain level.

**Processing intra-sentential and inter-sentential code switches in comprehension: An fMRI study**

Gangyi Feng South China Normal University, China; Huan-Chih Chen; Suiping Wang South China Normal University, China

Although proficient bilinguals are capable of switching from one language to another with much apparent difficulty in daily language comprehension, previous studies have shown that switching between languages activates several extra brain regions related to cognitive control. However, it is unclear whether processing code switches at different levels of linguistic structure involves the same neural substrates. Using the event-related fMRI technique, the current study investigated the neural correlates of two kinds of code switching effects (i.e., intra- and inter-sentential) during narrative reading. Inter-sentential switching refers to a language switch between two successive sentences, while intra-sentential switching refers to a switch that occurred on a specific word (always a noun) in the middle of a sentence. Forty Chinese-English bilinguals read a story containing the two types of code switches for comprehension. Consistent with previous studies, our results showed that switching between two languages activated an extensive network, including bilateral prefrontal, temporal and subcortical regions. More importantly, we found that processing intra- and inter-sentential switches produced different patterns of brain activation. Specifically, intra-sentential switches evoked increased BOLD signal changes in several brain regions in the “control network” and “language network”, including bilateral prefrontal, inferior frontal, middle temporal, anterior cingulate, inferior parietal, and precuneus/posterior cingulate cortex. In contrast, inter-sentential switches activated a language-related network, including bilateral frontal and temporal regions. These results suggest that recognizing and/or unifying two linguistic codes at different levels of linguistic structure may involve different language control mechanisms.

**The neuroscience of extreme adventurers**

Gerard Fennimore South Africa

Examples of extreme adventuring include projects such as summiting Mount Everest, walking to the South Pole or around the perimeter of an entire country and rowing unassisted across the Atlantic. The adventurers themselves consistently and with all sincerity claim that anyone can do what they do. The present study attempted to answer the question of whether there is indeed something different about the minds of those who can achieve these extraordinary feats. A sample of 20 subjects who conformed to the criteria of extreme adventurer was identified. Each participated in an extensive one-to-one interview to gain qualitative information about the subject. Furthermore, each completed a 16-PF personality assessment. Finally, using a 19-channel electrode set, the background EEG of each subject was recorded under conditions of eyes open, as well as eyes closed. Spectral analysis, as well as comparison with a reference database was performed on these data. Results indicated a tendency toward the emergence of a profile in both the psychometric as well as neurometric components of the study. While there is virtually no published material that attempts to link EEG profiles to personality assessments, this study concludes by tentatively suggesting some correlations. At the same time, the study reflects on how the minds of those capable of overcoming extreme physical challenges cope with the demands of ordinary day-to-day life.

**The relationship between attention, mindfulness-based stress reduction (MBSR) and psychological well-being: An event-related functional mri study**

Karen Fitzgawd University of Pretoria, South Africa; Patricia Luck; Ben Steyn; Ernesta Meintjes

This study examined the hypothesis that attention and well-being can improve with mindfulness training. This study was the first to make use of fMRI in Pretoria. A randomised control pre-test (T1) post-test (T2) design was used. Forty-four healthy novice adults were recruited. The experimental group underwent an 8-week MBSR course after T1. Psychometric tests and fMRI data were obtained at T1 and T2 from both groups. fMRI data from the long-term mindfulness facilitator was obtained at T1 and T2. The psychometric data were analysed by means of descriptive and inferential statistical techniques. Behavioural results of the ANT were analysed on E-prime. BrainVoyager QX was employed for the analysis and 3D visualisation of the fMRI data. The experimental group performed better on certain psychometric subscales. Compared to the control group, the fMRI data obtained from the experimental group showed a change in brain regions employed for the alerting, orientating and conflict conditions.

**Differences in integrity of white matter and changes with training in spelling impaired children: A DTI study**

Daniela Gebauer University of Graz, Austria

While the functional correlates of spelling impairment have been rarely investigated, to our knowl-edge no study exists regarding the structural characteristics of spelling impairment and potential changes with interventions. Using diffusion tensor imaging at 3.0 T, we here therefore sought to investigate (a) differences between children with poor spelling abilities (Training Group and Waiting Group) and controls, and (b) the effects of a morpheme-based spelling intervention in children with poor spelling abilities on DTI parameters. A baseline comparison of white matter indices revealed no differences between the two investigated spelling-impaired groups, but significant differences were found between controls and spelling-impaired samples, and they were mainly located in the right hemisphere (superior corona radiata (SCR), posterior limb of internal capsule (PLIC), superior longitudinal fasciculus). After five weeks of training, spelling ability improved in the training group, along with increases in fractional anisotropy and decreases of radial diffusivity in the right hemisphere compared to controls. Surprisingly, the comparison of the spelling-impaired training group and waiting group yielded only significant decrease of mean diffusivity in the right SCR. Our results suggest that spelling impairment is associated with differences in white matter integrity in the right hemisphere. We also provide first indications that white matter changes might occur during successful training, but this needs to be more specifically addressed in future research.

**Sex differences in interhemispheric transmission times for facial information: An ERP study**

Ornella Godard Center of Taste Sciences, France; Mohamed Rebai; Arnaud Leleu; Nicole Fiori

Studies on sex differences in hemispheric lateralisation during face processing have found stronger right-hemispheric lateralisation in men and bilateral activity in women. The aim of our study was to explore ERP correlates of sex differences in interhemispheric transmission times (IHTTs) during face processing using a divided-visual field paradigm. Sex differences were observed for N170-IHTTs with asymmetrical transfer (longer from the right hemisphere to the left than the reverse direction) in men and symmetrical transfer in women. Our results are consistent with data reported from studies using other materials, including words and spatial frequency gratings, and extend the pattern to face processing.

**Voice-specific brain responses: A neuropsychological evaluation using near-infrared spectroscopy**

Atsuko Gunji NINH, NCNP, Japan; Hiroshige Takeichi; Masumi Inagaki

Voice perception plays a major role in human communication. Functional magnetic resonance imaging (Belin et al, 2000, 2004) and magnetoencephalography (Gunji et al, 2003) studies reported voice-specific responses around the superior temporal sulcus. A neuropsychological evaluation of voice perception would be an index to assess the developmental stage and the psychological functioning. To develop an assessment tool for education and patient care, we measured voice-specific brain responses using near-infrared spectroscopy (NIRS). NIRS is a noninvasive neuroimaging technique...
which can measure the hemodynamic activity in the cortex without fixing the subject’s body. To make a direct comparison with the results reported by Belin et al. (2000), the same exact materials were used: Human voice, non-voice, spectrally scrambled voice and spectrally scrambled non-voice sounds. A stimulus with duration of 20 seconds contained spectrally scrambled portions (256 segments) at random timing according to an m-sequence for simultaneous electroencephalography measurement. Each of eight stimuli was presented once. Hemodynamic activities were measured using ETG-4000 (Hitachi Medical Corp.) with 44 channels in 14 healthy right-handed volunteers (25±3 years). Changes in the oxygenated hemoglobin (oxy-Hb) concentrations were larger for the voice sounds than the non-voice sounds in the bilateral fronto-temporal areas (p<.05). A neuropsychological evaluation using NIRS also provided evidence for perceptual specificity elicited by human voice.

Confident novelty judgment is dissociated from reduced familiarity in the anterior medial temporal lobe
Teruo Hashimoto Riken BSI, Japan
Although we sense novelty subjectively, it is indistinguishable from reduced/relative familiarity in oldness-based judgments. In this study, probabilities of novel stimuli were controlled to enhance novelty-based judgments and to dissociate neural substrates of absolute from relative novelty judgments using fMRI. Confidence judgments in face recognition tests revealed subjective absolute novelty signals in the left anterior medial temporal lobe (AMTL). Faster response times of confident novelty judgments relative to those of unsure judgments suggest that familiarity-based retrieval is unlikely. The explicit novelty effects found in the AMTL when probabilities of novel stimuli were extremely high (90%) suggest independence from relative distinctiveness. However, confident judgments of oldness were associated with enhanced activity in the anterior prefrontal cortex, dorsolateral prefrontal cortex, and inferior parietal lobule, suggesting the involvement of retrieval and monitoring processes. Both confident judgments for novelty and oldness yielded consistent neural activity in another recognition test with middle probabilities (50%) of novel stimuli. On the other hand, neural responses to unsure judgments were susceptible to stimuli probabilities. These results suggest subjective novelty could be processed independent from reduced familiarity.

Neural correlates of working memory training and transfer in aging
Stephan Heinzel Charite Berlin, Germany; Christine Stetzel; Norbert Kathmann; Henrik Walter; Johan na Onken; Stefanie Schulte; Wolf-R. Brockhaus; Andreas Heinz; Michael Rapp; Robert Lorenz
Age-related cognitive decline in working memory has been associated with alterations in brain activation in the prefrontal cortex (PFC). Here, we examined the cognitive and neural plasticity in working memory in healthy older adults via cognitive training (nback) and functional Magnetic Resonance Imaging (fMRI). An innovation of this study is the investigation of neural correlates of a further untrained working memory task (Stemberg), allowing the disassociation between updating and maintenance processes. In total, 57 old and 48 young subjects were randomly assigned to training or control groups. 52 out of those subjects participated in fMRI measurements while performing a numerical nback working memory task. 30 subjects also conducted a verbal Sternberg task in the scanner. The training groups participated in a 4-week adaptive nback working memory training (12 sessions). All subjects also completed a battery of neuropsychological tests. Behavioural performance in the trained nback task (p<0.01) and the untrained Sternberg task (p<0.05) increased after training. In older training subjects, fMRI analyses of both working memory tasks showed reduced neural activations in right lateral PFC, and right inferior parietal cortex (IPC) after the training (p<0.01). A behavioural transfer effect was observed in tests of processing speed and executive functions. The reported fMRI findings of training-related activation decreases in older subjects support the view of an increase in processing efficiency within working memory networks through cognitive training. Performance gains in untrained tasks seem to be observable if similar neural networks are involved in training and transfer tasks.

Sleep and gross motor learning
Kerstin Hoelddoerfer University of Salzburg, Austria; Juergen Birklbauer; Manuel Schabus University of Salzburg, Austria
There is now compelling evidence that sleep contributes to the consolidation of procedural types of memory and to motor learning in particular. Concerning offline processing of fine-motor skills, there is already profound knowledge supporting the role of sleep in the processing or reprocessing of motor sequence memories. However, data on gross-motor tasks are still missing. Therefore, the aim of our study was to investigate sleep effects on performance in a complex gross-motor task (riding an inverse steering bicycle). To find out whether sleep might have a positive effect on gross-motor learning, we tested 20 healthy male subjects aged between 20 and 28 years (M=23.8, SD=1.88) by a counterbalanced within-subjects design. Each subject participated in a 2 hr midday nap as well as a restful wake condition. In both conditions participants were previously trained on the gross-motor learning task (i.e., immediately prior to nap or resting) and tested for performance pre- and post-sleeping/resting. According to their initial gross-motor performance, subjects were divided into a low-skill and a high-skill group. Preliminary analyses revealed a significant negative relationship between REM sleep duration and gross-motor performance change. Furthermore, sleep spindle number was found to be generally enhanced in highly skilled subjects. Together these findings suggest that REM sleep during midday naps can improve gross-motor consolidation, whereas individual’s general gross motor learning ability is reflected in inter-individual differences of sleep spindle activity.

Working memory and N-acetylaspasrtate levels in hippocampus, parietal cortex and subventricular zone
Stanislav Kozlovskiy Moscow State University, Russia; Maria Pyasik; Alexander Vartanova; Irina Polikanova
Recent studies show that decreased N-acetylappaspartate (NAA) levels result in memory decline in animals (Xi, 2011) and in humans with mental disorders (Bertolino, 2003; Harris, 2006). In the present study we compared memory tests performance and NAA level in different brain structures of healthy subjects. 18 right-handed females (mean age – 59±16) without neurological and mental disorders were selected for this study. All subjects performed working memory tests - verbal and spatial N-back task and visual memory task of complex spatial figures (“snake”). NAA levels in hippocampus, inferior parietal cortex and subventricular zone of both hemispheres were measured with proton magnetic resonance spectroscopy performed with 3T MRI scanner. The received data was analysed by calculating non-parametric correlations (Spearman, p < 0.05) between individual behavioural and biochemical measurements. According to the obtained data, N-back task performance correlates negatively with NAA level in right hippocampus. Moreover, the amount of correct answers in verbal task variation correlates positively (0.71), whereas in spatial task variation the correlation is negative (-0.81). “Snake” test performance correlates positively with NAA level in left hippocampus (0.83). Reaction time in both variations of N-back task correlates negatively (-0.83 for verbal and -0.70 for spatial variations) with NAA level in subventricular zone. No significant correlations between memory tests performance and NAA level in inferior parietal cortex were revealed. Thus, NAA level in both hippocampi and subventricular zone might indicate working memory functioning characteristics in healthy humans.

Modification of risk factors depending on psychological symptoms and health behaviour in patients with TIA
Sandra Lettner Hospital BHS Ried Betreibsgmbh, Austria; Wilhelm Streb Brettcher; Harald Bilem; Andreas Kampf
BACKGROUND: Medication taking behaviour is an important step to optimizing the use of secondary prevention therapies in patients with transient ischemic attacks (TIA) and stroke. No well-defined data of TIA in relation to strokes are available. The importance of specific neuropsychological factors including personality factors, stress coping strategies and affective syndromes in medication taking behaviour in patients with TIA has not been investigated in detail. METHODS: Sixty patients with TIA in the anterior or posterior circulation from a academic teaching hospital are included in this study. Records from an external multicenter data bank were also included. The index event is classified as a TIA if neurologic symptoms resolve within 24 hours and neuroimaging (cerebral CT and or MRI) is negative. Vascular risk factors assessed at baseline and three months after the index event included hypertension, diabetes mellitus, hyperlipidemia, obesity, smoking status and alcohol consumption. Neuropsychological testing included stress coping test, personality test, affective questionnaires (anxiety, depression) and health behaviour questionnaire within 48 hours after admission and three months thereafter. RESULTS: We present the incidence of TIA in a well defined study population. Furthermore sociodemographic data, detailed risk factors and patient behaviour, as well as changes of these matters will be presented. CONCLUSIONS: Our data will document the adherence to secondary
stroke prevention therapies in regard to specific neuropsychological factors. Starting points of pre-
vention programmes will be discussed. Our results may improve the quality of care after stroke and
may reduce the risk of future cerebrovascular events.

The relationship between sleep and memory in post-traumatic stress disorder
Malgorzata Lipinska; Joanna Kierszewska; University of Cape Town, South Africa; Debbie Kaminer; Kevin Thomas; Marlene Gounder; Ridwana Timol
Research has shown that in normal individuals sleep is critical to memory formation. Successful
memory consolidation during sleep is contingent on slow-wave sleep (SWS), REM sleep and the suc-
cessful transition of stages across the night. In PTSD, both sleep and memory processes are dis-
rupted, but no previous study has examined whether these two variables are inter-related. This study
aimed to determine whether disrupted sleep is a mechanism underlying declarative memory deficits
in PTSD - investigating whether memory consoli-
dation during sleep is disrupted in PTSD diagnosed individuals in comparison with controls. partici-
pants were recruited to one of four groups – PTSD (n = 16), trauma-exposed non-PTSD (n = 15),
depression (n = 15) and healthy controls (n = 14). After screening, participants attended the Vincent
Pallotti Hospital sleep laboratory for one night. Participants completed declarative and procedural
memory tasks before and after an 8 hour sleep period. Declarative memory performance was
assessed using a story recall task. Procedural mem-
ory performance was measured using a finger tap-
ing task. Sleep variables such as total sleep time, sleep latency, number of awakenings, and REM and
SWS percentage were measured using sleep adapted EEG. Results were analysed using one-way ANOVA, for sleep and memory variables, and regres-
sion analysis. PTSD participants retained sig-
ificantly less information on a declarative memory
task than healthy controls after sleep. Further dis-
rup tions in SWS predicted poor memory perfor-
ance in at least one domain of declarative mem-
ory. Overall results show some support for the disrup
tion of memory consolidation during sleep in PTSD.

Emotional context impacts limbic striatal re-
ward prediction error
Robert Lorenz; Charité Berlin, Germany; Florian Schlagenhau; Michael Rapp; Juergen Gallinat; Si-
ome Kuehn; Werner Sommer; Torsten Wuesten-
berg; Lorenz Deserno
A frequent experience in every daily life is the impact of emotional context on learning processes.
Indeed, several neuroscientific studies have reported sub-cortical and cortical network activity
associated with reward prediction errors (RPE) dur-
ing instrumental learning. Nevertheless, the influ-
ence of emotional context on RPEs has not yet been studied. Here we conducted a probabilistic instru-
mental learning task with four spatial options dif-
f ering in reward probabilities. While 18 participants were instructed to identify the most rewarding op-
tion, a face was presented on each of the four spatial locations. The emotional expression of the faces
varied block-wise, yielding to a happy, fearful or
neutral emotional context for the learning task dur-
ing fMRI acquisition. A reinforcement learning
model was fitted to each participant’s choices and a trial-by-trial RPE was computed and used in fMri
analysis. The results showed a replication of the previously reported sub-cortical and cortical net-
work representing a RPE. Moreover, a main effect of emotional context appeared exclusively in the
limbic striatum. This effect was driven by the direct
comparison of fear versus happy blocks. Further-
more, this contrast correlated positively with the
arousal rating of fear stimuli. In conclusion, this
study demonstrates, for the first time, stronger
encoding of RPEs during a fearful-emotional con-
text in the ventral part of the striatum showing that
unexpected reward is coded more strongly in an
arousing and emotional negative context.

Neural correlates of dissociative states in
patients with borderline personality disorder
Petrta Ludaescber CnMH, Germany; Martin Bohus; Christian Schmahl
A profound negative influence on psychological processes based learning and memory can be
found in subjects suffering from frequent dissocia-
tive experiences. We recently demonstrated a sig-
ificant reduction of fear conditioning and emotion-
al learning processes during dissociative states. To
investigate dissociative states under experimental
conditions, we used the script-driven imagery tech-
nique, a method previously shown to be capable for
inducing dissociation. 15 medicated patients with
borderline personality disorder were investigated
during fMRI. Neutral and stressful autobiographic
scripts were both presented three times and disso-
ciative symptoms as well as pain sensitivity were
assessed after each script presentation. After the
stressful scripts, dissociation scores were signifi-
cantly higher as compared to the neutral scripts. On
a neural level, we found altered prefrontal ac-

divity during stressful as compared to neutral script
presentation. Patients with co-occurring PTSD
showed increased activity in the right insula and
the left cingulum. Script-driven imagery reliably
induced dissociation in patients with borderline
personality disorder. Our data support previous neu-
ral models of dissociation and resemble findings
from earlier studies in PTSD. Further studies will
focus on alterations in learning and memory pro-
cesses during induced dissociative states.

Negative expectation about pain correlates
attentional biases towards pain-related in-
formation
Fei Luo; Institute of Psychology, CAS, China; He Chuchong; Institute of Psychology, CAS, China; Jin Yan Wang
It is suggested that attention might play an impor-
tant role in pain diseases. A few published studies have investigated whether pain patients show atten-
tional biases (AB) toward pain-related stimuli, but
with controversial findings. All these investigations employed only words and pictures that directly
described pain. In this study, we applied stimuli that
indicated the coming of pain to determine (a)
whether people show AB to pain-related informa-
tion, and (b) whether this bias was related to pain
itself or the expectation of pain. 21 patients with
trigeminal neuralgia (TN), 16 pain-free close rela-
tives of these patients (either spouse or child), and
21 pain-free subjects, who had no relationship with
these patients, participated in our study. Two dot
probe tests were taken by these subjects. In one test,
face pictures with painful or neutral expressions
were instructed to identify the most rewarding op-
tion. In the dot probe test, the experimental group
was synchronized with an eye-tracker system, in
order to measure the pupil dilation, as an addition-
al contactless indicator of emotional reactions, and
the tracking of subjects’ gaze pointing to the PC
screen. Firstly, the data analysis revealed that the
most successful flyer, according to the expressed
opinions of the students, is characterized by a
specific pattern of neuro and psychophysiological
signals. In contrast, the least successful flyer was
associated with another specific pattern. These data
results might help in designing a procedure to test
advertising flyers based on neuro and psychophys-
iological reactions.

Eye-tracking recordings and psychophysio-
logical reactions
Maurizio Mauri; IULM University of Milan, Italy; Vincenzo Russo; Francesco Onorati
Nowadays the techniques that study consumers’
behaviour can take advantage of neuroscientific
findings. That is why researchers have initiated
discussions on a new research field, Neuromarket-
ing. Although this is a promising field, many
issues about the use and application of neurosci-
centific tools, methods and technologies are still
being debated in the scientific community. It is not
evident yet how to apply the results and methods
provided by neuroscience and psychophysiological
research into the practice of marketers, even
though other social sciences, such as economics,
have already integrated neuroscience into a new
research field called neuroeconomics. To add em-
pirical data to these topics, we showed 30 IULM
students 20 advertising flyers. They were asked to
come to the Brain and Behavior Lab on IULM
University campus and sit in front of a computer
while their neuro and psychophysiological reac-
tions were recorded with non-invasive sensors: namely, EEG, EMG, Galvanic Skin Response, Heart Rate and Respiration. The recording device was
synchronized with an eye-tracker system, in
order to measure the pupil dilation, as an additional
contactless indicator of emotional reactions, and
the tracking of subjects’ gaze pointing to the PC
screen. Firstly, the data analysis revealed that the
most successful flyer, according to the expressed
opinions of the students, is characterized by a
specific pattern of neuro and psychophysiological
signals. In contrast, the least successful flyer was
associated with another specific pattern. These data
results might help in designing a procedure to test
advertising flyers based on neuro and psychophys-
iological reactions.

Trait-judgments about self in a comparative
context: An fMRI study
Yan Mu; Peking University, China
Self-concept is developed through the process of
interaction and communication with others. Accu-
mulating fMRI studies have noted the involvement of the medial prefrontal cortex (MPFC) underlying self-reflexive processing (see Nordhoff et al., 2006 for review). However, the impact of social context on self-reference remains unclear because of the unspecified and ambiguous referential tasks in previous neuroimaging studies. In the present fMRI study, we used two types of tasks: 1) the general referential task in which subjects should judge whether a trait word described the self (S), a same-gender friend (F), or a public person (P); 2) the specified referential task in which they should judge whether a trait is more descriptive for the S/F/P1 when comparing with F/P1/P2 (another public person in the same field). Relative to judgments about the public person, both referential and comparative judgments on the self induced stronger activation in the MPFC. Conjunction analysis further validated that the MPFC activity during self-referential categories is age-growing, and the role of associations during production processes is not yet understood. In the present study, we investigated the neurocognitive mechanisms of single word and sentence production influenced by semantic associations. We tested two groups of healthy subjects with fMRI by using a classical and an adapted version of the picture-word interference paradigm. Target-distractor pairs were either associatively related or unrelated. At single-word level, speech latencies revealed facilitation for associations. At the neural level, we identified increases in left fronto-temporo-parietal (IFG, MTG, IPL), right fronto-temporal, and bilateral occipital (MOG/LOG) regions. At sentence level, the behavioural data indicate a shifted effect, i.e. interference. The fMRI data highlight a mainly left-lateralised network in fronto-temporal regions (IFG, MTG) and an involvement of the Cingulate. The facilitation effect during single word production indicates an automatic spread of activation between related concepts at conceptual level. At the neural level, the signal changes might reflect a conceptual focus of semantic associations processing. In contrast, the interference effect at sentential level reflects a shifted effect from conceptual to lexical level. Furthermore, the IFG seems to be involved during conceptual activation. These findings support the view that associations take effect at conceptual as well as lexical level during speech production.

Preservative responding for brain-stimulation reward in prenatally stressed rats Daiichiro Nakahara Hamamatsu University, School of Medicine, Japan; Toshihru Suegama; Shuibo Gao; Yuki Masao

Prenatal stress (PS) may increase the risk of developing a propensity for cocaine addiction in adulthood. A previous study showed that PS in rats enhances the responsiveness to cocaine and propensity to relapse into taking cocaine during adulthood in self-administration experiments. We examined if PS alters the ability of acute and chronic cocaine administration to increase and decrease the rewarding effectiveness of the medial forebrain bundle (MFB) using intracranial self-stimulation (ICSS). We also examined whether PS affects the extinction of the MFB stimulation response. Adult male offspring of female rats that received PS or no PS (nPS) were implanted with MFB stimulating electrodes, and were then tested in ICSS paradigms. ICSS thresholds, when tested immediately after injection, increased dose-dependently in all rats. However, there were no differences between groups in sensitivity to the rewarding effects of MFB stimulation itself and in the threshold-lowering effects induced by acute cocaine administration. On the other hand, reward thresholds, when ICSS testing occurred 24 hrs after daily drug administration over ten consecutive days, had a trend toward an increase in all rats. However, there was also no difference in the threshold-elevating effects of chronic cocaine administration between PS and nPS rats. Nevertheless, PS rats exhibited a higher resistance to the extinguishing of the response for brain-stimulation reward when acutely treated with cocaine, as compared to extinction without cocaine treatment. The results suggest that PS may increase perseverance of a response that is unrewarded under cocaine loading in adult rat offspring.

Hemispheric differences, information processing and event rate in sustained attention performance Alpana Paul Ewing Christian College Alld, India

The study examined the differences between hemispheres with regard to information processing capacities at low and high event rate conditions. 80 right-handed PG students, aged between 20 and 25 years, served as subjects. Successive and simultaneous discrimination type vigilance tasks were used. The exposure time was 100msec/signal. 15 and 30 signals were used for low and high event rate conditions, respectively. Targets were interspersed at the mean rate of one target/minute for both event rate conditions. Subjects’ task was to detect the target stimuli and no response was required for non-target stimuli. The design was a 2 (visual field: right and left) x 2 (vigilance task: successive and simultaneous discrimination type) x 2 (event rate; low and high) x 3 (time period; three blocks of 15 minutes) mixed factorial, with repeated measures on the last factor. Hits, false alarms, d’ (sensitivity) and B (criterion) were used as dependent measures. ANOVA showed all the main effects as significant. Higher d’ scores were found in right hemisphere than in left hemisphere candidates. Similarly, simultaneous discrimination and low event rates yielded higher d’ scores than successive discrimination and high event rate conditions. Results also revealed that the vigilance decrement in perceptual sensitivity in the successive discrimination task was greater for right hemisphere than for left hemisphere. For the simultaneous discrimination task, no hemispheric differences in decrement were found. The result demonstrated that each hemisphere possesses a capacity for sustained attention but its involvement may depend upon the exigencies of stimulus material, task parameters and other variables.

Changing fear: From animal models to race attitudes Elizabeth Phelps New York University, United States of America

Animal models of fear learning provide a basis for understanding human fears. This research has demonstrated that the amygdala is necessary for the acquisition, storage and expression of fear learning. In this talk I will explore how the neural mechanisms identified in animal models are consistent with human brain function and extend this research to the complex learning situations more typical of human experience. Specifically, I will first describe how the mechanisms of simple associative fear learning extend to the social acquisition of fear in humans. I will then focus on how fear, once acquired, can be diminished. Extinction and emotion regulation, techniques adapted in cognitive behavioural therapy, can be used to control fear via inhibitory signals from the ventromedial prefrontal cortex to the amygdala. One drawback of these techniques is that fears are only inhibited and can return. A more lasting means to control fear may be to target the fear memory itself through influencing reconsolidation. I will present evidence suggesting that the behavioural interference of reconsolidation in humans persistently inhibits fear and diminishes involvement of the prefrontal cortex inhibitory circuitry.

An eye-tracking study of learning from science text with concrete and abstract illustrations Patrik Pluchino University of Padova, Italy; Lucia Mason; Nicola Ariasi; Maria Caterina Tornatora

Most learning in school and academic contexts is based on successful text comprehension. This study investigated both on-line process of reading and off-line learning from an illustrated science text. To extend current research, we examined the effects of using a concrete or abstract picture to illustrate a text and adopted eye-tracking methodology to trace text and picture processing. Fifty-nine 11th graders (age: M=16.4 years, SD=4.6) were randomly assigned to three reading conditions to learn about the inclined plane: text only, text with a concrete illustration, and text with an abstract illustration in a pre-test, immediate, and delayed post-test design. Multiple basic and finer-grained eye-fixation indices were considered. Results showed that the text illustrated by either the concrete or the abstract picture led to better learning than the text alone. In addition, the eye-fixation data revealed that the abstract illustration promoted more efficient cognitive processing of the text. Analyses of the gaze shifts between text and illustration and vice versa documented that the readers of the text with the abstract illustration made a greater effort to integrate verbal and pictorial information. Furthermore,
The results showed that there is significant relationship between attitude towards gossip and personality characteristics of conscientiousness and agreeableness. In addition, negative affect had a significant correlation with the attitude towards gossip. These finding offer multiple directions for further research.

Behavioral adaptations: Neuronal mechanisms and implications
Olga Svaram Institute of Psychology RAS, Russian Federation
Living organisms demonstrate amazing ability to adapt to changing environmental demands throughout their lifetime. These behavioral adaptations (or learning) are underlined by changes in neuronal activity. Not all of the neurons are involved in this process. In our work we investigated the mechanisms of such neuronal selectivity related to different phases of the instrumental learning in rats. This learning was shown to induce changes in neuronal gene expression and, at the same time, to produce development of behavior-specific neuronal activity. However, the number of neurons involved in the process of gene expression changes after learning substantially exceeded the number of neurons that demonstrated task-related firing properties. At the same time, we observed changes in neuronal gene expression earlier than the first correct trial of the newly formed behavior occurred. We also found that the neuronal gene expression changes were proportional to the number of testing trials that were based on previously learned behavior, but not to the number of trials based on newly learned behavioral acts. Neuronal gene expression changes were observed in those neurons that were involved in the acquisition of the previous experience. All these findings imply that acquisition of the appropriate adaptive behavior is based on the selection from the tested behavioral trials which are accompanied by pre-existing memory modifications. The study is supported by RFHS 10-06-00939a, RFBR 12-06-00363a and SC-3010.2012.6.

Investigating the relationship between cortisol, sleep architecture and memory consolidation in an attempt to explain the content of dreams
Ridwana Timal University of Cape Town, South Africa; Kevin Thomas
This study aimed at measuring the short term effects of a single dose of oral glucocorticoids on memory, sleep and dreaming in healthy adults. Stress levels of cortisol have been associated with impaired episodic memory performance and sleep-dependent consolidation thereof. Participants (N= 24) were randomly assigned to 2 demographically-matched groups using a placebo-controlled, double-blind design. Baseline performance of verbal, episodic and procedural memory was measured within 15 minutes of oral intake of 25 mg of Prednisone or placebo equivalent. Participants were retested in the morning, with sleep as the independent variable and cortisol as the moderator variable. The direct effects of prednisone on other declarative memory were mediated by cortisol as the moderator variable. The direct effects of prednisone on other declarative memory were mediated by cortisol as the moderator variable. The direct effects of prednisone on other declarative memory were mediated by cortisol as the moderator variable. The direct effects of prednisone on other declarative memory were mediated by cortisol as the moderator variable. The direct effects of prednisone on other declarative memory were mediated by cortisol as the moderator variable.
Embodied neuroeconomics: A new approach in neuroeconomics
Zeng Wang Hebei Normal University, China
In real social life, the signals sent by the body and the physical presence of others influence the way we act and decide. In economic theory they do not. Embodied neuroeconomics rejects traditional views that economic decisions are only based on the brain, independent of the body for perception, action, posture, bodily states, and so on. In this essay, we review the development of embodied neuroeconomics: An approach to neuroeconomics that takes into account how information provided by the entire body and its coordination dynamics influences the way we make economic and social decisions.

The dissociation pattern of activity in dorsolateral prefrontal cortex during a parametric working memory paradigm in first-episode treatment-naive schizophrenia
Xiang Wang Central South University, China; Zhao- hui Fei; Shuqiao Yao; Xiaosheng Wang; Tingting Sun; Weijun Situ
Both hypo- or hyperactivation of discrete cortical regions in schizophrenia were shown by previous neuroimaging studies of working memory (WM). The aim of this study was to examine neural function changes at different WM loads to derive a more complete picture of WM dysfunction in first-episode, treatment-naive schizophrenia. We used an event-related parametric fMRI paradigm to test WM function at four distinct loads, which was a modified version of Wolf and Walter's WM Paradigm (2005). Thirty-five schizophrenia patients and 20 matched healthy controls were scanned in 3.0 T MRI scanner. Schizophrenic patients were generally slower and load-dependently less accurate than controls. Both groups showed WM load-sensitive responses in a widespread fronto-parieto-occipital network. However, schizophrenic patients showed significantly less activation of left dorsolateral prefrontal cortex (DLPFC) (BA 9/46) during all cognitive loads, whereas they showed higher activation in right DLPFC (BA 9) with moderate cognitive loads (load 2 and 3). We report dissociation between the left and right DLPFC during a parametric WM paradigm in first-Episode, treatment-naive schizophrenia. The underactivation of left DLPFC may be attributable to patients' deficit of executive function, for which they could not focus and allocate neural resources at task-appropriate levels effectively. However, the hyperactivation of right DLPFC may represent a compensatory strategy to recruit more neural resources for the executive dysfunction. This research was supported by NSFC (30700236).

Decoding truthful answers from the human brain
Zhi Yang Institute of Psychology, Chines, China
Men lie for various reasons, hiding their actual thoughts, which cognitive neuroscientists are eager to read using neuroimaging techniques, yet, they have to date not reached a clear-cut conclusion. Whereas most studies have compared the brain response between honest and deceptive answers, here we directly examined whether the truthful answers for yes-no questions (polar questions) about simple facts (in Experiment 1) and autobiographic information (in Experiment 2) can be decoded from the spatial patterns of BOLD-fMRI signals. With a task-cueing paradigm and multivariate pattern searchlight analysis, we found a set of regions in which the truthful answers could be decoded with 100% accuracy in all participants, and group-level accuracy achieved 84% in the left middle frontal gyrus. Further cross-condition classifications revealed a unique region in the left middle frontal gyrus in which the truthful answers could be decoded accurately regardless of honest/ dishonest intentions. Importantly, the role and the location of this region were robust across participants and were independent of stimuli modalities and types of questions. The finding of this "honest" region points to an alternative approach for fMRI lie-detection as well as brain-computer interface.

Maternal deprivation-induced depressive-like behaviours
Xiongzhao Zhu Medical Psychological Institute, China
To study aims to investigate the role of hippocampal microRNA let-7a on depressive-like behaviours induced by maternal deprivation and chronic unpredictable stress in rats. Eighteen newborn rats were randomly divided into three groups, maternal deprivation group (MD), chronic unpredictable stress group (CUPS), and control group (C). MD received maternal deprivation, CUPS received chronic unpredictable stress when ten weeks old, and Control received no experimental handle. The forced swimming, sucrose consumption and Open field tests were carried out. The float time in the forced swimming test, Sucrose preference rate in the sucrose consumption test and the crawl distance in the Open field were used to be indices of rats' depressive-like behaviour. Rats were decapitated after behaviour tests, and hippocampus samples were rapidly collected. The expression levels of microRNA let-7a in hippocampus were detected by Real-Time PCR. Both experimental groups were different from the control group on the floating time, the sucrose consumption rate and the crawl distance. There were significant group differences between MD and CUPS on the floating time, the sucrose consumption rate and the crawl distance. The lever of let-7a in the hippocampus in MD, CUPS were 25.21 and 0.12 times more than that of the control group respectively. Both the maternal deprivation and chronic unpredictable stress could induce depressive-like behaviours. The down-regulation of let-7a in rats' hippocampus may be associated with the maternal deprivation-induced depressive-like behaviours but not in chronic stress.

Odour evoked autobiographical memories recruit less strategic and more affective brain areas than memories evoked by words
Arin Arshamian Stockholm University, Sweden; Han-Seok Seo; Jonas Persson; Maria Larsson; Emilia Iannilli; Thomas Hummel; Johannes Gerber; Johan Willander
Behavioural evidence indicates that odour evoked autobiographical memories (OEMs) are older, more emotional, less thought of, and induce stronger time travelling characteristics than autobiographical memories (AMs) evoked by other modalities. The overall aim of this study was to explore the neural underpinnings of AMs evoked by odours. Participants were screened for specific OEMs and later presented with the odour memory cue and its verbal referent in an fMRI paradigm. At the same time as OEM was retrieved across both cue for- mats (odour and word), potential cue-dependent brain activations were investigated. The overall results showed that odour and word-cued OEMs
The processing of intensity of vocal emotion: ERP evidence

Xuhai Chen School of Psychology, Sunnu, China; Yufang Yang

The effect of different intensities of vocal emotion on event related potentials has yet not been studied. We therefore recorded EEG for neutral and happy voice which varied graduually and continuously in emotion intensity while 16 healthy participants listening to these voices and performing emotion-type (explicit) or sound-type (implicit) decision. The result indicated that neutral and happy voice can be differentiated on a P2 component under both explicit and implicit condition. Moreover, the peak latency and amplitude of P2 were linearly correlated with the rate of happiness, suggesting a graded processing of vocal emotion in the early stage. However, the brain distinguished neutral from happy in the P3 interval only when performing explicit task and exhibited a categorical feature. These results are consistent with the multistage model of vocal emotion processing and suggest that emotion intensity might be an important factor in vocal emotion study.

Use of cannabis enhances inhibition of return

Laura Esteban Garcia University of Almeria, Spain; Margarita Moreno; Angeles F. Estevez; Pillar Flores; Laura Esteban; Ana B. Vives

We conducted an experiment to study the temporal course of inhibition of return in users of cannabis. Twenty-five cannabis users who self-reported a regular frequency of cannabis use in joints per month, and twenty-six drug-free controls participated in the study. We employed a typical inhibition of return task with a single cue, and manipulated the time interval between the onset of the cue and the target (150, 350, 550, 1500 and 2550ms). Participants were asked to detect the onset of the target, regardless of its location. The group of cannabis users showed a significantly greater overall inhibition relative to the group of non-users. Furthermore, inhibition of return appeared earlier (at the 350 ms cue-target interval) in the user group. This is the first study to show that attentional inhibition is enhanced in cannabis users. More research is needed to determine whether greater inhibition represents an advantage or disadvantage for visual search performance of cannabis users.

Intelligence - a review of concepts

Marcos Cavalcante Faculdade Integrada Tiranentes, Brazil; Fernando Albuquerque; Gabriela Moura

I always thought of Homo sapiens as the only species endowed with intelligence and that other animals possess only innate instincts, learned behaviours and conditioning and that their actions were merely mechanical responses to the environment that provided them with incentives to do so. According to Ferreira (2008) intelligence is the faculty or capacity to learn, understand, adapt, and possess mental skill or insight. By this definition, a wide variety of species is placed in context. According to Haward and Gardner, there are seven known types of intelligence. According to neuroscience, intelligence is related to the development of the central nervous system, specifically with the complexity of the brain. There are animals that solve problems using systems that resemble those of humans. The concept of intelligence along with studies in Neuroscience and Psychology, has brought about a new vision to show that humans are not the only ones endowed with this ability. Studies with animals in their natural habitat show that all the inherent attributes of intelligence so far seen in the human animal, are also observed in other animal species.

Long-term odour and face recognition as a function of familiarity

Stina Cornell Kamekull Stockholm University, Sweden; Sverker Sikstrom Stockholm University, Sweden; Johan Willander; Maria Larsson; Fredrik Jonsson

This study investigated episodic recognition memory for odours and faces in the long-term as a function of familiarity. Eighty-three subjects (43 women, 40 men) encoded familiar and unfamiliar odours and faces and memory, and were assessed on four occasions: immediate, 4, 16 and 64 days after encoding. The results showed low recall of odours and faces across time, higher overall recognition memory for faces rather than for odours, better retention for familiar rather than unfamiliar information, and no influence of gender on memory performance. In addition, hit rate performance was positively associated with naming ability at encoding, although the relationship was much less pronounced for faces than for odours. Interestingly, the decline in odor memory was primarily driven by an increment in false alarm rates over time. This observation indicates that episodic retention of olfactory information is susceptible to the passage of time. This work is supported by the Swedish Research council to ML.

Issues of obtaining informed consent from individuals with intellectual disabilities

Marlon Danilewitz University of Ottawa, Canada; Robert Lorenz

Advancements in neuroscience have the potential to improve the functional capabilities and lifestyle of individuals with intellectual disabilities and their families, but this requires their participation in clinical trials, which mandates transparent and real informed consent from this vulnerable population. While there is an absence of medical studies involving this population as subjects, there have actually been a burgeoning number of social research studies involving this population. However, there has been a paucity of research examining the actual practice of obtaining informed consent in this population. Seven social researchers and institutional review board (IRB) members were interviewed regarding their experience with research involving this population. Moreover, an analysis of the consent methodologies of 21 studies, published in the last 20 years, involving social research with this population was conducted. There is a wide variety of methods employed in eliciting consent for research from individuals with intellectual disabilities and a paucity of clear information provided by studies, as to how consent for research was obtained. Moreover, there is a broad range of opinions amongst and requirements set by institutional review boards regarding research involving this population. These findings press the need for transparent, meaningful and standardised consent methods involving this population. Furthermore, there is resistance amongst IRBs to adopt alternative methods of acquiring consent, which seek to make the process more understandable for this population, for studies requiring full ethics review. This tendency unnecessarily forces studies to use surrogates in order to obtain consent from this population.

Maternal separation induces anxiety-related behaviour alterations, reversal learning and brain-derived neurotrophic factor expression in adult rats

Shao Feng Peking University, China; Xiaofang Xue; Weiwen Wang; Xiao Han

Early postnatal maternal and/or sibling separations can play an important role in the development of psychopathologies during ontogeny. In the present study we investigated the effects of repeated maternal and sibling separations (MS) that lasted for 3h/day during postnatal days 1–21 on locomotor activity and anxiety-related behaviors in Wistar rats using the open-field, spatial learning, and the reversal learning in the Morris water maze tests. Moreover, we examined the effects of MS on brain-derived neurotrophic factor (BDNF) protein expression in the medial prefrontal cortex (mPFC), nucleus accumbens (NAC), central amygdala nucleus (CeA), and the hippocampus. We found that repeated MS produced an anxiety-like profile (more time in the center of open-field), impaired reversal learning performance in the Morris water maze, and decreased BDNF protein expression in the mPFC and CeA. The present study enhances our understanding of the neurobiological and behavioral consequences of repeated episodes of MS in rats.

Hemispheric asymmetry reduction in prefrontal cortex at high working memory load and training-related changes in aging

Stephan Heinzel Charité Berlin, Germany; Quynh Lam Duong; Sabrina Saase; Juergen Gallinat; Michael Rapp; Laura Oliveras; Wolf-R. Brockhaus; Robert Lorenz

Recent studies in working memory, employing functional Magnetic Resonance Imaging (fMRI),...
have suggested recruitment of additional brain areas in the contralateral hemisphere in older, compared to young, subjects at high difficulty levels. In this study we tested hypotheses derived from the hemispheric asymmetry reduction in older adults (HAROLD) model and investigated the training-related changes at high vs. low difficulty levels. 34 healthy older participants were randomly assigned to training (N=16) or control group (N=18). Additionally, 18 healthy younger controls were included. The training group participated in a 4-week adaptive n-back working memory training (12 sessions). All subjects participated in one fMRI session while performing the n-back task at 4 different memory load conditions. All older subjects also conducted a second fMRI session after the training/waiting period. At high working memory load, fMRI analyses indicate a stronger recruitment of right lateral PFC and right inferior parietal cortex (IPC) in older compared to younger subjects (p<.001). After training/waiting period, neural activation in right lateral PFC, and right IPC was reduced only in the training group, not in the old control group (p<.001) when comparing high vs. low difficulty levels. In line with the HAROLD model, our results indicate that older subjects recruit additional areas in the contralateral hemisphere to cope with age-related neural decline. The findings of reduced right lateral PFC and right IPC activations in older adults after training support the view of a training-related increase in processing efficiency of working memory networks.

**COMT genotype affects training-related improvement in working memory in aging**

Stephan Heinzl; Charite Berlin, Germany; Andreas Heinz; Michael Rapp; Johanna Onken; Stefanie Schulte; Juergen Gallinat

Evidence from recent studies in older subjects, indicates that age-related decline in working memory performance are related to decreases in dopaminergic neurotransmission. In carriers of the val/val genotype of the enzyme catechol-O-methyl-transferase (COMT), a substantial decrease in dopaminergic neurotransmission. In carriers of the val/val genotype, individuals produce more false recognitions. However, little is known regarding the effect of emotion and long retention intervals on false memories. The current functional magnetic resonance imaging study enrolled young and older adults and presented both negative and neutral scenes (from the IAPS) during encoding. A yes/no recognition task was given at 3 subsequent sessions (S1: immediate; S2: one-week; S3: three-weeks). Although the proportion of emotional hits was higher than neutral hits, this effect vanished when correcting for false alarms (FA). The older adults produced more FA than the young, and this difference was more pronounced for negative items. Furthermore, within the older group, the rate of negative FA increased over time. Focusing on the older group, comparison of brain activity (negative hits vs. negative FA) at S2 and S3 revealed that hits elicited more activity in the left hippocampus, posterior cingulate and lateral occipito-temporal areas, which have been previously linked to recollection of detail information. Moreover, we showed differential activity along the posterior-anterior axis of the left lateral temporal cortex with more activity for FA in the posterior part and more activity for hits in the anterior part. This finding may reflect a semantic gist gradient where posterior temporal areas process generic information and anterior areas unique information. Overall, our findings suggest that after long delays older adults base recognition more on general than specific information from negative scenes, which can more likely be grouped within categories, leading to an increased proportion of false recognitions over time.

**Brain correlates of the effect of negative emotion on false recognitions over time in older adults**

Gregoria Kalpouzos; Karolinska Institute, Sweden; Lars Backman; Hakon Fischer

With advancing age, individuals produce more false recognitions. However, little is known regarding the effect of emotion and long retention intervals on false memories. The current functional magnetic resonance imaging study enrolled young and older adults and presented both negative and neutral scenes (from the IAPS) during encoding. A yes/no recognition task was given at 3 subsequent sessions (S1: immediate; S2: one-week; S3: three-weeks). Although the proportion of emotional hits was higher than neutral hits, this effect vanished when correcting for false alarms (FA). The older adults produced more FA than the young, and this difference was more pronounced for negative items. Furthermore, within the older group, the rate of negative FA increased over time. Focusing on the older group, comparison of brain activity (negative hits vs. negative FA) at S2 and S3 revealed that hits elicited more activity in the left hippocampus, posterior cingulate and lateral occipito-temporal areas, which have been previously linked to recollection of detail information. Moreover, we showed differential activity along the posterior-anterior axis of the left lateral temporal cortex with more activity for FA in the posterior part and more activity for hits in the anterior part. This finding may reflect a semantic gist gradient where posterior temporal areas process generic information and anterior areas unique information. Overall, our findings suggest that after long delays older adults base recognition more on general than specific information from negative scenes, which can more likely be grouped within categories, leading to an increased proportion of false recognitions over time.

**The gluten-brain connection: How allergies can lead to mental illness, a case study**

Hannelie Kemp; Learning and Hearing Centre, South Africa

In conventional medicine, and psychiatry, there is no real understanding of the causes of mental illness and the commonly used treatments with sedatives, stimulants, electro-shock psychotherapy, are purely symptomatic (Last, W. - Mental Illness). Unlike the heart, which visibly beats, we cannot see the brain work. When thoughts are disturbed for reasons that are not apparent we tend to blame the thinker (Gershon, M.D. The Second Brain). New evidence has been accumulating which shows food as the causative factor in mental illness. Hidden allergies may lead to prolonged periods of brain irritation, which will lead to uncontrollable excitement, anger, thought dissociation and mental abnormalities. This study follows a patient’s journey to the discovery of the causes of her mental illness as well as the solutions.

**Breathe well, be well: Using the body to control the brain**

Hannelie Kemp; Learning and Hearing Centre, South Africa

According to Corydon Hammond (2005:105), a robust body of neurophysiological research exists which indicates that functional brain abnormalities are associated with depression, anxiety and obsessive-compulsive disorder. Strong evidence also indicates that there are functional brain abnormalities associated with panic disorder and post-traumatic stress disorder. Biofeedback seems to hold promise as a methodology for retraining breathing patterns which directly control anxiety states.
neural basis of deception by finding brain regions in which deception-related activity is not influenced by the truthfulness of presented sentences. Twenty-nine right-handed healthy volunteers participated in this study. During two deception conditions (lie – answer yes, lie – answer no) and two truth conditions (true – answer yes, true – answer no), subjects were presented with 120 written sentence matching their memories in one half and non-matching in the other. fMRI results showed that several prefrontal, insular, and cerebellar areas were more active during deception conditions compared to truth conditions. However, most of those areas were also more active during "no" conditions compared to "yes" conditions. The deception-related activity, not confounded by the truthfulness of presented sentences, was found only in cerebellar vermis. The results suggest that activity in cerebellar vermis should be considered as a reliable marker of deceptive behaviour.

Anhedonia and impairment of cognitive flexibility: Correlation with decreased ERK signalling in mPFC following chronic unpredictable stress

Weiwen Wang Institute of Psychology, CAS, China; Wenjuan Lin; Xiaoming Luo; Shao Feng

The impairments of cortical-mediated cognitive flexibility are increasingly recognized as major components of depression. Until now little was known about the molecular mechanisms underlying the stress-induced impairments of cognitive flexibility. The present study aims at investigating the role of prefrontal ERK expression in the changes of cognition and emotion induced by chronic unpredictable stress. Wistar rats were randomly divided into stress (n=8) and control (n=8) groups. The stress group received chronic unpredictable stress for 14 consecutive days, and the controls were stress-free. After stress, rats were tested in a sucrose preference test and an attentional set-shifting test (AST). The expression of ERK 1/2 and phospho-ERK 1/2 (pERK 1/2) in medial prefrontal cortex (mPFC) and orbitofrontal cortex (OFC) were determined using Western Blotting. The rats exposed to chronic stress showed decreased pERK 1/2, and ERK 1/2 protein expression in OFC, as well as decreased pERK 1/2, and ERK 2 protein expression in mPFC. Chronic unpredictable stress induced the deficits of cognitive flexibility characterized by the impairments of simple discrimination (SD) and extra–dimensional shifting (ED) in AST. Furthermore, the trials of criterion in the ED stage was negatively related to ERK 2 and ERK 1/2 expression, in mPFC and OFC respectively. In addition, stressed rats exhibited a decrease in sucrose preference index, which was significantly related to pERK 1/2 level in mPFC. These results suggested that ERK signalling in mPFC might mediate both the deficits of cognitive flexibility and depressive-like behaviours induced by chronic unpredictable stress.
Session Type: Invited Addresses

Working memory and learning
Susan Gathercole MRC Cognition and Brain Science, United Kingdom

Working memory is now recognized as a vital cognitive system that supports learning, particularly during the childhood years. This lecture will provide an overview of the relations between working memory and other kinds of memory and executive functions, and evidence linking working memory with a range of aspects of academic attainment will be reviewed. The cognitive and behavioural characteristics of children with poor working memory skills will be described, and methods for minimizing the learning difficulties associated with working memory problems including both training and classroom interventions will be discussed.

Why do we dream?
Mark Solms University of Cape Town, South Africa

Sigmund Freud hypothesised that dreams protect sleep, and that they do so by fulfilling primitive wishes that arise during sleep. The discovery of the brain mechanisms of REM sleep (between the 1950s and 70s) cast considerable doubt on this hypothesis: REM dreaming occurs automatically in 90 minute cycles and it is generated by a ‘mindless’ part of the brainstem. This lecture will present findings which show that dreaming is not in fact identical with REM, that it does not occur automatically, and that it is generated by a part of the brain that is deeply implicated in ‘fulfilling wishes’. Recent findings will also be presented from an ongoing study which is directly testing the hypothesis that dreams protect sleep.

Session Type: Symposia

Symposium title: Neural bases of languages learning: Cultural and individual constraints
Convenor: Chuansheng Chen

Neural bases of language learning: Cultural and individual constraints
Chuansheng Chen University of California, Irvin, United States of America

Two decades of advances in neuroimaging technology have greatly improved our understanding of how language is processed in the brain. The language network has been clearly described, with specialised regions for tasks such as visual word processing, grapheme-to-phoneme conversion, and semantic analysis. With increasing knowledge of the language network, researchers have begun to realise that there are extensive individual and group/cultural differences in language processing. For example, research has documented differences in neural bases of different scripts (logographic vs. alphabetic scripts), orthographies (transparent vs. nontransparent orthographies), and tonality (tonal vs. atonal languages). Similarly, more and more studies have identified neural correlates (in terms of both function and structure) of systematic individual variations in language processing. In this symposium, we present the recent research on these topics from a couple of labs. In the first presentation, Dr Gui Xue and colleagues from Beijing Normal University, China, will discuss how orthography (opaque vs. transparent) significantly modulates the neural pathway of reading and shapes the behavioural and neural strategies in learning a new language. In the second presentation, Dr Patrick Wong of Northwestern University, USA, will present his recent work on neurogenetic, neuroanatomical, neurophysiological, perceptual, and cognitive correlates of second language speech learning. In the third presentation, Dr Chuansheng Chen and colleagues from the University of California, Irvine, USA, will describe their recent findings of functional and structural correlates of native, second, and artificial language learning.

Individual differences in language learning: Evidence from artificial language and native language
Chuansheng Chen University of California, Irvin, United States of America; Lilei Mei; Mingxia Zhang

In this presentation, we will briefly review the current literature on individual differences in neural bases of language learning, and present new data on functional and structural predictors of language learning (native, second, and artificial languages). We will use data from several artificial language training studies and one large-scale gene-brain-behaviour study. Based on artificial language training data, we will show that learners who rely more on the regions in the native language network would learn the artificial language better. For example, for visual word learning, greater neural activity in the left fusiform cortex (a key region for visual word form processing) during initial learning is associated with better learning performance and better long-term maintenance. Similarly, for auditory word learning, the neural activities in regions in linguistic network (e.g., the left posterior STS) are positively predictive of learning outcome. Analysis of structural data also identified neural correlates (e.g., fusiform areas) of individual differences in reading abilities. Discussion will focus on the implications of these results to our understanding of neural bases of language learning and interventions for individuals with reading difficulties.

Session Type: Invited Symposium

Symposium title: Eye-tracking studies on reading different languages
Convenor: Prakash Padakannaya

Oculomotor correlates of dysorthography
Piotr Francuz KUL, Poland; Aneta Borkowska

The object of this study was to search for oculomotor correlates of dysorthography. The hypothesis that the parameters of eye movements of dysorthographies (DYS) in the control (CTRL) subjects will be different when reading words that contain orthographic difficulties, was verified. Two experiments were conducted. In the first experiment, subjects (DYS = 32 and CTRL = 19) evaluated the accuracy of spelling 42 words in Polish (21 correct and 21 incorrect). The words belonged to four categories of orthographic difficulties, displayed on an LCD monitor. Eye movements, the RTs and accuracy were recorded. For use in the second experiment, a set of 32 artificial words (strings of 7-8 letters), which also contained letters belonging to four categories of orthographic difficulties were created. Subjects (DYS = 30 and CTRL = 19) learned the new words and then performed a test verifying the learning outcomes. During the test, eye movement, the RTs, and accuracy, were also recorded. Two three-way ANOVAs were conducted. It was found that the DYS subjects needed more time to recognize words; their interpretation was often incorrect; they had more points of fixation, longer amplitude of saccades and, they fixed their sight outside the words more often than those of CTRL. Differences between the categories of orthographic difficulties were also found. In light of the results, dysorthography is seen as a selective disorder of oculomotor activity associated with reading.

Individual differences in second language speech learning
Patrick Wong Northwestern University, United States of America

Speech sounds and phonological grammar are two aspects of second language (L2) that are notoriously difficult to learn. Both theoretical and applied lines of inquiry ranging from a focus on the nature of linguistic representation, to the application of effective L2 pedagogy, have generally been informed by data from learners as a group. Such group-driven approach often fails to explain why speech learning shows high variability in learning success, which in turn poses challenges to both theory and practice. In this talk, I present data from my research group that capitalise on individual differences in speech learning. We ask how variability in learning success can be predicted by neurogenetic, neuroanatomical, neurophysiological, perceptual, and cognitive characteristics internal to the learners. We then test how such predictors can be used to place learners into the most optimal training paradigms for them, considering factors that are associated with the cognitive and perceptual demands of the training. These series of initial experiments lead to our hypothesis of Personalised Learning. I will discuss the components of Personalised Learning and preliminary strategies for testing the hypothesis.
Culture shapes the neural pathway of reading

Gui Xue Beijing Normal University, China; Qi Dong

Reading is an integral part of life in today’s information-driven societies. Due to the relatively short history in the evolutionary time-scale, it is generally believed that the human brain is unlikely to have engineered a specialised module for reading. Instead, the reading network might be developed through years of experience and be constrained by both the characteristics of a specific writing system and the functional organisation of our neural system. On the other hand, the design principles of writings, such as Chinese and English, vary significantly across different language systems, including the visual form, the depth of orthography, as well as the form-semantic mapping. These vast differences across these languages should both reflect and contribute to historical cultural differences in human mind. Nevertheless, the neural mechanisms of this cultural effect have not been well understood, largely due to the methodological constrains. In this talk, I will mainly discuss the results from our cross-culture studies using functional imaging and artificial language training. These results provide clear evidence that suggest that whereas the visual form has relative small effect on the reading network, the depth of orthography (opaque vs. transparent) significantly modulates the neural pathway of reading, and also shapes the behavioural and neural strategies in learning a new language. These results not only help to delineate the neural substrates underlying language processing and learning and their dynamic changes (plasticity) as a function of language experiences, but might also inspire brain-based behavioural and neural interventions that could potentially facilitate language learning and language education.

Symposium title: The role of human basolateral amygdala in cognition, emotion and social behaviour

Convenor: Jack Van Honk

Hyper-vigilance for fear after basolateral amygdala damage in humans

David Terburg University of Cape Town, South Africa

Recent rodent research has shown that the basolateral amygdala (BLA) inhibits unconditioned, or innate, fear. It is however unknown whether the BLA acts in similar ways in humans. In a group of five subjects with a rare genetic syndrome, i.e. Urbach-Wiethe disease (UWD), we used a combination of structural and functional neuro-imaging, and established focal, bilateral BLA damage, while other amygdala sub-regions are functionally intact. We tested the translational hypothesis that these BLA-damaged UWD-subjects are hyper-vigilant to facial expressions of fear, which are prototypical innate danger cues in humans. Our data repeatedly show this fear hyper-vigilance in UWD-subjects. UWD-subjects show hyper-vigilant responses to unconsciously presented fearful faces in a modified Stroop task. They furthermore attend longer to the eyes of dynamically-displayed fearful faces in an eye-tracked emotion recognition task, and in that task recognise facial fear significantly better than control-subjects. These findings provide the first direct evidence in humans that the BLA inhibits the brain’s fear vigilance system, which has important implications for the understanding of the amygdala’s role in the disorders of fear and anxiety.

Altruism after basolateral amygdala damage

Jack Van Honk University of Cape Town, South Africa

It is proposed that instrumental and impulsive behaviours jointly underlie economic human decision-making. Rodent models suggest that the basolateral amygdala (BLA) sub-serves instrumental behaviours, while the central-medial amygdala (CMA) sub-serves impulsive behaviours. If these rodent amygdala models hold relevance for the human brain, instrumental choice in social-economic decision-making might depend upon the human BLA, while impulsive-driven e.g. altruistic decisions depend on the human CMA. Here we show that, compared to control subjects, humans with focal bilateral damage to the BLA - and a functional CMA - invest substantially, that is, near to 100% more money, in unfamiliar others in an economic trust game. Moreover, we establish that these generous investments are altruistic in nature, as they are not replicable on the basis of risk-taking preferences or social naivety, and they were done in the absence of any expectation of fair return. In sum, our data show that economic decision-making shifts from instrumental to altruistic after focal damage to the human BLA, which agrees with rodent models of BLA function.

Conscious and non-conscious perception of interactive bodily emotion expressions and the amygdala nuclei

Jack Van Honk University of Cape Town, South Africa

The amygdala is known to be an important structure in brain networks processing emotional signals. But many questions remain concerning its role in different types of emotional signals and the influence of attention or awareness and the influence of amygdala on emotion triggered adaptive action. We have shown previously that using whole body images rather than isolated facial expressions is particularly useful for bringing these non-verbal aspects to the foreground. We have recently extended investigations of bodily perception to perception of bodily interactions. This contribution will present new findings obtained with clinical groups suffering from schizophrenia, anxiety disorder or selective deficit of self recognition.

The role of human basolateral amygdala in cognition, emotion and social behaviour

Jack Van Honk University of Cape Town, South Africa

Anatomical research in rodent and primates has established that the amygdala is a heterogeneous complex, with structurally and functionally distinct subdivisions. Furthermore, animal lesion and pharmacological inactivation studies have given insight in the differential functions of the amygdala sub-regions, and have shown specifically that the functions of the basolateral amygdala and the central-medial amygdala are partly antagonistic. Unfortunately, because the possibility to image sub-regions of the human amygdala is a recent development and focal bilateral lesions of amygdala sub-regions in humans are very rare the functions of human amygdala sub-regions remain poorly understood. This symposium breaks new grounds by presenting the work of researchers from South Africa, the Netherlands, and England on the effects of focal basolateral amygdala damage on human cognition, emotion, and social behaviour (fear processing including eye-tracking, emotional body perception, working memory, risk taking and social economic behaviour). The data will be presented by Barak Morgan, University of Cape Town; Bea de Gelder, University of Tilburg; Chris Eisenegger, Cambridge University; and David Terburg, University of Cape Town. These data not only provide unique new insights into the role of basolateral amygdala in human cognitive and affective behaviour, but also provide the first translational evidence as the findings fit very well within recent sophisticated models of rodent basolateral amygdala function and promise to throw new light on clinical populations.
Assessing the utility of a peace promotion intervention for early childhood development centres (ECD) in a low-income community in South Africa
Toni Abrahams UNISA, South Africa; Natasha Hendricks; Rodney Eksteen
The need for peace promotion amongst South African children is rooted in the widespread exposure to violent conflict resolution. Peace education is one tool used to equip children with skills to resolve conflicts peacefully. Evidence for early aggression as a strong predictor of later violence, necessitates early, and developmentally appropriate, interventions that focuses on preschool children. Piloting such interventions is important to address issues such as acceptability, compliance, delivery, recruitment and retention. Accordingly, this paper describes the piloting of a peace promotion intervention amongst preschool children in ECD centres in a low-income community in South Africa, and considers its utility for the aforesaid context. The intervention comprised of teacher training and implementation of an adapted version of the Peacemaking Skills for Little Kids curriculum. Teacher training focused on factors conducive to peaceful classroom environments. Through structured lessons, the curriculum aimed to teach social and emotional competence core to the development of peacemaking skills. Ten teachers working in four ECD centres in Joe Slovo Park, Johannesburg received training to deliver five 45-minute lessons to 80 children aged 4–6 years, over the course of five weeks. Logistical and methodological issues were identified using process evaluations and preliminary data analysis. Pre- and post-assessment was conducted using the Preschool and Kindergarten Behaviour Rating Scale Second Edition. The data is currently being analysed, and will be detailed in the presentation. The findings will be used to inform refinements and adaptations for an intervention that is culturally and contextually congruent for South Africa and similar settings.

Global developments in the science and practice of peace psychology
Daniel Christie Ohio State University, United States of America
The growth in the number of citations of ‘peace psychology’ during the past four decades is well documented. Accordingly, the current presentation will delineate the scope of this emerging field and situate the science and practice of peace psychology within geo-historical contexts around the world. The recent growth of peace psychology in developing parts of the world has enlarged the scope of the field to include not only the problem of violent episodes, but also that of structural violence, which kills people albeit slowly through the deprivation of human need satisfaction. Generally, peace psychology in the global north tends to focus on the prevention and mitigation of violent episodes while structural violence is focal in the global south. More specifically, three waves of research and practice in the West can be delineated corresponding to inter-state conflicts, intra-state cycles of violence, and post 9/11 work on terrorism. Meanwhile, peace psychology in south and south-east Asia has emerged with an emphasis on addressing some vestiges of colonial occupation; namely, the resolution of inter-communal divisions and democratization movements to dismantle authoritarian structures. Latin America has given rise to liberation psychology scholars and activists who frame problems within the context of oppressors and the oppressed and pursue theory and applications that directly improve the well-being of the oppressed. The presentation will document other geo-historical developments and conclude with an examination of the current status of theory and practice in peace psychology.

Conducting psychosocial work with Palestinian adolescents in the West Bank
Despina Constantinides Palestine Red Crescent Society, Occupied Palestinian Territory; Sarah Kamens; Bassam Marshoud; Fathy Flefel
This research study examined the effects of a psychosocial intervention for Palestinian adolescents living in the West Bank. We developed a questionnaire to assess well-being and used a cross-sectional cohort design to analyse the effects of the programme across four years post-intervention. Results supported the hypothesis that participating children exhibited higher questionnaire scores than a control group. However, results did not support a second hypothesis that psychosocial well-being would be lower in cohorts for whom more time had passed after participation. Specifically, the positive psychosocial effects of the programme were greater at one, three, and four years after the intervention, but not at two years post-intervention. We present these results alongside qualitative reports from participants. Together, our findings appear to support the effectiveness of psychosocial interventions for adolescents living in a zone of political instability. We also present possible interpretations for the drop in programme effectiveness at Year 2, including the impact of programme termination and cohort effects. The political background of the programme is discussed as one potential explanation for the findings, as Year 2 children participated in the programme against the turbulent backdrop of teachers’ strikes and violent civil infighting between Palestinian factions. In addition to the above study, we present some personal reflections on our experiences as practitioners and researchers working in a zone of ongoing political conflict. The changing political landscape in the region is discussed as a unique challenge to both research and practice in psychology.

Accounting for courage collusion and contradictions reflecting on the legacies of conscription into the Apartheid State’s military system
Theresa Edlmann Rhodes University, South Africa
The compulsory military conscription of white South African men into the Apartheid State’s military system between 1968 and 1993 has received increasing public attention in recent years. There have been arts exhibitions, a public call from the Anglican Archbishop in October 2010 for society to create healing spaces for conscripts to speak, a rapid increase in the publication of books on these issues and the restaging of a 1980s theatre production about a white soldier’s experiences in the apartheid military at the 2011 South African National Arts Festival in Grahamstown. Based on recently completed PhD research at Rhodes University into the psychosocial legacies of men’s conscription into the South African Defence Force, this paper will outline the major findings of the research. It will also give an account and some reflections on events at the 2011 Arts Festival as a key moment in emerging dialogues concerning the creation of spaces for healing conversations with veterans of an often forgotten and invisible war.

The relationship between universal cognition and attitudes toward the outgroup amid ethno-religious violence
Katrina Korb University of Jos, Nigeria
In ten years of ethno-religious violence between Christians and Muslims in Jos, Nigeria, more than 3,800 lives have been lost (Human Rights Watch, 2011). The ongoing cycle of violence has resulted in a highly segregated society with little interaction between Christians and Muslims. This atmosphere has substantially increased suspicion and stereotypes between the two religious groups. A mechanism by which stereotypes can be reduced is necessary to prevent further deterioration of the society. Universal cognition is selectively attending to and emphasizing the similarities between the self and diverse others (Phillips & Ziller, 1997), as opposed to focusing on the differences between groups. Universal cognition has been proposed as a fundamental mechanism by which prejudice towards those in the out-group is reduced. The purpose of this study is to determine whether universal cognition is related to positive attitudes toward an out-group with whom one is engaged in violent conflict. A correlational research design was used. University students completed a questionnaire that assessed universal cognition as developed by Phillips and Ziller (1997), as well as other variables of interest including stereotypes, willingness to engage with the out-group, hope for harmonious co-existence in the future, and willingness to forgive. Pilot study results indicate that universal cognition has significant moderate correlations with attitudes toward the out-group. Therefore, peacebuilding efforts in Plateau State and other areas of violent conflict can include encouraging conflicting parties to focus on the similarities that they share with the out-group.

Rethinking military psychology
Donna Nassor NJ City University, United States of America; Ethel Tobach; Donna Nassor
The role of military psychologists in member nations of the International Congress of Psychology is variously differentiated and each of the different modes is examined. The particular mode in the United States is analysed as an example because of the influence the American Psychological Association has had in the formulation of other psychological associations around the world. Psychologists have an ethical obligation as healers to not engage in activities that expose subjects to gratuitous risk or harm. This paper examines how potentially dan-
gerous societally constructed labels of ethnicity, gender, religion, skin color and or power struggles to control natural resources might influence psychologists working for the military or other sponsoring organisation to ignore ethical doctrines. The application of more restorative and reparative methods could effectively assist psychologists in maintaining the responsibility of doing no harm in their efforts to address the physiological and mental health of veterans.

Socio-emotional competences and its relationship with disruptive behaviours in Mexican adolescents
Ruvalcaba Romero Norma Alicia University of Guadalajara, Mexico; Julia Gallegos Guajardo; Jose G. Salazar Estrada University of Guadalajara, Mexico
Emotional Intelligence Paradigms indicate that socio-emotional skills are a protective factor, versus the presence of psycho-pathological symptoms such as anxiety and depression in adolescents. Can these skills also prevent young people engaging in social risky behaviours such as criminal activity, violence or lawbreaking behaviour? To answer this question, we performed this study. Emotional Quotient Inventory Bar On Youth Version (EQ-i-YV: Bar-On & Parker, 2000) and Disruptive Behaviour Scale (Moral, 2011) were applied to a sample of 471 Mexican adolescents ranging in age between 12 and 16. The results were as expected. We found that involvement in fights, theft, gang activity and school dropout are negatively associated with socio-emotional skills, specifically with intra-personal competences (r = .141, p<.01), interpersonal competences (r = .250, p<.001), stress management (r = .355, p<.001) and mood (r = .245, p<.001). In analysing the demographic data of participants, we find that men have greater involvement in risky behaviours, likewise observed that the father’s educational level shows a slight correlation with participation in disruptive behaviours. Finally, we found that in the absence of a father figure, teens have a greater involvement in opposition and fights. Given this evidence, it becomes necessary to emphasise the importance of educational processes for identifying, developing knowledge and skills of emotional regulation, and smart resolution of conflicts to protect youth from involvement in this type of behaviour, and to prevent violent styles in social interaction and improve social well-being.

The role of indigenous practices in the reintegration and rehabilitation of female child soldiers in Northern Uganda
Lyn Snodgrass NICMMU Nelson Mandela University, South Africa; Anna Bertelson
Wherever there is violent conflict in Africa, there are children serving as soldiers, their duties more or less the same as an adult soldier’s duties. These children are abducted and recruited to fight, kill, loot and destroy property and lay mines both in their own and neighbouring countries. Beyond their use as soldiers, armies use them for their sexual services as “forced wives” and also as cooks, cleaners, porters, messengers and spies. Child soldiers, a vulnerable and marginalized group, are discriminated against by their communities who resist their re-integration when they try to return. Communities commonly believe that they should be punished for the atrocities that they have committed. This paper explores the perceptions and experiences of child soldiers regarding their rehabilitation and reintegration into their former communities in the aftermath of war. The approach to the research was qualitative, reflecting the phenomenological perspective which views human behaviour as a product of how people understand the world. In-depth, face-to-face interviews with 10 former female abductees in northern Uganda, Gulu District, were conducted. The findings indicate that a range of cultural and socioeconomic factors influenced the reintegration of these female abductees. Indigenous practices and local skills play an imperative role in empowering female abductees and facilitating rehabilitation and reintegration processes. This study has the potential to constitute a unique contribution to the literature on formerly abducted children – not only because of its focus on female abductees, but also because it explores their experiences relating to their re-integration into society.

Engaging youth in peace and safety action through photovoice: The confluence of knowledge-making and social agency
Shahnaaz Suffa Medical Research Council, South Africa; Umesh Bawa
Peacebuilding research and interventions that seek to engage youth as producers of knowledge and agents of change, are increasingly apparent both nationally and internationally. Such efforts strive to position youth voice and action within a social justice framework. A multitude of theoretical lenses and methodological tools have been invoked, to examine and support youth participation in peace-related engagement. Photovoice, with roots in liberal psychology and participatory methodologies, has emerged as an instrumental method and orientation to youth activism directed at influencing change towards socially just ends. Drawing on a multi-country study, aimed at exploring youth representations of peace and safety in marginalised communities, in five African countries, this presentation reports on the use of photovoice for engendering critical consciousness; promoting peace and safety among youth; and stimulating social action. The study located conceptual tools, analytic skills and hardware, in the form of cameras, within participants’ locus of power. Findings reflected that the material and discursive conditions that represent peace and safety for youth facing forms of marginality are multi-dimensional. Privileging of the knowledge and social lens of participants appeared to have catalysed varied forms of peace and safety activism, albeit within a limited range and realm of influence. The study suggests that photovoice may be a compelling methodological and intervention tool for promoting peace and safety in contexts where youth are under-represented in processes of social transformation. The study offers conceptual innovation in that it expands understandings of the interplay between knowledge creation, meaning-making, social agency and community engagement.

Rethinking military psychology: Reparative justice
Ethel Tobach American Museum of Natural History, United States of America; Donna Nassor
Although clinical psychologists working in the USA military are primarily involved in treating personnel who have suffered psychological damage related to serving in the military, other forms of militarism have become the norm in the American Psychological Association (APA). Violations of the most basic ethical tenets are ignored using the excuse that preventing "terrorist" activities is necessary. Many psychologists are opposed to participation in enhanced forms of interrogation (torture) and training of military personnel throughout the world in such forms, by APA members. We are concerned that the rationalisation used to explain psychological involvement in these activities are based on societally constructed differences meant to divide us and to maintain power and control over regions rich in natural resources of which the USA wants to control. Psychologists in nations following USA international policies around the world are being trained by APA members to use these destructive techniques. Ethnicity, religion, skin colour, and/or power struggles must never influence our decision to ignore our ethical doctrines. We must recognise these truths and transform ourselves without delay. This paper shall address how and why doing no harm must remain first and foremost in the practice and study of psychology within the military. We propose a move toward the inclusion of more reparative and restorative practices to be utilised by military psychologists in order to assist in the healing of those injured by conflict, armed and otherwise.

Session Type: Posters
Lead to succeed: A passion for compassion
Debra Danilewitz Bialik Hebrew Day School, Canada
The focus of this paper is to explore a school-wide Peer Mediation program. Grade 5 students are trained as Peacemakers and actively do reccesy duty by mediating conflicts that arise. In addition, they are Recess Buddies doing co-operative play with younger students. The Peer Helping program consists of Grade eight students who are trained in leadership roles within the school community. Promoting positive interactions among children is developed by teaching them to assert themselves effectively and mediate conflicts with peers in a peaceful way by teaching students pro-social skills, empathy development, mediation, communication and conflict resolution skills. Learning these aspects of character development empowers and enables students to be more effective individuals in their own communities. Children learn to develop inner resources as well as the capacity to help others in peaceful ways. Educating the whole child involves more than curriculum. It involves teaching students about developing a passion for compassion. Mature and socially adept students are able to transfer what they have learned socially by working with children, enabling them to improve the social skill development of students with social and emotional issues. Students learn to develop a passion for compassion through character education, ‘Tikkun Olam’ and real life experiences in different relationships. Service learning teaches students to respect themselves and others. Both Peer Helper and student gain so much in this relationship. Making a difference in the lives of others is the pivotal message underlying the Peer Mediation Programs.
Relationship between volunteering and Olympic core values
Bin Liang CBUU, Chongqing, China
By means of documentary and analytical induction, this article made a research on the development of Olympic volunteering spirit and its relationship with volunteering. Meanwhile the discussion on the internal unity of volunteering and Olympic core values was carried out. The results showed that Olympic volunteering spirit and volunteering are internally united and Olympic volunteering activities constitutes an important part of volunteering. It is evident that volunteering is an Olympic core value.

Diamond scale of nonviolence: A new measure for researchers
Dan Mayton Lewis-Clark State College, United States of America; Douglas Cruthirds Lewis-Clark State College, United States of America; Patrick Jones; Kylee Roberts
The relationship between levels of nonviolence (intrapersonal, interpersonal, societal, and world nonviolence) has not been empirically studied although it has been discussed in the peace literature because of the lack of measures to assess these four levels. The 90-item Diamond Scale of Nonviolence (DSN) was designed to assess intrapersonal nonviolence (20 items), interpersonal nonviolence (20 items), societal nonviolence (25 items), and world nonviolence (25 items). The DSN was administered on three separate occasions to about 175 respondents each time to establish its psychometric properties. The four DSN subscales showed good internal consistency (alphas between .85 and .87). Test-retest reliabilities were above .85 on all four subscales. The DSN-Intrapersonal significantly correlated with the 8-item Inner Peace section of the Emotional Empowerment Scale, the 15-item Self-Actualization Scale, and the 14-item Self-Acceptance Scale. DSN-Intrapersonal was significantly associated with the 15-item Intimate Justice Scale, a 4-item Driver Anger Expression Inventory, and the 12-item Propensity for Abusiveness Scale. DSN-World was significantly related to the 6-item Attitudes Toward War Scale and the 12-item Support for Diplomacy Scale. DSN-Societal was significantly correlated with some aspects of cultures of peace but not in as clear a way as expected. Factor analyses were conducted to reduce the size of the DSN subscales while strengthening the subscale validities. The DSN is now a psychometrically-sound instrument ready for research on nonviolence.

Teachers mental health and school violence in two Brazilian schools
Ana Carina Stelko-Pereira Sao Carlos University, Brazil; Lucia Williams
This study collected data regarding the prevalence of violence against school staff by pupils according to reports by school employees (N=64) of two urban schools located in a vulnerable neighbour- hood in South-east Brazil. Additionally, its correla- tion between teacher’s mental health, degree of occupational stress, and perception of school vio- lence were analysed. Three instruments were used: (1) School Violence Scale version for School Staff; (2) Occupational Stress Scale, and (3) Goldberg Health Questionnaire. 78.5% of school staff partici- pants were female, the median age was 35. It was noted that the employees were stressed and per- ceived many situations of violence in school (QSG mean score=1.96, SD=0.45; EVENT mean score =36.10, SD=10.81; EVE teachers victimization mean score=4.30, SD=5.45; EVE students victimization and perpetration=28.03, SD=19.32). There was a significant correlation (p<0.001) between teachers occupational stress, and perception of violence in school (r=0.63) and (r=0.47). Multiple linear regression analysis indicated that the best fitting model to predict rate of mental health disturbance involved only one predictor (perception of school violence, \( \chi^2 = 0.014 \)) which explained 38.4% of the variance (F (1,49)=30.49, p<.001). Preventive interventions to school staff should consider this relationship.

Session Type: Invited Addresses
International perspectives on peace, war, terrorism and torture
Sherri Mccarthy Northern Arizona University-Yum, United States of America; Jas Jaafar
The Personal and Institutional Rights to Aggression and Peace Survey (PAIRTAPS) developed by the Group on International Perspectives of Governmental Aggression and Peace (GIPGAP) at Boston University includes several Likert-Scale items such as: "Governments Have the Right to Invade another Country" which respondents rate on a 7-point scale. Respondents provide definitions of Peace, War and Terrorism. The survey has been distributed in 40 countries. This presentation will compare the divergent responses of citizens from countries in Asia, Europe, South America, North America and Australia. Most respondents agree that peace is a basic human right and that it is achievable, but definitions differ. For example, the Russian sample was more likely to define peace as an absence of violence and destruction, the Malaysian sample was more likely to define peace as related to a stable and economically profitable society and the Brazilians were more likely to define peace as the presence of positive qualities such as harmony, co-operation and safety. Participant groups from most countries, including Japan and China, consisted of less than 100 respondents. Some countries had samples of less than 50. Samples from Malaysia, South Korea, Philippines and Australia exceeded 100 participants, with the largest samples coming from Australia (272 participants) and the Philippines (240 participants). This paper will present data on terrorism, torture, and war included in the most recent books compiling results of the GIPGAP research. It will address the implications for building a peaceful world.

Session Type: Invited Addresses
Towards a theoretical framework for understanding high levels of violence in the perpetration of instrumental crimes in South Africa
Brett Bowman Wits, South Africa
Violence is a serious public health problem globally and its impacts extend across the human lifespan. As a low-to-middle income country, South Africa experiences high levels of instrumental crime, violence and violent crime. While the various relationships between instrumental crime and violence have been studied in many parts of the world, the historical, social and psychological dimensions that characterise this crime-violence nexus in South Africa have only recently been prioritised for research. This is important given the high levels of violence that are frequently reported to accompany seemingly instrumental crimes in the country. In an attempt to further current knowledge of this nexus, this presentation reviews the current literature on crime, violence and violent crime with a view to providing a theoretical framework for understanding the complex interactions that may explain the South African case. The review demonstrates that South Africa's history and current levels of structural inequality present formidable challenges to many of the current theories and typologies used to understand, prevent and manage crime and violence and so, understanding the high levels of violence that accompany seemingly instrumental crimes in South Africa, Asia, and the Americas, this address analyses how to contribute to effective, sustainable, contextually appropriate psychosocial support and how to avoid causing unintended harm. It analyses how unintended harm is often caused by the imposition of outside models, constructs, and terminology, and how harm can be avoided through the use of grounded analysis, culturally appropriate approaches, and local empowerment and ownership. It suggests the importance of taking a holistic, multidisciplinary approach that is appropriate to the socio-historic, economic, political and cultural context. In contexts of political violence, this requires working in a conflict-sensitive manner and with an eye towards engaging with vulnerable people such as war-affected young people as peace builders rather than as trouble makers. Within this framework, psychologists have a key role to play in helping to rebuild disaster-affected societies. In contrast to the role of direct practice and support that has been emphasised in the past, the address highlights the need to learn about, document, and strengthen indigenous approaches, to bring in the approaches of Western psychology through a process of dialogue, consultation, and local decision-making, to mediate between different groups and to support human rights, and to use a facilitative approach to building capacities and strengthening internal systems and supports. The address will end with a reflection on how psychologists’ engagement can either strengthen colonial processes or contribute to empowerment and social transformation for peace and social justice.
Africa requires the development of innovative theoretical frameworks. These local frameworks would need to integrate the yields of critical theory in accounting for the psychosocial effects of the country’s structural inequalities with the gains clearly demonstrated by the use of epidemiological methods in violence prevention research worldwide.

**Symposium title: The rationality of human reasoning**
**Convenor: Jean-François Bonnefon**

**Ethnic uprising in India**
Sushma Suri* Jamia Millia Islamia, New Delhi, India
Ethnic uprising is a global issue of the contemporary world that requires management with understanding and vision. This study examined the identity of Dehliites, Bombayites, Assamese, Kashmiri, Punjabis and Biharis, undergraduate and post-graduate students (N=600). Identity Scale by Husain and Suri (1990) consisted of 24 items with four dimensions viz. National, Religious, Cultural and Linguistic, was administered to the subjects. Obtained scores were analysed with the help of t-test and percentages. The results revealed that Dehliites and Bombayites showed different trends of identity scores as compared to their Assamese, Punjabi, Bihar and Kashmiri counterparts who have been affected by ethnic uprising in their respective states. Participants from Metro city had stronger national identity and relatively poor cultural and linguistic identity whereas others showed poor national identity. The study also depicted the root cause of ethnic uprising through a detailed discussion with the subjects. The demand of state autonomy and their linguistic reorganisation accentuated and made permanent the regional factor in the Indian states. Language and culture formed the basis of regionalism. The tendency towards regional identity assertion has grown. As a result India grows more in its regional identity compared to national identity. There can be no integration without participation in the political and cultural life of the country. Participation must be fostered and sustained by the practice of fairness and justice to inspire confidence, identification, concern and interest with nation.

**Session Type: Symposia**

**Symposium title: Child survivors of armed conflict and violence in Africa**
**Convenor: Nicholas Wood**

**Women who bear children through rape in Goma, Eastern Congo**
Helen Liebling* Coventry University, United Kingdom; Nicholas Wood
This paper outlines research assessing the role of stigma, and justice and health provision for rape survivors who bore children in Goma, Eastern Congo. Seventy-six women survivors were interviewed regarding their rape experiences and of bearing a child from rape and the service responses. Thirty semi-structured interviews were carried out with police, legal and health officials and non-state providers. The findings were triangulated in discussion with key informants and survivors. Young women described rape, gang rape and sexual violence, and their experiences of conceiving children. They disclosed rape by military forces, rebels, soldiers and civilians, many of whom had weapons. There was untold suffering and numerous untreated health problems. High levels of traumatic effects including stigma and shame were exacerbated by the complex emotion of bearing a child of rape and rejection and abuse by families, husbands and communities. Despite the apparent end of the conflict, sexual violence continues at very high rates in eastern Congo. The numbers of adolescent women who require health and justice responses are very high. However, there exist very minimal services to respond to their needs and those of their children. Participants reported low levels of health care access with several challenges including: limited treatment, lack of health facilities and infrastructure, and lack of support and training for staff. Likewise there were severe weaknesses in the justice system and overwhelming challenges including logistical problems, bribes, threats to safety and impunity. Specific policy and service recommendations are made.

Justice and health responses for survivors of sexual violence: A case study of northern Uganda
Helen Liebling* Coventry University, United Kingdom; H Liebling; Nicholas Wood
This paper outlines a recent study assessing the justice and health provision for survivors of sexual violence in Kitgum, northern Uganda. 51 men and 47 women abductees were interviewed in groups and individually. Each was asked their experience of sexual violence, and of justice and health provision. 85 semi-structured interviews were carried out with police and health officials, and non-state providers. Findings were triangulated in discussion with health and legal professionals, human rights organisations, local and government leaders. Young women former abductees described extensive sexual violence experiences during captivity, where eighty percent conceived children. Young men disclosed rape by military forces. Participants reported a continuing culture of sexual exploitation and increasing domestic violence in their communities. There was untold physical, spiritual, social and cultural suffering, including numerous untreated health problems. Young women reported chronic gynaecological health difficulties. High levels of traumatic effects were exacerbated by harassment from communities following captivity. Despite the apparent end of the conflict, sexual violence continues at very high rates. The numbers who seek health and justice service responses from sexual violence are very great. However, there exist very minimal health and justice services. Participants reported low levels of access to health care, lack of health facilities and infrastructure and lack of support and training for staff. Likewise there were severe weaknesses in the criminal justice system due to low levels of reporting: understated, under-trained and under-resourced police, failure of court cases and the court system. Specific policy recommendations are made.

Self-construing and forgiveness in former child soldiers
David Winter* University of Hertfordshire, United Kingdom
This paper presents the findings of a study of young people who had experienced the brutal civil war in Sierra Leone, some as child soldiers and others as non-combatants. 34 young people, 24 of whom were former child soldiers, were recruited from a school and a displacement camp. Participants completed a repertory grid, and were also asked to write narratives, and to attend focus groups, concerned with forgiveness. Surprisingly, construing of the self now and during the war was more favourable in former combatants than non-combatants. Former combatants also had tighter construct systems, and construed forgiveness rather more positively. The findings may be explained in terms of both individual construing processes, and broader social constructions and processes. In regard to the latter, participants’ narratives and interview responses highlighted the role of forgiveness. Ways of facilitating forgiveness and resilience in communities that have emerged from major conflict will be considered.

**Narrative analysis of loss of limb experiences within a Sierra Leone amputee football team**
David Winter* University of Hertfordshire, United Kingdom; Nicholas Wood
An opportunistic sample was obtained within Sierra Leone of an amputee football team, comprising seven participants interviewed around their loss of limb experiences from the civil war. Interviews focused on the narrative process of how participants had made sense of their experiences over time, as well as their feelings towards the perpetrators of their limb loss. Furthermore, they were asked about factors they considered as contributing towards their ongoing difficulties as well as their resilience and adaptation. Issues around developing identity both as an amputee and as a member of a football team were also considered. All interviews were recorded and will be subject to a narrative analysis, focusing on the narrative themes as well as the structure of participant stories. Issues likely to emerge will be around the impact of trauma, loss of limb and how adaptation and identity change may occur to process traumatic stories, with group affiliations perhaps aiding this process. However, it is also likely that new and surprising themes may emerge from the data, which will be analysed before the 2012 ICP Conference and presented in full. The findings are likely to provide guidelines as to possible therapeutic working with people who have experienced war trauma, including limb loss, particularly around possible narrative work. However, it may also identify themes of resilience and hope.

**Child survivors of armed conflict and violence in Africa**
Nicholas Wood* University of Hertfordshire, United Kingdom
This symposium will present the outcome of four research projects carried out in Sierra Leone, eastern Congo and northern Uganda. Three of the presentations focus on former girl and boy child soldiers’ experiences. The fourth paper highlights the experiences as well as the health and justice responses to women and girl survivors of rape who become pregnant. Studies draw on a range of methods of analysis including narrative analysis, thematic analysis and repertory grid technique.
Research Area: Personality

Session Type: Papers

Self-esteem in relation to emotional intelligence
Jamillya Akhmetova Al-Farabi KazNU, Kazakhstan; Alla Kim; Zhanerke Aidossova
Self-Esteem has direct connection (relation) to Emotional Intelligence, as it is emotional substructure of the whole personality or Self-Concept. High level of emotional intelligence could be a strong basis for person’s perfect Self-Esteem’s development. The aim of this paper is (1) to contribute to an empirical evaluation of this view and in particular, to try to describe the features of Self-esteem and EI of the adults at the age of 18-20, (2) to explore the features of the connection between Self-Esteem and emotional Intelligence at this age. Results of data indicates that there are some significant correlations between the substructures which define understanding and managing of the emotions of the other people and some measure-scales of Self-Esteem: intellectual Self-Esteem, Self-esteem of the level of understanding others, Self-esteem of the level of managing other’s emotional state.

The influence of children’s communication with pets on their moral development within the family
Nadiya Akhtayeva Kazakh National University, Kazakhstan
The research studies the problem of the influence of children’s communication with pets, on children’s moral development within the family. Data of two samples were compared (presence and absence of children’s communication with pets in the family). 5 methods were used: J. Rotter’s modified version questionnaire; VSC (volutin self-control) questionnaire by A. I. Zemchenko, M. M. Kerminskaya, S. R. Pantaleev; A. G. Shmelev, E. V. Eydman; “Conscience scale” by V. V. Melnikov, L. T. Yam-polskii; Testing of behavior tactics in a conflict situation by C. Thomas; Buss-Durkee’s inventory of aggression state. The research revealed significant differences between the moral development of children whose families had pets, and those whose families did not. Data were processed using the Spearman rank correlation test, Mann-Whitney test, and qualitative data processing. According to the research results, the children, whose families had pets, tend to feel responsible for family issues; they are less querulant, more self-confident, they do not have aggression, envy and hatred towards people, they are more humane than children with no pets in their families.

It’s in the mix: Psychological distress differs between combinations of alexithymic facets
Elf Alkan Haertwig Languages of Emotion, Germany
Alexithymia is a personality trait characterized by difficulties in identifying, describing, and communicating one’s emotions. It is a risk factor for several psychiatric disorders. The aim of the study was to examine the distinct combinations of alexithymic features as a risk factor for psychological distress within a population of high-alexithymic German adults (N=217). Latent profile analysis (LPA) was employed to test for possible underlying subgroups on the basis of the Toronto Alexithymia Scale (TAS-20) and the Bermond-Vorst Alexithymia Questionnaire (BVAQ). A four-profile solution showed the best fit. The different latent profiles of alexithymia were characterized as profile 1 “low load on all facets of alexithymia”, profile 2 “few problems on identifying emotions”, profile 3 “specific problems on identifying emotions, a lower level of externally oriented thinking and less restricted fantasizing”, and profile 4 “high load on all facets of alexithymia”. Additionally, logistic regression was employed to distinguish between the profiles in facets of personality, emotional experience and psychological distress. Profile 3 shows the highest level of psychological distress and this group of high alexithymic individuals has high attention to their feelings accompanied by low emotional clarity. The present study indicates the importance of a specific combination of alexithymic features as a risk factor for psychological distress, rather than total alexithymia scores.

Associations between schema domains and personality traits: A study conducted with Turkish adults
Kose Bahar Middle East Technical University, Turkey
The aim of the study was to examine the associations of three different Young Schema Domains (1996) (i.e. Perception of Insufficient Self [PIS], Inhibition in Expressing Emotions [IEE], and Insufficient Ego Control [IEC]) with basic personality traits (i.e. Extraversion, Conscientiousness, Agreeableness, Neuroticism, and Openness) of Turkish adults, after controlling for age and gender. Participants were 501 Turkish adults (300 females and 201 males) whose ages varied between 18 and 30 (M = 29.68, SD = 8.74). Regression analyses after excluding the significant variance accounted for by age and sex revealed that, characteristics of the PIS domain were significantly associated with higher tendencies towards Neuroticism. Furthermore, those with higher IEE domain characteristics had lower tendencies for Extraversion, Conscientiousness, Agreeableness, Neuroticism, and Openness personality traits. Finally, people having high levels of IEC domain characteristics indicated higher tendencies towards Extraversion, Agreeableness, and Neuroticism personality traits. Results were discussed in light of the literature.

Educational attainment, country of residence and marital status as predictors of spiritual help-seeking behaviour in women
Shyngle Balogun University of Ibadan, Nigeria; Sunday Odalipo
Literature across different countries of the world, has consistently revealed that large proportions of those who attend spiritual houses are women, and they tend to seek help on diverse issues. However, it is not known if one’s country of residence, educational attainment and marital status will predict one’s spiritual help-seeking behaviour. This study attempted show how these variables would predict spiritual help-seeking behaviour of women in Nigeria, Iran and Cameroon. Using an ex post facto design and multistage sampling, 314 participants who participated in the study were drawn from Nigeria, Iran and Cameroon, 163 (51.9%) were never married, 144 (45.9%) were married, while 7 (2.2%) were separated from their husbands either by death or divorce. Their ages ranged between 20–60 years, with the lowest educational qualification being a secondary school-leaving certificate and the highest educational qualification, a Ph.D. Validated scale was used to collect data. Two of the three hypotheses tested were accepted after conducting a one way ANOVA and Scheffe’s Post-Hoc statistical analysis. Thus, country of residence and marital status significantly predicted spiritual help-seeking behaviour of women. Deriving from the above, professionals should begin to focus on the development of cross-cultural spiritual therapeutic measures that will address women’s specific problems, as well as considering the level of educational attainment of help-seekers in addressing their problems.

Concomitants of personality, attention and rate of information processing
Werner Barkhuizen Saville Consulting, South Africa
The purpose of this study was to expand the current understanding of the relationship between attention and personality. The key underlying variables of attention and personality were investigated. Such variables include concentration ability, distractibility, information processing, reaction time, locus of control, extraversion, emotional stability, and openness to experience. One hundred and sixty four participants completed the questionnaires and test battery for this study, in which it was found that attention was statistically significant in relation to personality. Correlations between concentration ability and personality variables ranged from -0.26 to 0.60. Distraictibility correlated negatively at -0.32 with openness to experience. Based on the results of the current study, the measures of attention showed stronger correlations with the measures of personality than did measures of information processing or reaction time. Both personality (Morrison, 1977; Kirton, 1985; Sternberg, 1986) and intelligence (Ackerman, 1987; Murphy, 1989) represent important influences on individuals’ ability to adapt to environmental changes and to acquire new skills (Lewin, 1947; Stone, Kenmmerer & Gueutal, 1994). An understanding of the relationship between attention and personality can serve as a platform for developing appropriate strategies to improve recruitment, selection and development practices, work and academic performance, as well as enhancing social relationships.

It's getting darker: Three plus one dark traits
Bianca Berti University of Vienna, Austria; Jakob Pietschnig; Martin Voracek
The Dark Triad of personality, comprising narcissism, Machiavellianism and psychopathy, has been well established in previous research. These traits have been shown to correlate moderately with each other, but to still reflect distinct personality facets. In a recent investigation, a novel construct labelled the Dark Tetrad was proposed, suggesting sadism as a fourth personality trait important in the framework of the dark personality traits. However, there has been only one single study investigating this novel
had higher contradicitoriness. (2) Female archers adopted avoiding and transcendent coping style. (3) Thinking style significantly correlated to coping style, and could predict coping style significantly. The covariance and integrity of thinking could positively predict positive coping style (problem-focused coping and emotional-focused coping); while the variability of thinking could positively predict negative coping style (avoiding coping and transcendent coping).

A study on the relationship between explicit/implicit self-esteem and mental health Fu Chunjiang China

With subjects of 106 students, this study examined the relationship between explicit/implicit self-esteem and mental health based on the Implicit Association Test and scales. The results indicated that: (1) There was an extremely significant negative correlation between explicit self-esteem and MHT. (2) The correlation between evaluative implicit self-esteem and MHT was insignificant, while it was extremely significant between affective implicit self-esteem and MHT. Affective implicit self-esteem can predict anxiety about study, anxiety about person and reproving self. (3) There was an extremely significant positive correlation between the discrepancy of explicit/implicit self-esteem and MHT.

The relationship between alexithymia and mental and behavioural disorders among Iranian adolescents Amir Ghamarani University of Isfahan, Islamic Republic of Iran

This study investigated the relationship between alexithymia, depressive symptoms, and Youth Self-Report (YSR) self-image profiles among 15-18-year-old adolescents (n = 200) attending school in Birjand, Iran. Participants completed structured self-rating questionnaires (Toronto Alexithymia Scale [TAS] 20, Beck Depression Inventory [BDI], and YSR) during class periods at school. The overall prevalence of alexithymia was 9.3%. However, girls in all age groups were more frequently alexithymic than boys. Regardless of sex, alexithymic youths reported more depressive symptoms as well as internalizing and externalizing problems than the others. The TAS-20 correlated significantly with the BDI score, YSR total score, and with internalizing problems. Results indicate that the alexithymic adolescents are at high risk of mental and behavioral disorders and require treatment interventions.

The relationship between emotional schema and depression Fatima Ghanbari Jahromi Science & Research Branch, Islamic Azad University, Islamic Republic of Iran; Majid Barzegar; Ghaseem Nasiri

The aim of the current study is evaluation of relationship between emotional schemas and depression. Emotional schemas used to refer to plans, concepts, and strategies employed in response to an emotion. People with negative emotional schemas are more likely to be depressed, anxious and worried (Leahy, 2002). Participants were 200 nonclinical university students that were assigned by stratified random sampling (160 males and 40 females). Each participant completed the Leahy Emotional Schemas Scale (LESS) and the Depression Anxiety Stress Scales- short form (DASS-21). Pearson correlation and multiple regression were used to analyse the data. Results showed that validation, comprehensibility, higher values, control, numbness and acceptance of feelings had negative relationship with depression and some schemas including guilt, simplistic view of emotion, rumination and blame had significant positive relationship with depression. Some schema had a better ability to predict depression among these emotional schema. Treatment of depression will involve some degree of exposure, which requires the activation of emotional schema. So, understanding the role of emotional schema in relation to depressive response can be useful to decrease resistance of patients.

Personality pattern and emotional display rules for visually and hearing impaired students Anjali Ghosh Indian Statistical Institute, India

The present study examined the personality pattern and display the rule of emotions towards different target persons for visually and hearing impaired students. Data were collected from 844 visually and hearing impaired students selected from different regions in India through the Big Five Inventory of John, Donahue and Kentle (1991) and Display Rule Assessment Inventory of Matsumoto et al. (2005). Findings of the study indicate that visually impaired students are significantly more extraverted, more agreeable, more conscientious and more open than hearing impaired students. Correlation analyses reveal that personality dimensions for example, extraversion and conscientiousness are significantly related to overall expressivity scores for the emotion ‘happiness’ towards parents and teachers for both visually and hearing impaired students. But for the hearing impaired students traits like agreeableness and openness were also observed to be significantly related to ‘happiness’. The study implies that the impairment of sense organs determine one’s personality pattern, which in turn is reflected in the overall expression of emotions towards different target persons.

Personality assessment of institutionalised children Krishna Gogoi Dibrugarh University, India

The present study aims at assessing the differentiating personality dimensions of institutionalised children who are put into certain institutions at an early formative period of life. The purposive sampling technique was used in the study. The Rorschach Test was employed for data collection by using a 2x2 factorial design for the study. A total sample of 200 was taken, comprising 100 institutionalised and 100 home-reared children located in Assam, India, with an age range of 6 to 11 years. The findings of the study confirm that institutionalised children have poor cognitive ability, low perceptual ability as well as intelligence, in comparison to home-reared children. Institutionalised children develop extensive negative behavioural patterns like anxiety and depression.
Personality dimensions of musicians and non-musicians: A comparative study
Ramswami Gopalakrishna, Bangalore University, India
This paper considers the differences between musicians and non-musicians in their personality dimensions, specifically: emotional adjustment, social concern, assertiveness, value orientation, leadership qualities, communication skills, self-awareness, self-confidence, interpersonal relations, and stress management. The differences between the two groups are considered. As there were two groups to be studied, two different sample types were chosen: purposive and random (100 each). A semi-structured interview schedule and a personality index was used to collect data. Analysis of variance done among four groups (male musicians, female musicians, male non-musicians and female non-musicians) revealed significant difference in communication skills. A T-test conducted between the musicians and non-musicians revealed a significant difference for the personality dimensions of communication skills, interpersonal relations, and leadership qualities. A T-test conducted between male musicians and male non-musicians revealed significant differences in communication skills. A T-test conducted between female musicians and female non-musicians revealed a significant difference in value orientation. Psychology and music are two serious disciplines. Music holds a key position in regulating orderly expression of emotional forces. Thus, all the deep-seated urges of man can find their outlet in music. For education to be comprehensive, it must care not only for the physical and intellectual needs, but also to the emotional and aesthetic needs for harmonious development of the personality.

The mechanism of goal content effect: Field experiment with Chinese students
Xiaoyong Hu, Central China Normal University, China; Yuan Tian, Xiaoxing Li; Yongyu Guo; Jing Li, Central China Normal University, China
With 749 Chinese middle school students, the present field experiment tested the self-determination theory (SDT; Deci & Ryan, 2000) hypotheses that satisfaction of the basic needs for autonomy, competence and relatedness would mediate the relations between holding an extrinsic goal, relative to an intrinsic goal, and learners’ positive and negative learning outcomes. For this purpose, all participants completed a series of questionnaires that assessed the degree to which (a) they had deeply processed the text material, (b) the test anxiety, (c) the satisfaction of basic psychological needs, and (d) the persistence. The needed data were collected and a meditational model with SEM was tested (LISREL VIII; Wen, Hau, & Chang, 2005). The specified model proved that basic psychological needs can be fully or partially mediated by the goal content and learning outcomes. The present study results were consistent with SDT’s predictions, which also demonstrated the cross-cultural generalizability of goal content effects theory.

The research on the differences of gender role between undergraduates in China and America
Qi Huang, Soochow University, China; Dianzhi Liu
This research is based on an investigation among more than 200 undergraduates students in USA. Compared with the former conclusion, the results show that the amount of androgyny in students in the USA is typically greater than it is in China, and the amount of undifferentiated students is lower. With the students’ gender role development, Chinese male students show no distinct difference from American male students. Chinese female students’ gender equal-role development is lower than in America, especially in the science department. In America, students’ gender role develops smoothly from grade one to grade four. In China, it changes over the years. The difference in gender role between Chinese and American students disappears in grade four, and American students show their maturation at an earlier age than those in China. American families’ style of upbringing does not result in their children’s gender role difference.

Result of scientific research: "Psychology of success"
Ilunona Ilina-Lototska, Kostiuik Institute of Psychology, Ukraine
We’ve developed the universal scientifically-grounded mental model of success taking into account gender, ages, cultural, and philosophical-religious aspects. Our team have defined psychological co-ordinates of successful of adults. The aim for this symposium is to present our result. Within the project we have gathered data from CIS and EU countries and the USA, and SEA in order to carry out the comparative analysis (opinions, attitude to success and successful people). We have developed a model of life successfulness for CIS also. We have some results of international research of models of success (Ukraine, Russia - 1000 resp. and countries of the CIS, EU, USA, South-east Asia 1000 resp.): connotations of the term ‘success’, attributes of success in different cultures, myths and prejudices in the successful model, pay for success, reason for mistakes and wins, biographical analysis of more than 750 real-life stories and the results of the experiment (a group of ordinary people, the successful people, people with mental health problems and prisoners), acceptable ways to achieve success, and have developed a mental model of the life choices that lead or do not lead to success. We have built the distance learning course ‘Development of psychological skills of success’ for adults (http://moodle.dlc-success.org).

Moving towards adulthood: (Re)defining the concept of an "emerging adult" amongst African refugee youth in Canada
Ernest Khailema HSRC, South Africa; Jane Khaemba; Rosslyna Zulla HSRC, South Africa; Sophie Yohani HSRC, South Africa
Emerging adulthood is characterised by a period of exploration of identity, social relations and goals. The period of adulthood is denoted by the arrival of roles transitions whereby individuals get married and have a child thereby becoming a parent. In some traditional cultures, becoming an adult is marked by those times when a boy becomes a man and a girl becomes a woman (Arnett & Galambos, 2003). However, within the current generation in Western post industrial societies, markers of adulthood have moved towards individualism (Arnett, 1998, Nelson & Barry, 2005). For immigrant and refugee youth who constantly live in dual worlds, and work towards finding a confluence in the value and social system of their native and adopted country, the entry into the adult world can be blurred and ambiguous. Often, the development of being an adult is informed by the intersection of their individual and family needs. The current study employs a framework analysis to examine the worldview of African emerging adults who immigrated to Canada as refugees and are currently permanent residents, or Canadian citizens. Semi-structured interviews explain their perspectives of what it is to become adult, in the context of a dual developmental transition and settlement process. Implications of this study will inform the discourse on the developmental process of immigrant youth who are growing up as adults in a new country.

The ‘competitive personality’ concept
Olga Kliueva Tver State University, Russian Federation; Diana Bogoyavlenskaya
The concept of ‘competitiveness’ has been most thoroughly developed in the framework of modern economics and management and embraces, apart from economic ones, also social and psychological factors. The analytical review of the psychological and educational case studies of the competitive personality problem has brought to light the ambiguity in comprehension and a multitude of models that distinguish individual aspects in the ‘competitive personality’ concept. Most authors of various models emphasise the role of external determination of competition as a prerequisite for competitiveness of personality. The impressed model of competitive personality unambiguously suggests that competition is a stimulus for development, thus, as we believe, reducing the psychological content of the ‘competitive personality’ concept. Theoretically and experimentally the authors substantiate their disclosure of the ‘competitive personality’ concept via its creative potential. With the aid of the content analytical study of the free interview with 1,000 representatives of various professions and the monographic method of personality examination under criteria of objective success and achievements in professional occupation, from the total sampling we selected a group of most successful professionals who subsequently participated in the psychodiagnostic survey using the developed psychodiagnostic method of Creative Field (D. Bogoyavlenskaya). Results of the in-depth study confirm that the ability to develop success at one’s own initiative anticipates the requirements of competition and appears to be the backbone factor for competitiveness of personality.

Comparison of Germany and Mexico with scales based on McClellands 4-stage-theory of power motivation
Martin Kriegl, University of Magdeburg, Germany
For the first time, a questionnaire based on McClelland’s (1976) 4-stage-theory of power motivation was developed in German, and translated into the Spanish language. The theory includes not only the need for dominance (stage III), but also the need to feel strong, by support of another stronger person (stage I), by controlling one’s own behaviour (stage II, autonomy) and the need to influence others for a higher goal (stage IV). McClelland’s second stage was broadened by two other aspects of autonomy:
self-determination and independence. For every power stage, hope for strength and fear of weakness items were developed. One goal was to test the theory in two different cultures, and another to compare the countries on the questionnaires’ dimensions. 505 German and 342 Mexican students filled in the questionnaire. For each country a principal component analysis with promax-rotation was computed separately. Factor structures differed clearly from McClelland’s theory. All stages were separated into several factors. In both countries factor I revealed as trait anxiety/fear of weakness factor. The autonomy factor divided into the three factors “behavioural control,” “self-determination” and “independence.” Whereas in Mexico, a factor “fear of loneliness” was shown, no such factor was shown in Germany. “Trait anxiety” was significantly higher in Mexico as well as “behavioural control,” “self-determination,” “fear of injustice” and “giving strength to others.”

Mobile phone addiction and loneliness as a cyber entertainment motive
Hong Liu Anshun University, China; Hongli Wang Anshun University, China
The aim of the study is to expand the mobile phone addiction research and explore how loneliness influences mobile phone addiction by adopting a medi-ate variable. By stratified sampling from four uni-versities in China, a total of 442 college students were surveyed with the Mobile Phone Addiction Index, UCLA Scale and Mobile Phone Using Mo-tive Scale, then correlation analysis, analysis of muti-variance and structural equation models were adopted. There were significant positive correla-tions between mobile phone addiction, mobile phone using motive and loneliness. There were significant group differences, divided by different levels of loneliness in mobile phone addiction and cyber entertainment motive. The lonely students scored the highest, then the common students and the non-loneliness group scored the lowest. Lone-liness can positively predict mobile phone addiction. Cyber entertainment motive had a mediating effect between loneliness and mobile phone addiction. Loneliness played an important role in mobile phone addiction, which can either directly or indi-rectly predict mobile phone addiction. Therefore, the intervention of mobile phone addiction should focus on it. Still, the role of cyber entertainment motive instead of traditional interpersonal motive should be paid attention to in the connection between loneliness and mobile phone addiction.

Narratives from fathers in a rural area of Southwest China: Fatherhood and their re-demptive self
Yanping Liu Beijing Forestry University, China
The purpose of this study is to analyse fathering and its meaning to the redemptive self in China’s rural areas, and participation in his father’s father com-pensatory sense of self-development. Dan P. McAdams (2006) reviewed the impact of narrative the-ories and approach to personality psychology during the past 25 years. Narrative theory and approaches can be used to study the meaning of life. McAdams and his colleagues conducted a series of research on generativity of midlife Amer-ican adults, emphasising life-stories as redemptive narratives. In the current research, I interview 15 fathers (six have already been interviewed), who are living in the same village located in the Southwest of China. The fathers’ ages range from 20 to 74 years old (there are about three fathers for each ten year period). Focusing on the fathering stories they tell, I will analyse why they are involved in their children’s upbringing and its meaning to them, using McAdams’ redemptive self theory. The study is in progress, but some clear conclusions can be found, for example, even though none of these low-income fathers cannot afford to meet the children’s economic needs, they are satisfied with having a child and think that the economic situation will be improved with effort. They are inclined to avoid fostering the ways they had experienced as kids, but are glad to continue carrying on the way they like when they father their own kids, without consider-ing the pay/back from their children. They do what they can in order to benefit their children, which itself functions as self-outliving.

A holistic developmental model of mental health: A conceptual review
Hing Keung Ma Hong Kong Baptist University, Hong Kong
A unique theoretical model of mental health based on a holistic developmental perspective is con-structed. In the formulation of the concept of mental health in human growth, an integration of Chinese and Western psychological perspectives is attempted, and a practical definition of mental health is proposed. In this theoretical model, human growth is defined in terms of the following seven aspects: (1) Physical development, (2) cognitive development, (3) psycho-sexual development, (4) moral development, (5) psychosocial development, (6) emotional development, and (7) spiritualistic and faith development. It is hypothesised that healthy development should have the following three characteristics: (a) It consists of the healthy development of the above seven aspects of human growth. (b) The developmental process should be in general happy and pleasant. (c) The developmental outcomes should be positive and effective. It is argued that positive whole-person development should have a moral basis. Mentally healthy people are supposed to have higher moral competence and prosocial orientation and will participate more ac-tively in voluntary services for disadvantaged peo-ple. The moral behaviour of a mentally healthy person will be based on empathy and humanity. In addition, moral judgment is made based on the principle of universal justice and the principle of universal love. Finally, two large-scale whole-per-son education or holistic development projects (‘Life and Ethics Education Programmes’ and ‘Ad-olescent Holistic Development Programme’) will be presented to provide some empirical evidence for this positive concept of mental health.

The development of diagnostic criteria for the borderline personality disorder
Daleen Macklin University of Pretoria, South Africa
In the 2001 edition of the “Nedersaks Rorschach Tijdschrift”, Phillip Erdberg and Johannes van Kemenade published preliminary quantitative and qualitative criteria for the identification of a variety of personality disorders based on the Rorschach Inklblot Method. This paper comments on an
exploitative study of 15 South African adult women diagnosed with borderline personality disorder. The aim was to supply some empirical support for the suggested preliminary findings of specifically borderline personality disorder (Macklin 2003). Although the results supported some of the suggested quantitative criteria, such as Ego < 0.33 ± 0.45, CF + C > FC, PHR = GHr and FQ- elevated; others, such as S > 3, AG > 3 and WSum6 elevated, had little representation in the research sample. In order to contribute to the search for specific criteria on the Rorschach for borderline personality disorder, potential criteria (EB = Ambivalent. X% < 0.70 and WDA% < 0.75, X-% > 0.15, X-% < 0.55 and MOR elevated) were identified based on the characteristics of the South African research sample.

Do values really differ by generation? An empirical investigation
Kevin Meyer Hogan Assessment Systems, United States of America; Jeff Foster
One of the most popular topics in current management training and development literature is managing workers from different generations. The common assumption is that generations differ in what motivates and drives them. However, little empirical evidence has been put forth to test these assumptions. We will present results from an analysis of a large, global sample (N = 255,479) of data from the Motives, Values, Preferences Inventory (MVPI); a 200-item self-report measure of ten dimensions of values and interests. We coded the generation for each case based on birth year; 1946-1964 for Baby Boomers (N = 73,653), 1965-1977 for Generation X (N = 109,950), and 1978-1992 for Millennials (N = 70,123). To examine group differences, we ran one-way ANOVAs to determine the impact of generational membership on values results for each MVPI scale. All ANOVAs and individual contrasts comparing pairs of groups were significant (p < .001). Effect sizes based on standardised difference scores ranged from .03 to .52. In general, our results show that generation has a significant effect on values and these differences are relatively stable over time, although their effects are generally small. In contrast, culture had a much larger effect. Also, generation and language produced a significant interaction, indicating that the impact of generational membership on values varies by culture.

Depression predictors in adulthood: Differences by age
Consuelo Moran Leon University, Spain; Ester Neznes dos Anjos
Several studies related personality, and more specifically neuroticism, with depression evaluated with the fourth scale of Goldberg’s GHQ-28. 860 adults persons participated in this quasi-experimental study. We wanted to find out how depression relates to the five factors of normal personality. These include self-esteem and other measures of GHQ-28, as well as anxiety and social dysfunction. Personality was evaluated with the NEO-FFI of Costa and McCrae and self-esteem with the Rosenberg self-esteem scale. Multiple regression analyses find that severe depression is associated with high anxiety and low self-esteem. By age groups, neuroticism is the strongest predictor of depression in young students, anxiety and insomnia in middle-aged persons, while the depression’s strongest predictor is social dysfunction in older persons. Gender differences indicate that women are superior to men in neuroticism, somatic symptoms, anxiety, and depression, as well as lower self-esteem.

Differences in agreeableness among people with or without religious beliefs
Consuelo Moran Leon University, Spain; Ester Neznes dos Anjos
The aim of this study was to identify differences in Agreeableness, a dimension of the Five Factors of Personality, in people with or without religious beliefs. The five-factor model consists of hierarchical trait organisation and comprises five basic personality dimensions: Neuroticism, Extraversion, Openness, Agreeableness, and Conscientiousness. Costa & McCrae (1992) propose this trait affects mood, interpersonal relationships, and coping. Coping strategies are the efforts that people tend to contain, moderate or, if it is possible, finish the effects of menacing situations. Coping religion means the tendency to turn to religion in stressful situations, increasing participation in religious activities. Some research asserted that studying how an individual uses religion to solve problems with stress is more important than investigating how an individual practises their religion (e.g., church attendance, prayer). This adaptive use of religion is called religious coping, defined as a belief in a higher power and use of that belief for solving problems, managing stress, and maintaining strength when faced with adversity. Participants were 938 students (35.3% men) from two universities of Manaus (Brazil). They completed the Portuguese version of the NEO PI-R (Costa & McCrae, 2005) to evaluate the five personality factors. The NEO Personality Inventory-Revised (NEO PI-R) is a self-report inventory, one of the most widely used measures of the Five-Factor model (Manga, Ramos, & Moran, 2004). Religion coping was assessed with the Religion subscale of the Brief COPE (Carver, 1997). Brief COPE is a multidimensional self-report questionnaire to evaluate fourteen coping strategies, one of which is ‘return to religion’. The study of the psychometric properties of the Spanish version, analyzing its factorial structure, in a second order factor analysis with the subscales of Brief COPE, found four factors with the two items of Religion in a unique factor (Moran, Landero, & Gonzalez, 2010). The statistical analyses were made with SPSS 17.0. Cluster analysis found four groups in the coping strategy return to religion: (1) very low religion, (2) low, (3) middling and (4) high religion. Differences in personality appear in the extreme groups in religion coping in the agreeableness dimension: (1) The clusters having middle scores in religion had scores near to the mean in the five dimension of NEO PI-R. (2) The two extreme clusters in religion had the highest differences in agreeableness: (a) The highest in religion coping are high in agreeableness and, (b) Those lower in religion coping are lower in agreeableness. Personality may directly facilitate or constrain coping, but relations of personality to coping have been inconsistent across studies, suggesting a need for greater attention to methods and samples. A richer understanding of the role of personality in the coping process requires assessment of personality facets and specific coping strategies.

Replicable types of personality with the NEO-PI-R in Brazil
Consuelo Moran Leon University, Spain; Ester Neznes dos Anjos
Research over the last 20 years has identified a set of three replicable personality types: resilient, undercontrolled, and undercontrolled. The resilient type was characterized by a pattern of well-adapted behaviour and social competence, the overcontrolled type by high emotional constraint, and the undercontrolled type by high impulsiveness and an inability to delay gratification. The NEO Personality Inventory-Revised (NEO PI-R) of Costa and McCrae (1992) is a self-report inventory widely used to measure the Five-Factor model of personality. We studied whether the three major personality types can be replicated across NEO-PI-R in a sample of Brazilian adults. Participants were 958 university students of Manaus (Brazil). The NEO PI-R Brazilian version was applied. Cluster analysis with scores of the five factor measures was made. We obtained three types: The resilient type (40%) is the better adapted by their emotional stability (low scores in neuroticism), the highest in conscientiousness, with middling scores in extraversion, agreeableness, and openness. The overcontrolled type (33%) was emotionally unstable, with the lowest scores in extraversion (introverted), responsibility, openness, and agreeableness. The undercontrolled type (27%) was high in neuroticism, extraversion and openness and middling in responsibility and agreeableness. The three replicable types were confirmed. This composition of types quite corroborate the distribution found by other researchers. In addition, we can identify key areas of controversy. It is concluded that the search for a hierarchical taxonomy of people will require more investigation and discussion.

Personality and individual differences of self-regulation as predictors of actions’ reliability in stressful conditions
Varvara Morosanova Psychological Institute, Russian Federation; Nailya Kondratyuk
Various psychological studies have investigated the relationship between personality traits and job success. This study examined the relationship between personality traits (neuroticism and extraversion), stylistic features of individual differences of self-regulation voluntary activity, and action reliability as accuracy in stressful conditions. Voluntary self-regulation is defined as a conscious organisation process of psychic activity that assures goal-setting and corresponding to the achievement of these goals. Stylistic features manifest themselves in individual differences of planning the goals, modelling of conditions, programming of actions and result evaluation in different situations and type of human activity. Stylistic features are characterised by flexibility, regulatory reliability, autonomy, and general level of self-regulation. Our previous studies have showed that stylistic features of self-regulation mediate the influence of personality traits on human behaviour (Morosanova, 2003). The sample:
123 rescuers, age 20-57 years. Methods: the Self-regulation Profile Questionnaire, SPQ (Morossanova, 2010), EEP-S (Russian version, 1998) and questionnaire measuring rescuers’ actions reliability. We used Structural Equation Modelling to explore whether personality traits and self-regulation stylistic features predict rescuers’ reliability of actions. The results indicated that the direct influence of neuroticism on the reliability of actions was not significant, while the indirect influence via individual differences of self-regulation (modelling, programming and regulatory reliability) was significant and negative. The direct or indirect influence of extraversion on actions reliability was not significant. However extraversion found significant correlation with stylistic features of self-regulation. It was concluded that self-regulation is a mediator between neuroticism and reliability of actions.

### Relationship of personality, attachment to parents, religious orientation, and academic achievement to resilience

**Ghasem Naziry Islamic Azad University, Islamic Republic of Iran; Fatima Ghanbari Jahromi Islamic Azad University, Islamic Republic of Iran**

The aim of this study was to investigate the relationship of personality, attachment to parents, religious orientation, and academic achievement to resilience. It was also to determine the relative importance of variables in prediction, resilience and academic achievement. Participants were 327 high school students. They completed Junior Eysenck Personality Questionnaire, Parent and Peer Attachment Inventory, Connor-Davidson Resilience Scale and Religious Orientation Test. Results showed that personality, attachment to parents, religious orientation and academic achievement were associated with resilience. Neuroticism, extraversion and psychotism follow as the most important personality predictors of resilience. Among the variables neuroticism, extraversion and religious orientation were the most important predictors of resilience. Furthermore, the most significant predictor variable for academic achievement was determined by resilience and religious orientation.

### The psychopathology of St Paul: The thorn in the side of Christianity

**Richard Oxtoby South Africa**

One of the particularly influential thought-leaders in Christianity has been St Paul. It is well known that he suffered some affliction which he described as ‘a thorn in my flesh’. There has been some medically well-informed speculation that the thorn in Paul’s flesh was epilepsy and whatever else may have been going on, an epileptic attack was part of his conversion experience. Whatever truth there may be in that hypothesis, Paul was undoubtedly a divided personality. Careful analysis of the epistles of Paul indicates that he held some inconsistent and incompatible beliefs on a number of topics. A fundamental split was between the concept of God as a loving, compassionate being and one of God as a harsh, punitive tyrant. This led him at times to recommend an empathetic, forgiving approach to dealing with what he regarded as wrongdoing, and at other times recommending harsh punitive action. One of the most flagrant examples of this was his astonishing display of viciousness when he wrote in his epistle to the Galatians, “I wish those who unsettle you would castrate themselves.” In this paper I shall examine this outburst and the light it throws on some of the inconsistencies in Paul’s thinking, especially his psychopathologically negative feelings towards the body and sex.

### Generational differences on the dark side of personality

**Alex Pires Jopie van Rooyen and Partners, South Africa; Aimee Ferreira**

The recent interest in generational differences in the workplace, has inspired many organisations to focus on creating cohesion and cooperation between generations. As various generations appear to handle organisational demands and pressures differently, the element of derailment between generations has become a focus area for researchers. Very few studies on this topic have been conducted in the Southern African context. It has therefore become imperative that we understand the nature of derailment across generation groups, as this can assist in building and maintaining sustainable organisations. We used the Hogan Development Survey (HDS) as a measure of 11 derailing interpersonal styles in a number of Southern African organisations, yielding a total sample of N = 988 individuals. We allocated individuals to generational group based on their year of birth: 1946-1964 for Baby Boomers (N = 211), 1965-1977 for Generation X (N = 576), and 1978-1992 for Millennials (N = 201). We compared scores across generational group on each of the derailers by running one-way ANOVAs and found statistically significant differences on seven of the 11 scales. Differences in the number of derailers also emerged across generations. We will discuss the results of this study in depth, along with implications for managing people from different generational groups.

### The relationship of personality traits and motivation to teaching career choice

**Kevin Quin Monash University, Australia**

A longitudinal study of the motivations of teacher recruits identified teaching commitment motivational factors of planned effort and planned persistence in teaching (Watt & Richardson, 2007). These researchers also discuss the effect of personality characteristics on teachers’ work longer term commitment and burnout (Richardson & Watt, 2010). The relationship of personality traits as measured by the Big-Five model of personality and performance has been examined in some depth (Judge & Ilies, 2002). The results of this study encouraged further consideration of the relationship between personality and motivation. It has been further suggested that motivational variables are intervening variables between personality traits and job performance (Hurtz & Donovan, 2000). It has also been suggested that specific facets of the big five factors might provide better predictive validity for job performance (Paunonen & Ashton, 2001; Paunonen, Rothstein, & Jackson, 1999). The present study examines the relationship between facets of personality and the motivational factors of planned persistence and planned effort in a group of 74 trainee secondary teachers. Using a personality measure designed for the study, a relationship between the selected motivational factors and personality facets was identified. A modified version of the personality test was then administered to 120 experienced secondary teachers. The responses of the trainee teachers and the experienced teachers on the personality measure were remarkably similar suggesting that there are identifiable personality traits in teachers. Future suggestions for refinement and development of this measure are discussed.

### Typological and personal determinants of burnout in students

**Olga Radchuk Univer. della Svizzera Italiana, Switzerland; Sergii Tukalev; Sergii Krizhanovskyi; Tatiana Vasheka**

The aim of our investigation was to detect the typological and personal determinants of burned-out university students. 213 first to 3th year psychology and biology students of National Taras Shevchenko University and National Aviation University, Ukraine participated in this study. We used the following tests: Syndrome of emotional burnout (by V.Boyko), Temperament Diagnoses Test (by J. Strelau), EPI Test (by H.Eysenck), Manifest Anxiety Scale (by J.Taylor), State-Trait Anxiety Inventory (by C.Spiemberger, Y.Hanin), Sensation Seeking Scale (by M.Zuckerman), diagnostics of neurotization level (by L.Wasserman), diagnostics of emotional response to environmental stimuli (by V.Boyko). It was shown that the main typological determinants of burnout were as follows: high level of neurotization, neuroticism, introversion, weakness of arousal and inhibition and low-level mobility of neural processes. The main personality factors related to burnout were high level of anxiety and dysphoric and refractory reactions to external stimuli. The main independent determinants influencing burnout in women were high levels of neuroticism, dysphoric reaction to stimuli and lower level of arousal, and in men; high levels of neuroticism and low level of inhibition processes. We can assume that in women with lower level of arousal burnout appears due to inability of the nervous system to cope with prolonged frequent arousal and further protective inhibition. The relationship between burnout and the level of neurotization and neuroticism was more significant in men. Thus both constitutional traits and personality features influence the development of burnout in students during their study.

### Relationships between personality and coping with stress: An investigation in Swedish police trainees

**Joerg Richter Center for Child and Adolescent, Norway; Lars Erik Lauritz; Nofissa Cassimjee; Elizabeth du Prez; Mehdi Ghanimou**

The major aim was to investigate relationships between personality characteristics derived from Cloninger’s personality theory and ways of coping. We investigated 103 police trainees from one Swedish police academy by the Temperament and Character Inventory (TCI) and Ways of Coping Checklist (WoC). There were several particularities characterising trainees within various personality profiles relating to coping. Each WoC scale was
significantly predicted by varying personality sub-scales with temperament subscales mainly contributing to the prediction. Only personality domains harm avoidance, reward dependence, and self-directedness could significantly be predicted by coping scales. Personality and coping are comprehensively interrelated; some coping behaviours often jointly occur depending on the specific stressful situation, and these combinations are related to particular personality trait constellations. Structural similarities exist between personality and coping and certain personality traits are likely to facilitate particular coping behaviours, thereby affect coping strategy selection, but coping responses are not only epiphenomena of personality.

The relationship between the expression of anger and personality
Katherine Roper Jopie van Rooyen and Partners, South Africa; Angelique Da Silva; Hannelle Knoetze
Research has found that anger is a short-term state-based affect. However, personality traits have been shown to be far more stable than affective states. This study aims to determine whether there is a relationship between personality traits and the expression of anger. The relationship between the state-based characteristics of anger expression and the more stable construct of personality was therefore investigated. Employees from the protective services division (n = 171) of a leading mining company were therefore assessed using the State-Trait Anger Expression Inventory-2 (STAXI-2) and the Basic Traits Inventory (BTI). These assessments measure state-based anger expression and personality respectively. Correlations between the STAXI-2 and BTI were then investigated. Results indicate that there is a relationship between personality and anger expression. Particularly, anger expression exhibited a positive correlation with the personality facets of the BTI such as Affective Instability, Depression, Self-Consciousness and Anxiety. This indicates that there is a relationship between certain neurotic traits found in personality and the expression of anger. Conversely, the facets of Positive-Affectivity and Compliance have a negative correlation with the expression of anger. Results also indicate that neurotic traits are negatively correlated with anger control. Evidence therefore exists for the relationship between personality and the expression of anger. This may indicate that the expression of anger is dependent on more stable personality factors.

Exploratory structural equation modelling of abridged Big Five dimensional circumplex IPIP scales
Tomasz Rowinski Cardinal Stefan Wyszyński University, Poland; Jan Cieciuch; Włodzimierz Strus; Tomasz Rowinski
Exploratory Structural Equation Modelling (ESEM) proposed by Marsh and colleagues (2010) is a useful tool for analysing the structure of personality scales. The procedure was used to analyse the structure of some Big Five measures (i.e. Marsh et al., 2010; Lang et al., 2011). The ESEM combines two methods: an exploratory and a confirmatory factor analysis (CFA). Therefore, it overcomes some limitations of CFA and avoids some well-known problems with using CFA in validation of the personality questionnaires in the Big Five approach. We assume, that ESEM is a useful procedure for testing the structure of personality, also at the scale level, especially when the theoretical structure is more sophisticated, and expected cross-loadings are significant. This is the case of the circumplex model proposed by Hofstee, de Raade & Goldberg (1992). The purpose of the presented research was the validation of the personality structure in the Abridged Big Five Dimensional Circumplex (from Goldberg et al., 2006) due to the ESEM procedure. Hofstee and colleagues (1992) describe personality in terms of ten circles containing forty five variables. These are derived from various combinations of each pair of the Big Five dimensions. Finally, each of the main five factors contains nine sub-scales connected to the factors in some order. Therefore, this model assumes, that cross-loadings are not only meaningful, but also theoretically expected. The ESEM has revealed that almost all sub-scales had the greatest loadings on its first factor and additionally the most significant cross-loadings on the second factor according to the theory.

Studying the parameter of hardness as a factor of personal prosperity
Marina Salitova Saint Petersburg State University, Russian Federation
In contemporary psychology more researchers turn to describing the characteristics which are in a way integral for a personality. The concept of hardness can be considered one such characteristic. This research concentrated on the relation of parameters of hardness to value characteristics of personality’s sphere. The importance of shifts in the system of values was studied. Retesting analysis was carried out in order to define what values exactly had the most considerable shifts after retesting, dynamics of changes also was taken into consideration. The ESEM has revealed that almost all sub-scales had the greatest loadings on its first factor and additionally the most significant cross-loadings on the second factor according to the theory.

The use of medical hypnoanalysis in guiding emotionally vulnerable adolescents towards growth in emotional maturation
Lizzie Schoeman South Africa
Because of deficiencies in, and neglect of adolescents’ developmental needs, some seem to lack the necessary emotional maturity to cope with demands made on them by a rapidly changing society. There is an urgent need for a dynamic, short-term therapy for delving into the actual underlying causes of the symptoms presented. The objective of this investigation was to determine whether medical hypnoanalysis is an effective therapeutic technique in guiding emotionally vulnerable adolescents towards growth in emotional maturation. Medical hypnoanalysis and its application to emotionally vulnerable adolescents was elucidated by means of a literature study and a number of case studies. The general population from which the test sample was made up, comprised 9 grade 11 adolescents. The test sample who participated in this investigation, comprised 9 grade 11 learners. The MACI, HSPQ, General Wellness Questionnaire, Vulnerable Adolescent Questionnaire and graphic expression media were the instruments used for test results. Emotional maturation qualities which served as criteria for growth were identified. Three sub-hypotheses were formulated tested and accepted: the occurrence of emotional vulnerability in adolescents can be related to traumatic experiences from conception to early childhood; age regression can provide information on the initial events that caused emotional vulnerability; the change in thought and behaviour patterns which stem from adolescents’ earliest memories can be related to growth in emotional maturation in emotionally vulnerable adolescents. This investigation indicated that medical hypnoanalysis is an effective therapeutic technique in guiding emotionally vulnerable adolescents towards growth in emotional maturation.
The characteristics of ERPs of children with different levels of self-control
Yue Shen License Normal University, China; Lizhu Yang; Fong Song; Zhongqiang Jiang
The study combined the Children Self Control Teacher’s Rating Questionnaire and event-related poten-
tials (ERPs) experiment (Go/Nogo), and children were tested (n=33) on the ERP components (N2, P3), to study whether the N2 and P3 components can predict the level of self-control, indicating the ERP results’ social significance; and to find the development-
mental characteristics of self-control brain mechan-
isms of the children with different levels. Results showed that: 1. The smaller P3 peak amplitude related to higher ability of children to comply with rules, better impulse inhibition, and actual performance of inhibition. The P3 component in the child period reflects the operation-specificity for the task, and also reflects the children’s inhibition ability and the actual performance. 2. The smaller N2 peak amplitude related to higher levels of self-control in children, persist-
ence and self-delay of gratification. The function of the N2 component in the children’s period may simply reflect a general ability for self-control, but cannot predict actual performance, which may also be related to early childhood brain development.

The lived experience of being a street beg-
gar: A qualitative study
Christopher Stones University of Johannesburg, South Africa
Street begging has been a subject of social scientific research for several decades and especially as eco-
nomic down-turns occur (Borland, 2009; Bose & Hwang, 2002; Hills, 2009; Horn & Cooke, 2001, inter alia). Characteristically, research findings tend to be related to questions about employment oppor-
tunities, earning capacity and potential, family discord, social alienation, self-concept, and the inadequa-
cy of formally-organised social support systems. However, what appears to be lacking is literature regarding what it means to be involved in street begging: What is the experience of being a beggar? To explore this hitherto unexamined aspect of beg-
ging, several street beggars in a large metropolis (Johannesburg, South Africa) were approached with the request that they agree to be interviewed about their experiences. Comprehensive interviews were conducted with four street beggars, aged between 23 and 36 years. Moreover, one of the researchers spent considerable time on the streets begging in order to better understand the experiential dynamics of begging. The interview material was explicated through a series of well-established steps aligned to a broadly-based descriptive phenomenological ap-
proach (Giorgi, Moustakas, Schweitzer, etc). The out-
come of this research suggests that to a large extent, the personality, self-esteem and social dynamics of the participants varied across the sample age range. The implications of this are discussed with a view to better understand what it means to be a street beggar.

Religious/spiritual well-being, personality and mental health: A review of results and conceptual issues
Human Uninterlaver Institute of Psychology Graz, Austria; Alimee Ferreira
We present the recent research findings of our group that allowed us to investigate the potential links between religiosity/spirituality and different indicators of mental health. Thus this paper represents a synoptic overview of the most important results which were gathered by applying the Multidimen-
sional Inventory for Religious/Spiritual Well-Being (MI-RSWB) to different personality dimensions and to different facets of subjective well-being and mental health in several studies. The MI-RSWB was applied on different clinical samples (e.g. de-
pressive or addiction inpatients) and non-clinical samples together with different well established measures for personality (e.g. NEO-FFI), subjective well-being (e.g. Sense of Coherence-scale) or men-
tal illness (e.g. Beck Depression Inventory). Data were evaluated by conducting correlation statistics as well as GLM multivariate for group compar-
sions. Taken together, this body of research suggests that there is substantial evidence for religiosity and spirituality being positively related to a variety of indicators of mental health, including subjective well-being and positively correlated with the per-
sonality dimensions of extraversion and negatively correlated with neuroticism. Overall we found out that religiosity and spirituality can play an impor-
tant role in the process of recovering from mental illness as well as providing a protective function against addictive or suicidal behaviours. However, further research is needed to examine the mechan-
isms through which religiosity and spirituality has an impact on health related conditions.

The influence of self-concealment on Internet addiction: A test of multiple mediating effects
Hua Wei Central China Normal University, China; Zongkui Zhou; Hui Zhang
The current study examined the relationship of self-
concealment, social support, self-esteem and Inter-
et addiction, probing the mechanism of the effects of self-concealment on Internet addiction. A total of 546 undergraduate students participated in this study. The results showed that self-concealment was negatively correlated with self-esteem and so-
cial support, and there was a negative relationship between self-esteem and Internet addiction. In ad-
dition, self-concealment not only exerted an impact on Internet addiction directly, but could also influ-
ence the latter through multiple mediating effects of social support and self-esteem. Furthermore, the relationship of self-concealment and Internet addic-
tion is partially mediated by social support and self-
estem. The results of this study confirmed the compensation view of Internet addiction, indicating that individuals become Internet dependent because they can get compensation which cannot be obtained from real life, such as a safe space to pour out, win social support and enhance their self-es-
tem.

The difference between indecisiveness and procrastination
Hong-Xing Xiong School of Psychology, China; Jing Zhang
This study investigated the specificity of indecisive-
ness compared to procrastination. A reasoning task paradigm was used to examine the delay, uncertain-
ty and information consumed and an information board paradigm (Payne, 1976) was used to trace the decisional process with regard to choosing a course. A sample of 468 college students participated in this research. Indecisiveness predicted more delay, uncertainty and information consumed in the rea-
soning task, and also predicted more decision time and more total information collected in the process-
 tracing methodology. The effect of indecisiveness on these decisional problems remained significant after controlling for procrastination, providing fur-
ther evidence for the specificity of indecisiveness.

Self-regulation failure: An overview
Liao Yanran School of Psychology, SWU, China; Zhang Jinfu
Self-regulation is an essential component of person-
ality which cast shadows on an infinite array of human life. A vast body of studies have been trying to reach deep to the core of self regulation but research on how failures actually happen is still underway. Here we reviewed literature including both theoretical models and empirical findings, as well as cross-sectional and longitudinal works in this area and tried to extract an assemblage of the leading factors which contribute to self-regulation failure. The factors that we identified were: delay of gratification; self-control/impulsity; external stimu-
li; automatic affective reaction; goal setting; self-
efficacy; cognitive factors like recognition of self-
control dilemma; misguided efforts; transcendence; lapse-activated disinhibition; emotional factors; at-
tention; ego/resource depletion; use of regulation strategies; acquiescence; interpersonal drive; and
social context. We present an outline that emerges from the intersection of these findings with recent studies on mechanisms of their biological and neural bases. Hopefully this article can demonstrate a clearer picture of how can self-regulation failures happen in a variety of ways and may offer some indication for future investigations.

Type D personality as a risk factor for premenstrual syndrome in female undergraduates

Jinyao Yi, Medical Psychological Institute, China; Xiongzhao Zhu; Mingtian Zhong; Shuqiao Yao

The aim of this study is to examine whether Type D personality is a risk factor for Premenstrual syndrome (PMS) in female undergraduates. 1409 female undergraduate students ranging in age from 17 to 24 years (M =19.79, SD =1.13) finished the Type D Scale-14 (DS14), the shortenned premenstrual assessment form (SPAF), the General, Academic, Social Hsses Scale for Students (GASHSS) and a general information form. The prevalence of PMS scores of the three subscales of SPAF and the GASHSS were compared between Type D subjects and non-Type D subjects. Logistic regression analysis was used to examine the related factors affecting the PMS. 470 female undergraduates who scored 10 points or more on both dimensions of DS14 were classified as Type D (33.4%) while the other 939 subjects were classified as non-Type D (66.6%). The prevalence of PMS of the sample was 12.7%. PMS was more prevalent in Type D female (21.3%) than in non-Type D female (8.4%), p<0.05. (3) Compared to the non-Type D subjects, Type D subjects got higher scores on three subscales of SPAF (pain:7.45 vs 2.60, v5.80 vs 2.43; affect: 10.54 vs 3.78 vs 8.33 vs 3.39; water retention: 6.54 vs 2.53 vs 5.12 vs 2.19), p<0.05. The logistic regression analysis showed that females with Type D personality and higher stress level were at an increased risk for the occurrence of PMS. Type D personality is a risk factor for Premenstrual syndrome in female undergraduates, psychological intervention for Type D personality should be included in the PMS management strategies.

The affect intensity and cognitive emotion regulation strategies in subjects with borderline personality disorder

Jinyao Yi, Medical Psychological Institute, China

The aim of this study is to explore the affect intensity and cognitive emotion regulation strategies in subjects with borderline personality disorder and examine their moderating role in the relationship between stress and depressive symptoms. A sample of 8689 undergraduate students finished the borderline personality disorder (BPD) subscale of the Personality Disorder Questionnaire-4+ (PDQ-4+), the Short Affect Intensity Scale (AIS-S), the Cognitive emotion Regulation Questionnaire (CERQ), General Social and Academic Hsses Scale (GASHSS) and the Center for Epidemiologic Studies Depression Scale (CES-D). Hierarchical multiple regression analysis with CES-D as the dependent variable and AIS-S, CERQ, GASHSS, BPD subscale, GASHSS 'CERQ, GASHSS' BPD in successive steps as independent variables were performed. According to the cut-off score of BPD subscale of PDQ-4+, the prevalence of BPD was 18.4%. Subjects with BPD got higher scores on negative affect intensity and on negative coping dimensions ( rumination, catastrophising, self-blame, blaming others), while got lower scores on positive coping dimensions (acceptance, positive refocusing, positive reappraisal and putting into perspective) than subjects without BPD. Hierarchical regression indicated significant negative affect intensity, negative emotion regulation strategies, higher levels of stress and BPD were all associated with depressive symptoms significantly (p<0.05), while BPD and negative emotion regulation strategies moderated the relationship between stress and depressive symptoms. Compared to subjects without BPD, stress has greater impact on the occurrence of depressive symptoms for subjects with BPD, who are characterised by higher negative affect intensity and more negative emotion regulation strategies.

Personality factors and tendency to violence:
Meditating role of identity statuses

Ali Zadeh Mohammadí, Shahid Beheshti University, Islamic Republic of Iran

The present study investigated the relationship between the five factors of personality and tendency to violence, and the role of identity statuses as a moderate variable was also evaluated. In a cross sectional study, 458 students (267 girls and 218 boys) were selected through a stratified sampling method from the Tehran government universities. Students completed a short form of the NEO Personality Inventory, an Extended Version of the Ob jective Measure of Ego Identity Status (EOM-EIS2) and a violence index of youth risk factors questionnaire. To describe and analyse central, dispersion and correlation indicators SPSS-16, and for deter mination path analysis, LISREL software was used. Results showed Neurosis personality factor had a positive relationship with violence and openness, agreeableness and conscientiousness personality factors found a negative relationship with the violent tendency index. Path analysis showed an indirect significant effect of neurosis and conscientiousness on tendency to violence including a mediating effect of diffusion status of identity. Also, results showed an indirect effect of extraversion and openness personality factors on violence with a mediate of moratorium status of identity. The study supported the relationship between personality and tendency to violence and moderate role of identity related to personality and violence.

Personality traits among substance abusers

Maryam Zarnaghash, Shahid Chamran University, Islamic Republic of Iran; Hadi Farhadi

The aim of present research was considering Personality Traits (Normal, Hysteroid, Manic, Depressive, Antisocial, Paranoid, and Eileptoid) of substance abusers. The sample group included 112 subjects. Substance abusers were referred to the Center for Self-Reference in Shiraz city. A revised Chinese edition of Frost Multi-dimensional Perfectionism Scale (CFMPS) and the General Procrastination Scale (GPS) were administered to 315 college students. Parent rejection and over protection correlate positively with their children’s maladaptive perfectionism. Maladaptive perfectionism correlates with procrastination positively, while adaptive perfectionism correlates with procrastination negatively. There is a mediator effect of perfectionism on the relationship between parenting styles and procrastination. Improper parenting styles contribute to maladaptive perfectionism; maladaptive perfectionists are more inclined to procrasti-
Self-confidence and interpersonal disturbances: The mediating effect of clarity
Jiuyuan Zhang Southwest University, China; Chongzeng Bi

Self-confidence plays a key role in Chinese youth’s life today. However, the relationship between confidence and interpersonal disturbances is not clear. To explore the relationship between self-confidence and interpersonal disturbances, and the possible mediating effect of self-confidence clarity in this relation, 315 undergraduates (male=122, female=193, age=21.04±1.47) completed the general self-confidence questionnaire, the self-confidence clarity questionnaire and the interpersonal relationship integrated diagnosis questionnaire. The results showed that there was a significant correlation between self-confidence and interpersonal disturbances. Self-confidence could be conducing to decreasing one’s interpersonal disturbances; the more self-confidence, the less interpersonal disturbances. The effect of self-confidence on interpersonal disturbances was partially mediated by self-confidence clarity, and the mediating effect made up 40.8% of the total effect. The finding of this study implies that the function of self-confidence is not only dependent on itself, but also influenced by its structural characters.

The image of the future of the Russian, British and Americans
Svetlana Zhdanova Perm State University, Russian Federation

The purpose of the research is to study representations of the future in relation to ethnicity. The sample consisted of three representatives of ethnic groups (Russian, British, American), 30 people in each, between 20 and 60 years of age. The methods of unfinished sentences, free description, and the picturesque technique were used. Data was processed using method of content analysis and the Fisher method. Differences were found in perceptions about the future in relation to ethnicity. The British and Americans have similar views on the future model. Their vision of the future is not clear. They are characterized by a pessimistic attitude toward the future, insecurity. They are more focused on tangible assets, such as receiving a quality education, a successful professional career, material wealth, and professional development. The Russians’ view of the future is more specific. They are clearly aware of their objectives and of opportunities to implement them. They are characterized by a positive attitude towards the future, confidence in the future, taking responsibility, and a willingness to implement their plans. They are more concerned with the future of social values. They consider the most important values to be those involving family, birth and raising children, and also attach great importance to professional work, and material well-being. It can be concluded that there are differences in view of the future in relation to ethnic group. These differences relate to the degree of awareness of the future, an emotional relationship to it, and a measure of responsibility for its implementation.

Session Type: Posters

Relationship between self-esteem, anxiety, and proficiency in foreign language(s)
Mohammad Abdolmaleki IAU, North Tehran Campus, Islamic Republic of Iran; Reza Safdarian; Houman Mohsbei; Homeira Ghazvininejad

The lips of academicians in any psychology circle have always been a welcoming nest for the very concepts of "self-esteem" and "anxiety," and the premise that boosting the former and diminishing the latter is a life-long dream for every individual, is a mature speculation. The upcoming study has attempted to discover whether or not a relationship exists between individuals’ proficiency level in foreign language(s), self-esteem, and anxiety levels. The participants of the study were a population of randomly selected 80 Iranian adults of both sexes, who knew at least one foreign language at elementary level or higher. Their anxiety and self-esteem levels were measured via two standardised tests devised by Catel, and Rosenberg, respectively. The analysis of the data highlight that there is a direct positive relation between the foreign language(s) proficiency level and self-esteem. This relationship was even stronger among those who knew more than one language, whereas the anxiety was revealed to have a negative correlation with foreign language mastery.

The relationship of parenting styles with narcissism in students of Shahid Chamran University in Iran
Vahid Ahmad; Shahid Chamran University, Islamic Republic of Iran; Sareh Mirshekar; Saeid Ahmad; Yadollah Zargar; Mahnaz Mehrabzade Honarmand; Nasrin Arshadi

During the past few decades attention to narcissism among the normal population increased. The present study investigated the relationship between parenting styles (authoritative, authoritarian and permissive) with narcissism. The population of this study consisted of students (2010-2011) of Shahid Chamran University in Iran. The sample of this study consisted of 200 students (100 male, 100 female) who selected randomly by multi-stage random sampling method. The instruments for collecting data consisted of Narcissistic Personality Inventory (NPI-16) and Baumrind’s Parenting Style Questionnaire. Data were analysed using correlation method and hierarchical regression. The results of simple correlation showed that a negative relationship exists between authoritative and narcissistic, and positive relationships exist between authoritarian, permissive and narcissistic. The regression analysis also revealed that parenting styles (authoritative, authoritarian and permissive) have important role in predicting narcissism. According to the finding of this study it can be stated that parenting styles (authoritative, authoritarian and permissive) can regulate narcissism. This results should be considered in educating parents, counsellors and mental health professionals.

Coping intelligence as an important constructive mechanism in professional activities
Nadiya Akhtayeva Kazakh National University, Kazakhstan

The aim of the research was to measure two samples of 60 future teachers. The study data were collected by means of the following instruments: VSC (volitional self-control), Test of behavioral tactics in conflict situation by Buss-Durkee, Diagnosis of a personal aggressiveness and conflictness (E. P. Ilyin, P. A. Kovalev), Diagnosis methods of coping and defense strategies (A.V. Libina 2002, 2003) and a version of a Coping Intelligence Questionnaire written on its basis (2004, 2006), and the Subjective evaluation scale of personal satisfaction with life, created in English and Russian simultaneously (A. V. Libina 2002, 2003, Libin E. 2004, 2006). We compared data of two samples (a group that went through the training on coping strategy development using A.V. Libina’s emotional self-reports, diarising with a description of an emotional state, life situation playbacks etc, and a control group that did not experience any treatment listed above). A considerable difference in the results of the study allows us to assert that the behaviour of future teachers from the experimental group in conflict situations, demonstrates maturity and a constructive approach, and a tendency to concentrate on effective resolution of personal problems in groups. Methods of data processing: Spearman’s rank correlation test, Mann-Whitney test, qualitative processing.

Creative crisis as psychological phenomenon
Julia Babaeva Lomonosov MSU, Russian Federation; Valeria Mazanova; Yana Varvaricheva

Creative crisis is a significant, crucial, but insufficiently studied aspect of a creative person’s biograph. Its adequate overcoming influences not only the creator’s career but even his/her life. Despite of the painful emotional condition involved, creative crisis performs not only destructive functions but also a range of constructive ones. The aim is to investigate creative crisis’ experienced characteristics, to analyse its causes, functions and role in evolution of a subject’s creative activity. We conducted a series of studies in which 139 respondents participated. The sample included art schools students, people established as artists (writers, musicians, actors etc.), and art school graduates no longer working in arts. The complex method included The Rokeach Value Survey (RVS), techniques "Symbol of creativity" and "Life-line" (modified variant). Interview data were analysed using the Grounded Theory method (Strauss, Corbin, 1990). While in a large part of the contemporary Russian population creativity value remains consistently low, our respondents put it high on the list. Differences in implicit conceptions of creativity were found. Obtained data confirm our hypothesis about existence of creative crisis positive functions (signal, diagnostic, developmental, protective and creative) and allow us to assume that bringing them into consciousness contributes to successful crisis overcoming. Using GT resulted in description of creative crises’ reasons, peculiarities of experiencing and different overcoming strategies. These strategies may include performing destructive patterns. However creative crisis may become a stimulus to positive changes; usually in this period new ideas and ways of creativity evolution arise.

Social-psychological adaptation of former Soviet scientists to market conditions
Anara Baishukurova Kazakh National University, Kazakhstan; Nadiya Akhtayeva

During the Soviet period, scientific study was prestigious. Researcher training was practically aimed.
Research fellows worked in narrowly-specialised fields. In the post-Soviet period, many institutions were unable to continue research for a number of reasons: economic; former scientific relations with the republics of the Soviet period were lost; research problems were not accepted in science and practice; the need for specialists with knowledge of English; new computer programs; new, previously non-existent specialties appeared. "Flexible" fellows made cool stuff; received new knowledge needed in the new circumstances. Persons with a Soviet mentality weren’t able to adapt to new requirements of life, or overcome the problems encountered psychologically. To gain a skill that could be sold, to present their capacities seemed unsolvable for many. Much of this was due to destruction of past generations’ ideals – the Soviet spiritual base. The ideology of the priority of material wealth over the spiritual had occurred. Not all researchers managed to survive as scientists and even as persons. Many of them left for abroad and successfully continued their scientific career, but many moved into other areas and were not able to pursue their scientific activities. Younger generations more easily mastered new professions and specialities, but they differed quite markedly from their grandparents. They have different values and priorities. Is it good or bad? - Time will tell. There is a real hope that the link between generations wouldn’t be interrupted, and that youngsters will appreciate the best inheritance of our complex past.

The relation between attachment and personality
Lilly Both University of New Brunswick, Canada; Lisa Best
The purpose of this study was to examine the relation between personality dimensions and attachment style. 157 adults (115 females, 42 males) with a mean age of 20.96 years (SD=4.80) completed the NEO-PI-R personality inventory and two measures of attachment (Relationship Questionnaire; and Relationship Scales Questionnaire). There were statistically significant correlations among the measures of attachment and the NEO-PI-R personality domains and facets. A secure attachment style was related to low neuroticism, high extraversion, low conscientiousness, and high agreeableness. A fearful attachment style was related to high neuroticism, low extraversion, low agreeableness. A fearful attachment style was hypothesised to exist among children who have different hand preferences. We also hypothesised that the existing developmental differences among children differ significantly in the two groups [F (2,27)=4.76, p<.05], and that the two groups’ perceived discrimination scores were significantly different [F (2,27)= 7.71, p=.005].

Traits, character strengths and basic human values in the structure of personality
Jan Cieciuch University of Finance and Management, Poland; Justyna Harasimczuk; Małgorzata Najderska; Maria Klym; Dominika Karas
What are the basic dimensions of personality? The most prominent answer is that of Costa and McCrae, who claim that there are five dimensions, called personality traits. McCrae (2009) compares the five dimensions to the physics of personality. Cieciuch (2012), in his polemic with McCrae, argued that the first level of personality should be complemented by the motivational dimension proposed by Schwartz in his theory of values (Schwartz et al., 2012). Additionally, the last years have witnessed some proposals to introduce into psychology, the construct of virtues which share characteristics of both: traits in terms of Costa and McCrae and values in terms of Schwartz. Peterson and Seligman (2004) describe 24 character strengths defining six core virtues: wisdom, courage, humanity, justice, temperament and transcendence. Another approach was applied by Cawley (1997), who created a list of 140 virtues on the basis of the English dictionary. The aim of our study was the empirical investigation of the relationship between traits, values and virtues. We measured traits by scales from the International Personality Item Pool of Goldberg in the Polish adaptation by Strus, Cieciuch and Rowiaska (2011), values by Portrait VIA in the Polish adaptation of Najderska and Cieciuch (2012). The results are discussed in terms of basic characteristics of the first level of personality.

Faking self reported health behaviour
Cynthia Fekken Queen’s University, Canada; Ronald Holden; Bonnie McNeilly; Jody Wong
Measuring self-reported health behaviour (e.g., smoking, exercise, etc.) is conceptually straightforward, efficient, cost-effective, and non-invasive. This study examined whether a widely used self-report measure of health behaviour could be faked. One hundred and fifty undergraduates completed four health behaviour scales plus measures of the “Dark Triad” personality traits. Participants were then randomly assigned to an honest response, fake good or fake bad condition; again they completed the health behaviour scales plus four faking detection inventories. Instructions produced the predicted strong, significant faking effects relative to honest responding. Moreover, successful good fakers scored higher on Accident Control and Preventative Health and lower on Traffic Risk and Substance Risk than respondents who were caught faking good; successful bad fakers scored higher than unsuccessful fakers only on Traffic Risk. Similar findings were obtained using alternate definitions of faking. That is, people can deliberately make themselves look more or less healthy on a self-reported health behaviour measure. They are adept at faking good, especially on preventative health behaviour dimensions. Finally, the Dark Triad traits were not related to successful good or bad faking, but Narcissism and Psychopathy were positively correlated with Traffic and Substance Risk whereas Machiavellianism was negatively related to Accident Control and Preventative Health. Individual differences in subclinical personality are differentially related to the preventative and risk taking health behaviour dimensions. Researchers and clinicians should not simply take self-reports of health behaviour at face value.

Development of Japanese version of implicit association test-anxiety
Tsutomu Fuji Kawasaki University/CREI, Japan
In this study, the Implicit Association Test (IAT; Greenwald, McGhee, & Schwartz, 1998) and questionnaire (STAI-T; Spielberger et al., 1970) were used to measure participants’ implicit and explicit anxiety as a trait. Previous research showed that the IAT-Anxiety had enough predictive validity and stability. Egloff & Schmukle (2002) demonstrated that implicit anxiety uniquely predicted to changes participants’ experimenter-rated anxiety and performance decrements after failure (i.e., uncontrollable behavior). However, it was not examined whether similar results obtain in Japan. In study 1, the Japanese version of IAT-Anxiety (JIA-Anxiety) was developed and tested its predictive validity. 44 university students were assessed with regard to their implicit and explicit anxiety, by JIA-Anxiety and questionnaire (STAI-T). The author then collected participants’ trait and state anxiety by the friends of participants’ rating (i.e., others’ rating). As a result of multiple regression analysis, similar
results to previous study were demonstrated. Others’ rated state anxiety (i.e., uncontrollable behavior) was uniquely predicted by participants’ JIA−Anxiety score. In study 2, twenty university students completed the JIA−Anxiety twice with a time lag of 1 week. The Test−retest correlation was .76. Thus, enough predictive validity and stability of JIA−Anxiety were revealed. In a final study, the author focused on the discrepancy of implicit and explicit anxiety. The characteristic of a person who has a discrepancy between implicit and explicit anxiety, and their usual adaptation was investigated. Finally, future problems and perspectives were discussed.

Discrepancy between explicit shyness and implicit shyness: Its relation to narcissism
Tsutomu Fuji Gakushuin University/CRET, Japan; Atsushi Aikawa; Takafumi Sawaumi
Implicit Association Test (Greenwald et al., 1998; IAT), Jordan et al. (2003) proposes two kinds of self-esteem (SE) patterns: secure and defensive SE. Specifically, individuals with secure SE denote those who hold high SE at explicit level as well as implicit level, whereas individuals with defensive SE denote those who hold high explicit SE but are low in implicit SE, namely, discrepant in SE. Jordan et al. argue that narcissism is one of the characteristics in defensive SE holders. Following their research paradigm, we investigated the effect of discrepancy in shyness, which has been shown to be negatively associated with SE (e.g., Check & Buss, 1981), on narcissism. Seventy-seven Japanese college students completed a computerized version of the sensation seeking scale (SSS) and the SEEK scale of the Affective Neuroscience Personality Scales (ANPS). Glutamate concentrations in the ACC were acquired using 3-Tesla proton magnetic resonance spectroscopy (1H-MRS) in two age groups (20-35 Years; 60-75 years). 16 participants have been included in the analysis at present, however further acquisitions are in progress. A significant correlation of glutamate concentration in the ACC with age was present. The sensation seeking sum score as well as the SEEK scale correlated with the glutamate concentration (r = 0.66 for SSS and r = 0.64 for SEEK). The present findings indicate that glutamate might be a crucial factor in age associated decline in the sensation seeking personality trait. Furthermore, we were able to confirm the earlier findings on age related decline of glutamate in the ACC.

Adolescence, sensation seeking and eveningness: A behavioural risk factor?
Monserrat Goma-I-Freixanet Autonomous University of Barcelona, Spain
Individual differences in biological and physiological rhythms, and in daily behaviour among humans, can be explained by the "morningness"/"eveningness" dimension. Previous studies have reported that morningness increases throughout adulthood, while a greater tendency to eveningness is found during adolescence. In adolescents, morningness has been associated with poorer academic achievement, earlier substance use or risky behaviour. However, the relationship of morningness with personality in adolescence has not been widely studied. In adulthood, morningness is associated with high levels of activity, consciousness and agreeableness, whereas eveningness correlates with higher levels of impulsivity and sensation seeking. In order to explore the association between morningness and the sensation-seeking trait in teenagers, a sample of 745 students (51% males and 49% females), from 12 to 16 years old, completed Spanish versions of the Morningness-Eveningness Scale for Children (MESC) and the junior Sensation Seeking Scale (J-SSS), which includes 4 subscales measuring Thrill and Adventure Seeking, Experience Seeking, Disinhibition and Boredom Susceptibility. Multiple Analyses of Covariance showed that evening-type adolescents scored significantly higher on J-SSS total score and on all subscales, except on Boredom Susceptibility. These results indicate that evening-type adolescents prefer stronger stimulation and show a greater desire for varied, new, complex and intense sensations, being ready for experiencing more risks than morning-types. It is concluded that evening-types adolescents may be more vulnerable for developing risky behaviours which might be mediated by extreme scores on the sensation-seeking trait of personality.

Personality and sexual orientation
Ascension Fumero Universidad de La Laguna, Spain; Adelia De Miguel
The relation between personality and sexual orientation was examined in a Spanish sample of 26 lesbian women, 39 bisexual women, 1024 heterosexual women, 59 gay men, 16 bisexual men, and 418 heterosexual men. 30 facets of basic tendencies, 9 personality disorders, 5 self-concept factors, and 10 clinical symptomatology dimensions, were used to classify by a discriminant analysis the three sexual orientation groups. The first canonical function refers heterosexual group vs. two homosexual groups, and the second canonical function refers gay group vs. lesbian group. Gender, Openness and Conscientiousness facets and Physical self-concept are the factors which correctly classify 65.5% of homosexual people, 52.4% of heterosexual people and 53.8% of bisexual people. The gender inversion hypothesis and evolutionary ideas received important support.

Glutamate concentration in the anterior cingulate cortex and sensation seeking over the lifespan
Tobias Gleich Charite Universitaetsmedizin, Germany; Juergen Gallinat; Simone Kuehn; Michael Rapp; Robert Lorenz
Cognitive deficits have often been observed in older age. In addition, a negative relationship of age and glutamate concentration was found in the anterior cingulate cortex (ACC). Furthermore, the function of the anterior cingulate cortex (ACC) has been linked to motivation, drive and other higher cognitive functions. A positive correlation of glutamate concentration in the ACC with the sensation-seeking personality trait was also reported, and sensation-seeking was observed to decline with increasing age. Therefore, we hypothesised that an age related decline in glutamate concentration in the ACC accompanied by a decrease in sensation-seeking scores. We measured sensation-seeking scores using the sensation seeking scale (SSS) and the SEEK scale of the Affective Neuroscience Personality Scales (ANPS). Glutamate concentrations in the ACC were acquired using 3-Tesla proton magnetic resonance spectroscopy (1H-MRS) in two age groups (20-35 Years; 60-75 years). 16 participants have been included in the analysis at present, however further acquisitions are in progress. A significant correlation of glutamate concentration in the ACC with age was present. The sensation seeking sum score as well as the SEEK scale correlated with the glutamate concentration (r = 0.66 for SSS and r = 0.64 for SEEK). The present findings indicate that glutamate might be a crucial factor in age associated decline in the sensation seeking personality trait. Furthermore, we were able to confirm the earlier findings on age related decline of glutamate in the ACC.

Chronic Fatigue Syndrome and the alternative five factor model
Monserrat Goma-I-Freixanet Autonomous University of Barcelona, Spain
Neuroticism has been the most frequent personality dimension associated with Chronic Fatigue Syndrome (CFS). The majority of studies have also shown that CFS patients are less extraverted than non-CFS patients, although its statistically significant effect is inconsistent, probably as a consequence of not taking into consideration the major facets of this dimension. The objective of this study is twofold: to assess, for the first time, the personality profile of adults with CFS under the AFFM perspective, and to test the discriminant validity of the ZKPQ in differentiating CFS subjects vs. normal-range controls. The CFS group consisted of a sample of 132 patients. We used a case-control design: every case was matched by age and gender with a control subject randomly obtained from a community sample. A cross-validation procedure, using logistic regression, was executed to test for the accuracy of the discriminant model. Low levels on Activity (Wald = 13.59, p < 0.05, OR = 0.81) and high on Neuroticism-Anergy (Wald = 10.90, p < 0.05, OR = 1.15) showed the best discriminant capacity between CFS and controls. The results of this study are concordant with previous literature on the relevance of Neuroticism in CFS characterisation, but it extends the sparse existing literature in a significant manner in relation to the Activity trait. For a better conceptualisation of this medical condition, we encourage researchers to take into account the facets of extraversion rather than the dimension itself.

Validating the OCEAN personality trait scale (OPTS) with a two-stage factor analysis process
Tsai-Wei Huang National Chiayi University, Taiwan; R.O.C.; I-Chi Tsao; Chiao-Lin Huang
The five factors of personality model (OCEAN) has been applied prevalently around the world. This study aimed at developing an OCEAN personality scale (OPTS) with a two-stage factor analysis process: exploratory and confirmatory. Initial 30 items were designed, based on the five personality factors and were analysed in a pretest that was participated in by 176 valid 5th and 6th graders in Taiwan. Items had been reduced to 22, due to the values of factor loadings lower than .5 during an exploratory common factor analysis. Overall OPTS with an internal consistency coefficient of Cronbach α as .91 (sub-scales ranged from .57 to .87) and a total of 56.35%
variance explained. Items were distributed to the five personality factors: Agreeableness (trustworthily, gentle, helpful, kind, forgivable, and merciful), Conscientiousness (hard-working, self-requesting, organised, responsible, and endurable), Extraversion (talkative, sociable, vigorous, active and inter-personal oriented), Openness to Experience (curious, creative, original, and non-traditional), and Neuroticism (restless, nervous, and wrathful). In the second-order confirmatory factor analysis stage, there were 700 valid subjects, including 351 boys (50.14%) and 349 girls (49.86%), who participated in the 22-item scale. Good model-data fitting evidences were shown. Standardised regression coefficients between items and specified factors were from .47 and .80 with an overall composite reliability of .95 and a latent variance extracted of .50. This indicates that the OPTS is reliable and valid.

Mind-wandering and individual differences in worry
Yudai Iijima The University of Tokyo, Japan; Tanno Yoshikiko

The attentional bias toward negative stimuli in high anxiety, is constantly being investigated. From this, the relationship between the attentional bias and worry is pointed out. Although worry is not an external experience but rather, an internal one, the relationship between worry and the attention toward inner experience, such as mind-wandering, is not investigated. Against this background, the present study investigated the mind-wandering in worry-prone individuals. A total of 43 undergraduates performed a simple Go/No-Go task. While the participants performed the task, 4 classified conscious experiences (on the task, distractions by experimen- tational tasks, task relevant interference, and mind-wandering) that varied along two dimensions ("task-relatedness" and "stimulus-dependency") were sampled using thought-probes. After the task, they completed the questionnaire assessing trait worry. Analysis of multilevel model indicated that the probability of mind-wandering was increased with time (B = 0.008, t = 5.56, p < .001). Moreover, the effect of time course on mind-wandering was moderated by trait worry. Further analysis revealed that the increase of mind-wandering with time was more significant in high worry individuals (B = 0.012, t = 5.81, p < .001) than low worry individuals (B = 0.004, t = 2.05, p < .05). The implications of these data and several problems are discussed.

Comparative study on core self-evaluations and the big five personality traits
Hong Jiang Capital University of Economics and Business, China

The most widely used personality theory until now, the Big Five personality, has a fairly stable five-factor structure, good cultural compatibility and excellent applicability. Judging from a research approach, it belongs to the narrow trait approach, which uses narrow traits to describe and measure personality. Its five dimensions’ acronym is "OCEAN" indicates the universality and the compatibility of the Big Five personality. The Core Self-Evaluation (CSE), as a broad trait approach developed by Judge, represents a kind of new development trend in personality study. The contradiction between precision and broad trait approaches exist in the personality measurement field. In Chinese contexts we compared the constructs of Big-Five personality and the CSE based approach on a sample of 865 college teachers. The study used the correlation analysis and regression analysis to test their predictive validity and incremental effect. The result showed that CSE works for Chinese context, but is also different from the big-five personality. Both CSE and big-five personality can predict job satisfaction, affective commitment and in-role behavior. The comparison of the incremental effect of the two constructs showed that the Big Five Personality has better incremental validity for job satisfaction and in role behaviour compared with the CSE, while the CSE has only better incremental validity for affective commitment. It indicated that the narrow and precise personality measurement, the big-five personality, could bring a better and more powerful understanding to personality, which worked better in predicting work related attitudes and behaviours.

Personality disorders, personality traits and temperament
Olivier Lavenderière Université de Sherbrooke, Canada; Kristel Lortie Lapierre

Personality disorders (PD) have been studied in relation to personality traits and temperamental dis- positions. In this framework, PD features are con- ceptualised as extreme variants of normal personal- ity traits, mainly as exaggerated elevations of neuroticism or negative affectivity (Saumland & Page, 2004). Given the close association between temperament and personality traits models, the Five-Factor Model (FFM) has frequently been used to explore the relationship between PDs and temper-ament (e.g. Widiger, 2005). Notwithstanding the results linking the FFM with genetics and heritabil- ity, the model of adult personality is far from the definition of temperament dimensions. Rothbart’s model of adult temperament contains various dimensions that are more closely linked to emotional and attentional processes, compared to the lexical approach of the FFM (Rothbart, Ahadi, & Evans, 1998). Thus, the aim of the current study is to explore the relation between PDs, FFM and adult temperament dimensions. The sample is composed of 387 participants that completed the Personality Disorder Questionnaire – 4+ (Hyler, 1995), the Mini-International Personality Item Pool (Mini-IPIP; Donnellan, Oswald, Baird, & Lucas, 2006) and the Adult Temperament Questionnaire (Evans & Rothbart, 2007). Multiple regression analysis revealed that FFM dimensions significantly explained each PD. The addition of temperament dimensions yielded significant increases in variance explained. The importance of specific temperament dimensions and subdimensions differ according to PD. The discussion highlights these differential associations as well as their clinical implications.

Developing the finding benefits scale and investigating influences of finding benefits on resilience
Takeuchi Mio Gakushuin University, Japan; Tsuto-mu Fuji Gakushuin University, Japan

The purpose of this study was to develop the Finding Benefits Scale (FBS), to examine its reliability and validity and to investigate influences of finding benefits and resiliency on resilience. Finding bene- fits is the result of the exploration of positive mean-ings in a traumatic event and it reduces negative aspects in a difficult situation. In Study 1, 297 Japanese university students described a negative life event which they were going through at that moment and completed questionnaires (included FBS). Factor analysis revealed that FBS had two factors: Giving Positive Meanings (GPM) and Ap- preciation for Human Relationship (AHR) and it was showed that they had high internal consistency and test-retest reliability. GPM had significant pos- itive correlations with importance of the negative life event, refraining from catastrophic thinking and resiliency, and had a significant negative correlation with suffering. AHR had a significant positive cor- relation with importance of the negative life event. These results revealed that FBS had enough reli- ability and validity. In Study 2, participants evalu- ated the negative life event that they had described in Study 1 five months before and we examined influences of finding benefits on mental condition they were in afterwards. The results of structural equation modeling indicated the process of mental recovery that finding benefits affected resiliency and resiliency reduced suffering and threats for the negative life event. In other words, it was suggested that finding benefits reduced suffering and threat for the negative life event through resiliency. Final- ly, we discussed problems of this study.

Analysis of the relevance of a 3D virtual programme to detect drug use behaviors and bullying
Consuelo Moran Leon University, Spain; Adolfo Cangas; Jose Alberto Carmona Torres

The psychometric data of a new computer science tool of three-dimensional simulation (3D) designed for the detection of risk of drug taking behaviours and bullying in adolescents is presented. In partic- ular, Mii School (the name of this new program), recreates 17 conflicting situations of drug use and bullying, where the participant must respond when they are immersed in different situations of risk. The computer program has shown good reliability properties (α=0.82) and validity (showing a factori- structure composed of 8 factors that explain 57.26% of the total variance). The study is con- ducted on the basis of differently realised studies: One discusses the capacity and utility of the pro- gram as a tool of detection of behaviours of drug consumption and bullying in young people, as well as the potential applicability of this program in educative contexts.

Engagement and burnout in Portuguese tea-chers
Consuelo Moran Leon University, Spain; Maria Ildia Duarte

The purpose of this study was to find the relation- ship between the burnout syndrome and the engage- ment dimensions in a sample of Portuguese tea- chers. We apply the MBI (Maslach Burnout Inventory) to evaluate burnout and the UWES (Utrecht Work Engagement Scale) to assess work engagement in 94 teachers of pre-school to second- ary school. The data showed moderate-strong links and negative between burnout and engagement. We
also found positive correlations between personal accomplishment with vigour, dedication, and absorption. Also in Portuguese teachers, it confirms the hypothesis that engagement presents a potential value to predict well-being in teachers and to protect against chronic stress at work.

The relationship between integrity and personality in South Africa
Cilla Myburgh University of Pretoria, South Africa; David Marais
Integrity as a psychological construct is receiving more attention in South Africa as more companies require integrity profiles of applicants in addition to personality profiles, as part of the selection process. The purpose of the study was to investigate the empirical relationship between integrity, as a psychological construct, and sixteen personality factors. Integrity refers to the degree to which individuals act in accordance with relevant moral values and norms. In particular, the degree to which an individual is honest, norm abiding, responsible, trustworthy and punitive towards rule breaking. The study aimed to determine whether there is a relationship between integrity and various personality factors. The sample consisted of 873 respondents of the South African working population who completed the South African Integrity Scale (SAIS) and the Sixteen Personality Factor Questionnaire (16PF). Not assuming a normally distributed sample, the relationship between the variables was tested by means of Spearman’s Correlation Coefficient. The findings of the study present novel information on the relationship between personality and integrity, providing a new profile on persons with high integrity. Contrary to previous research, the results indicate that a person with high integrity is characterised as a self-assured, confident person who is relaxed and patient, feeling emotionally stable, quite trusting and accepting in nature, as well as being socially bold and venturesome. The results are discussed and presented on the poster.

A comparison of impulsivity and sensation seeking in pathological gamblers and skydivers
Helga Myrseth University of Bergen, Norway; Susanne Hagatun; Camilla Lindgren; Renate Tvera; Olav Olsen (16PF).

The aim of this study was to compare pathological gamblers and skydivers in relation to measures of impulsivity and sensation seeking. The Eysenck Impulsivity Scale - Narrow Impulsiveness Subscale and the Arnett Inventory of Sensation Seeking were administered to pathological gamblers (n = 29), skydivers (n = 93), and a control group (n = 43). A two-way multivariate analysis of variance was conducted to explore differences in impulsivity and sensation seeking between the groups and possible group by gender and group by age interaction effects. The significant effects were further investigated using follow-up univariate analysis of variance. The results showed significant main effects of Group, Gender and Age, and a significant Group by Gender interaction effect. The results showed no statistically significant differences in impulsivity between pathological gamblers and skydivers; however, both groups scored higher than the controls. The skydivers scored higher compared to the pathological gamblers and controls on both sensation seeking subscales. Pathological gamblers scored higher than the controls on the subscale Need for Stimulus Intensity, although lower than the controls on the subscale Need for Novelty. We conclude that skydivers and pathological gamblers do not seem to differ in terms of impulsivity, but that the two groups differ in terms of sensation seeking. Skydivers are hence characterised by more sensation seeking compared to pathological gamblers. Skydiving as a form of pathological gambling, is not considered a psychiatric disorder, and skydiving may represent a more non-pathological way to fulfil the need for stimulus intensity.

Exploring personality conceptions of white and coloured Afrikaans speaking groups: A comparative study
Jan Nel North-West University, South Africa; Carin Hill; Marais Bester
The present study forms part of the development of the South African Personality Inventory (SAPi), which explores the implicit personality structure in the 11 official language groups of South Africa. The objective of this study was to investigate the personality conceptions of two ethnic groups within South Africa, namely white and coloured Afrikaans speaking groups. The researchers used a qualitative design, and drew a combined convenience and quasi sample from 60 Afrikaans speaking groups (n = 30 white participants; n = 30 coloured participants). The sample differed in terms of age and socio-economic status within South Africa. Semi-structured interviews were conducted, and the data were analysed by the use of content analysis. The derived personality-descriptive terms were categorised and clustered based on their semantic relations in iterative steps involving group discussions and contacts with language and cultural experts. Initial analysis showed little differences in conceptions of personality between white and coloured Afrikaans speaking groups, but there were differences regarding the responses accumulated. The coloured participants were more inclined to use concrete terms when describing the self or others, while white participants employed more abstract terms. Relational aspects were more mentioned within the coloured groups, while the white groups were more inclined to use individualistic terms in their descriptions. It can be recommended that when items are being developed for the personality questionnaire, the focus should be on the identification of commonalities between these two ethnic groups, consequently excluding items that may be lead to bias and inequivalent measurement of personality.

The relationship between parental rearing patterns and Machiavellianism
Yujia Peng Peking University, China; YinYu Zhang; Jingwei Sun
The present study investigated the relationship between parental rearing pattern and Machiavellianism by using the Machiavellianism VI questionnaire, which attempts to measure an individual’s degree of confidence in the trustworthiness, honesty, goodness, generosity and brotherliness of other people. A Chinese-language version of the Swedish Egma Minnen av Bardndosnauppforstran(EMBU) inventory, was used. This instrument has subscales measuring the degree to which each parent was abusive, depriving, punitive, shaming, rejecting, overprotective, overinvolved, tolerant, affectionate, performance-oriented, guilt-engendering, stimulating, favouring siblings, or the subject. The questionnaires were administered to 186 undergraduate students of Peking University (99 boys and 87 girls). The results showed that both father and mother’s factor 1 (family cohesiveness and understanding) had a significant positive correlation with the score of Machiavellianism, and the mother’s factor 3 (refuse and deny) had a significant negative correlation with the score of Machiavellianism, but there was no significant gender difference on the score of Machiavellianism. These results imply that the parental rearing pattern might impact the child’s Machiavellianism. The family cohesiveness and understanding might be positive predictors of the score of the child’s Machiavellianism; while a mother’s “refuse and deny” score might be negative predictor of the score of child’s Machiavelianism. The theoretical and practical implications of the findings from the study are discussed.

Life management strategies as predictors of multidimensional model of mental health in late adulthood
Moja Petric Faculty of Education, Slovenia; Tina Kavlic; Maja Zupancic; Blanka Colneric
Baltes (1997) proposed a general model of successful development, which includes four life management strategies for coping with every problem: elective, loss-based selection, optimization and compensation (SOC). The SOC strategies are positively related to various aspects of well-being in old age but the use of strategies as predictors of a comprehensive, multidimensional model of mental health (Keyes, 2007) has not yet been examined. The present study expected the use of SOC to predict mental health outcomes in elderly. Over 150 adults (73% female), aged 65 to 87 years (M = 72) and living in the community, completed the SOC questionnaire (Baltes et al., 1999) and the short version of the Mental Health Continuum (MHC; Keyes, 2009). The MHC provides continuous scores of emotional, psychological and social well-being, as well as assignment to three mental health categories: flourishing, moderately mentally healthy, and languishing. Our results support the importance of SOC in predicting all major domains of well-being. Loss-based selection contributed to emotional and psychological well-being; optimization predicted psychological and social well-being. However, elective selection was negatively associated with emotional well-being in the elderly. Languishing individuals reported using the loss-based selection, optimization and compensation the least frequently, while they employed elective selection the most often. The study suggests that the use of SOC may serve as a means of maintaining good mental health in old age. Thus, the strategies could present a foundation for intervention aimed at enhancing several dimensions of mental health in the elderly.

The "Big Five" personified
John Magnus Roos Center of Consumer Science, Sweden; Aimee Ferreira
This study aims to explore the potential of transforming a verbal personality scale, the HPS (Gustavsson,
Jönsson, Linder & Weinbry, 2008), to a non-verbal (visual) personality scale. Instead of relying on the use of words, we give the respondents an opportunity to report personality traits (i.e. neuroticism, openness, conscientiousness, agreeableness and extraversion) using cartoons. According to Desmet (2006), non-verbal scales increase the pleasure of participating and allows researchers to uncover aspects that people are unwilling and/or unable to verbally express. We validate our non-verbal scale versus verbal items in HPS in order to investigate to what degree the five different cartoons (e.g. extreme personalities) correspond to the verbal meaning we would like them to express. Each cartoon is measured by 15 items; three items for each factor. The scale used for each item was a four-level scale: completely agree (coded as 1), partly agree (coded as 2), partly disagree (coded as 3), completely disagree (coded as 4). The validation criteria were as following: (i) the three items measuring a particular factor must in average have an average of 1.35; (ii) every item must correspond more to the factor it is supposed to measure than to other factors. The study discusses problems, challenges and opportunities with visualising a verbal scale. The study also discusses cultural differences in body language and facial expressions. The cartoons are developed with designers at Ergonomidesign in Sweden and validated using 300 international students. The study is financed by the central bank of Sweden.

Effect of a music intervention in South Africa on students’ outlook

Michael Roy
Elizabethtown College, United States of America; Karendra Devroop; Laura Getz

In the spring of 2009, we started a fully functional concert band programme at a high school in Kwa-Zulu-Natal, South Africa. In the fall of 2011, we returned to the school to measure the impact of the music intervention on the students’ attitude and outlook. During our initial and return visits, we measured feelings of self-esteem, optimism, positive affect, negative affect, motivation to avoid losses and motivation to seek gains. We compared participants in our music intervention group to a control group of students at the school who were not part of the music intervention programme. At the second testing there were 20 of the original students remaining in the concert band and 11 of the original students in the control group. In the two and a half year period, all students (music intervention and control) experienced an increase in self-esteem and in motivation to avoid losses. Specific to our interests, the band members, and not members of the control group, showed increased levels of optimism and motivation to seek gains as a result of the intervention. There was no change in either group during the period in either positive or negative affect. The music intervention appears to have improved certain aspects of attitude and outlook for participants in the programme: Students in the band were more likely to be motivated to seek gains in life and also more likely to have an optimistic attitude as a result of the programme.

Identity formation and perceived parenting in Greek late adolescents

Spyridon Tantaros
University of Athens, Greece; Elias Besevegis

Identity formation is a dynamic process of person-context interactions. Most research on adolescent identity has so far conceptualised identity in terms of Marcia’s paradigm (Marcia, 1993, 1966). Consequently, there has been a lot of evidence on identity formation, although not so much regarding its relations to parenting. Parents are a very important part of this context, even in late adolescence. There are several theories on parent-adolescent relationships supporting the idea that parents influence the process of identity formation. However, up to now, empirical evidence for this link is limited. This study investigates the relationships among the ego identity statuses and parenting styles. The participants of the study were high school students (N=297), as well as students at the first year of the university (N=244). The Ego Identity Process Questionnaire (adaptation in Greek by Georganti, 2010) was used to assess identity status as conceptualised by Marcia. Parenting style was measured using the Parental Bonding Instrument (translated in Greek by Kafetsios & Sideridis, 2008). Findings show that identity exploration is more intense when mothers have a university degree or fathers are married, while both identity exploration and commitment are predicted by mother’s care.

The relationship between self-concept and acceptance of death compared among adolescents and old age

Gaytri Tiwari
College of Home Science, India

The human lifespan can be divided into three stages: namely childhood, adolescence and old age. The attitudes, values and beliefs of adolescents and the aged differ significantly. This study focused on assessing the impact of: type of family, age and gender, as well as issues of fear, extraversion-neuroticism, optimism-pessimism of adolescents and the aged on death anxiety. The locale of the study was Udaipur, India. The sample comprised 120 adolescents (18-21 years) and 120 older people (60-75 years). This sample was further divided on the basis of sex and type of family. Standardised research tools were used. The data were statistically analysed. Results revealed that the level of death anxiety was equal among extended and nuclear families. Youth reflected higher scores compared to those of the aged. Males had higher death anxiety than females. Regarding fear, the scores were higher in respondents belonging to nuclear families. Youth and males were found to be more fearful. In relation to optimism and pessimism, all the respondents were marginally ambivalent. Adolescents from extended families had higher extraversion. Respondents from nuclear families and youth were less neurotic. A significant positive relationship was found between death anxiety and fear. Optimism-pessimism were extraversion were negatively correlated. It was concluded that proper and suitable measures should be taken to strengthen joint family systems. Governmental organisations and NGOs should plan different programmes for capacity-building of adolescents and the aged to overcome negative emotions which will help in developing a positive attitude towards death.

Towards developing a psychological profile for Underwater Explosive Ordnance Disposal Specialists

Charles Van Wijk
South Africa

It is thought that the demands involved in underwater explosive ordnance disposal (U-EOD) would require a particular kind of person to be successful in that environment. This study aimed to describe the psychological profile of the South African Navy U-EOD teams, and to compare them to to land-based EOD operators and naval divers. The psychological profile of 45 qualified U-EOD disposal operators were explored using a number of personality and vocational scales. These include the 16 Personalityfactor Questionnaire, Rotter’s Internality-Externality Scale, the IPAT Anxiety Scale, the Sensation Seeking Scale, and the Selfdirected Search Questionnaire. The personality traits most descriptive of the U-EOD operators are those of confidence, adventurousness, assertiveness, and trust. They score high on thrill and adventure seeking and low on dis-inhibition, and report low generalised anxiety and a greater internal locus of control, while conforming to a realistic-social-investigative occupational interest profile. Their profile closely follows that of both land-based explosive ordnance disposal operators and naval clearance divers. The profile is at times more accentuated (e.g. high adventure seeking), and these slight differences can be attributed to the confluence of the two occupational fields – ordnance disposal and naval diving. The U-EOD profile does not form a distinct entity, but incorporates the attributes of both land-based EOD and naval divers, and as such appears contextually appropriate to the specific field of work.

The development of imagination test of concept combination

Ching-Wen Wang
National Chung Hsing University, Taiwan, R.O.C.; Ruey-Yun Horng

Based on the theory of concept combination, this study develops a scale measurement called ‘Imagination Test of Concept Combination, ITCC’. The tested items are consisted of two unrelated concepts such as ‘cell phone-justice’. The respondent is required to think up a word to connect these two
concepts such as ‘police’, and then explain the association process and reasons. The respondent can answer the questionnaire in a free-writing way.

The purpose of this scale measurement is to test level of imagination of students, and provide references for university in designing curriculum and activity. Data are collected from 602 undergraduate and graduate students. Based on statistical data, items with more than 5% respondents with the same answers are given 0 point, 1 point for between 2%-4%, and 2 points for under 2%, in order to establish the test’s score handbook. The statistical result shows that each item and total score are significantly correlated, representing the discrimination of the scale measurement. The test-retest reliability is .878; the rater reliability is .854. The criterion validity is .227. In terms of validity, as compared to Torrance Tests of Creative Thinking and creative perception scale measurement, the imagination test developed in this study is distinguished from creation tests. In summary, the results indicated that the scale measurement test of this study has fairly good reliability and validity.

Are perceptions of self and others similar: Evidence from memorial self-complexity? Yulan Wang Southwest University, China; Chongzeng Bi People are significantly diverse in perceiving others in the way that they perceive themselves. Brown (2009) found that self-complexity is reflected in perception complexity of meaningful others. The study tests the perception complexity of self and others (mother, friend, the nation’s president). 45 undergraduates (male 16, female 29) were required to complete a card-sorting task which measures self-complexity. In order to control error of the self-complexity and perception complexity of others, subjects completed the task at one-day intervals. They then completed the self-reference memorial task which could measure their closest others of the self in collectivist culture. The results showed that self-complexity and perception complexity of mother did not differ when the mother was included in the self. Further, when the friend and the nation’s president weren’t included in the self, the difference between self-complexity and perception complexity of friend and the nation’s president were significant. The results suggest that perceived structure of the self and others included in the self is similar.

The possible selves of freshmen in China: Expecting to obtain achievement Yulan Wang Southwest University, China; Chongzeng Bi During life transitions, individuals often think of questions about self and future success. Possible selves theory describes how future-oriented thought provides self-relevant information, and the motivation to pursue self-relevant goals. Without the careful supervision of teachers and parents, whether freshmen still focus on achievement in the first year of university, is very important to their lives. 379 freshmen (154 males, 222 females) completed the Possible Selves Questionnaire one month after enrolling at university. The results showed that 67% possible selves’ goals and 89% “balanced” possible selves’ goals belong to the content of the achievement. Furthermore, the freshmen obtained higher scores on expected goals than on feared goals (t=10.76, p<0.01), especially the achievement expected goals (t=27.78, p<0.01). There is no gender difference in the achievement domain. Freshmen with rural life experiences did not score higher on achievement goals than those from urban areas. The results imply that achievement is the most important content of the self-future scheme of the freshman.

The filial piety personality of contemporary university students in China: Development and construct validation of a psychological measure Fang Yi Jiangxi Normal University, China; Caishang Zhong; Xiaoaqi Su This paper aims to explore the construct of Chinese filial piety personality by assessing the factural-self in the relationship with their parents. An ideographic assessment is firstly employed to derive a high frequency word list concerning the factusal-self in the relationship with their parents. In order to obtain the original items of the Filial Piety Personality Inventory, the study then undertakes a nomothetic assessment, in which 200 undergraduates are asked to rate on a 4-Point Likert scale, to what extent each word in that high frequency word list is appropriate to describe the factusal-self in the relationship with their parents. Finally, the Filial Piety Personality Inventory is administered to a sample of 378 undergraduates, and a seven-factor construct of the Filial Piety Personality is derived through an exploratory factor analysis (n=189) and validated through a confirmatory factor analysis (n=189).

The self-discrepancies of Chinese contemporary college students in filial piety Fang Yi Jiangxi Normal University, China; Qinjuan Liu; Xiaoaqi Su This paper aims to study the self-discrepancies of Chinese Contemporary College Students in filial piety, which has adopted both an ideographic approach and a nomothetic one. In the ideographic assessment, 118 college students were asked to respectively, choose 10 words to describe each type of their actual, ideal, and ought selves in filial piety. The high frequency word lists of the respective selves were used as further testing materials. In the nomothetic assessment, another 200 college students were required to rate on a 4-Point Likert scale to what extent each word in those high frequency word lists is appropriate to describe the self(factual): ideal; ought in filial piety. The results show that: the ideal-self and the ought-self in filial piety are monopolar and consistent with each other, while the factusal-self in filial piety is bi-polar and inconsistent with the other two. The differences between the selves may indicate the dynamic features of the self-discrepancies of Chinese Contemporary College Students in filial piety.

Developing a Chinese version of the depressive personality disorder inventory Mingtian Zhong South China Normal University, China; Jiniao Yi South China Normal University, China; Xiongzhao Zhu; Shuqiao Yao; Yu Ling South China Normal University, China

The objective of this study is to develop a Chinese version of the Depressive Personality Disorder inventory (DPDI) and to examine its reliability and validity applied to Chinese university students. A final Chinese version of the DPDI was approved after repeated translation and back-translation. A sample of 7349 university students finished the DPDI, the depressive personality disorder (DPD) subscale of the Personality Disorder Questionnaire-4+ (PDQ-4+) and the Center for Epidemiologic Studies Depression Scale (CES-D). 187 of them finished the DPDI twice with a one-month interval inbetween. We evaluated the Cronbach’s alpha coefficient, the mean inter-item correlation coefficient (MIC), the test-retest reliability coefficient of the DPDI, and the Pearson correlation coefficients between the DPDI and the CES-D subscale of PDQ-4+. The DPDI showed adequate internal consistency (Cronbach’s α=0.93, MIC=0.23) and good stability (test-retest reliability was 0.89). The correlation coefficients between the DPDI and the CES-D subscale was 0.79, and the correlation coefficients between the DPDI and the CES-D was 0.68, ps 0.05, supporting its convergent validity. Based on the DPDI cut-off score of 170, the prevalence of DPD was 7.3%. Among the 535 subjects with DPD, 467 were also classified as DPD by the cut-off score of DPD subscale of PDQ-4+. This supports the conclusion that the DPDI has high positive predictive power. The Chinese version of the DPDI was a reliable and valid measure for assessing DPD in undergraduate students.

Session Type: Invited Addresses

Personality assessment for organisational and community applications in Asia Elizabeth Nair Work & Health Psychologists, Singapore

Personality assessment is increasingly applied in Asia in work, educational, counselling and community intervention scenarios. Issues of test validity, reliability and appropriate interpretation in contexts far removed from initial test development is examined in this symposium. Presenters will discuss their experiences, challenges faced, and steps taken to ameliorate possible interpretation errors. Discussants will provide comments on constructive strategies that may be adopted in similar undertakings in the years ahead.

Personality predictors of achievements of gifted students in math, humanities and music Andrzej Sekowski John Paul Catholic University of Lublin, Poland

The study was based on Renzulli theory of giftedness and Sternberg’s theory of successful intelligence. Experiments were conducted in Poland and Germany. School achievement of gifted individuals enables diagnosis of underachievers, as well as optimization of the achievement of other gifted students. The participants were secondary school students.
They were divided into groups of students with outstanding school achievements and those with average school achievements. Also the type of achievements, including achievements in math, humanities and music, was taken into account. The following testing tools were used: Raven Matrix Scale, Rokeach Value Scale, Costa and McCrae NEO Five-Factor Inventory (NEO-FFI), Urban and Jellens Test for Creative Thinking-Drawing Production, and Sears’ Self-Esteem Inventory. Students with outstanding achievements in math had a high level of intelligence, a high level of creative abilities, a high self-esteem regarding their functioning at school, and a low self-esteem regarding their social functioning and their fitness in sports. Students with outstanding achievements humanities had a high level of intelligence, a high level of creative abilities, and a much higher self-esteem regarding their social functioning than mathematically gifted students. Musically talented students had a high level of creative abilities, a high general self-esteem, and a preference for artistic education. Students with outstanding achievements in humanities had a high level of intelligence, a high level of creative abilities, and a much higher self-esteem regarding their social functioning than mathematically gifted students. Musically talented students had a high level of creative abilities, a high general self-esteem, and a preference for artistic and esthetic values. The results indicate a significant dependence of school achievement on intellectual factors, as well as on self-esteem and preference of values. Underachievement of gifted students is mainly associated with low self-esteem and impairments of social functioning.

Session Type: Symposia

Symposium title: Cross-cultural applications of personality in applied settings
Convenor: Gideon De Bruin

Personality, culture as moderators in demands-control-support model of job strain
Gideon De Bruin University of Johannesburg, South Africa; Jurgen Becker; Christiina Grykas; Koorosh Massoudi; Jerome Rossier

Existing job strain models underemphasise the role of personality and culture. We demonstrate with South African and Swiss data that personality attributes and culture moderate the relations of job characteristics (demands, control and support) with job strain and job growth (burnout, work engagement). In addition, three-way interactions between personality, culture and job characteristics are observed. Results emphasise the role of personality, but also show that this role may be different across cultural contexts. The implications of these interactions for explaining and treating job strain are discussed.

Age and gender differences in adolescent personality: Data requirements and substantive findings
Gideon De Bruin University of Johannesburg, South Africa; Marleen de Bolle

The present study extends the examination of age and gender differences in personality to early and late adolescence, examining observer ratings of adolescents aged 12 to 17 years (N=5,109) collected in the course of the Adolescent Personality Profiles of Cultures project (APPOC), a collaborative study running in 24 cultures. Data requirements for such comparisons will be empirically examined and discussed, and evaluated against substantive and replicable findings on personality development and group differences.

Personality testing in South Africa: Where are we going?
Sumaya Laher University of the Witwatersrand, South Africa

The assessment of personality is at the forefront of both research and practice in South Africa. This presentation explores the status of personality testing in South Africa first from a research perspective and then from a more applied perspective. This is done to firstly highlight the disparities that exist between the two and a possible way forward to bridge this gap will be presented. There are also some common challenges that are equally applicable to research and application in all settings (organisational, clinical, counselling, educational), most notably that of language, culture, acculturation, globalisation, socioeconomic status, and quality of education. These will be addressed in the presentation and some ideas to take the field forward in South Africa will be presented.

Personality assessment in very heterogeneous populations
Fons Van De Vijver Tilburg University, Netherlands

I will discuss issues that arise in the assessment of personality in populations that are very heterogeneous. Examples are assessment for global talent, assessment for positions in profit and non-profit organisations with a strong international orientation, and assessment in countries with many languages and cultures. Salient assessment problems to deal with are knowledge of the language and culture of the instruments, validity of the instruments, and the frequently observed problem of test norms that are either missing or of unknown validity. I will discuss solutions that have been proposed and the evidence (required and gathered) to support solutions.

Symposium title: Multiple goal and task management: Interdisciplinary perspectives
Convenor: Julia Vogt

How working memory capacity shapes desire-goal conflict in everyday life
Wilhelm Hofmann United States of America; Kathleen Vohs; Roy Baumeister

In their daily lives, people have to manage and balance the pursuit of multiple goals. This talk will be about the emergence and consequences of goal conflict in everyday life. We assumed that goal conflict emerges, whenever a focal desire stands in opposition with one or multiple "background" goals that are salient at a given time. We further hypothesised that the intensity of experienced goal conflict depends on the absolute number of conflicting goals and on the commitment to these goals. Furthermore, we investigated whether trait working memory capacity (WMC) may intensify desire-goal conflicts, because people may represent internal desire-goal conflicts more clearly. To test these assumptions, we sampled more than 7000 desire episodes from people’s everyday life using experience sampling (Hofmann, Baumeister, Forster, & Vohs, in press). We found that conflict experiences increased with increasing number of conflicting goals and as a function of commitment to these goals. Conflict in turn increased the use of self-control to inhibit behaviour. High WMC was associated with a stronger than average relationship between commitment to conflicting goals and experienced conflict, and with a weaker than average relationship between the number of conflicting goals and experienced conflict. These results suggest that WMC may intensify desire-goal conflict to the extent that people commit to desire-opposing goals; controlling for the commitment effect, however, being high in WMC may at the same time attenuate the degree of conflict stemming from the perception that multiple goals collide with one’s current desire.

Symposium title: New findings in human values theory
Convenor: Jan Cieciuch

The old structure of values in new data and new structure of values in old data
Jan Cieciuch University of Finance and Management, Poland; Michele Vecchione; Shalom Schwartz; Eldad Davidov

Schwartz and colleagues argued that the domain of values can be partitioned into broader or more fine-grained value constructs, depending on how precisely one wishes to discriminate among motivations. Confirmatory Factor Analysis (CFA) in 10 countries on the new Portrait Values Questionnaire (PVQ-57) has supported the possibility of discriminating 19 values, in accordance with the refined theory of values. One can argue, however, that the possibility of partitioning values into less or more fine-grained values should not depend on the measurement instrument used. To address this issue we tried to identify: 1) the 10 "old" basic values using data collected with the PVQ-57, designed to measure 19 values and 2) more precisely defined "new" values using data collected with the PVQ-40, designed to measure 10 values. In order to examine whether the 19 values can be combined to recapture the original 10 basic values, we performed a second-order CFA on data collected in 10 countries using the PVQ-57. Results confirm that the new values can be combined in the original 10 value types. In order to examine whether the items of the PVQ-40 can be partitioned in more narrowly defined values we compared CFA models in 12 countries. Results showed that models with more narrowly defined values fit significantly better than the original model positing ten values. These findings provide a strong support for the refinement of the theory of human values.

Exploring the developmental origins of values: Assessment approaches in early childhood
Anna Doering University of Muenster, Germany; Fabrizio Butera; Patricia Collins; Wolfgang Bilsky; Elena Makarova; Caroline Pulfrey; Jan Cieciuch

We build our research on Schwartz’s (1992) theory of universal human values and aim to trace value development from infancy through childhood and adolescence up to adulthood. Established assessment instruments such as Schwartz et al.’s (2001) Portrait Values Questionnaire (PVQ) have proven highly fruitful in studies with adults and, to a
smaller extent, also with adolescents. However, we reached an age threshold (around 10 years), as we tried to apply the PVQ in childhood. For this reason, we have developed, employed, and evaluated new assessment approaches that are carefully suited to children’s vocabulary, cognitive-developmental background, and life context. Our data have been collected in Germany, Switzerland, Poland, Bulgaria, Italy, the USA, New Zealand, and Australia. We present three different approaches: (1) the Picture-Based Value Survey for Children (PBVS-C; Döring et al., 2010, targeted to elementary-school age), (2) an animated best-worst scaling instrument (Lee et al., 2011, targeted to elementary-school age), and (3) the Value Puppet Interview (Ciecioruch et al., 2011, targeted to preschool age). Our findings indicate that Schwartz’s basic value structure emerges very early in childhood and gradually differentiates as children grow older. In view of these challenging findings, we aim to identify probable precursors of values and to exemplarily outline how these may be assessed in infancy.

A revised theory and new instrument to measure basic individual values

Shalom Schwartz The Hebrew University of Jerusalem, Israel

The Schwartz theory of 10 basic human values has spawned hundreds of studies since 1992. Distinguishing 10 values was, however, an arbitrary, scientific convenience. This presentation introduces a revised theory that partitions the circular continuum of values more finely. Researchers have largely ignored a central assumption of Schwartz’ theory of basic individual values: The array of values represents a circular continuum of motivations analogous with the circular continuum of colors. Partitioning the continuum into 10 discrete values was an arbitrary scientific convenience. One could reasonably partition the domain of values into broader or more fine-tuned value constructs, depending on how finely one wishes to discriminate among motivations. I present a revised theory intended to provide greater predictive and interpretive power than the original 10 by partitioning the value continuum into 19 distinct values. This theory retains the strengths of the original because the 19 values can be combined to recapture the original 10 or the 4 higher-order values. I also present an experimental instrument to measure the 19 values that is designed to provide improved reliability and validity.

Symposium title: Online assessment and candidate performance
Convenor: Andreas Lohff

The impact of impression management on international personality testing
Fred Guest TTS-Top Talent Solutions, South Africa; Achim Preuss; Katharina Lochner; Maike Wehrmaker

Being able to predict the degree of impression management in personality testing is important for ensuring the quality of the data and for providing adequate feedback. However, social desirability scales frequently used for doing so are problematic in several ways (e.g., Mueller-Hanson, Heggestad, & Thornton III, 2003). Therefore, we used the ‘auxiliary’ data gathered during an online administration for predicting the degree of impression management. N = 100 students gave a true and a forged self-description on a questionnaire that assesses job-related competencies. The degree of biased responding was correlated with item and scale variance as well as percentage of points allocated. Integrating these variables into an index yields to a consistency value that is an indicator for the extent of impression management. The indicator was validated using a sample of 189316 applicants for different jobs. Based on a global sample the impact of impression management in international recruitment is discussed.

Well-being promotes when conscientiousness increases: Effect of belief in just world
Cen Chen Peking University, China; Lei Wang Peking University, China

Previous research has indicated that there is a relation between Big Five Traits and subjective well-being (SWB), and both extraversion and neuroticism have been explored. But few researchers have reported the influence of conscientiousness on SWB. The current research focuses on the relation between conscientiousness and SWB. Besides, we also examine the moderating effect of the personal belief in a just world (PBJW) on personality-SWB relation. PBJW is identified as the belief that the world is more just for me than in general. 593 citizens from Shenzhen, China were tested by a questionnaire assessing SWB (tested by Oxford Happiness Inventory), PBJW and locus of control. Multiple regression analysis indicated that individuals with internal control were associated with higher SWB. PBJW served as a moderator between locus of control and SWB: when citizens had a high score in PBJW, a positive relation between internal control and SWB appeared more significant. Implications for theory, research and practice are discussed and more research is needed in the future.

Symposium title: Predictors of subjective well-being: From age and income to personality
Convenor: Jiajin Tong

The moderating effects of equity sensitivity on the relationship between age and subjective well-being
Xiaoli Di Peking University, China; Luning Ren; Lei Wang Peking University, China

Previous researches have indicated that there is a relationship between age and subjective well-being (SWB), but the findings are contradictory. Most researches demonstrated that age related to SWB positively, while others indicated adverse result. This study aimed to clarify the mixed findings, and we hypothesised that equity sensitivity could be a moderator of the relationship between age and subjective well-being. Using a cross-aged sample, we tested this hypothesis with a sample of Chinese residents (N=566) from 98 communities by means of a set of questionnaires assessing the degree of people’s subjective well-being (tested by Oxford Happiness Inventory) and equity sensitivity (tested by Justice Sensitivity Scale). Multiple regression analysis revealed that there was no main effect of age on subjective well-being. Moreover, as we predicted, equity sensitivity moderated the relationship between age and subjective well-being. Specifically, when equity sensitivity was high, the relationship between age and subjective well-being was positive, and when equity sensitivity was low, the relationship between age and subjective well-being was negative. These findings contribute to the literature on the relationship between age and subjective well-being. The implications of the findings are discussed.

Subjective well-being in relation to locus of control: Moderating effect of personal belief in a just world
Ying Ma Peking University, China; Luning Ren; Lei Wang Peking University, China

Previous studies have indicated that locus of control associates with subjective well-being (SWB), but there are divergences among these results. Most researches demonstrate that internal control relates to SWB positively, while other researches indicate an adverse result. So which conclusion is more credible? In the present study, we hypothesise: (1) the locus of control has significant correlation with SWB; (2) Personal Belief in a Just World (PBJW) moderates the effect of locus of control on SWB. PBJW is identified as the belief that the world is "more just for me than in general." 593 citizens from Shenzhen, China were tested by a questionnaire assessing SWB (tested by Oxford Happiness Inventory), PBJW and locus of control. Multiple regression analysis indicated that individuals with internal control were associated with higher SWB. PBJW served as a moderator between locus of control and SWB: when citizens had a high score in PBJW, a positive relation between internal control and SWB appeared more significant. Implications for theory, research and practice are discussed and more research is needed in the future.

Big Five traits moderate association between equity sensitivity and subjective well-being
Hao Yu Peking University, China; Lei Wang Peking University, China

Subjective well-being (SWB) is one of the most widely concerned issues recently. Many variables have been reported to have impact on subjective well-being. Based on equity theory, the present research focuses on the relationship between the sense of justice (Equity Sensitivity) and subjective well-being and how personality (e.g., Big Five Traits) influences this relationship. Data were collected from a sample of 566 residents in China by a cross-sectional questionnaire survey design. The results showed that there was no significant relationship between equity sensitivity and subjective well-being. But two dimensions of Big Five Personality traits, conscientiousness and agreeableness, had moderating effects in this relationship. When residents were low in conscientiousness or agreeableness, the positive relations between equity sensitivity and subjective well-being became more significant, whereas for those high in conscientiousness or agreeableness, this relationship was weaker. Explanations and implications of these findings are discussed.
The primary aim of this research was to provide an opportunity for women (40-55 years) and their adolescent daughters (16-19 years) to explore and re-examine their own altruism (i.e., attitudes and behaviours towards helping others). Thirty Hindu and Catholic women from Mumbai who were either managers or school teachers and their school-going daughters participated in the study (n = 60). The critical paradigm, which has traditionally been used to transform power relationships in oppressive contexts, undergirded this research. With the premise that altruism is liberating, we engaged in a multi-step, one-on-one dialogue with each participant to help her expand her view of her own altruism. At step one, women and daughters described their own altruism. At step two, participants re-examined their helping behaviours in the previous three months (e.g., reflecting on what had hindered their altruism). At step three, participants engaged in various exercises (e.g., a story exercise) which entailed reflection and insight. Data were analysed qualitatively using theme extraction and thick description, and quantitatively using descriptive statistics. Most participants described conventional ways and attitudes towards helping others in the first stage of the dialogue (e.g., frequency and duration of help were highest for immediate family members and lowest for strangers). In contrast, after the story exercise, mothers’ and daughters’ insights included the value of unconditional help and that all deserved help. Findings were interpreted using Indian and non-Indian spirituality literature.

Measurement of spirituality and religiousness: Perspectives from India
Anuradha Bakshi N N College of Home Science, India
India is a multi-faith country especially renowned for the richness of its historical and contemporary religious and spiritual traditions. Research on religiosity and spirituality in USA and Europe has increased substantially in the last two decades. The integration of perspectives drawn from India will make an invaluable contribution to the international literature on religiosity and spirituality. The aim of this research was to develop measures of spirituality and religiousness using (a) a survey of 100 multi-faith adults (through individually-administered questionnaires), (b) a survey of 60 Hindu college-going women, 30 of whom were participating in a spiritual movement (through individually-administered interviews), and (c) an examination of Indian theological literature. All participants were selected from Mumbai using judgmental sampling. Thirty-two variables measuring spirituality and religiousness were constructed. Examples of spirituality variables included being open-minded to multiple religions, experiencing God or wisdom within the self, and experiencing unity between the self and others. Religiousness was measured using variables pertaining to the practice of rituals of one’s own religion. Summed scores for spirituality and religiousness had adequate reliability. A highly significant, moderately strong positive correlation between spirituality and religiousness was obtained (r = .605, p < .0001). Findings are discussed using Indian and non-Indian psychology and theology literatures.

Sharing experiences online: When peer responses decrease the negative impact of emotional disclosure writing
Anika Batenburg VU University Amsterdam, Netherlands; Enny Das
Online support group participation is beneficial for psychological and physical wellbeing (e.g., Lieberman et al., 2003), but little is known about the processes that bring about such positive changes. The present study tests the effects of (1) expressive writing and (2) responses from peers on psychological and physical wellbeing. Offline expressive writing studies showed that writing about emotional life events positively affects wellbeing. An explanation regarding the underlying psychological processes of writing suggests that emotional expression in itself is not sufficient to come to emotional recovery, but it helps people to cognitively reevaluate their life circumstances to come to new solutions or acceptance (Pennebaker & Chung, 2007). One important difference between on- and offline writing is the opportunity to receive responses from peers, which fulfills socio-affective needs and sometimes cognitive needs. Both writing and receiving peer responses could be helpful in getting individuals through the process of coping with their situation. Hypotheses were tested in a 2 (Writing style: cognitive reappraisal vs. emotional disclosure) x 3 (Response type: cognitive reappraisal vs. socio-affective vs. no response) factorial design among 117 participants. Results showed that receiving a cognitive reappraisal response, rather than a socio-affective response or no response, decreased negative emotions and symptom reporting in the emotional disclosure writing group and had no effects in the cognitive reappraisal writing group. The current study showed that cognitive reappraisal responses in support groups might be most effective because they provide a positive way out of negative emotions.

Meaningful attachment: The effects of attachment patterns and ageism on meaning in life across adulthood
Yvo Bergman Bar-Ilan University, Israel; Sara Cohen-Fridel; Ehud Bodner
The presence of meaning in life (PML) and the search for meaning in life (SML) have been shown to greatly affect individual well-being and personal satisfaction with one’s own existence. The current work, which includes two studies, presents a novel attempt to examine the contribution of attachment patterns, together with views regarding the aging process, for understanding the aforementioned two dimensions of meaning in life across different stages of adulthood. In Study 1, 181 Israeli participants between the ages of 21-30 completed the Meaning in Life Questionnaire, the Experiences in Close Relationships Scale, which measures attachment patterns, and the Fraboni Scale of Ageism. In Study 2, 847 Israeli participants, who were divided into three age-groups (21-30; 31-50; 51-65), completed the same scales, together with an aging anxiety measure. Hierarchical multiple regression analyses consistently demonstrated the positive connection between attachment security and PML, while SML was predicted by high attachment anxiety and low attachment avoidance. Aging anxieties were found to nullify the effects of ageism on PML, but both were significant predictors of SML. Additionally, age differences were found regarding the manner in which attachment and aging variables contribute to both PML and SML. The important connection between meaning in life and the independent variables in different stages of human development is discussed, and possible implications of our findings are presented.

Positive psychology and aging
Harpreet Bhatia University of Delhi, India
Positive psychology is the study of the processes and conditions which contribute to the optimal functioning of individuals. The aim of this paper is to indicate how recent trends in the emerging science of positive psychology can be applied to the development of a positive and graceful aging. It is important for professionals working with older persons to understand the potential of positive psychology as an increasing proportion of the clients of psychologists in the future will be older adults. Gerontology, the study of aging, is an ideal field in which to explore the possibilities of positive psychology because relatively little work has been...
done to identify how recent trends in the emerging science of positive psychology can be applied to the development of a positive psychology of aging. Evidence is emerging about the unrealised potentials of older adults in all domains. Historically, the deterioration of old age has been over-emphasised. This is possibly so because it is easier to recognise attributes in which older people perform poorly than those in which they may excel. Empirical evidence is emerging which demonstrates the hitherto under-recognised skills, potentials, and contributions of older adults. The emerging science of positive psychology can contribute a great deal towards enabling the potential of older adults to be realised.

The effect of the lifeplan programme on the psychological wellbeing of a rural community in South Africa

Annelize Bonthuys NWU, South Africa; Annamariie Kruger; Alida Nienaber; Karel Botha; Fazel Freels

This study explored the effect of the Lifeplan programme on a rural South African community’s psychological wellbeing. Participants were adult individuals (N=99) between 20 and 83 years (mean age = 43 years, SD=13.28). A mixed method sequential explanatory research design was followed. Participants were com-bined to form a self-regulation and communal mastery group, and the significance of the contribution of the themes was assessed with Pareto statistical analysis. Results indicate a complex interplay between individual self-regulation and group-based communal mastery during proactive decision-making, goal attainment, and responding to conflict and adversity. The findings suggest that communal mastery is an additional strength, rather than a replacement of self-regulation, within this rural collectivistic community. Finally, some recommendations are provided regarding future self-regulation research as well as promoting psychological well-being in rural South Africa.

Psychofortology of adults recovering from a substance-use disorder

Tanielle Bubb Nelson Mandela Metropolitan University, South Africa; Ottillia Brown

Evaluating the psychofortology of adults recovering from a substance-use disorder has been identified as a research priority in South Africa. This is in line with calls from researchers in diverse fields of psychology for more attention to the resilience, strengths, resources and capacities of people. This study therefore aimed to explore and describe the coping resources, sense of coherence, happiness and satisfaction with life of adults recovering from a substance-use disorder within the Nelson Mandela Metropole. The sample consisted of 99 voluntary participants from various managed recovery centres. Participants were asked to complete a biographical questionnaire and four standardised paper and pencil measures; the Coping Resources Inventory (CRI), the Sense of Coherence Scale (SOC-29), the Affectometer 2 (AFM-2) and the Satisfaction with Life Scale (SWLS). A quantitative, non-experimental exploratory-descriptive research method was used. Data was analysed using descriptive statistics and the Pearson product-moment correlation coefficient. Key findings include the following: Results on the CRI revealed low average mean scores on both the Coping Resources Inventory and within the five subscales. Results of the SOC-29 revealed a high average mean score for sense of coherence. Results of the AFM-2 revealed that more positive affect than negative affect is present, resulting in happiness. Results of the SWLS revealed an average level of satisfaction with life, with most participants reporting neutral levels of satisfaction with life. There were significant positive correlations between the coping resources, sense of coherence, happiness and satisfaction with life of the sample.

Stress and coping in fathers with severely disabled institutionalised children

Anthony Constantiandis P remed Child and Family Unit, South Africa

The aim of this study was to reveal how the fathers of severely handicapped, institutionalised children differ from the mothers in terms of their perceived stress, resources and coping strategies. Parents of handicapped children experience ongoing grief and recurrent distress-generating crises. The extent to which parents are able to process their loss and manage this tension may predict their adjustment. A review of relevant literature shows that child characteristics, the presence of another handicapped child and cultural factors affect parental stress. Certain parental characteristics also act as mediators of stress. Informal support systems are identified as possible mediators of stress. Formal support systems are not seen by parents as primary sources of support. Coping behaviors and strategies also function as mediators of stress. In this study, 77 parents were examined by means of the Questionnaire for Resources and Stress, the Perceived Stress Scale, the Sense of Coherence Scale, the Fortitude Questionnaire and the COPE Inventory. Results show that (a) the parents with high levels of perceived stress will be more prone to make negative appraisals of their severely handicapped child, their internal stress-reducing ability and of their available social support systems, (b) the father may be more vulnerable than the mother due to his dependence on the mother as his main source of social support, and (c) the father with high levels of perceived stress may be more vulnerable than the mother with high levels of perceived stress.

The expression and enactment of positivity

Frederik Crous University of Johannesburg, South Africa

Lakoff and Johnson, in their ground-breaking work Philosophy in the flesh, highlight three major findings of cognitive science: The mind is embodied; thought is mostly unconscious; abstract concepts are largely metaphorical. The aim of this study was to explore what extent these findings may be expressed and enacted in the domain of positive psychology. The following process was followed: Firstly, the literature on embodied cognition in general, and the approach of Lakoff and Johnson in particular, was reviewed from which a root metaphor by “which we live by positively”, embedded in concrete bodily experiences, was identified. There-
of the research was to collect a rich source of narrative material from the experiential world of the participants (Du Preez, 2004; Du Preez & Roos, 2008; Robertson, Venter & Botha, 2005). On a process level, this resulted in an integration between the qualitative research conducted with seven South African psychologists in private practice and the fortigenic perspective (Strümpfer, 1995; 1998a; 1998b; 2001; 2007). This has been useful in the process of presenting the various complex levels of the research in a coherent and integrated manner. In the findings of the research, positive psychology is presented as a both/and model. Thus, a model which includes its polar opposite options and which does not exclude these possibilities. The study proposes that it is then also the capacity to contain and understand ambivalence, which leads to resolution and well-being (Watzlawick, Weakland and Fisch, 1974). The focus of the research shifts away from 1st order fortigenic detail, such as only naming the specific fortigenic characteristics, to identifying the 2nd order fortigenic perspective in reflecting resilience, coping and well-being through the interaction of the various 2nd order cybernetic components of the research.

Fortigenic factors buffering compassion fatigue and stress of conscience amongst psychologists in private practice

Erica De Lange NWU, South Africa

Research done in the United Kingdom by Mehta (2004) investigated compassion fatigue and burnout among clinical psychologists. It was found that a significant proportion of this population was at critical stage and 47% indicated a likelihood of leaving their jobs. These statistics can be compared to American statistics of a 40% burnout level amongst psychologists, While Norcross, Karg and Prochaska (1997) found that on a direct question of career options, only 9% of clinical psychologists in private practice express dissatisfaction with their jobs. Mehta (2004) also made the suggestion that the practitioners suffering from compassion fatigue and burnout might be providing unethical, poor quality work to their clients. A recent study conducted in Sweden amongst health care personnel explored burnout and ‘stress of conscience’ (Glasberg, Eriksson & Norberg, 2007). They defined health care as a moral endeavour. The current research study takes a closer look at these different findings, exploring the resilience of seven South African psychologists in private practice, through a qualitative research design. The fortigenic factors that buffer stress of conscience on a moral and ethical level are identified, as well as the importance of self care, and the relevant research findings such as the fortigenic resiliency model, are presented to the audience.

Positive psychology and the study of well-being: Cross-cultural challenges

Antonella Delle Fave Università degli Studi di Milano, Italy; Fanny Cheung

During the second half of the previous century several efforts were made to unveil the cultural biases embedded in the theories and evaluation instruments of psychological research. This awareness, which is far from being common to all psychologists even today, first derived from cultural studies. Social scientists from various disciplines highlighted the prominent role of culture in influencing the psychological development of individuals. The features of the bio-cultural environment - comprising survival strategies, ecological constraints, social structure, opportunities for learning - can support or hamper the growth of specific abilities and cognitive functions in the individual. Hence, psychological studies cannot overlook the cultural background individuals have been raised in during childhood and are exposed to during adulthood. In particular, more attention should be paid to this issue in the domain of positive psychology and well-being studies. Current research on well-being is substantially grounded in the Western tradition, with its individualistic features shared by a minority of nations. The terms ‘hedonia’ and ‘eudaimonia’ themselves, which identify the two main current approaches in positive psychology, stem from ancient Greek philosophies. Nevertheless, happiness has always been an object of interest and investigation in most cultures. Its definition and evaluation are largely influenced by cultural norms and values, which do not necessarily coincide with Western ones. More extensive comparative studies on conceptualizations of well-being, individual and social resources, and development promotion could allow researchers to better understand the relationship between happiness-related concepts, associated behaviors and cultural evolution trends. Cultures, communities and groups could be studied according to their effectiveness in providing their members with opportunities for personal growth and the pursuit of complexity and harmonious functioning. From this perspective positive psychology, as an approach focused on resource promotion and implementation, can become more incisive by taking into account the implications of its findings and interventions for both individual growth and community empowerment.

The moderating effects of equity sensitivity on the relationship between age and subjective well-being

Xiaoli Di Peking University, China; Luning Ren; Lei Wang Peking University, China

Previous research has indicated that there is a relation between age and subjective well-being (SWB), but the findings are contradictory. Most researchers demonstrated that age relates to subjective well-being positively, while others indicated adverse result. This study aimed to clarify the mixed findings, and we hypothesised that equity sensitivity could be a moderator of the relationship between age and subjective well-being. Using a cross-aged sample, we tested this hypothesis with a sample of Chinese residents (N=566) from 98 communities by means of a set of questionnaires assessing the degree of people’s subjective well-being (tested by Oxford Happiness Inventory), age and equity sensitivity (tested by Justice Sensitivity Scale). Multiple regression analysis revealed that there was no main effect of age on subjective well-being. Moreover, as we predicted, equity sensitivity moderated the relationship between age and subjective well-being. Specifically, when equity sensitivity was high, the relationship between age and subjective well-being was positive, and when equity sensitivity was low, the relationship between age and subjective well-being was negative. These findings contribute to the literature on the relationship
between age and subjective well-being. The implications of the findings are discussed.

The role of coping in the relationship between life stressors and suicidal ideation

Edwin Du Plessis University of the Free State, South Africa; Henriette van den Berg University of the Free State, South Africa

The role of life stressors in adolescent suicidal behaviour is well established within literature. However, the relationship appears to be non-linear as the way in which adolescents cope with life stressors plays an important role in determining the outcome of this relationship. This study investigated whether a relationship exists between life stressors and suicidal ideation amongst 1033 multi-ethnic secondary school learners from Free State province. A criterion group design was used. Participants completed the Suicidal Ideation Questionnaire (SIQ), the Life Stressors and Social Resources Inventory (LISRES), and the Coping Orientations to Problems Experienced Questionnaire (COPE). Product-term regression analyses were conducted to investigate the role of coping strategies in the relationship between life stressors and suicidal ideation. Significant correlations were found between suicidal ideation and the two stressor subscales parents and negative life experiences. A significant correlation was also found between the stressor friends and suicidal ideation for the white participants, and the stressor family and suicidal ideation for the white and coloured participants. Coping strategies did not mediate the relationship between life stressors and suicidal ideation amongst any of the three ethnic groups. Coping strategies did, however, act as moderators in this relationship for all three of the ethnic groups. The results suggest that ethnicity might play an influencing role in the experience of suicidal ideation and life stressors amongst South African adolescents.

Towards understanding the psychological processes underlying posttraumatic growth

Larise Du Plessis University of Johannesburg, South Africa

The experience of trauma is universal. But how people process, experience and react to trauma vary across cultures and ages and can range from the pathological to posttraumatic growth. Posttraumatic growth is an emerging area of research concerned with the positive psychological changes that can follow the experience of trauma. The conditions that promote the likelihood of posttraumatic growth are not widely researched and this paper aims to address this particular area. The paper describes themes of posttraumatic growth as extracted from the experiences of a woman who spontaneously pronounced that she had experienced psychological growth after the diagnosis of cancer. Her account demonstrated positive psychological changes in her cognitive-emotional understanding of herself and her world. The thematic analysis is then discussed in relation to Janoff-Bullman’s (2006) three models of the process of growth viz (1) strength through suffering; (2) existential re-evaluation; (3) psychological preparedness. The analysis is in agreement with Janoff-Bullman’s understanding that the processes of growth posttrauma are not unitary, but represent a complexity of disparate processes that may or may not interact. A greater understanding of the different psychological processes of change in the aftermath of trauma may enhance therapy in clients who have experienced traumatic events.

Social change and psychosocial wellbeing: A cross-cultural mixed methods study

Francisco Jose Eiroa-Orosa Universitat Autònoma de Barcelona, Spain; Adil Qureshi

Research addressing the influence of social change on the psychosocial wellbeing of individuals has been a major issue in psychological research, although under-studied heterogeneous methodological approaches and ideologies. The possibility of the development of a multidisciplinary field which could have multiple applications from clinical practice to public health management is hampered by the heterogeneity of social change itself as well as disciplinary approaches to its analysis. In spite of this heterogeneity, in the last years, the work of Pinquart, Silbereisen, Kim, Kopp, Almeida-Filho and many others, has opened new perspectives in this incipient field giving us the opportunity to design a large-scale research project. Bandura’s self-efficacy, Rotter’s locus of control and Bronfenbrenner’s ecological systems, amongst others, appear to be key concepts in the understanding of the relationship of social dynamics and individual wellbeing. Because the study will be international and cross-cultural in scope, we consider a mixed methods approach optimal as it is well suited to get at both the locally specific, as well as internationally common variables. The aim of this research project is to generate preliminary cross-cultural data on which to build an international network of observatories on social change and psychosocial wellbeing. In this presentation, we will describe the objectives, hypothesis, methodology and preliminary results of this project. The idea is to not only present the project but also to have attendees interact and participate with us in the construction of the network.
The affect, intentionality, effort and adaptation to a life event measure

Danilo Garcia University of Gothenburg, Sweden

The present study tested the affect, intentionality, effort and adaptation to a life event measure (AIEALEM), which was specifically constructed to monitor characteristics such as affect elicited by the memory of the event, time frame of the event, rumination about the event, whether the life event is part of life goals, intentionality, effort and hedonic adaptation. High school pupils (N = 89) were first asked, at random, to write down the most positive or the most negative event that had influenced their happiness in the last three months. After answering the AIEALEM, participants reported how central the event is in their lives and to their subjective well-being (SWB). Four weeks later, participants read their own description, responded to AIEALEM and self-reported centrality and SWB for a second time. For AIEALEM Cronbach’s α varied between .78 and .94, and test-retest correlations between .49 and .86. Compared to the negative condition, adolescents judged positive events to have more influence on their happiness and to be more due to their own doing, and they put more effort into making a positive event happen than they put into avoiding a negative event. Moreover, time frame, unpleasant affect, and activated unpleasant affect were related to SWB. Intentionality and effort were related to hedonic adaptation. AIEALEM measures characteristics of life events that might explain adaptation or long-term changes in SWB. Moreover, these characteristics might influence the event to become central in adolescents’ concepts of themselves.

Predictors of academic achievement in adolescents with resilience and non-resilience dispositions

José Gaxiola Universidad de Sonora, Mexico; Sandybell Gonzalez Lugo; Eunice Gaxiola Villa

According to systems development theory, the interplay between the biological, psychological, and socio-contextual variables affects life span in different ways, as a result, some individuals behave in adaptive ways, and the others show desadaptive behaviours. Using that mark of reference, resilience implies individuals going beyond the risks. There are risk and protective factors influencing academic achievement in high school adolescents, these factors can be contextual and individual. The contextual factors can be the negative friends and the negative neighbourhoods. Individual factors can be the goals and the self-regulation capacities. Based on the above findings, the aim of this research was to prove a general structural equation model, in two equivalent groups of 60 high school students of northwestern Mexico. One dispositional resilience group, and the other non-dispositional resilience group, to evaluate the effects of contextual and individual variables on academic achievement. Previous informant consent, to measure each of the selected variables, was applied to a battery of validated instruments. The data was tested in a structural equation model. The results indicated some important differences in the variables that explained academic achievement in both groups. In the non-resilience group, the risk established by socio-contextual variables predicted the lack or poor results in their academic achievement, by contrast, the resilience group showed the buffering effects of resilience and self-regulation variables. The results are discussed in terms of their implication to generate preventive and rehabilitation programs to improve the academic achievement of high school students on risk.

Gratitude and subjective well-being among south african adolescents

Tharina Guse University of Johannesburg, South Africa; Sarah Crawford

Gratitude is a psychological strength associated with enhanced positive psychological functioning. The relationship between gratitude and subjective well-being (SWB) has been confirmed in adults, but studies among adolescents and specifically South African adolescents, is scarce. The aim of this study was to investigate the prevalence of gratitude, and the relationship between gratitude and SWB among a group of adolescents from Gauteng (N = 821) from four population groups (Black, coloured, Indian and white). Participants completed measures assessing state gratitude (the Gratitude Adjective Checklist), trait gratitude (the Gratitude Questionnaire Six-item Form) and SWB (the Satisfaction with Life Scale, Multidimensional Student’s Life Satisfaction scale, Aff ectometer 2). Data was analyzed by examining mean scores, conducting two-way analysis of variances (ANOVA), as well as Pearson’s product moment-correlation coefficients, and a multivariate analysis of variance (MANOVA) and follow-up ANOVAs. Adolescents in this study experienced relatively high levels of gratitude. Female participants reported a higher prevalence of both state gratitude and trait gratitude than male participants while Indian adolescents reported higher scores on state gratitude than white adolescents. Both trait and state gratitude were related to SWB, although the relationship between trait gratitude and SWB was stronger than the relationship between state gratitude and SWB. The findings support existing research on the relationship between gratitude and SWB.

Life satisfaction among urban South African adolescents

Tharina Guse University of Johannesburg, South Africa

Life satisfaction is a key construct within positive psychology. Although there is a large research base on adult life satisfaction, research on adolescent life satisfaction is still lagging behind. Moreover, published research on life satisfaction among South African youth is scarce. Specifically, little is known about domain specific life satisfaction as experienced by adolescents from different population groups. The aim of this study was to investigate the levels of global life satisfaction and domain specific life satisfaction among a group of adolescents (N = 849, mean age = 16.03) from the greater Johannesburg area. Levels of life satisfaction were compared among participants from four population groups (Black, Coloured, Indian and White) as well as among male and female adolescents. Participants completed measures assessing global life satisfaction (Satisfaction with Life Scale) and domain specific life satisfaction (Multidimensional Student’s Life Satisfaction Scale). Data was analysed by inspecting mean scores and implementing ANOVAs and t-tests for independent samples. Adolescents in this study indicated being “slightly satisfied” in terms of global life satisfaction (M = 23.37, SD = 6.28). White adolescents reported significantly higher levels of global life satisfaction in comparison to Black adolescents. There were also significant differences in levels of some facets of domain specific life satisfaction (satisfaction with school, self and living environment) among adolescents from different population groups. Male and females adolescents only showed differences in facets of domain specific life satisfaction (satisfaction with friends and school). The findings will be discussed with reference to the South African context.

Psychological capital and employee well-being: The moderating role of psychological capital in the stress-burnout relationship

Marthine Herbert University of Stellenbosch, South Africa; Gina Gorgens

Organisations should actively promote positive psychological health and occupational well-being in order to harness the full potential of their workforce and increase organisational performance. This study empirically examined the relationships between burnout (The Copenhagen Burnout Inventory;Kristensen et al., 2005), employee engagement (Utrecht Work Engagement Scale; Schaufeli & Bakker, 2003), occupational stress (Perceived Stress Scale; Cohen, Kamarck & Mermelstein, 1983) and psychological capital (PsyCap; Psychological Capital Questionnaire, Luthans, Avolio & Avey, 2007) in a South African sample. Another goal was to investigate whether PsyCap is a moderator in the occupational stress, burnout relationship. A convenience sample of 209 permanent employees of a medium size construction company within the Western Cape, South Africa, participated in the research. The results revealed that higher levels of hope, optimism, self-efficacy and resilience (and the PsyCap total score) were associated with lower levels of occupational stress and burnout, as well as higher levels of employee engagement. Optimism and self-efficacy, as PsyCap sub-dimensions, emerged as the two strongest predictors of employee engagement. The results further suggested that PsyCap is a moderator in the occupational stress and burnout (i.e. personal and work burnout) relationship. This suggests that although occupational stress is inevitable in any work environment PsyCap as a personal coping resource may buffer the development of burnout over time. Through developing the hope, optimism, self-efficacy and resilience of employees an organisation can create a healthier, more engaged workforce that possess the psychological capital resources to deal with the demanding, ever changing work environment.

The role of situational factors in a cohort of South African teachers’ choice of coping strategies

Maria Hugo North-West University, South Africa; Johan Potgieter; Luilda Boshoff

Amirkhan (1990) developed the Coping Strategy Indicator (CSI) as a measure of general coping strategies underlying specific responses to stress. The measure has been found to represent those modes of coping (Problem-solving, Seeking Social Support and Avoidance) most widely used across
individuals and events. This three-factor structure has emerged in various American samples. Despite the scale’s proven validity in Western contexts, and frequent use in different cultural settings, it remains unclear what role the stressor’s nature might play in the choice of coping strategy in non-Western contexts. This study aimed to identify the relationship between the stressor’s nature and the choice of coping strategy within a South African context, and how this relates to ethnicity and gender. A cohort of 409 teachers from the North-West Province in South Africa participated in the study, consisting of 101 African males, 99 African females, 101 Caucasian males and 108 Caucasian females, aged between 25 and 62 years. Validity of the three-factor structure of the CSI for this cohort was established and its internal consistency proved sufficient. After content analysis was used to classify the types of stressors reported by participants, ANOVA’s were used to identify associations between types of stressor, and preferred coping strategies within the different ethnic and gender groups. Results attested to the CSI’s applicability within this cohort. Recommendations are made for its use within this and possibly other non-Western contexts.

Just-world beliefs and wellbeing in South African adolescents
Salome Human-Vogel University of Pretoria, South Africa; Claudia Dalbert
In the present study we examine the relationship between South African adolescents’ general and personal belief in a just world and two dimensions of wellbeing, namely mood level and life satisfaction (Dalbert, 2001). Studies have indicated that the belief in a just world (BJW) act as a psychological resource and is positively correlated with wellbeing. We test this hypothesis in a South African sample of 188 adolescents. Instruments used were Dalbert’s (2000) General and Personal Belief in a Just World Scales, as well as Dalbert’s (1992) Trait Wellbeing Inventory (TWI). Results supported the construct validity of the General and Personal BJW, and the TWI, with some mood level items being problematic. Correlations between the scales were significant (p<0.01) as expected, with the Personal BJW generally more strongly correlated with Wellbeing than the General BJW. In addition, adolescents who described their relationship with their parents as complicated and tense, scored significantly lower on the mood level scale (p<0.05) when compared to adolescents with a more close and uncomplicated relationship with their parents. The difference was observed for life satisfaction (p<0.001). There were no significant differences observed for the General and Personal BJW. The results of the present study suggest that valid measurements of the General and Personal BJW and the TWI can be obtained with South African adolescents.

Family cohesion, family adaptability and psychological well-being of professional groups in Malaysia
Rosmi Ismail Universiti Kebangsaan Malaysia, Malaysia; Hazfizah AnNadiah Azlan; Fatimah Yusoff
This study examined the relationship between family cohesiveness, family adaptability and psychological well-being of professional groups in Malaysia. There were 179 respondents (the majority married adults from various professional groups) who voluntarily participated in the study. Family cohesion and family adaptability were measured using Family Cohesiveness and Adaptability III. These scores were then correlated with OQ-H Oxford Happiness Questionnaire and respondents’ demographic variables. The results showed that economy and occupational status were the two main factors in determining the happiness level among Malaysian professionals. The doctors and teachers reported the highest on the happiness scales, engineers and executives were at the moderate level whereas administrators experienced the least. The findings were explained in light of profession specific role demands and expectations. The findings have an implication for both clinical and public policy, for example, introducing family-stress program interventions should focus on effects of job stress on the relationship of both husbands and wives.

The necessity of creating for living
Blagoya Janakov University of Skopje, The Former Yugoslav Republic of Macedonia
Here the meaning of the term “creating” is wider than usual. Forms of the creating process are: changing, constructing, innovating, transforming, inventing, originating. Creating is a component of activities generally called: doing, making, producing, playing, working, building, etc. Some concrete activities are: children’s play, cooking, writing, imagining, dreaming, playing chess, driving a car, talking, painting, and rearranging one’s home. Internalisation and externalisation, acquisition and expression, learning and use of knowledge are in fact processes of creating. The purposes of creating are: adaptation, self-presentation, achieving or maintaining subjective well-being, healing, personal development, changing reality, etc. The products of creating are extremely different: short-term and long-term, stable and unstable, mental and material, small and big, useful and useless; images, sentences, diseases, foods, technical products, buildings, children, etc. Dreaming is one of the creating processes. It is a subjective/personal phenomenon which is strange and marvelous. In dreaming, the impossible is possible, things happen which in reality do not, including things that could not happen; there are beings and phenomena which do not exist in reality. Dreams lead to changes in mentality and living. There is strong evidence that life is impossible without dreaming. The question “Is creating present in and necessary for psychological practice, especially in psychotherapy”, has been considered. Creating processes are a necessary part of human mental functioning and essential for the life of every person. Everyone creates. Living ceases, the being dies without creating.

Positive psychological factors and suicide ideation among Malaysian and Indian adolescents
Aqeel Khan University of Malaya, Malaysia
The present study identifies the differences of positive psychological factors (i.e., resiliency, social support, positive affect, subjective well-being, sense of coherence, and coherence) and suicide ideation among Malaysian and Indian adolescents. In addition, it examines the influences of positive psychological factors on suicide ideation among 181 Malaysian participants and 191 Indian participants. The following scales were used to gather data: Satisfaction with Life Scale (SWLS), Resiliency Scale (RS), Multidimensional Scale of Perceived Social Support (MSPSS), Positive Affect Scale (PAS), Orientation to Life Questionnaire (OLQ),COPE Scale (CS) and Suicide Behavior Questionnaire (SBQ). Means and t-test were applied. The results showed significant differences among Malaysian and Indian samples on resiliency, social support, coping strategy and suicide ideation. The means indicate that Malaysian adolescents are significantly higher on resiliency and social support while the Indian students are significantly higher on coping strategy and suicide ideation.

Mental health, coping self-efficacy and contextual correlates among Setswana-speaking older persons
Itumeleng Khumalo North-West University, South Africa; Marie Wissing; Q. Temane
There is a rise in life expectancy and growth of the older persons population. Late adulthood is accompanied by risk of a decline in physical and mental health. Research on aging has neglected mental health, cultural diversity and subjective self-report, in favour of objective problem focused physical assessments. The present study explored the profile of self-reported biopsychosocial health and well-being among a sample of Setswana-speaking older persons. A sample of 365 people above the age of 60 years, and 845 adults aged between 30 and 59 years took part by completing self-report measures enquiring about aspects of their well-being and health. Variables of interest were positive mental health, depression, coping self-efficacy, gender, age, and rural/urban residence. Results reveal that the older group reported higher levels of positive well-being than the younger one, but no differences were found for negative well-being indices between the groups. A high percentage of the older persons sample was found to be flourishing. Environmental setting and perception of somatic symptoms significantly influenced the experience of depression. Urban residents and those who perceived more somatic symptoms reported higher levels of depression. Coping self-efficacy was found to be a robust determinant of positive mental health but not associated with depression in late adulthood. These findings have implications for the study, measurement and promotion of mental health and well-being as components of healthy aging in an African context.

Resilience characteristics in Afrikaans and English speaking families with a child with Type 1 Diabetes
Guzelle Keugenbol University of Stellenbosch, South Africa
A chronic illness such as Type 1 Diabetes, not only impacts the individual’s physical and psychological well-being, but ultimately their family’s well-being as a whole. The family typically fulfills the role as primary support structure for the diabetic child. Regardless of the physical and psychological challenges that form part of the illness, a large quantity
Hearing their voices: Narratives and discussions of families’ psychosocial well-being in a South African context

Vicki Koen North-West University (VTC), South Africa; Chizanne Van Eeden

The general aim of this study was to explore and describe aspects that contribute to the psychosocial well-being of families from diverse cultures in the South African context by analyzing data obtained through narratives, drawings and interviews with families. Thirty six participants were involved by means of interviews, twenty three through written narratives, and fourteen through drawings (N=76). These different methods of data collection provided rich data on family psychosocial well-being in a multi-cultural South African context and the aspects that influence family psychosocial well-being. The findings suggest that communication, support, doing things together as a family and spirituality are the most prominent contributing factors whilst financial difficulties and conflicts or arguments are the most prominent hindering factors with regard to family psychosocial well-being in this group of participants.

Applications of positive psychology to community policing programmes in national central police academy in South Korea

Sang-Bok Lee Kangnam University, Republic of Korea

The objective of the study was to validate how the contents of positive psychology have been applied to community policing training programs in South Korea. (1) Emotional Sensitivity Training Program (ESTP) and (2) Mentoring Program for Moral Sensitivity (MPMS) for the police candidates in the National Central Police Academy were designed and administered. A forty-hour emotional sensitivity training manual based on the ten thematic topics of positive psychology was developed and 35 instructors (n=35; male=33/female=2) were selected and trained about how to use the manual. In addition, primary goals and contents of the Mentoring Program for Moral Sensitivity were implemented. Results: Thirty five instructors successfully completed the ESTP manuals and they taught about four thousand police candidates during the year 2010 and MPMS is in progress. Conclusion: For the first time, the ESTP manual based on positive psychology in South Korea has been developed and this manual has been used effectively.

A primary design of happiness questionnaire of Chinese youths

Xiaowen Li Central China Normal University, China; Jing Li Central China Normal University, China; Yongyu Guo; Xiaoyong Hu

Happiness is the common goal of all human beings. The present Chinese youths, who grew up in tempestuously changing time, are encountering kinds of challenges that have never appeared before. It is important to find out the happiness status of this special group. Based on the review of former research and results of an open-end questionnaires with 83 youths, the preliminary youths’ happiness structure was constructed. After reliability and validity data was collected, 1300 youths filled out the questionnaires. The results are as follows: (1) Happiness of Chinese youths has a multi-level and multi-dimensional structure, including cognitive, emotional and behavioural happiness. (2) The happiness questionnaire of Chinese youths was accomplished according to the special structure. The data of repeated reliability, internal consistency, content validity, criterion validity, constructive validity are all up to statistic demand. (3) There are several points of Chinese youths’ happiness. Except gender effects, the score differences of ages, marriage status, living places, education levels and times of volunteering are all significant.

A model of positive psychotherapy: ”Living the positive life you want”

Stefan Lison Center for Positive Psychology, Israel

Throughout its history, psychotherapy has been effective as Seligman has put it, to bring clients "from minus five to zero." Therapy that responsibly and professionally brings clients beyond emotional coping and survival to a place where they live thriving, positive lives, is integral to the province of psychotherapy and essential in the long run. This is so because it is critical that therapists offer a substantial professional contribution to enhancing emotional well-being and thriving at a time when the field of coaching has carved out such a significant niche in this area. The Positive Psychotherapy model presented here is positive in its formulation and expression. It offers underlying tenets by which positive psychotherapy be conducted; and outlines objectives such as achieving safety from within, experiencing immediacy, embracing ourselves and releasing our joy that enable clients to push forward to intentionally pursue a full and positive life. The programme, which is essentially eclectic in nature, suggests techniques and exercises for each of its seven principles, drawing its interventions and procedures from a variety of sources that are effective and efficient including EMDR and Voice Dialog. Selected aspects are briefly outlined in this paper. This approach aims at freeing clients to live fully in the present and directs them to be intentional in pursuing fulfilling, meaningful lives and relationships. Clinical vignettes are included that point to encouraging therapeutic outcomes; however there are many research challenges still ahead.

Respiratory sinus arrhythmia is associated with trait positive affect and positive emotional expressivity

Wei Lu Shanzai Normal University, China; Zhenhong Wang

Respiratory sinus arrhythmia (RSA) indexes are important physiological aspects which are associated with affect and expressivity. The vast majority of previous studies have focused on the relations of RSA with transitory emotional states and context-specific emotional expression. Little research, however, has sought to explore the link between RSA and trait affect as well as dispositional emotional expressivity. In the present investigation, the association between RSA and dispositional emotional positivity (i.e., trait positive affect and dispositional positive emotional expressivity) was assessed. Before physiological data collection, both the Chinese version of the trait Positive and Negative Affect Schedule (PANAS) and the Chinese version of Emotional Expressivity Scale were administered to 98 healthy university students, and then participants’ physiological data were collected during baseline, film-viewing and recovery period in the lab. Participants were then asked to complete the questionnaires again 4 months later. Results showed that, separated by 4 months, baseline RSA was stably associated with both trait positive affect and positive emotional expressivity. RSA inhibition or RSA recovery was not associated with trait positive affect or positive emotional expressivity. Nor were RSA parameters associated with trait negative affect or negative emotional expressivity. These findings suggest that resting vagal tone has been proposed as a stable trait-like physiological variable of individuals with trait positive affect and positive emotional expressivity.

The work-life balance of restaurant owners

Martin Lukes Prague University of Economics, Czech Republic; Stanislav Duranchek

The study focuses on the perception of balance between managing a self-owned restaurant and the personal life of the entrepreneur. It also analyses different factors that may influence how entrepreneurs perceive this balance. The sample of 40 entrepreneurs managing a restaurant in Prague, the Czech Republic, were interviewed. As a part of the interview, the established scales of self-efficacy and work-life balance were utilised. The results show that lower work-life balance is perceived by entrepreneurs who are motivated by profit, who manage a growing firm, do not delegate responsibilities, do not care much about their own health, have lower self-efficacy and are divorced, single or have bad family relationships in general. On the other hand, age, education, gender, co-ownership and, most surprisingly, the amount of hours worked per week did not influence the perceived work-life balance. The entrepreneurs’ perception of the work-life balance is thus largely subjective, influenced rather by qualitative factors, their priorities, attitudes, family background and how activities are planned and performed.
Transformation of the personal meaning in a crisis situation
Victoria Lyachenkova Moscow State University, Russian Federation
We have analysed different theoretical approaches to the concept of personal meaning and its transformation in a crisis situation, empirically studied the connection between meaning transformation and human activity, including concern activity. The purpose of this study was to examine ways and results of the personal meaning transformation of people with different meaning sphere structures in various kinds of crisis situations. The notion of meaning traditionally attracts people’s attention. The activity-notional psycho-transformative approach is a new approach to the concept of personal meaning studied on the victims of catastrophes, veterans of Afghanistan since 1988 in MSU. The relationships between personal meaning, its transformation, and human activities are considered under this approach. The research is devoted to depicting the nature of meaning transformation in various crisis situations. On the basis of qualitative and quantitative methods we have shown the relationship between the personal meaning transformation and behaviour orientation to success or failure. The meaning transformation has been considered in terms of two factors: Life -and Death-meanings (Magoned-Eminov, 1997). In the study, we have demonstrated the relationship between the nature of the meaning transformation in a crisis situation and a person’s involvement in taking care of somebody. The study can contribute to the further theoretical and methodological understanding of the personal meaning transformation in a crisis situation and to the development of psychological assistance to people in crisis situations, restoring their capacity to take care of themselves and others.

Psychological well-being of HIV counseling and testing (HCT) counselors
Princeess Mabota University of Pretoria, South Africa
HIV counseling and testing (HCT) has become a routine function that is exclusively reserved for lay counselors. They occupy the front line of HIV and AIDS service delivery, even though they are not formally employed in the health care system, they only have basic training and are not adequately remunerated. They are expected to educate clients about HIV and AIDS, encourage them to test and to change their behavioral practices. They have to convey test results and assist those who test positive, including their families, in coping with psychological challenges associated with the diagnosis. This paper focuses on the stress HIV counselors experience, how they cope and what motivates them to work as volunteers and what impact it has on their psychological well-being. The psychological well-being of 50 HCT counselors working in the City of Tshwane clinics was assessed using the Bar-On Emotional Quotient Inventory (EQ-i) the Maslach Burnout Inventory (MBI-HSS), the CES -D and the Brief Cope scale. Findings of the research indicated that EQ-i scores were low. Findings on the MBI-HSS indicated that they experienced high levels of emotional exhaustion while having high levels of personal accomplishment. Younger and female counselors experienced high levels of depression. Positive coping was used more often than negative coping. It can be concluded that counselors experienced both positive and negative well-being as a result of their work. Altruism, a sense of purpose and clients’ appreciation motivates them to continue volunteering.

The roots of resilience among female street-involved children in South Africa
Macalane Junel Malindi North-West University, South Africa
Several studies showed that children who adopt streetism in South Africa are mainly African and male. Much has been said about the determinants of resilience among boys involved in streetism however, not much is known about what enables resilience in girls who adopt streetism in South Africa in the context of risk. This paper reports the finding of an on-going qualitative study that seeks to explore the risks and the roots of resilience among female street-involved children in South Africa. I sampled purposefully to obtain 30 girls who are classified as children on the streets. They were aged between 13 and 17. I asked them to make drawings of what enabled them to cope with their lives. The drawings were accompanied by short narratives that explained the drawings. I then conducted semi-structured, purposeful and focused interviews with 13 of the girls whose drawings and narratives needed to be examined further. I conducted an inductive content analysis of the data and this process yielded personal (ability to adapt, ability to tolerate frustration, ability to act resourcefully and having a sense of autonomy) and contextual (social connectedness) resources that facilitated buoyancy in street-involved girls. The findings showed that girls befitted from combinations of personal and interpersonal resources in order to cope resiliently in the context of streetism. The implication is that although female street-involved girls can be vulnerable, researchers and practitioners will do well not to be blind to mechanisms that promote buoyancy in them.

Fields of happiness: Farmers’ resilience and protective psychosocial resources for psychological well-being
Charlotte Mahire Université Paul Verlaine-Metz, France; Cyril Tarquinio; Jean-Baptiste Lonfranchi
The change and intensification of their working conditions, farmers are part of a suffering professional group, confronted with chemical, physical and psychosocial risks (suicide, musculoskeletal disorders, etc.). Based on the Conservation of Resources Model (Hobfoll, 1989, 2001), the main objective of this study is to understand which material, energy, psychological, and social condition resources are the most protective for the farmers’ health. Data were collected from 50 French farmers (80% men and 20% women) aged from 21 to 59 years old (m = 42). The questionnaire contains the conservation of resources rating scale (COR-E, 1985), a vigor scale (SMVM, Shirom, 2004), the material, energy, psychological, and social condition resources (beta = .18) favours it. The results are therefore in the expected direction and also highlights the important role of material, energy (financial security), psychological (hope, sense of goals accomplishment, optimism, etc.), social condition (feeling close family members, employment status, etc.) resources to maintain and develop the farmers’ well-being.

Resiliency factors in families with an adolescent substance abuser
Roxanne Masters University of Stellenbosch, South Africa
Most studies focus on the negative implications of substance abuse. More recently, however, researchers have begun to move away from the pathogenic approach, to a more strength-based approach. Therefore, the aim of this study will be to investigate what those factors are that can be associated with family resilience in families with an adolescent substance abuser. Given the complexity of resilience, the Resiliency Model of Family Stress, Adjustment and Adaptation (McCubbin & McCubbin, 1988) will be operationalised in this study. Factors indicating a strong correlation with family adaptation can be considered as resiliency factors, since the family’s level of adaptation after a crisis can be
seen as a demonstration of their level of family resilience. A combination of quantitative and qualitative methods will be used to gather data from a convenience sample drawn from the Western Cape area in South Africa, in collaboration with substance abuse support organisations. Participants will consist of spouses who will serve as representatives for their respective families and who have in their families the presence of an adolescent substance abuser. Once the study has been completed, the information gathered from this study could be used to evaluate, improve, or develop intervention programmes and strategies to assist those families who find it difficult to adjust and adapt. The result may also be able to broaden current literature regarding family resilience.

Dynamics of positivity and well-being
Papri Nath Indian Institute of Technology, India; Rabindra Pradhan
The present study examines the mediating role of psychological resilience in the relationship of positive affect to physical health and psychological well-being. The study also observes the role of emotional intelligence and the big five personality factors in the concerned relationship. The data was collected on a sample of 307 engineering students. Results following the Baron and Kenny (1986) approach of mediation indicate that psychological resilience (b=0.41; p<.255) and physical health. Similarly psychological resilience (b=0.39; p<.001) also mediates the relationship between positive affect (b=0.15; p<.089) and psychological well-being of a person. Results also show that emotional intelligence, extraversion and openness moderate the influence of positive affect on psychological resilience. The results thus establish the significance of positive affect in enhancing well-being through psychological resilience, and also identify the personality factors which influence an individual’s psychological resilience. Therefore it could be said that increased levels of positive affect facilitate a person’s finding positive meaning in various life events and growth out of adversity which further increase the sense of physical and psychological well-being.

Emotional skills and its relation with the family environment in Mexican homes
Ruvalcaba Romero Norma Alicia University of Guadalajara, Mexico; Jose G. Salazar Estrada University of Guadalajara, Mexico; Maria Valadez Sierra; Tatiana Lopez Ruiz
The aim of this study was to analyse the relationship between emotional skills and emotional atmosphere within the home. A study was conducted with parents who had at least one child of school age and who lived in the metropolitan area of Guadalajara, Mexico. A survey with demographic data, the TMM-S-24 to measure Perceived Emotional Intelligence and the Family Environment Scale (FES) was applied to a sample of 468 parents with an average age of 36.6 years. The results indicate significant correlations between the subscales of emotional clarity and emotional repair with the subscales of cohesion, expressiveness, organisation, and involvement in activities of an intellectual, cultural and religious sort. It also showed a negative correlation with the conflict in the relationships. About the socio-demographic variables, note that it was the parents’ education level, those had a greater number of correlations with the emotional abilities and the perception of the social environmental characteristics of the family. By analysis of variance (ANOVA) by gender, we found that fathers promote an achievement orientation more than mothers. These results show the importance of developing educative programs that promote a better understanding of emotional states and mechanisms to regulate them, because they improve parenting styles and foster a positive atmosphere in the home and in general to improve the well-being of its members.

The interplay between positive and negative individual-level effects of social and political change
Martin Obschonka Friedrich-Schiller-University, Germany; Rainer Silbereisen
Our modern times, characterized by accelerated macro-level change (e.g., globalization, technological progress, demographic and economic change), come along with new challenges and opportunities for the individual. Psychological studies that systematically examine these individual-level effects are, however, still scarce. This particularly applies to possible positive effects. Analysing representative cross-national data from young adults in work, we examined perceived gains in self-determination and increasing opportunities for new learning at work as positive everyday manifestations of the change. We further examined their interplay with negative manifestations (increasing work-related uncertainties, more stressful working hours). We analysed two corresponding surveys from Germany and Poland (each datasets includes around 1500 participants), and a smaller German follow-up sample. Path analysis revealed that positive and negative manifestations interact in the prediction of (change in) psychological well-being: Gains in self-determination buffered the negative effect of increasing uncertainties. The results further indicate that institutional filters (work status, regional characteristics) modulate the effect of the macro-level change on the individual. Finally, we applied discriminant analysis to better understand the socioeconomic background and psychological resources and adjustment that are associated with individual constellations of positive/negative manifestations. The results revealed a clear picture across the two countries. The more privileged faced the positive side of the change (low uncertainties, high new learning), and the least-privileged the negative side (high uncertainties, low new learning). Implications for future research and social policy are discussed.

Socially committed coaching: A global framework for social impact
Ruth Mutawalli Coaching Psych Group (Ireland), Ireland; Eunice McCarthy
This paper discusses a framework that was adopted by the Irish Coaching Psychology Group in response to the worst recession to affect the country in its history. The Coaching Psychology Group set up a Socially Committed Coaching committee to provide pro-bono services to the general public. It was decided due to the current circumstances to target people directly affected by the recession, in particular the unemployed. With this in mind the Coaching Psychology Group partnered with MyMind, which is a mental health organisation, Coaching Psychology Group and the Coaching Psych Group (Ireland) in response to the need for support for their respective families and who have in their families the presence of an adolescent substance abuser. Once the study has been completed, the information gathered from this study could be used to evaluate, improve, or develop intervention programmes and strategies to assist those families who find it difficult to adjust and adapt. The result may also be able to broaden current literature regarding family resilience.

Resilience and coping in Australian high school students from refugee backgrounds
Michael Oliver Flinders University, Australia
Each year, 4000 to 5000 young people from refugee backgrounds enter Australia. These young people are considered an at-risk group for adverse mental health outcomes, due to the number of challenges they face, and the social and material resources that have been lost to them throughout the course of their refugee experiences. However, a number of young people from refugee backgrounds adapt positively to these challenges and demonstrate notable resilience. Due to the fewer external resources available to them, these students may be more reliant on personal assets, such as their own coping strategies, in order to positively adapt. This paper describes a study of Australian high school students from refugee backgrounds, who discussed their own experiences of coping, adaptation and resilience. Through a series of semi-structured interviews and focus groups, students told their stories of resettlement and schooling, discussed the challenges they faced, and the ways in which they sought to overcome those challenges. Qualitative, thematic analysis identified a range of coping strategies that young people deployed and perceived to be effective in adapting to the demands of their schooling, acculturation to Australian society and personal challenges in their lives. This paper will discuss the complexity and diversity of coping strategies described by participants and potential implications their stories have for understanding positive adaptation following a refugee experience.

Making the world a better place to live through positive psychology
Jan Olsen Aalborg University, Denmark
The purpose of this paper is to outline a theoretical and practical model for the role of positive psychology at a societal level. Although the world is facing tremendous problems in terms of lack of natural resources, poverty, pollution, conflicts and the consequences of global warming, there seems to be a movement of people and organisations who want to see a better world. This paper will discuss the complexity and diversity of coping strategies described by participants and potential implications their stories have for understanding positive adaptation following a refugee experience.

Positive Psychology
Opening up South African learners to new learning experiences through Frederikson’s broaden-and-build model

Cm Oosthuizen North West University, South Africa; Alida Nienaber

Frederikson’s (2000) broaden-and-build theory focuses on relationships between positive emotions and better cognitive functioning. According to her, positive affect broadens the scope of attention, intuition and creativity. Ruthig, Raymond and Chipperfield (2007) found that there is direct link between learners’ well-being and academic control, which is associated with well-being and better year end performance. The objective of this study was to determine the effect of Frederikson’s theory on new learning experiences. A mixed method designed was used. Primary and secondary learners from different cultural groups were asked to complete a broaden-and-build exercise at the introduction of new learning material. They were then asked to write a test on the newly acquired knowledge. This was compared with learners who did not do the exercise. The results indicated significantly higher test performance than the groups who did not do the exercise. The learners who did the exercise reported being more relaxed, attentive, and felt positive towards their teachers. This caused them to open up more to receive and absorb new information. In conclusion the application of Frederikson’s theory resulted in enhancing learning experiences and promoting positive affect towards teachers.

Psychological empowerment: A neglected concept for South African society

Richard Oxtoby Private, South Africa; Despina Learmonth

The concept of empowerment is very familiar to South Africans. Political empowerment and economic empowerment are held up as much-desired goals for post-apartheid South Africa. However, another equally important empowerment concept, psychological empowerment, has received very little attention. One of the many damaging consequences of the apartheid era has been the creation of a mindset in many South Africans that our destiny is not in our own hands. The laws of the land and the authoritarian, militaristic social environment were not conducive to the development of an empowered, ‘can do’ state of mind. Rotter’s work on Internal versus External Locus of Control, Seligman’s on Learned Helplessness, and Bandura’s on Self-efficacy have provided a sound framework for understanding the multi-faceted benefits of feeling psychologically empowered. The psychologically-empowered person is prepared to be proactive, to take initiatives, and is willing to try out novel solutions to old problems. The psychologically disempowered have learned to be obedient to the dictates of authority, and, governed by fear of punitive consequences, to inhibit any impulses they might have for independent action. This presentation will examine a research-based psychological model derived from the work of Rotter, Seligman, Bandura, and Berne, which can provide a powerful guide in running psychological-empowerment workshops in health, community, and business environments.

The theory, research, and practice of positive interventions

James Poweński University of Pennsylvania, United States of America; Norman Duncan

With the founding of the field of positive psychology almost 15 years ago came the term ‘positive intervention.’ A number of positive interventions have been developed and tested, including the ‘Three Good Things Exercise,’ the ‘Gratitude Vis-it,’ and ‘Acts of Kindness.’ Yet developing a precise definition of the term ‘positive intervention’ can be quite difficult. What, exactly, is an intervention, and what is it that makes some interventions ‘positive’? This talk will explore some answers to those questions and present an important new way of understanding positive interventions that has profound implications for how they are studied scientifically and how they are applied practically.

Achievement, integrity and survival: A model for human functioning

Henry Price MindPath Consulting, Australia

Humanity in the new millennium faces numerous challenges - environmental care, globalisation, poverty, religious and cultural tolerance, among many others. The model of Achievement, Integrity and Survival is presented as both a way of considering such issues and a framework for assisting human welfare and development. The model suggests three broad levels of human functioning: Basic survival, maintaining integrity and pursuing achievement. The optimal use of each is described and assessed. Defining and elaborating on integrity in its original meaning of ‘intact’, the model proposes integrity as the key to all three modes. Achievement without integrity can be viewed as one of the ‘ills’ of an affluent high technology society, while survival without integrity results in depression and loss of meaning. Developed over many years through Henry’s counselling and organisational psychology practice, the model can be usefully applied with individuals, groups, communities and organisations. It seeks to avoid prescriptive self-help formulas, instead emphasising a mindful approach based in fundamental human integrity. The presentation will introduce the model and applications before suggesting its further development to address key human challenges. This is not a research-based presentation with a testable hypothesis, nor is it focussed on a specific field of human endeavour but is derived from 30 years of work as an independent consulting psychologist with a focus on high-level achievement, problem solving, growth, and conflict resolution.

Psychological trauma experienced by emergency medical personnel and its effect on marital satisfaction

Mashakgene Ramokgopa University of Limpopo, South Africa; Takalani Ramulwela

This study investigates the psychological trauma (Posttraumatic Stress Disorder, Secondary Traumatic Stress and Burnout) that is experienced by EMS personnel, and its effects on marital satisfaction. It was hypothesised that EMS personnel experience psychological trauma at their workplace and these trauma has a negative effects on marital satisfaction. The study was conducted in Capricorn district – Limpopo Province (South Africa). A total of 200 participants Male=152, Female=48, aged between 19 to 65 years and who are working with traumatised people. Instruments utilised to measure psychological trauma and marital satisfaction are PTSD Checklist- Civilian Version (PCL-C), Professional Quality of Life (ProQOL-R III) and Marital Satisfaction Questionnaire for Older Persons (MSOFOP). The findings indicate that the majority of EMS personnel incur Secondary Traumatic Stress and Posttraumatic Stress Disorder as a result of their work. The findings also indicate that EMS personnel do not experience burnout at their workplace. In addition, findings show significant correlation between psychological trauma (secondary traumatic stress and posttraumatic stress disorder) and marital satisfaction. It is most likely that Traumatised EMS are dissatisfied with their marriage.
Exploring the relationship between workplace spirituality and stress resiliency
Renu Rastogi
Indian Institute of Technology, India; Santosh Sharma

Historically, stress and resiliency has always been the prime focus for organisational and behavioural scientists. Workplace spirituality has also been recognized as a valuable and prominent construct among organisational and management researchers especially working in the domain of positive psychology. Theoretically, it has been argued that, workplace spirituality plays a vital role in reducing stress and enhancing resiliency, however there are a very few studies which examine and analyse the impact of workplace spirituality on stress resiliency empirically. Realising this gap, the paper aims to explore the relationship between workplace spirituality and stress resiliency. The present study is also an attempt to analyze the effect of workplace spirituality on stress resiliency in a sample of 224 Indian managers. Data have been collected through questionnaire based surveys. Correlation and regression analysis has been carried out. The findings divulge the fact that workplace spirituality is a key driver that develops effective mental habits for coping with stressors which help managers to become stress resilient.

Workplace spirituality as a predictor of psychological well-being
Renu Rastogi
Indian Institute of Technology, India; Santosh Sharma

The dawn of 21st century has heralded with the development of ‘workplace spirituality’ as a valuable construct among organisational and management researchers especially working in the field of positive psychology, however, there is a dearth of empirical studies in this newly developing area. Realising this gap, the paper aims to study the impact of workplace spirituality and its three dimensions (meaningful work, sense of community, and alignment of personal values with organisational values) on psychological well-being and its six dimensions (autonomy, environmental mastery, personal growth, positive relations with others, purpose in life and self-acceptance) in a sample of 224 Indian managers. Data have been collected through questionnaire based surveys. Correlation and regression analysis has been carried out. The findings divulge the fact that when managers experience workplace spirituality they feel autonomy, environmental mastery, personal growth, positive relations with others, purpose in life and self-acceptance which in turn determine their psychologically well-being.

Practicing and validating positive psychology coaching: Empowering strengths, positive emotions, hope and well-being
Joana Ribeiro De Carvalho
Land Of Dreams, Portugal; Bianca Neeskens; Helena Marujo

The present research was developed by a Portuguese solidarity institution (Terra dos Sonhos/ The Land of Dreams) that is specialized in creating conditions to fulfill dreams in large samples of chronically ill children and children with life-threatening diseases. A previous study with this population showed posttraumatic growth and positive effects on the psychological and physical well-being of the participants after fulfilling their dreams. Aims: the current study explored the impact of a positive psychological coaching intervention in the development of a form of empowerment involving promotion of hope, strengths, positive emotions, pro-active and resilient reactions to treatments and well-being. The sample enrolled children that were chronically ill/having life-threatening diseases, and their families. Methodology: the research was qualitative, transformative, appreciative, solution-focused in nature, based on principles from positive psychology coaching. The intervention enrolled 30 children (10-18 years old), 15 mothers and fathers. The results showed that the positive psychology coaching program was associated with significant increases in goal striving, pathways thinking, well-being and hope with gains sustained on positive emotions, resilience, and hope for the future during 6 months. Children showed better adherence to treatments and higher acceptance of the disease. The intervention program appears to have a positive impact on this type of group, instilling positive emotional and relational consequences in families and children. Recommendations for conducting future intervention studies are provided, including involving healthcare professionals and the importance of qualitative, transformative and appreciative methods in evaluations and research.

The experience and expressions of authenticty
Shivantika Sharad
Vivekananda College, Delhi University, India; Girishwar Misra

This research tried to identify the contours of the construct of authenticity and to examine its correlates following a multi-method approach through four studies. Studies I and II involved scale construction and mapping of the correlates of authenticity on two samples (n=1*316; n=2*194). Factor analysis revealed a three-factor solution consisting of responsible agency, concern for other, and non-defensiveness, non-compulsive behaviour. Authenticity was positively related to healthy psychological functioning. Study III that qualitatively analysed (auto)biographies of Sri Aurobindo and Mahatma Gandhi yielded a “growth model of authenticity”. The model represents markers of an authentic person along with his transformative journey. Study IV, a grounded theory analysis of interviews of participants of different age groups (n=26), resulted in a core category characterising authenticity as the process of maintaining a sense of balance in an on-going dialectic of self and society. The four studies converged on the view that authenticity is being objectively aware of one’s own self, fully aware of the environment (the context, the person and the relational dynamics) as well as the potential repercussions of one’s behaviour on others before exercising a choice. It comes alive as a relational process of transacting and balancing without compromising on one’s sense of being. In a sense this process is self-transcendental. Authenticity also arose as the fundamental basis of best of relationships and rich in terms of its bearing on education, socialisation, health and well-being.

Construction of trust and hope by women who lived through trauma: A grounded theory approach
Manjari Srivastava SIBM, NMIMS University, Mumbai, India

The purpose of this study is to understand and explore the development of ‘trust and hope’, a positive approach adopted by women to overcome the trauma in their life successfully. It aims to understand what it takes to counter depressing moments and develop positivity in life, thus (a) to identify causal conditions that underlie the development of trust and hope, (b) to identify the phenomena, i.e. trust and hope, that develop from these causal conditions, (c) what strategies were employed during the process? (d) the intervening conditions that might have influenced the strategy development, and (e) the consequences of these strategies. The proposed study is based on grounded theory approach, hence the data collection and research analysis employs a qualitative method. The researcher plans to collect data through theoretical sampling method. The educational qualification of participants is being kept at graduation level. No differences are being made with respect to marital status, religion, employability and economic status. Qualitative research methods are particularly suited to uncovering meanings people assign to their experiences (Hoshmand1989). To clarify participants’ understanding of their experiences the methods to be employed are: (1) Developing codes, categories and themes rather than going ahead with predetermined classification. (2) Generating working hypothesis from the data. (3) Analyzing narratives of participants’ experience of traumatic events and their positive approach towards life. The research was not restricted to any particular type of trauma. Traumatic events are put into the category of certain personal events like the death of near ones, divorce, separation, failed love affair, any kind of mental or sexual abuse and accident. The researcher hopes to come up with a theoretical framework on trust and hope as a coping strategy for trauma. The results of the study could be utilised by the researcher, academicians and other professionals in the field. It is certainly a contribution towards developing and strengthening positive psychology.

Good vibrations: Science and psyche
Reinette Steyn South Africa

Since the recent World Conference of Quantum Physics and Consciousness, the fields of psychotherapy and counseling have been enriched by the latest findings in so-called energy medicine, based on principles applicable to atomic and molecular levels of neuroscience. Implications of some of these findings for Cognitive-Behavioral Therapy, counseling and life coaching will be presented in lay terms. Practical examples and exercises will be described and demonstrated.

Teachers’ support needs through the lens of positive psychology
Verena Strydom Stellenbosch University, South Africa; Marietjie Oswald; Min-qiang Zhang Stellenbosch University, South Africa

This study aimed to understand the support needs of teachers involved in the life skills education and mental health promotion of learners. Teachers, particularly those involved in life skills education, are key role players in the mental health promotion of learners. In accordance with the study’s underlying framework – positive psychology – the argument can be made that the three characteristics of positive functioning, namely positive institutions, positive
Emotions and positive individual traits, need to be promoted throughout the school community to support teachers in fulfilling their roles. The study was qualitative in nature and was embedded within the interpretive paradigm. Written reflective notes as well as semi-structured focus groups and individual interviews were used to collect data. Furthermore, qualitative content analysis was used during data analysis. Several ethical considerations were made during the research process, all of which were guided by the ethical guidelines for psychological research. The study’s findings supported the need for a whole school development approach to mental health promotion. The facilitation of positive and supportive school communities is therefore critical to the successful implementation of life skills education, and consequently, mental health promotion. Support needs to be offered to teachers by all role players in the school community, from the department of education to school management, to foster the well-being and competence of teachers effectively in order to meaningfully facilitate learners’ holistic development.

**Beating the odds of poverty: Stories from resilient South African students**

_Linda Theron NWU, South Africa; Adam Theron Resilience, or the process of adjusting positively to significant adversity, is influenced by the social ecology in which young people are situated. This growing understanding has led to authoritative researchers, such as Ann Masten and Margaret Wright (2010), and Michael Ungar (2011), calling for studies that foreground how culture and context shape resilience processes. Using the theoretical lens of ‘the Social Ecology of Resilience’ (Ungar, 2011), our paper focuses on how traditional African-centric culture and contexts shape black South African university students’ resilience. We explore how African-centric cultural beliefs and practices inform attachments, which in turn influence how black South African youth adjust positively to the hardships of abject poverty. To do so, we draw on multiple, rich case studies of black South African university students who have lived experiences of beating the odds of poverty. Using these young people’s narratives and visual explanations of their resilience processes, we theorise about how traditional African-centric contexts, philosophies, and customs encouraged resilience-promoting transactions in which youth and their extended families collaborated, and about the influence of spiritual (religious and ancestral) beliefs in how youth resided. We draw tentative conclusions about the influential role of familial and existential attachments, how these shape meaning-making and problem solving uniquely, and encourage equanimity, thereby promoting resilience._

**Pathways to resilience: Lessons of positive adaptation from a five-country study**

_Linda Theron NWU, South Africa; Michael Ungar; Guoxiu Tian; Luis Duque; Linda Liebenberg; Macalane Malindi; Robyn Munford; Alexandra Restrepo; Jackie Sanders; Xiyang Wang; Sergio Cristancho_ Many young people, whose contexts place them at risk for negative outcomes, do well in life. This begs the question: why do some young people adapt positively to adverse life circumstances? More specifically, what patterns of formal service and informal support work are best in varied cultural contexts to mitigate risk and promote well-being? To answer this, the Pathways to Resilience Research Project employed an iterative mixed methods design. Youth (aged 14-19) from high-risk neighbourhoods in Canada, Colombia, China, South Africa and New Zealand were invited to co-construct knowledge on youth pathways to resilience. Six thousand adolescents, including service-using youth, functionally resilient youth (i.e., youth identified by local advisory committees as doing well by community standards despite adverse environments) and a matched non clinical comparison cohort of youth from each of these communities, completed the Pathways to Resilience Youth Measure (PRYM). Subsequently, a stratified sample of about 300 youth was selected using the PRYM scores: equal numbers of male and female youth who a) face high risk but scored high on the resilience subscales, and b) score high on risk exposure but have low resilience scores generated qualitative, localised understandings of risk, resilience, and service and support ecologies (by means of individual and focus group interviews and visual data collection methods). Our symposium draws on the findings of both the quantitative and qualitative studies to offer insights into the generic and unique, formal and informal pathways that resilient young people from these specific ecologies navigate in their efforts to adjust well to adversity. Paper One: Studying the Social Ecologies of Resilience Across Cultures: The Pathways to Resilience Project’s Rationale and Methodology (Michael Ungar & Linda Liebenberg)Paper Two: Service-facilitated Pathways to Resilience (Luis Duque, Jackie Sanders, Robyn Munford, Sergio Cristancho & Alexandra Restrepo)Paper Three: Informal Pathways to Resilience (Guoxiu Tian & Xiyang Wang)Paper Four: Cultural Pathways to Resilience (Linda Theron & Macalane Malindi)Discussion: Prof David Donald (Professor Emeritus, UCT)_

**Pathways to resilience: Understanding adversities among Chinese youth**

_Guoxiu Tian C Baptist Normal University, China; Xiyang Wang_ As part of a comparative mixed-method resilience research among at-risk youth in four counties, namely, Canada, South Africa, Colombia and China, 80 resilient Chinese adolescents were interviewed and 1200 questionnaires collected in Beijing, China. In this paper, we illustrate the general adversities that Chinese Youth faced in their daily lives, and report their subjective understanding of adversities compared to intellectual definitions. We will also describe their culturally specific and generic strategies to cope with adversities. We aim to answer the question of how the fast-changing cosmopolitan Beijing City impact on the developmental experience of Chinese adolescents at risk. The implications of further resilience studies and social work interventions to at-risk youth are discussed._

**Psychological well-being of children treated for chronic, life threatening illness**

_Henriette Van Der Berg University of Free State, South Africa; Brenda Talbot University of Free State, South Africa_ The objective of this study was to investigate the resilience of children receiving treatment for life threatening illnesses. An availability sample of 44 children was recruited from oncology treatment centers at private and public healthcare facilities in South Africa. The age of the children ranged from 10 to 18 years. Ethical approval was granted by the Ethics Committees, University of Free State and stringent ethical guidelines were adhered to during the study. The whole sample participated in a quantitative study involving the completion of the following self report measures: the Satisfaction with Life Scale, Coping Resources Inventory, Fortitude Scale and the Children’s Hope scale. A regression analysis was executed to determine the relationship between the predictor variables and life satisfaction. The quantitative analysis was followed by a thematic exploration of the experiences of six children who displayed high levels of resilience. The quantitative results reflected average levels of life satisfaction and helpfulness. The predictor variables explained 38.9% in life satisfaction (1% level of significance), with hope, social support and coping strategies as significant predictors. The qualitative analysis emphasized the role of family support and health care professionals as sources of information and support as well as the role of cognitive and spiritual coping strategies. A stronger focus on the provision of mental health services and psychosocial support for the children and their families is recommended._

**Work engagement and autonomous motivation of volunteers: The impact of work design and organisational practices**

_Susan Van Schie ETH Zurich, Switzerland; Stefan Guentert; Theo Wehner; Jeannette Oostlander_ Volunteering is an area of growing political and scientific interest. Even though volunteering touches on genuinely psychological issues, work and organisational psychology has largely neglected volunteering. This study addresses work design, organisational practices, and their impact on various outcomes reflecting satisfying and sustained volunteering. Volunteers join a specific organisation with personal goals and expectations. Organisations depend on their willingness to accept organisational constraints and to give performance not only with respect to behaviours focused on the personal cause of volunteering, but also to those activities that primarily benefit the organisation. We apply self-determination theory (SDT) in order to understand the mediating processes by which work design and organisational practices influence outcomes. We present selected results of the first measurement period of our longitudinal study. Based on the data of 2261 volunteers, we calculated a structural equation model (SEM) in order to test the postulated hypotheses. There is evidence for two different motivational processes: Work design influences the cause-oriented autonomous motivation, which in turn accounts for the work engagement of volunteers. However, organisational practices are strongly related to the organisation-oriented autonomous motivation and in turn account for Organisational Citizenship Behaviour. The focus on work design and organisational practices promises unique practical relevance, since expertise of work and organisational psychologists will be made available to volunteerism. From a theoretical perspective, the project contributes to a better understanding of how
The development and evaluation of a positive psychological intervention aimed at increasing happiness of students
Llewellyn Van Zyl University of South Africa, South Africa; Sebastiaan Rothmann
Most individuals would argue that achieving sustainable happiness and avoiding depression/sadness/pain is at the top of their ‘bucket lists’ (Lyubomirsky, 2011). Yet very few individuals achieve lasting happiness (Keyes, 2011; Lyubomirsky, 2011). A great deal is known about the antecedents and positive consequences of happiness, however very few studies have strived towards developing positive psychological interventions (PPI) aimed at increasing happiness (Sin & Lyubomirsky, 2009). An 8 month-long pre-experimental longitudinal study examined the immediate and long-term impact of a positive psychological intervention aimed at increasing happiness of students (n = 20) in a tertiary educational environment. The PPI was presented in two phases: (a) A three day self development workshop and (b) six sessions of individual coaching. Our results indicated that the overall happiness of a student may be increased through developing individuals on both an emotional and psychological level. We conclude that PPIs are more than just placebos, but are vital to ensuring lasting and sustainable happiness.

The world database of happiness: Tool for ordering the growing pile of research findings
Ruut Veenhoven Erasmus University Rotterdam, Netherlands
Social scientists are producing an ever-growing stream of research findings, which is ever more difficult to oversee. As a result, capitalization on earlier investment declines and accumulation of knowledge stagnates. This situation calls for more research synthesis and interest in synthetic techniques is on the rise. To date, attention has been focused on techniques for meta-analysis, with little attention paid to the preliminary step of bringing the available research findings together. What we need is (a) techniques for describing research findings in a comparable way, (b) a system for storing such descriptions in an easily accessible archive, to which (c) research findings can be added on a continuous basis. The World Database of Happiness is an example of such a tool. The archive is tailored to meet the requirements of assembling research findings on happiness; both distributional findings (how happy people are) and correlational findings (what things go together with happiness). With its focus on ‘findings’ the system differs from data-archives that store ‘investigations’ and from bibliographies that store ‘publications’. As yet there is no established term to describe this tool for research synthesis. I call it a ‘focused findings archive’. The substantive focus of this database is on subjective enjoyment of one’s life as-a-whole. The database involves five related collections on this matter: (1) The Bibliography of Happiness, which involves about 6,500 publications, (2) a collection of acceptable Measures of Happiness that contains about 700 variants, (3) the collection of Happiness in Nations that lists the distributional findings of some 4,500 general population surveys in nations studies, (4) the collection of Happiness in Publics containing the results of some 3000 studies among particular categories within nations and (5) the collection of correlational findings, which involves some 14,000 findings on covariates of happiness. These collections can be browsed on the Internet. In this paper I describe how that works and discuss the strengths and weaknesses of this approach. I call for cooperation in keeping the collection up to date.

The role of positive affects and psychological resilience in investment decision-making
Cai Xing Renmin University of China, China; Yue Wen; Han-min Sun; Jie Chen; Yue Gu
Past studies have suggested that positive affects produce a wide range of desirable outcomes because they help people build lasting resources. Underlying this explanation is the assumption that these resources that positive affects build overtime could explain the beneficial effects of positive affects in stressful encounters. However, this assumption has not been directly tested by empirical studies. This question is important in that it helps clarify the underlying mechanism through which individuals with more positive affects could bounce back from adverse situations. With a well-designed stressful task that included 20 rounds of risky investment choices, the current study examined whether psychological resilience, an important personal resource that positive affects fuel, could account for the beneficial effects of positive affects. The results demonstrated that psychological resilience could indeed help explain happier people’s enhanced outcomes: they chose higher return although more risky investment options and experienced more positive affects at the end of the task. The current study supported the notion that individuals who experience frequent positive emotions thrive through various challenges not simply because they feel good, but because they have resources that they could utilize to deal with those challenges. Findings from the present study warrant further unpacking the important relationship between specific positive affects, psychological resilience and performance in risky investment tasks.

Meditation is one way to increase creativity
Ni Nyoman Wiranti University of Udayana, Indonesia; Made Sri Inten
Meditation is not only beneficial to reduce stress, but meditation also has the potential to increase creativity, but the effectiveness of meditation is highly dependent on the individual aspects (including imagination preference, individual life experiences, memories and emotional involvement). Research conducted in Bali aims to determine how the meditation is done according to the portions can affect creativity. The results of this study indicate that the hypothesis be accepted.

The five traits moderate association between equity sensitivity and subjective well-being
Hao Yu Peking University, China; Luning Ren; Lei Wang Peking University, China
Subjective well-being (SWB) is an issue of wide concern. Many variables are reported to have an impact on subjective well-being. Based on equity theory, the present research focuses on the relationship between the sense of justice (Equity Sensitivity), and subjective well-being and how personality (e.g. Big Five Traits) influences this relationship. Data were collected from a sample of 566 residents in China by a cross-sectional questionnaire survey design. The results showed that, there was no significant relationship between equity sensitivity and subjective well-being. But two dimensions of Big Five Personality traits, conscientiousness and agree-
The development of the implicit view about subjective well-being in Chinese adolescent students

Jianhong Zheng; Zhanjiang Normal University, China; Qiuxia Cheng; Hongji Wu

A questionnaire (which was based on the pre-investigation) was developed to investigate the implicit view of subjective well-being in 1012 adolescent students (including: 346 senior high school students; 363 junior middle school students; 303 college students). The results showed: 1) The structure of the implicit view about subjective well-being in senior high school students, junior middle school students and college students included four factors; 2) There were age differences in the development of the implicit view about subjective well-being in adolescent students; they had different contributing domains to well-being at different ages. 3) All the adolescent students had consistently attached the importance of affection to interpersonal relationships on their well-being, and didn’t regard their academic achievement as the most important factor concerning their well-being.

Recovery from depression builds character strengths and positive coping strategies

Ya Zhou; The Chinese University of HK, China; Fung Ying Siu

A complete science of psychology should include a holistic understanding of human distresses and strengths. How are these two separate variables related to each other? Several studies, using western samples, suggested that traumatic experiences may allow the display of greater character strengths. The present study was particularly interested in whether previous episodes of depression had a similar effect of building character strengths among Chinese subjects. Besides, given that coping strategies are vulnerability factors for depression, the present study also aimed to explore whether history of depression had positive influences on coping strategies. There were initially over 200 participants: 43 were identified as currently depressed, 32 as recovered from depression, and 40 as never depressed. All participants completed online the Values in Action Inventory of Strengths (Peterson & Seligman, 2001) and the Coping Strategies Questionnaire, developed by a Chinese scholar Xiao (1995). For individuals recovered from depression: 1) Creativity was higher than those never depressed (b = -0.24, p<.01) and (2) several strengths were higher than those currently depressed; love, gratitude, creativity, love of learning, hope, forgiveness, bravery. As for coping strategies: 1) The recovered group scored higher on positive strategies and lower on negative strategies than the currently depressed group, (2) no difference was found on positive strategies between the recovered group and the never depressed group.

Explanation of the mediating role of role breadth self-efficacy

Hong Zhu; Hong Kong Baptist University, Hong Kong; Longzeng Wu

Drawing on social cognition theory, this study examined the link between transformational leadership and employees’ proactive behaviour by focusing on the mediating role of role breadth self-efficacy and the moderating role of employees’ future orientation. Based on a sample of 258 supervisor-subordinate dyads employed in two oil and gas companies in China, we found that: (1) Transformational leadership was positively related to proactive behavior. (2) Role breadth self-efficacy mediated the relationship between transformational leadership and proactive behavior, (3) employees’ future orientation strengthened the direct effect of transformational leadership on role breadth self-efficacy and its indirect effect on proactive behavior. We discuss the implications of these findings for theories and research, as well as for management practice.

Session Type: Posters

Internal psychological resources that contribute to the resilience of an adolescent who heads a family

Charnee Beddy; University of Johannesburg, South Africa

The aim of this study was to investigate the internal psychological resources of resilience within an adolescent who heads a family due to the loss of her parents through AIDS. A qualitative case study was conducted with “Thandi” within a theoretical framework of resilience theory. The data collection methods included semi-structured interviews with Thandi and the managing director of a non-governmental organisation. Three of Thandi’s teachers completed self-administered questionnaires, the compilation of which was guided by the internal resources of resilience as identified by McGrath and Noble (2003). Thandi constructed a collage to explore her inner psychological strengths that contributed to her resilience in the midst of life’s challenges. Data was subjected to content analysis to determine the themes and sub-themes that emerged. The findings revealed that Thandi appeared to exhibit all the internal resources of resilience as identified by McGrath and Noble (2003), however the degree to which they were evident differed. The original contributions of this study are evident in several themes that allude to Thandi’s psychological resilience, namely: religious beliefs; moral values; treating others with respect and kindness; dealing with grief and loss; and managing loneliness, stigmatisation, anxiety and stress. Based on the findings several recommendations are made on the enhancement of resilience through the nurturing of internal psychological resources in adolescents in a similar situation as Thandi.

Validated questionnaire for Eudaimonic well-being in South African samples

Lusilda Bashoff; North-West University, South Africa; Maria Wissing

Scholarly understanding of psychosocial well-being from Eudaimonic perspectives has become increasingly centre stage in positive psychology in recent years, and new measures are being developed, amongst others, the Questionnaire for Eudaimonic Well-being (QEWB) of Waterman et al. (2010). These measures need to be validated in other cultural contexts than those of the original validation.

Psychological capital and difficulties in career decision making

Li Bin; Central China Normal University, China; Yon-gyu Guo; Ling Lin; Fuming Xu; Hongyu Ma

This study examined the relationship between psychological capital to career decision-making difficulties. A total of 190 university students consisting of 40 freshmen, 50 sophomores, 50 juniors, 50 seniors (aged19-23yrs, 48% female) filled out both the Chinese Career Decision-Making Difficulties Questionnaire (C-CDQQ) and Chinese Positive Psychological Questionnaire (C-PPQ). The 22-item C-CDQQ (a=.68-.84) measures seven categories of difficulties such as lack of information and so on. The 26-item C-PPQ (a=.76-.86) measures facets of hope, resilience, optimism, and self-efficacy with six items for each subscale. While controlling for demographic factors (such as age, sex), hierarchical regression showed that psychological capital was negatively related to career decision-making difficulties (b = -34, p<.05). The results imply that psychological capital may play an important role in helping young adults to make better career decision.
samples, before implementation. This study aims to explore the validity of English, Afrikaans and Setswana versions of QEWB in South African samples. The original QEWB was translated into Afrikaans and Setswana by using an adapted version of the Brislin-method. Data were gathered with the three versions in mother tongue speakers of English, Afrikaans and Setswana. Amongst other measures included for validation purposes were the Mental Health Continuum-Short Form (MHC-SF) and Patient Health Questionnaire-9 (PHQ-9). Descriptive statistics and reliability measures were calculated for the three versions of the QEWB. Criterion related validity was determined and construct validity explored with exploratory and confirmatory factor analyses. Results will be reported on the psychometric properties of the three versions. Applicability of the translated versions and the specific underlying eudaimonic perspective as understood in the relevant South African contexts will be considered.

The influence of subjective experiences on challenges and skills in various social contexts
Chao-Yang Cheng National Chiao Tung University, Taiwan, R.O.C.; Sunny S. J. Lin
This study investigated whether there are associations linking four subjective experiences (concentration, motivation, activation, and happiness) with the levels of challenges and skills in four social contexts (with family, with friends, at school, and alone). Based on Day Reconstruction Method, 233 participants were asked to write a journal based upon the previous day activities, the perceived challenges/skills and the subjective experiences according to self-defined episodes. We estimated the models by using the HLM 6. The random coefficient model is specified by a Level-1 model (within-subject episodes) and a Level-2 model (persons). The model showed an adequate fit for all four subjective experiences. Skill was a positive predictor for concentration and motivation in each of the social contexts while it was a positive predictor for activation in three contexts (friends, school and alone) and for happy in two (school and alone). Challenge was a negative predictor for happy in each of the four social contexts and for motivation in school, while it was a positive predictor for concentration in the contexts of friends and alone. The effects of the perceived challenges and skills on subjective experiences are different in various social contexts. In a given workday, our college students perceived higher skills than challenges from all activities. We also found skills had positive association with subjective experiences but challenges had negative association with motivation and happiness. College students in Taiwan should seek activities with higher level challenges than what they commonly have now to improve the quality of everyday life experiences.

Exploring the differences in the perception of OE in a diverse work context
Rowenna Erin Cuff University of Pretoria, South Africa; Nicole Barkhuizen University of Pretoria, South Africa
Scholars and managers alike have begun to realise the influential role that the thoughts and emotions of employees play in shaping the actions of the latter within the workplace (Bruch & Ghoshal, 2003; Bruch & Vogel, 2011; Cameron & Spreitzer, 2011, Luthans & Avolio, 2009). An individual’s subjective culture provides the basis through which they perceive their social environment, which in turn discourages certain behaviours and cultivates others (Anastasi, 1990, as cited in Schaepp, Buys, & Olickers, 2005). This affects how the individual interprets and responds to specific concepts in the work environment (Prinsloo & Elbersohn, 2002). Thus, meaningful comparison of responses from multiple cultural or language backgrounds is dependent on the equivalence of the constructs being measured (van de Vijver & Poortinga, 1997). To explore the differences in perception of Organisational Energy among a diverse South African Workforce. A cross-sectional survey research design was followed with data being collected from employees (N=303) from South African institutions. The EnergyScapes Profile (Tosey & Llewellyn, 2002) and the Productive Energy Measure (Cole, Bruch & Vogel, 2011) were administered. Descriptive statistics were utilised to interrogate the data. The empirical results indicated significant differences between different demographic groups and their perceptions of Organisational Energy. It is hoped that an understanding of how diverse workforces perceive organisational energy will assist organisations in identifying practices, processes and initiatives which can have a positive impact on organisational energy and, in turn, on the reten
tivity, productivity and satisfaction levels of their employees.

Resilience in relation to creativity, openness to experience and emotional support
Ervins Cukurs University of Latvia, Latvia; Sandra Sebre
Creativity, as inherently linked with elasticity, flexibility and divergent thinking, has been theoretically connected to resilience, but there is a dearth of empirical research exploring this association. The aim of this study was to explore various personality and social factors, as well as creativity as potential predictors of resilience. Participating in the study were 120 adults who completed the following questionnaires: Resilience Scale of Adults (Hjemdal, Friborg et al.); the Test for Creative Thinking – Drawing Production (Urban & Jellen, 1995); the personality measure Big Five Inventory (John & Srivastava, 1999), and items regarding emotional support in childhood. Multiple regression analysis shows that Emotional Support, Extraversion and Openness to Experience ratings are significant predictors of Resilience, but that Creativity ratings are not related to Resilience directly. However, Creativity ratings are associated with Openness to Experience which is then further associated with Resilience. Differences in association by gender were also found. The practical implications of this study indicate that creative expression in itself is not necessarily a facilitator of resilience, but that if the creative endeavors include an openness to new experience, then this may encourage the seeking of new problem-solving strategies, and new coping approaches, which then further engen
der resilience.

Meta-analysis of psychological crisis intervention
Wenxiu Geng East China Normal University, China
This work aimed assessing the effects of psychological crisis intervention in China through a literature review. 320 research reports which were published on the CSSCI (Chinese Social Science Index) journals, and were chosen for analysis from thousands of papers on the subject after May 12, 2008. We also conducted face to face interviews, when visiting the Sichuan earthquake area. More than 200 teachers and students who had gone through the disaster were interviewed.
We also examined the crisis intervention programmes of Shangai and Wenzhou disasters. We found: (1) under the leadership of local govern ment, the health department organized psychiatrists who have right of prescription, and psychologists from universities to provide psychological crisis intervention. The model is well managed by the government and essentially effective. (2), volunteers with basic training in counseling actively engaged in various kinds of psychological services. Though the service was convenient, its qualification was queried. (3) after the massive and spectacular intervention, a small group of people still suffered delayed PTSD. Teachers in the middle and primary schools were overburdened and some of them felt burnout. The stricken areas and the affected people need long-term, continuing and standard psychological interven tion and services.

Time management and the hospitality training environment: The roles of flow, happiness and life satisfaction
Ita Gyser University of Johannesburg, South Africa; Freddie Crous; Madelyn Molenhuyys
There is ample evidence that optimal experience (flow), happiness and life satisfaction play a positive role in the creative culinary training environment. The effect that time management has on these roles is investigated. The objective of this study was to investigate the relationship between time management, the hospitality training environment and the roles of optimal experiences (flow), happiness and life satisfaction. Further, the moderating role of time management on performance and flow was explored. An investigation into the concept of flow, happiness and life satisfaction on time management in the culinary environment will add to the body of knowledge in the field. Research Method: This study utilised a quantitative research design. Data were gathered with the use of an online questionaire (cross-sectional survey). A sample of n=229 students within the culinary environment, within a tertiary institution spanning across different ages, racial groups and educational levels was gathered. Significant relationships were found between flow, happiness, life satisfaction and time management. Life satisfaction proved to have a significant main effect on flow. The dimensions of time management had a significant interaction effect on the relationship between life satisfaction and flow. The implications are that time management would become more prominent in the practical training for hospi tality students. Successful time management skills can prove to be beneficial to increase the flow, happiness and life satisfaction outcomes of the students.
An exploration of an older woman’s coping strategies in dealing with difficult life experiences
Jolinda Hugo
Nort-West University, South Africa

Coping strategies are essential for human beings to deal with difficult life experiences. The theoretical background supporting this study is positive psychology where the focus is on assets, and the positive constructs of people’s functioning. The conceptual framework that informed this study is that, despite the fact that old age is associated with many challenges, people apply adaptive coping strategies to deal with it. The purpose of this presentation is to investigate coping strategies that an older Afrikaans woman, aged 64, applied to deal with difficult life experiences. An exploratory case study design was used and the gathered data included person-centered interviews and a journal of her own reflections. The coping strategies applied by the older woman, were spirituality, love for family and friends and finding meaning through her suffering. Literature confirmed that spirituality and social support are regarded as important coping strategies for older people. The novice contribution of this study is the older woman’s way of using meaning as an effective coping strategy in difficult life experiences. Here meaning-making implies the older woman’s ability to find meaning despite challenges associated with difficult life experiences. To her, meaning implies that, despite suffering through life experiences, she wouldn’t have missed it, because through it she experienced personal growth. She regards herself as wiser, happier and more focused. In conclusion; making meaning throughout life can be an effective coping strategy. It is recommended that further studies regarding the importance of meaning-making as coping strategy, for old aged, should be conducted.

Development of a family commitment scale: Exploratory study
Salome Human-Vogel
University of Pretoria, South Africa

Family commitment involves the study of commitment in a relational, non-romantic context. In the present study family commitment is conceptualised as commitment to one’s family-of-origin. The family is a primary context for the socialisation of children (Grusec & Davidov, 2010), yet is becoming increasingly fragile as more and more children experience a breakdown in the family unit (Coleman & Glenn, 2010). In the present study I argue that adolescents’ wellbeing is enhanced when children are socialised in the context of a loving and supportive family unit, and when they are committed to the family unit. Family commitment is conceptualised as meaningful identification with one’s family, as well as feeling a sense of connection to one’s family unit and commitment to family values, may demonstrate better wellbeing. The Family Commitment Scale, adapted from the Rushult et al. Inventory of Family Commitment (1998) was adapted and administered to 188 adolescents between the ages of 16 and 18 years. Exploratory factor analysis indicated a four factor structure. Full scale Alpha was 0.83. Reliabilities for the subscales ranged between 0.84 and 0.94. The pattern of correlations obtained for the Family Commitment Scale with the Trait Wellbeing Scale (Dalbert, 2003) support the construct validity of the adapted instrument and suggest that it may be an appropriate instrument for measuring commitment to the family of origin.

The relationship between optimism, locus of control and academic achievement
Negar Karimian
University of Allameh Tabatabai, Islamic Republic of Iran; Korosh Namdari

According to Seligman (1998), counsellor and therapist must show the same attention to the strengths, improvement of the quality of human life and the promotion of mental health, as to the weaknesses, vulnerability and behavioural problems. The purpose of this study was to investigate the relationship between optimism, locus of control and academic achievement. For this study, 50 students (25 female, 25 male) from Esfahan University were randomly selected. All participants completed the life orientation test (LOT) and Nowicki-Strickland Locus Of Control Scale (N-SLOC). Data analysis involved using descriptive statistics, Correlation test and T-Student test. Results showed optimism is associated with internal locus of control (P<0/05). Optimism is not associated with academic achievement. There was a direct and significant relationship between locus of control and academic achievement in boys. We also found no difference in the amount of optimism for girls and boys and observed that female students use more external locus of control than male students.

A comparison of psychological well-being constructs between teachers in different school settings in South Africa
Illasha Kok
North-West University, South Africa; Iltemeleng Khumalo; Johan Potgieter

This study aimed to compare the psychological well-being constructs, psychological distress and social support of two groups of teachers, and investigates the possible factors that contribute to the difference between them. Psychological well-being is a positive construct that refers to improvement of quality of life. This cross-sectional, comparative study formed part of the SABPA (Sympathetic Activity and Ambulatory Blood Pressure in Africa) project. A sample of 408 (200 Black and 208 White) male and female teachers (aged 25 and 62 years) participated. The ambiguity as regards psychological well-being among race and setting formed the basis of comparison between Black and White teachers. Data were gathered using the Mental Health Continuum-Short Form (MHC-SF), Patient Health Questionnaire (PHQ-9), General Health Questionnaire (GHQ-28), and Fortitude Questionnaire (FORQ), and analysed by applying descriptive statistics, reliability indices, inter-scale correlations, mean comparisons, and regression analysis. The prevalence of well-being differed between the two groups. Significantly higher scores for emotion-al well-being and social support from friends and others were reported by the White group of teachers. Differences in the influence of social support and psychological distress on positive mental health were found between the two groups. These findings indicate the differential association and influence of psychosocial factors on positive mental health in different teacher samples. In conclusion psychological well-being of Black or White teachers may differ as a result of their social support and potential distress in different school settings.

Applications of positive psychology to military counseling program in South Korea
Sang-Bok Lee
Kangnam University, Republic of Korea

This study measured how positive psychology based military counseling programs influenced and enhanced army officers’ counseling competence, psychological well-being, and satisfaction. It was hypothesised that a forty hour military counseling education program would contribute to enhancing army officers’ counseling competence, psychological well-being and satisfaction. A total of 425 army officers participated in the researcher’s educational sessions. Selected participants voluntarily joined the survey reports after the educational training sessions. The contents of education sessions were based on positive psychology, covering empathy, trust, resilience, optimism and hope, love, flow and mindfulness, and strength-based leadership. The positive psychology based military counseling program was proven to be a useful educational tool for army officers in South Korea to enhance counseling skills, the rate of counseling competence, and overall psychological well-being. It was the first project for the South Korean army officers to utilise the contents of positive psychology in South Korea.

Promoting subjective well-being through income: Exploring the moderating role of social dominance orientation
Mengying Li
Peking University, China; Luning Ren; Lei Wang
Peking University, China

Is higher income effective in eliciting greater subjective well-being (SWB)? Why are there differences in the degree of social dominance orientation: the degree of preference for inequality among social groups, is introduced, and we argue that greater income will be associated with stronger subjective well-being, and that this relationship will be moderated by the social dominance orientation. We tested this hypothesis with a sample of Chinese residents (N=566) by means of a set of questionnaires assessing the degree of people’s SWB, income and SDO. Results indicated that there was no significant relationship between income and subjective well-being (r=0.034). However, social dominance orientation moderated this relationship (AR=0.014, p<0.05): When social dominance orientation was high, people’s income and subjective well-being showed a negative relationship, whereas, when social dominance orientation was low, the relationship of these two variables was positive. The results suggest that income is not necessarily beneficial to people’s subjective well-being. Instead, the impact of income hinges upon people’s degree of social dominance orientation. Implications for the understanding of income and subjective well-being are discussed.

Psychology students in China: Measurement and value orientation of career choice
Li Li
Education Department, China

Positive psychological capital is a positive psychological state during the process of individual growth and development. It includes four aspects of self-efficacy, hope, resilience and optimism. Value orientation of career choice is a tendency attitude as people pursue, orient, evaluate, and select professional values as they seek employment. To explore the relationship between university students’ positive
psychological capital and value orientation of career choice in China, two related investigative questionnaires were applied to 276 college students of three universities in China. The data were counted and analysed by using SPSS16.0. The results are as follows: (1) At the self-efficacy aspect, there were some significant differences in the types of university, gender, and subject. Some significant differences of the hope aspect appeared in gender; and the same significant differences of the resilience aspect lay in family location. (2) In the value orientation of career choice aspect, there were some significant differences of both individual value orientation level and social value orientation level of career choice in universities, gender and subjects. (3) Positive psychological capital of university students in China was positively related to their value orientation of career choice. Positive psychological capital has significant predictive effect on the university students’ value orientation of career choice. So, university students should be encouraged to strengthen the level of their positive psychological and form reasonable value orientation of career choice in the course of seeking jobs.

Influence of psychological and political characteristics of individuals in a multicultural society
Ilmikhanova Lyazzat Kazakh National University, Kazakhstan; Jakupov Satybaldy; Perlenbetov Mukhan; Mussakievka Alfiya; Komekbayeva Lyazzat; Jakupov Satybaldy; Gazi Telzebayev; Satybaldy Ozhakupov
The essence of the experiment is to find a connection between the psychological, political, and other qualities of people who make political decisions, and their possible political behaviour. Using a variety of approaches in the study of politics has an important meaning. Firstly, the course of political events is analysed and predicted, based on the study of political culture. Political psychology performs an epistemological function associated with the provision of human thinking. Unlike other forms of political consciousness (eg, science or ideology), which also contribute to the knowledge of political realities, political feeling cannot only supplement the information received by people through rationalisation and logic, but can be replaced with their choice of political position. To build a culture of interethnic communication in a multicultural educational environment, respect for the people of various nationalities should be cultivated. This should be for all living in the region, their language, values, development of respect for the peoples inhabiting their native land, the formation of internationalism, focusing on national and universal moral values, the best achievements of human civilisation and consciousness of belonging to the international community, education, and tolerance. This would take into account characteristics of ethno-national, national merit, promotion of an uncompromising attitude to the manifestation of chauvinism, nationalism and racism.

Happiness and academic achievement
Akbar Mahdiloo Zanjan Teacher Training Center, Islamic Republic of Iran; Javaad Ghanbari Zanjan Teacher Training Center, Islamic Republic of Iran; Ali Ahmadi; Hassan Eslahifar; Aliasgar Naderlo
The relationship between happiness and academic achievement was examined in this study. The methodology used in this research is descriptive correlational method using the statistical society of students of Abhar Azad University that randomly selected 375 people as samples. Oxford Happiness Inventory was performed on them; criterion of achievement was scores of students in units. Using Independent T Statistical Tests, Pearson’s Correlation Coefficient showed that happiness and academic achievement in 99% cases are related, and the Multivariate Regression Analysis showed that happiness is a significant predictor for academic achievement (p<0.005). There is a relationship between happiness and academic achievement. Those who have high scores in happiness, also have high academic achievement.

Resilience among South African orphans: A visual exploration
Maculane Junel Malindi North-West University, South Africa
This paper reports the findings of a multiple method qualitative study that explored the resilience pathways of orphans affected by AIDS in South Africa. We used the Draw-and-tell approach in which we invited 150 orphans aged between 9 and 14 to make drawings that represented their lives at the time and to write narratives that explained their drawings. We also asked them to draw a person in the rain, a projective technique that indicates whether or not a child is psychosocially vulnerable. Using inductive content analysis, we analysed the drawings and narratives. Our findings showed that protective resources such as future focus, the determination to go ahead despite risks, connectedness to competent adults, having a sense of humour despite risks, perceiving schools as safe places, happiness and joy of life, and playing football enabled the participants to cope resiliently in the context of risks. From the positive psychology perspective, the findings show that resilience is possible in the context of HIV and orphanhood and the participants had personal and ecological strengths that enabled them to cope resiliently. Methodologically the findings showed that less intrusive, child-centred methods such as drawings can be useful in eliciting needed data in contexts where young people are discouraged to discuss intimate details of their lives with strangers.

Psychological capital as personal potential in organisational context
Elena Mandrikova Higher School of Economics, Russian Federation
Psychological capital (PsyCap) is a positive state-like capacity, which is defined as an individual’s positive psychological state of development that consists of efficacy, optimism, hope and resilience (Luthans, Avolio, et al., 2007). The same integral construct – personal potential – a new theoretical framework proposed to explain the mechanisms of psychological well-being and achievement (Leontiev et al., 2007), in organisational context personal potential, describes the personal resources of employees. The research was devoted to explore the relationship between PsyCap and personal potential of employees. We explore our hypothesis on a sample of Russian employees (N=250). For research purposes we use the set of questionnaires (mentioned at the order of appearance to participants). Data were collected from Russians through an on-line platform: PsyCap Questionnaire (Luthans, 2007, in adaptation of Mandrikova, Chaika); Self-determination Scale (Sheldon, Deci, 1996, in adaptation of Osin); Trait Hope Scale (Snyder et al., 1991, in adaptation of Osin); Self-efficacy Scale (Jersulem, Schwarzer, 1981, in adaptation of Goredeva); Hardiness Questionnaire (Maddi, Koshaba, 2001, in adaptation of Leontiev, Rasskazova); Ambiguity Tolerance (MSTAFI) (McLain, 1993, in adaptation of Lukovitskaya); Dispositional Optimism Test (LOT) (Carver, Scheier, 1985, in adaptation of Goredeva, Sychev, Orlova); Socio-demographic and formal data about position at organisation level and type of work. We have revealed significant (p<0.05) correlations between all components of psychological capital and personal potential of employees, so, even driven from different theoretical backgrounds, empirical data show similarities of psychological capital and personal potential constructs.

Predicting global well-being through personality and coping
Rosario J. Marrero University of La Laguna, Spain; Monica Carballiella; Hector Morales
Several studies have been conducted to identify personality traits and coping resources involved in well-being. However, few studies have analysed, jointly, subjective well-being (SWB) and psychological well-being (PWB). In this research, the main purpose was to analyse the personality profile of individuals with high psychological and subjective well-being. A sample of 1201 adults, aged 17-78, was assessed on personality dimensions, self-esteem, optimism, social support, coping, subjective well-being (life satisfaction, positive affect and negative affect) and psychological well-being (self-acceptance, autonomy, purpose in life, positive relationships with others, environmental mastery, and personal growth). ANOVA were performed comparing individuals with low well-being versus individuals with high well-being. The results showed that individuals with high psychological and subjective well-being had lower Neuroticism and higher Extraversion, Openness to Experience, Conscientiousness, Agreeableness, optimism, self-esteem, and social support than individuals with low well-being. Also, individuals with high well-being used coping strategies such as Seeking Social Support, Humour, Planning and Active Coping, Personal Growth and Positive Reinterpretation. Regression analyses indicated that low Neuroticism, high Openness to experience, high personal growth and high optimism explained a quarter of variance in high psychological and subjective well-being groups. In conclusion, personal characteristics explained only 24-29% of the well-being variance.

Subjective well-being and optimism in Mexican undergraduate students
Rosario J. Marrero University of La Laguna, Spain; Jose Angel Gonzalez-Villalobos; Monica Carballiella
Subjective well-being (SWB) has been defined as a broad construct comprising two different main components: One affective, which includes both positive and negative emotions and another cognitive, referred to the individuals’ evaluation of their life satisfaction. The main objective of this study was to analyse the relationship between optimism and SWB. Additionally, four indicators about satisfac-
tion in specific life domains were used: Job satisfaction, sentimental satisfaction, health satisfaction and satisfaction with leisure activities. Data are from a sample of 299 Mexican undergraduate students aged 17-49 (M= 19.38; SD= 3.19). The results showed moderate associations between gender and satisfaction with job, life satisfaction, happiness and optimism. Also, people who are maintaining a sentimental relationship showed higher satisfaction in these areas. Optimism was associated to all the previous measures of SWB, although the relationships with global measures were greater than the relationships with the specific life domains. One-way analyses comparing three groups: Low-level optimism, which were below the 25 percentile, medium-level optimism, which were around the average, and high-level optimism, which were above the 75 percentile. Results showed that high and medium-level optimism groups reported more life satisfaction and positive emotions, less negative emotions, and more satisfaction in all specific life domains than the low-level optimism group. There were no differences in SWB measures between high and medium-level optimism groups. The results suggest that optimism is a relevant personality trait to improve global well-being of the individuals.

Influence of coping on happiness, life satisfaction and self-esteem according to age
Rosario I. Morrera
University of La Laguna, Spain
Monica Carballeira
Coping styles, as important resources to manage negative life events, can also contribute to improve personal well-being. The main objective of this study was to examine the influence of coping strategies on self-esteem, happiness, and life satisfaction in a sample of 1184 individuals from the general population (535 men, and 649 women) aged 18-78 (M= 36.18; SD= 13.64). In order to explore these influences according to age, different multiple regression analyses were carried out in four groups: The youngest (between 18 and 24 years old; N= 381), young-adults (between 25 and 39 years old; N= 273), middle age adults (between 40 and 55 years old; N= 427), and old adults (between 56 and 78; N= 103). Results showed that in all groups of age, coping was a better predictor for self-esteem, than for life satisfaction and happiness, although the most powerful coping strategies varied according to the variable considered. Disengagement predicted negatively self-esteem, happiness, and life satisfaction in the youngest and in the middle old adults groups, and Distraction Activities in young-adults group. Restraining Coping was a powerful negative predictor for the three variables in old adults group, followed by Planning and Active Coping for happiness and life satisfaction, and Humor (positively in both cases) for happiness and self-esteem. These findings underline the importance of considering the age in the interventions promoting adaptive coping strategies to improve self-esteem, happiness, and life satisfaction.

Exploring motivations of disadvantaged tertiary peer educators through self-determination theory
Julie McFarlane
Stellenbosch University, South Africa; Tony Naidoo
This study explored the motivations of individual students participating in the Peer Educator Programme at TSiBA, an a typical private tertiary institute in South Africa, which offers a four-year university degree to students who would not otherwise have had access to higher education. The study located within a positive psychology approach utilised Self-Determination Theory which advances that experiencing need satisfaction in autonomy, competence and relatedness has psychological benefit for the individual and the community to which they belong. Peer education by its nature and intention has an impact on the communities which it reaches. From a practical standpoint, association of the SDT with Peer Educator Programmes would reveal two-tailed effectiveness - optimising mental health in the community through the educators and through the programme message. On a micro level, research providing understanding of the motivations of peer educators may be of benefit to recruiters of peer educators; can impact on the policy makers and conveners of such programmes and implicate the effectiveness of peer education programmes themselves. Initial pilot study findings indicate association between the assumptions of Self-Determination theory and the motivations as expressed by the peer educators. The results of the study will add to the sparse knowledge in the fields of volunteerism - specifically peer education; SDT praxis and factors affecting mental health in developing countries.

The effect of Fordyce happiness training on blood pressure and happiness of patients
Mahnaz Mehrbaziadeh Honarmand; Shahid Chamran University, Islamic Republic of Iran; Shahin Abdolah; Mansour Sodani
The purpose of this study was to investigate the effectiveness of Fordyce happiness training on blood pressure and happiness of Abadan Oil Company Hospital patients. The sample consisted of 40 patients that were selected by simple random sampling. The patients divided into two equal groups (experimental and control groups). Participants completed the Oxford Happiness Inventory and their blood pressure was measured at pre-test and post-test phases. After 8 sessions of Fordyce happiness training, results of MANCOVA were statistically significant at p<0.01. Therefore it is suggested that Fordyce happiness training decreased systolic blood pressure and increased happiness of the experimental group compared with the control group. In addition, the effect of Fordyce happiness training lasted for one month.

Psychometric properties of the Argentinian Flow State Scale in pro-social activity for children and adolescents
Belen Mesurado; CIIPME - CONICET, Argentina; Maria Richaud
The optimal experience or flow, is a concept developed by Csikszentmihalyi (1997, 2000), who defines it as the mental state of operation in which the person is fully immersed in what he or she is doing, characterised by a feeling of energised focus, full involvement, and success in the process of the activity. Jackson and Marsh (1996) developed The Flow State Scale (FSS) to assess the flow experience in sports, although it can be adapted to other contexts such as work, education, etc (Garcia Calvo et. al., 2008). The purposes of this research were: to adapt The Flow State Scale to examine the optimal experience in pro-social activity in children and adolescents and to study its psychometric properties. The sample included 500 participants, of both sexes, aged 10 to 15 (M = 10.95; DT= .84), of middle socioeconomic level, from Argentina. Exploratory and confirmatory factor analyses were run to test construct validity. The convergent validity was measured using with The Optimal Experience Scale for Children and Adolescents (Mesurado, 2008). The results revealed satisfactory validity and internal consistency of the instrument, obtaining a factor model made up of a main factor and nine sub-scales as proposed by the original authors.

Exploring the adaptive behaviour of an older woman after significant relational losses
Lazya Muller
North-West University, South Africa
Relational losses like the loss of loved ones and relocation of family and friends are common when people age. In an intergenerational research project, which aimed to explore the value of social media in promoting intergenerational relationships, older persons shared their life stories with younger people. In one older woman’s life story it was noted that she applied adaptive coping behaviour after significant relational losses. This study is conceptualised from a positive psychology perspective that focuses on the abilities and assets of people. A Case Study design was used to gather data about a 85 year old, Afrikaans-speaking woman who currently lives independently in an apartment on her son’s property. Data were obtained through the Mmogo methodology (Roos, 2008; 2012), (a visual presentation using clay, beads and straws), a reflection journal and person-focused interviews. The textual and visual data gathered were thematically analysed. This woman actively sought opportunities for interaction with friends, family and people with mutual interests. She also created opportunities to interact with people on a broader social level by making herself available for extra tuition to assist pupils with academic learning content. She also joined a service centre for the aged where they aim to help elderly people participate as active community members. The findings indicated that adaptive behaviour encouraged a sense of cohesion and engagement with other people that contributed to her coping. It is recommended to explore more adaptive behaviour after significant relational losses.

Resilience in families living with a child diagnosed with hyperactivity/attention deficit disorder
Tania Muthen
Livingstone Hospital, South Africa; Greg Howcroft; Ottilia Brown
Livingstone Hospital, South Africa
There has been limited South African research to date on family resilience as well as on the resilience of families living with children diagnosed with AD/HD. We aimed to explore and describe the factors that facilitate adjustment and adaptation in families after a child has been clinically diagnosed with AD/HD. The Resilience Model of Family Stress, Adjustment and Adaptation served as a framework to conceptualize the families’ adjustment and adaptation processes. The study was triangular in nature,
The positive experiences of master’s students in professional psychology programmes in South Africa
Lindi Nel University of the Free State, South Africa
The aim of this poster is to describe the psycho-fortigenic experiences of master’s degree students in professional psychology programmes in South Africa. Since most research on the topic of master’s students in psychology is conducted from a pathogenic paradigm, this study aimed to describe these students’ experiences from a positive psychology approach. A strength-based paradigm allows both the researcher and the participants to understand their journey through the lens of personal growth, professional development, coping strategies and attempts to make sense of the related difficulties. Eight participants were purposively selected from four universities. The participants engaged in reflective writings and three semi-structured interviews over a one-year span. Four rich cases were identified and data were analysed according to Interpretative Phenomenological Analysis (IPA). Themes were conceptualized and operationalized within the structure of psychological well-being (Ryff, 1989), general positive psychology literature, as well as literature based on the development and dynamics of master’s students in professional psychology training. thorough interpretation of the findings yielded eight themes of significance across cases, which all were indicative of enhanced levels of psychological well-being as an outcome of the participants’ experiences. Overall, the important finding was that, while the experience of becoming a psychologist is known to be a long and difficult journey, it can also be rewarding and holds the potential to enhance psychological well-being.

Wellness needs of students at a South African university of technology
Hester Oberholzer Central University of Technology, South Africa; Liesl Hoare
The primary aim was to evaluate the wellness needs of students at a South African University of Technology. The secondary aim was to evaluate the effectiveness of current wellness interventions so as to improve these interventions and hereby improve the holistic wellness of students. Data was obtained with an anonymous self-report questionnaire which recorded biographical information and assessed the effectiveness of wellness campaigns and the wellness needs of students. The questionnaire was available to all participants at a Wellness campaign with the total of n=158 questionnaires obtained and statistically analysed. Students have a big need to address physical health needs. N=82 (52%) view HIV/AIDS testing as important. Testing for cancer, blood sugar and cholesterol levels was also viewed as important. These tests are currently conducted at all wellness interventions. Pertaining to psychological wellness, n=98 (62%) and n=86 (54%) stated that the wellness campaigns influenced their psychological wellness positively in the short-term and long-term respectively. N=102 (64%) stated that the wellness campaigns influenced them to change their lifestyle in a positive way. Needs that students do not perceive as being met and can be used to improve future wellness interventions include financial management, relationship issues, grieving stress and depression, abortion and youth pregnancy, and domestic violence. It is evident that, although interventions do meet students’ needs, there are still needs that can be met to improve the wellness interventions and subsequently the overall wellness of students.

The coping orientation and self-esteem of Black learners enrolled in state under-reourced schools in the Nelson Mandela Metropole
Zimbini Ogie Nelson Mandela Metropolitan University, South Africa
It is common knowledge that delivery of high quality, well-resourced educational service to learners enrolled in state schools in the Eastern Cape has ground to a halt, and this lack of service delivery has now become a pervasive problem. South African education has, to a large extent, failed to meet the needs of Black learners. Schools, like other contexts of childhood and adolescence, are intimate places where youths construct identities, build a sense of self, and develop the capacity to sustain relations and forge the skills to initiate change. These are the contexts where youth grow or shrink. Buildings in disrepair are not, therefore, merely a distraction, they are identity-producing and self-defining. Previous studies have highlighted that self-esteem and resilience play a role in academic achievement. This study explored and described the coping orientation and self-esteem of Black learners enrolled in under-reourced state schools in the Nelson Mandela Metropole. An exploratory, descriptive survey design was employed and 85 research participants completed the Orientation to Life Questionnaire 29 Item, Battle’s Culture Free Self-Esteem Inventory Form AD and a biographical awareness questionnaire. Findings revealed fairly high mean scores on the OLEQ 29 Item and low total self-esteem scores. Findings revealed average General, Social and Personal self-esteem. The results also revealed that learners with a high sense of coherence are likely to have high self-esteem, hence high sense of coherence is better explained by high self-esteem and low sense of coherence is better explained by low self-esteem.

Psychological experiences in South African society before the 2010 FIFA World Cup
Rudolf Oosthuizen University of South Africa, South Africa; Pieter Koortzen
A literature review was conducted to analyse the assumptions of systems psycho-dynamics, the Tavistock model of group relations, object relations theory and the most relevant constructs in the systems psycho-dynamic perspective. Secondly, the assumptions and most relevant constructs in the positive psychology perspective were described in order to theoretically analyse the psychological impact of large-scale sports events on a community or country. The objective of the empirical study was to investigate some of the unconscious emotions, fears, anxieties and conflicts i.e. dynamics prevalent in South Africa before the 2010 FIFA World Cup as well as some of the positive emotional experiences associated with the 2010 FIFA World Cup. The specific objective of the study was to analyse and describe the psychological experiences of South African society before the 2010 FIFA World Cup. The research design, approach and method were done from both the systems psycho-dynamic and positive psychology perspectives. The study comprised a qualitative, explorative and social phenomenological study. The researchers’ access to employees in different organisations and the existence of professional working relationships with the participants, led to a convenience sample. A total of 24 participants were interviewed. The results seem to indicate that a number of positive and negative experiences existed in South African society before the 2010 FIFA World Cup. The findings are presented as a number of systems psycho-dynamic and positive psychology themes and working hypotheses. This study represents original research that contributes valuable new knowledge to the positive psychology and systems psycho-dynamic perspective.

Subjective well-being and health perception in Portuguese people from the community
Jose Pais-Balseiro Porto University, Portugal
Subjective well-being (SWB) refers to people’s evaluations of their lives, like judgments of life satisfaction, and evaluations of moods and emotions. There are evidence that SWB causally affects health and longevity (Diener & Chan, 2011). The objective of the present study is to analyse how different measures of subjective well-being explains health perception. Participants are 517 individuals from the community, mean age 35.18 years, 54.2 females. Material used are, Andrews and Withey Life as a Whole, Diener Satisfaction With Life Scale, Cummins Personal Wellbeing Scale, Lyubomirsky Subjective Happiness Scale, and the short-form with 12 items from the Medical Outcomes Study to access health perception, grouped in two components, namely, physical health and mental health. Results show correlations between the indicators of SWB of .63, .88 and .78. Correlations between SWB, the four indicators, and mental and physical health are mainly around 40s. Regression analysis, physical health as dependent variable, and the four subjective measures as independent (Durbin-Watson

Positive experiences of visiting museums
Eloisa Perez-Santos Complutense University Madrid, Spain
In recent years, museums have become attractive places to share experiences that allow us to learn
and enjoy at the same time. The study of the conditions that facilitate learning and satisfaction is crucial to provide data to assist the design and management of museum services. This study focuses on the subjective experience of the visitor. The intensity of this experience is translated into cognitive, sensory and emotional outcome variables in relationship with the personal and social context. This is the first work of a research agenda carried out by a University Consortium of Madrid research team, in collaboration with the Permanent Laboratory for Public Museums of the Spanish Ministry of Culture. We have designed a subjective scale that includes different factors of the elements that can contribute to a quality museum experience. The Positive Museum Experience Scale (PMES) was administered to 7680 individual visitors to 12 major Spanish state museums. The results show how the visitor’s experience in state museums is very positive and a similar pattern was observed in most of them. Visitors seem to feel high and similar levels of relaxation, purpose, attention, orientation and somewhat lower, but similar, levels of security in their abilities and sense of learning in all of the museums surveyed. While the joy, fascination, immersion and involvement are low in almost all of them, the study also found that some variables investigated were able to discriminate among visitors with better and worse museum experience.

Self-regulation and psycho-physiological well-being in an African context: The SABPA study
Johan Potgieter North-West University South Africa; Nelmarie Boshoff; Leonie Malan
The aim of this study was to explore the association between self-regulation (SR) and psycho-physiological health and well-being in an African context. Recent research, predominantly performed in individualistic Western contexts, links SR to psychological well-being and physical health. Cultural and contextual factors are however known to directly impact well-being, and the South African context is particularly void of various challenges to individuals’ ability to maintain healthy functioning. Associations found between self-regulation and psycho-physiological health and well-being in Eurocentric contexts may therefore not be valid in the African context. Data was collected through a cross-sectional design with a purposively selected study population. Participants were urbanised black African teachers (N=200) who underwent a thorough evaluation of their psycho-physiological health and well-being. Participants completed the 31-item Short Self-Regulation Questionnaire (SSRQ), and a number of measures of psychological well-being. Physical health indicators included hypertension, waist circumference, glucose, triglycerides and high-density lipoprotein. Results showed a strong relationship between the self-regulation and participants’ self-reported levels of psychological well-being. The association between SR and physical well-being, as represented by the relative absence of metabolic syndrome indicators, was however not as clear, and requires further evaluation. In spite of SR being considered an individualistic construct, these early results lend support to its potential use in facilitating mental health in the African collectivist context.

The prevalence of various degrees of psychological well-being among Tanzanian university students
Janvier Rugira Mount Meru University, United Republic of Tanzania; Marie Wissing; Aldia Nienaber
The aim of this study was to explore the prevalence of levels of psychological well-being in a group of Tanzanian university students. A quantitative cross-sectional survey design was implemented for data-gathering. A convenience sample of 277 undergraduate students (19 to 40 years) from three universities completed the Mental Health Continuum – Short Form (MHC-SF) as a measure of levels of well-being. Findings indicated very high levels of flourishing - much higher than found in previous studies. Various possible explanations are suggested. Significant differences were also found among the university in percentages of the various levels of well-being, and possible explanations forwarded. Maintenance of well-being in students who are flourishing, and enhancement of mental health in those who are moderately mentally healthy or languishing are indicated via the implementation of promotive and preventative well-being programmes.

Happiness at work among South African educators
Lutterbie Simon Opener Institute, United Kingdom; Jessica Pryce-Jones; Katie Demain
This study compared the Happiness at Work of educators in South Africa with the Happiness of Work of employees around the world. 164 educators completed the iOpen People and Performance Questionnaire (iPQ). In general, the participants reported above-average Happiness at Work. However, the situation became more varied when specific aspects of Happiness at Work were examined. Happiness at Work is a mindset which enables action to maximize performance and achieve potential. It is characterized by feelings of making a contribution to one’s work, having the short-term conviction to perform, enjoying a fair and supportive workplace culture, having long-term commitment to one’s work and feeling confident in one’s abilities. Happiness at Work has been shown to predict both individual and organizational success; therefore, understanding employee’s Happiness at Work benefits both employees and employers by creating more enjoyable and higher-performing workplaces. South African educators scored above average on each main component of Happiness at Work. However, they scored below average on “feeling able to achieve work goals” and “feeling able to overcome challenges”, among others. The results suggest an overall positive situation with several areas where focused effort could yield notable improvement. A more in-depth analysis will be presented, and the results considered in the wider context of South African working life. Specific recommendations will be made for improving the Happiness at Work of South African educators, and the potential implications of such efforts are considered.

The psychofortology of female psychiatric out-patients: Living with mood and anxiety disorders
Chantelle Steyn Nelson Mandela Metropolitan University, South Africa; Greg Howcroft; Paul Fouche
Depression and anxiety are estimated to be two of the most important causes of disease burden in the world, and they appear to be more prevalent among women than men. The present study aims to explore and describe the psychofortology of female psychiatric out-patients living with mood and anxiety disorders. An exploratory descriptive research design was used. The participants were selected by means of non-probability purposive sampling. The sample consisted of 60 female psychiatric out-patients who were selected from the Nelson Mandela Metropole in the Eastern Cape. The sample was based on predetermined inclusion criteria. Data were gathered through the administration of a biographical questionnaire, Hammer and Marting’s Coping-Resources Inventory, Antonovsky’s Sense of Coherence Scale, Dieren, Emmons, Larson and Griffin’s Satisfaction-with-Life Scale, and Flett and Flott’s Affecometer-2. These data were then analyzed according to the aims of the study by the use of descriptive statistics, inferential statistics and multivariate data analysis. The results of the study indicated that the female psychiatric out-patients with mood and anxiety disorders generally experienced lower levels of coping and subjective well-being when compared with normative data. The results also identified three clusters, which revealed that the psychiatric out-patients with mood disorders, although they experienced low levels of coping and subjective well-being, obtained higher scores than the patients with anxiety disorders. The findings of the research also address the management and care of these patients.

An experimental study of the positive emotion on the effect of English vocabulary memory among Chinese college students
Xiaojiie Sun Dongbei University of Finance & Economics; Jinping Yang; Zhujun Lin
Existing research often assumes that positive emotion leads to better cognitive function, although few studies directly test the link. Extending from prior emotion and memory findings, using negative and neutral emotion as references, an experimental study was conducted to explicitly test whether positive emotion is linked with the enhanced memory of English vocabulary. Sixty-three Chinese college students were randomly assigned into three groups with equivalent English levels. Two videos were used to induce different emotions including positivity, negativity and neutrality. Two sets of English vocabulary tests of equivalent difficulty were applied to each group in the form of pre- and post-tests to explore the effects of positive emotions on memory. T-test was performed and the result showed that the positive emotion group memorised significantly more new English words in the after-test than in the pre-test: negative Scale neutral emotion groups showed no change in their memory scores between pre-test and post-test. This result proves that positive emotion improves English vocabulary memorisation among college students. It suggests that college English teachers should introduce positive emotions into English classes.
Emotion and responses in daily counselling: Recipients with high/low social skills
Miekko Takahira Chubu University, Japan
This study focused on what kinds of emotions and responses occur when Japanese college students were asked for advice by their friends about difficult problems. Takahira (2011) suggested that students experienced one positive emotion and four negative emotions: pleasure, anxiety, sadness, irritation, and helplessness. Students’ responses were classified into four categories: (a) active listening, (b) problem solving, (c) cheering, and (d) affirmation. There was particular relevance between these emotions and responses. In this study, survey data from 180 Japanese college students were analysed to examine whether the effects of these emotions on responses differed for students with high and low social skills. The results of structural equation modelling analysis suggested that pleasure increased (a) active listening, (b) problem solving, and (d) affirmation. Anxiety increased (a) active listening and (c) cheering. Sadness increased (c) cheering, and (d) affirmation. Irritation decreased (a) active listening and (b) problem solving. Helplessness decreased (b) problem solving, and (d) affirmation. These results were the same patterns for both students with high and low social skills. However, helplessness increased (a) active listening only for students with low social skills.

The analysis of the concept of life satisfaction on university students
Fatma Dilek Tel Anadolu University, Turkey; Tugba Sari
The purpose of this study was to investigate life satisfaction levels and the relationship between gender and romantic relationships among university students. The study is a descriptive work composed of 1082 participants from 1st, 2nd, 3rd and 4th grades. The data was collected from Abant Azizet Baysal University, Educational Faculty, Science and Art Faculty, Medicine Faculty, Engineering and Architecture Faculty, Health Occupational High School, Physical Educational High School, Kemal Demir Physical Therapy and Rehabilitation High School. Sub-problems are analysed by using descriptive statistics and the independent simple t-test. According to the research, the life satisfaction level was X = 4.16. Females had significantly higher scores than males on the life satisfaction scale and the students who have romantic relationships had significantly higher scores than the students who have no romantic relationships.

Peace in yourself. Peace in your relationships. Peace in the world
Jeremy Thompson Balgowlah Medical Practice, Australia
Have you ever wondered why some people are more contented than others? As a family practitioner I have observed the different ways people approach life and studied the reasons behind their contrasting behaviours. Many of my patients deal with their issues constructively and can relate to people positively. When a problem arises they know who they are and what they want to do about it. On the other hand, there are many who don’t feel clear about themselves. Life is a struggle and they often succumb to anxiety, depression and substance abuse. What is it that makes the difference? A strong sense of ‘self’. Yet many people don’t know themselves – their heads are filled with self-deprecating thoughts that adversely affect their progress. They are judged accordingly. In this presentation I will reveal a new approach that I call ‘Positive Centred Psychology’ from my book to be published by Pan MacMillan in 2012. This provides a model for people to separate their negative thoughts from the true heart of their personality and identify with their inner talents and desires, the basis of who they are. It is imperative that people see themselves as being fundamentally good; that their negative behaviours are externally acquired and are not part of their core. Only by connecting with their positive characteristics can they deal effectively with life’s difficulties and keep their communications channelled positively towards others. These principles can be extended into the community and form a blueprint for resolving conflicts and enhancing social cohesion.

Coping styles of college students from low-income families in China: Evidence of resilience
Yuehua Tong University of Jinan, China
College students from low-income families as a disadvantaged group have drawn greater attention in China in recent years. Some researchers focused on investigating psychological well-being, social support, and coping styles in college students from low-income families. The present research aimed at examining the coping styles of college students from low-income families. 69 college students from low-income families completed the Chinese Coping Style Questionnaire. The results revealed that most college students from low-income families adopted positive coping styles, namely, problem-solving and help-seeking. They also used other coping styles such as fantasy, avoidance, and rationalization, with self-blame as the last choice. These results add to our understanding of resilience. Resilience involves the ability to adapt in the face of adversity or significant challenges, to achieve adaptive outcomes. In the situation of the widening socioeconomic gap in China, possessing such strengths is extremely important for this group of the population. It helps them to face the financial hardship and to deal with the challenge effectively. Implications for providing a social support system and counseling services are discussed.

Stress, wellbeing, lifestyle and coping among of sectoral professional students
Nistha Tripathi Indian Institute of Forest Management, India; Bal Krishna Upadhyay
Stress as a matter of research has been extensively studied by scientists since the research of Hans Selye. Students are also facing various stresses, and with the change of values and modern rearing practices shaped by new media, the nature of stressors has changed. This study tries to identify and evaluate the lifestyle causes of stress and examine the impact of the same on well-being. Furthermore, the study also deals with examining the coping mechanisms that are used by the students. For the study, students of a professional management course were selected (N=100) from a reputable sectoral management institute located in Central India. The analysis was done by applying statistical techniques correlation and regression analysis with the help of SPSS. The investigation revealed that a majority of respondents had a passive way of coping with stress. The increasing trend towards passive coping patterns is also a significant factor. This pattern was studied in terms of its relation with educational background and lifestyle patterns. The results are as follows: Positive Coping is positively correlated with Academic Oriented, Socially Oriented and Trend-Seeking lifestyles, and is negatively correlated with Family-Oriented lifestyle. Active problem solving is more distinct among Career-Oriented and Family-Oriented, and is found in very low levels among Trend-Seekers. Passive Problem Coping was found to be negatively associated with the Family-Oriented lifestyle.

Flow experience in online video gaming: Empirical study
Alexander Voiskounsky Psychology Department, Moscow State University, Russian Federation; Olga Mitina; Shi Wang
Positive experience, including flow, is essential for development of individuality and happiness. In numerous studies intrinsic motivation characterizes videogaming. Flow experience accompanies online gaming and this partly explains its popularity. Flow experience was studied within a sample of online gamers in mainland China. The questionnaire was originally worked out in Russia, then adapted to be used in France and the USA. We adapted it to a sample of Chinese videogamers. It included 4 items on demography and gaming experience and 24 items to measure Flow. It was administered both online and paper and pencil (N=1574). 64.7% respondents were males, 55.7% between 17 and 25, 60% played videogames over 3 years, 25.2% reported that they play over 10 hours per week. The results show that the level of flow is rather low (2.90±0.03, while the expected mean value is 3.0), also that males experience flow more frequently than females (p<0.000) and that adolescents experience flow more often than adults (p<0.000). Interest in attaining intrinsic motivation is a rare reason for Chinese gamers to play online. The results can be explained by referring to social ideals of collectivism, which are common in the traditional Chinese culture. According to these ideals and contrary to the Western culture, individuality is not encouraged. Shortage of positive experience can be shown to impact the development of Internet addiction among online gamers in mainland China.

Quality of life in old age: Results from SF-6D
Sofia Von Humboldt ISPA, Portugal; Isabel Leal
This quantitative research aims at examining the relationships between older adults’ quality of life (QoL) and adjustment to aging (AAt). For the purposes of this study, the Health Survey Questionnaire (SF-6D), one measure of cognitive functioning, the Mini-Mental State Examination (MMSE) and demographics, were included. Measures were completed using a variety of culturally appropriate methods, including self-administration and interviews. All variables had fewer than 1% missing values and there complete data were available for
Assessing time perspective and age representation in Portuguese and Angolan older adults

Sofia Von Humboldt (SPA), Portugal; Isabel Leal

A focus in a balanced time perception is linked to higher levels of life satisfaction in senior years. The aim of this study was to analyse the determinants of age representation (AR), and to explore the differences of latent constructs that can work as major determinants in AR, in Portuguese and Angolan older populations. Measures were completed, including demographics and interviews. Complete data were available for 32 Portuguese and Angolan older adults aged between 74-90 years (M=80.4; SD = 5.3). Data were subjected to content analysis. Representation of the associations and latent constructs were analysed by a Multiple Correspondence Analysis (MCA). The most prevalent response of the interviewed participants for AR was ‘present challenge’ (14.9%). Findings showed a model for each nationality. AR for Portuguese participants was explained by a two-factor model: ‘present fatalistic’ and ‘future-oriented’. A two-dimension model formed by ‘present hedonistic’ and ‘past positive’ was indicated as a best-fit solution for elderly Angolans. AR is strongly explained by increased likelihood of specific constructs in its definition, although within distinct time perspectives. This cross-cultural study demonstrates links among time perspective and age representation in older age, warranting further study across cultures among older populations. Recommendations for future research on older adults’ time perspective and clinical practice are also discussed.

An exploration of the perception of young adults of their own creativity

Anna Petronella Zaaiman (NWU), South Africa

The purpose of this study is to explore the perception of a group of young adults about their own creativity, while participating in a research project that requires the application of creativity. Different definitions exist of the comprehensive concept, “creativity”. The theoretical background of this study is the positive psychological view of creativity as a virtue or strength and it is regarded as the ability to improvise and find highly original and inventive solutions to problems. In this study 18 people of both genders, aged 21 to 30, participated in the Mnogo-method TM, a visual projective research data-gathering method (Roos 2008; 2012). This method uses clay, straws and beads and requires the participants to make visual images after being prompted by an open-ended statement, such as: “Use the material to project your experience of your relationship with older people.” They apply creativity to perform this task. After performing the task, participants reflected on their experience of this method. Visual and textual data were obtained and thematically analysed. Various participants’ perception of their creativity originated in primary school art classes, where children who excelled in artwork were considered creative and therefore creativity was associated with aspects of artistic talent. Some participants were apologetic about their creative ability which excluded the possibility of applying it in an innovative manner to solve problems. It is recommended that further studies are conducted to explore how people apply their creativity in everyday life activities which require creativity, and to promote their awareness of creativity as a strength.

The working model of psychological monitors from the perspective of positive psychology

Qisheng Zhan (ITU, China)

Psychological Monitors are a special social group that originated from mental health education in Chinese colleges. The working model of Psychological Monitors is relevant to peer counselling in the USA and European Countries. However, Psychological Monitors have their own characteristics which are related to managerial institutions of Chinese colleges. This article integrates better foreign experience about peer guidance and constructs a new working model of Psychological Monitors from the perspective of positive psychology. This model includes: how to popularise positive mental health theories, how to bring positive mental health counselling into effect and how to build up positive mental states and relevant behavioural patterns.

The psychometric properties of a leadership empowerment questionnaire

Desiree Zikola (NWU, South Africa)

The world of work has now become a place where we need to compete globally and therefore skills, talent and knowledge are crucial in order to survive. This greatly indicates the importance of people management across the globe. Human capital is an organisation’s most valuable asset and requires considered development and proper management. Effective leadership plays a key role in the success of organisations. This gives us an indication that good leaders who empower their employees are required to play a crucial role in the retention of human capital within organisations. A need exists for empirical study of leadership empowerment, more specifically regarding a measurement tool that can be used to assess the level of leadership empowerment of employees in South African organisations. The objective of this study was to assess the construct validity and internal consistency of the Leadership Empowerment Behaviour Questionnaire (LEBQ) for employees in selected organisations in South Africa. A cross-sectional design with a convenient sample (n=933) was used. The LEBQ was administered. An exploratory factor analysis confirmed a three-factor model for the LEBQ. More research needs to be done on this topic and this study serves as a good starting point for further research.

Session Type: Invited Symposia

Symposium title: PANEL: Positive psychology: Past, present, future

Convenor: Antonella Delle Fave

Panel abstract

James Pawelski University of Pennsylvania, United States of America

Composed of leaders in the field of positive psychology, this panel will focus on timely topics in this burgeoning area of psychology. The session will serve as an overall orientation to this area of research and practice, and will provide information on some of the very latest developments in basic research and on its application to a variety of domains including education, psychotherapy, and public policy. Information will be presented about a number of positive psychology associations, including the International Positive Psychology Association (IPPA) and the nascent African Positive Psychology Association (APPA). This is intended to be an interactive session with plenty of time for questions and comments from the audience.

Session Type: Symposia

Symposium title: Family resilience studies within the South African context

Convenor: Abraham Greff

A theoretical orientation for studies in family resilience

Abraham Greff (University of Stellenbosch, South Africa); Guzelle Koegelenberg; Roxanne Masters; Melanie Deist

Research in the salutogenic paradigm (health orientated) focuses on strengths and positive characteristics that contribute to the growth and development of the system (individual, family, group or community). This positive seeking orientation requires the researcher to find answers to the following question: What characteristics are present in families that overcome trauma and enable members to continue to live satisfactory lives? The theoretical foundations of empirical studies are firmly grounded in the formulations of McCubbin and McCubbin (1996) and Walsh (2003). The main assumption of McCubbin and McCubbin’s model is that change and adversity will challenge all families as a normal part of the life cycle. The model consists of two related phases. Firstly, the adjustment phase describes the family’s pre-crisis functioning and the influence of protective or resistance factors and secondly, upon the advent of a family crisis, the family enters into the adaptation phase that involves the functioning of recovery factors, referring to the family’s ability to adapt in a family crisis situation. Walsh (2003) has a slightly different approach to family resilience and explains it in terms of nine key family processes within three broad domains of functioning: Family belief systems, organisational patterns and communication patterns. Both theories will be discussed to give a better understanding of
the findings obtained by the empirical studies that form part of the symposium about Family resilience studies within the South African context.

Symposium title: India Association of Positive Psychology: Global initiatives and concerns

Convenor: N.K. Chadha

Positive psychology and aging
Harpreet Bhatia University of Delhi, India

Positive psychology is the study of the processes and conditions which contribute to the optimal functioning of individuals. The aim of this paper is to indicate how recent trends in the emerging science of positive psychology can be applied to the development of a positive and graceful aging. It is important for professionals working with older persons to understand the potential of positive psychology as an increasing proportion of the clients of psychologists in the future will be older adults. Gerontology, the study of aging, is an ideal field in which to explore the possibilities of positive psychology because relatively little work has been done to identify how recent trends in the emerging science of positive psychology can be applied to the development of a positive psychology of aging. Evidence is emerging about the unrealised potentials of older adults in all domains. Historically, the deterioration of old age has been over-emphasised. This is possibly so because it is easier to recognise attributes in which older people perform poorly than those in which they may excel. Empirical evidence is emerging which demonstrates the hitherto under-recognised skills, potentials, and contributions of older adults. The paper will highlight how emerging science of positive psychology can contribute a great deal towards enabling the potential of older adults to be realised and cherished.

Need for positive psychology today
Harpreet Bhatia University of Delhi, India

In the past, Psychology has focused primarily on the negative aspects associated with disabilities, illnesses, and mental health. The future of psychology needs to readdress the problems faced in the past and outline bene

Spiritual intervention in old age: A move towards positive psychology
N.K. Chadha University of Delhi, India

Recent developments in the field of positive psychology have broadened the scope of the effect of variables like spirituality/transcendence on the psychological well-being of people. Drawing from the 6 virtues of positive psychology proposed by Peterson and Seligman (2004), the present symposium gains its aims and the rationale of this study, which was conducted on the elderly population residing in India. The objective of the study was to see the effect of spiritual intervention on the cognitive functioning of the elderly. For this purpose 30 participants (60 years and above) who voluntarily agreed to be a part of the intervention were selected. Following a pre and post-test design, the participants level of cognitive functioning was assessed using Mini Mental State Examination (MMSE) test developed by Folstein. In the intervention phase, training in spiritual development was provided through meditation, pranayama, concentration exercises, japa (recitation of the name of Supreme) and some yoga practices. The effect of training (2-3 months) on the cognitive functioning of the participants was then analysed using MMSE. T-test was computed to see if there were significant differences in the two conditions. Results indicated that spiritual intervention led to improvement in the cognitive functioning in old age. The research throws light on the role of positive psychology variables like spirituality/transcendence in well being of the elderly. Positive result suggests that further training programs can be conducted on a much larger scale for the sustenance and improvement of cognitive functioning in old age.

Promoting positive parenting
Dinesh Chhabra University of Delhi, India

Parenting is the most important job parents will ever have. It is also one of the most challenging. Parenting may well be one of the most important public health issues facing our society. Parents and caregivers have a significant role to play in facilitating their child's development. Positive developmental interactions with parents improve young children's social competence and their overall capacity to learn. The use of positive parenting skills is also linked to the reduction of unsatisfactory approaches to child discipline and may reduce child abuse. Promoting positive parenting is of particular importance in the present time of economic crisis, where tensions within families may increase due to unemployment or general economic insecurity. In the present era, maltreatment of children is growing. Research shows that well-designed evidence-based parenting programs can strengthen family relationships, reduce harsh discipline practices that are often precursors to maltreatment, and lower future rates of child maltreatment. Positive parenting plays a vital role in reshaping the social dynamics of our planet which is facing an imminent threat from within active societal interactions. The present paper attempts to highlight several factors of positive parenting that has to be given due attention by parents in making their children better citizens. In addition, social implications of positive parenting have also been highlighted to strengthen the global social system and positive parenting has been suggested as a tool for positive social growth. Parenting should be designated as a domain of public policy and all the necessary measures should be adopted for supporting positive parenting and creating the conditions necessary for positive parenting.

Application of positive psychology to gerontology
Bir Priya University of Delhi, India

Positive psychology, according to its founders and leading proponents Seligman and Csikszentmihalyi (2000), is a science of positive subjective experiences, positive individual traits, and positive institutions which identify the factors that allow individuals, communities, and societies to flourish. Its aim is to expand the focus of scientific psychology beyond a perceived dominant preoccupation with pathology to also building positive qualities, and has as its basic premise the viewpoint that human beings are self-organising, self-directed, and adaptive entities. It is important to explore the possible applications of positive psychology to gerontology, the study of aging, for three main reasons. Firstly, aging has stereotypically been associated with losses and declines, and relatively little work has been done to identify gains and areas of growth. Secondly, if positive psychology can improve peoples mental and physical health, this will reduce dependency and therefore the costs of aged care in the future. Thirdly, given that an increasing proportion of the clients of psychologists in the future will be older adults, it is important for psychologists working with older people to understand the potential as well as the limitations of older adults to respond to interventions designed to improve their level of functioning. The current approach for professionals working with older clients, including clinical psychologists, counselors, and health and aged care professionals, tends to focus on compensating for the deficits rather than bringing out the strengths of older people (Gridley et al., 2000). A major paradigm shift in orientation is required, mirroring the shift in attitudes of psychologists in general and those highlighted in the present paper. Further research into the positive psychology of aging can help to bring about this paradigm shift.

Symposium title: Online assessment and candidate performance

Convenor: Andreas Lohff

The impact of trait emotionality on ability test performance
Andreas Lohff cut-e Group, Germany; Katharina Lochner; Maike Wehrmaker; Achim Preuss

Performance on a test is not only influenced by ability, but also by motivation and emotion. There are a great number of studies investigating the impact of test anxiety on test performance (Hem-
bree, 1988). However, other emotions have hardly been investigated so far. There are a number of theories on the influence of emotions on test performance (Lyubomirsky, King, & Diener, 2005). They are, however, contradictory. For example, resource models predict the performance on complex tasks to be better in good than in bad moods (e.g. Ellis & Ashbrook, 1988) whereas other models that refer to mood-dependent thinking styles (e.g. Kuhl, 1983b) predict the opposite or a moderating effect of the type of task (e.g. Fiedler, 1990). In a total sample of N=992, we compared groups that were low, medium, or high on trait emotionality with respect to their performance on a test measuring logical reasoning. We found that those high in the positive trait emotions balance and joy did better on the tests than those intermediate or low on these traits. This is in line with Ashby, Isen and Turken’s (1999) neuropsychological theory of positive emotions that posits working memory to be best in mild positive affect. Risk aversion was negatively associated with test performance. With respect to hope, participants with intermediate levels did best on the test. Thus, test performance is likely to be related to emotionality as well as to ability.

Symposium title: Pathways to resilience: Lessons of positive adaptation from a five-country study
Convenor: Linda Theron

Paper 4: Cultural pathways to resilience
Linda Theron NWU, South Africa; Macalane Malindi

This paper speaks specifically to how the informal and formal pathways to resilience are nuanced by the cultural contexts in which young people are nested. Drawing on qualitative data generated across the participating sites, we report on generic protective processes across sites, but illustrate how these processes are influenced by local culture. The generic processes of attachment, self-regulation, service-use, meaning-making, and problem-solving are shaped by the cultural beliefs and practices of youths’ sociocultural ecologies. The findings discourage mental health practitioners from accepting culturally neutral explanations of resilience processes.

Paper 3: Informal pathways to resilience
Guo-Xiu Tian China; Xiying Wang; Janice Ikeda China

This paper speaks specifically to informal pathways to resilience, using quantitative data as well as qualitative data generated by the youth at participating sites. Informal pathways include relational and physical resources within families and communities, as well as technologically facilitated networks. The findings highlight that formal and service-based pathways to resilience cannot account fully for resilience processes - youth flourishing relies in part on relevant and meaningful contextual resources being informally available to them. These findings implicate communities and families in youth navigations towards resilience. This raises the importance of systemic support to families and communities if youth resilience is to be sustained.

Paper 1: Social ecologies of resilience across cultures - resilience and methodology
Michael Ungar Dalhousie University, Canada; Linda Liebenberg

In this opening paper, we will outline the PRP methodology, including the integration of the Child and Youth Resilience Measure-28 developed by the authors. Phase one of the research involved an assessment of young people’s individual, family and neighbourhood risk factors, service use patterns, resilience, and functional indicators of successful psychosocial development such as school engagement and prosocial involvement with peers. Qualitative methods will also be discussed, including the protocol for selecting a stratified sample of youth based on their resilience and risk exposure scores. Overall findings will be discussed with emphasis on cross-site comparison of results from the first phase of data collection which has demonstrated support for an ecological interpretation of resilience. Results suggest that positive adaptation under stress across cultures and contexts can be accounted for most by environmental factors, or the interactions between environmental and individual factors. The implications of these results to the design of mental health services in different contexts will be discussed.

Symposium title: Positive psychology in the workplace
Convenor: Elsabe Diedericks

Psychological contract fulfilment and violation and flourishing of information technology professionals: The role of psychological need satisfaction
Sebastiaan Rothmann North-West University, South Africa

The information technology (IT) industry in South Africa is a fast-paced, aggressive and highly competitive environment. Organisations in the industry are challenged by high turnover, often attributed to high demands employees face as well as a lack of support from their employers. Positive employer-employee relations are essential towards enabling individuals to flourish at work and in life. Managing the employee-employer relationship effectively is highly relevant in the IT industry. - A psychological contract provides a framework that can be used to understand how employees are affected by the employment relationship. The aim of this study was to investigate the relationship between psychological contract fulfilment and violation, satisfaction of psychological needs and job satisfaction, work engagement, turnover intention and flourishing. A convenience sample (N = 205) was taken of employees in information technology organisations in South Africa. A biographical questionnaire, the Psychological Contract Inventory, Violations of Psychological Contract Questionnaire, Work-related Basic Need Satisfaction Scale, Job Satisfaction Scale, Work Engagement Scale, Turnover Intention Scale and Mental Health Continuum Short Form were administered. The results showed that psychological contract breach and violation strongly and negatively impacted flourishing at work and in life. The results provided support for a model in which psychological contract breach and violation had both direct and indirect effects via satisfaction of psychological needs (i.e. autonomy, competence and relatedness) on job satisfaction, work engagement, turnover intention and flourishing of IT professionals.

Positive psychology in the workplace: Asking what is the best work can be?
Sebastiaan Rothmann North-West University, South Africa

Positive psychology is a loosely-organized network of research programs joined in the common belief that psychology can learn about and inform societies about maximizing human potential and experience. Most of this work has carried on in the traditional way of psychology, studying aggregations of individuals and constructing arguments about what is or is not important to the flourishing of individuals. The workplace provides a compelling, yet still relatively untapped resource for pursuing the aims of positive psychology in groups, rather than individuals. This presentation examines some of the reasons why workplace organizations are a natural fit for scientifically-grounded positive psychology research and applications, and uses the
example of meaningful work to illustrate some intriguing possibilities for how positive psychologists can ask and answer the question, ‘what is the best work can be?’

**Authentic happiness of managers, and individual and organisational outcomes**

Sebastiaan Rothmann North-West University, South Africa

The importance of measuring happiness has been emphasised in recent years and happiness has been proposed as an important indicator of well-being. However, research that investigates the happiness of managers and the relationship thereof with individual and organisational outcomes is sparse. The aim of this study was to investigate managers’ orientations to happiness, and the relationship thereof to individual and organisational outcomes. A cross-sectional survey design was used with managers in the agricultural sector in South Africa (N = 507). The Orientations to Happiness Questionnaire, Satisfaction with Life Scale, Job Satisfaction Scale, Organisational Citizenship Behaviour Scale and Organisational Commitment Scale were administered. The results showed that orientations to happiness (i.e. pleasure, meaning and engagement) had strong direct effects on subjective well-being, job satisfaction and organisational citizenship behaviour. Orientations to happiness also impacted job satisfaction indirectly through subjective well-being. Subjective well-being had a strong direct and positive effect on job satisfaction. Both orientations to happiness and subjective well-being affected organisational commitment indirectly through their effects on job satisfaction.

**Secondary traumatic stress, psychological well-being and life satisfaction of social workers in Namibia**

Michael Steger Colorado State University, United States of America

The vulnerability to develop secondary traumatic stress in professional caregivers is significant, since high emotional demands are inherent in these professions. Notwithstanding contradictory evidence postulating personal growth through adversity, demands are high and result in overexploiting personal resources. This significantly increases the probability to develop secondary traumatic stress. Social workers in Namibia experience high environmental demands, for example, one social worker being available for approximately 50 000 community members in the most affected post-war regions. The aim of this study was to investigate the relationships among secondary traumatic stress, psychological well-being (purpose in life, environmental mastery, and self-acceptance) and life satisfaction of social workers of Namibia. A cross-sectional survey design was used with a sample population of 116 social workers. The Secondary Traumatic Stress Scale, three subscales of the Psychological Well-being Scale, the Satisfaction with Life Scale and a biographical questionnaire were administered. The results showed that secondary traumatic stress (including arousal, avoidance and intrusion) was negatively related to purpose in life, environmental mastery, self-acceptance, and life satisfaction of social workers. Satisfaction with life was best predicted by environmental mastery and low arousal. Avoidance impacted life satisfaction indirectly and negatively via low environmental mastery.

**Antecedents of flourishing of managers**

Johannes Swart South Africa

The subjective well-being of managers is valued in the high-commitment / high-involvement strategic human resource management approach, which aims to elicit and support behaviour that is primarily self-regulated rather than controlled by sanctions and pressures. Keyes (2002, 2007) distinguishes between three types of subjective well-being, namely emotional well-being (indicating whether a person is “feeling well”), and psychological and social well-being (indicating whether he or she is “functioning well”). The concepts of flourishing and languishing are used to describe opposite-end points on a continuum of mental health, indicating the well-being of individuals in terms of these three dimensions. The objective of this study was to investigate the relationships between task characteristics, supervisor relations, personal resources and remuneration, psychological needs satisfaction, and job satisfaction, work engagement, and flourishing of managers in South Africa. A cross-sectional survey design was used with managers in the agricultural sector in South Africa (N = 507). The Antecedents Scale, the Work-related Basic Needs Satisfaction Scale, the Job Satisfaction Scale, the Work Engagement Scale and the Mental Health Continuum Short Form were administered. The results showed that task characteristics, supervisor relations, availability of resources, and remuneration impacted job satisfaction, work engagement, emotional and psychological well-being indirectly via autonomy satisfaction. The availability of resources impacted work engagement and psychological well-being via competence satisfaction. Task characteristics, supervisor relations and availability of resources impacted work engagement and psychological well-being via relatedness satisfaction.

**Counselling for the dying process**

Anna Rita Ravenna Italy

Usually, people talk about death and the dying process from a wide range of philosophical and anthropological perspectives because they consider them to be events that are external to the narrator. It is uncommon to encounter narratives that draw upon individual life experiences and the feelings that are connected to this process, to this set of events that are so meaningful and personal and universal at the same. This type of narrative, which draws upon autobiographical - albeit emotionally enthralling – experiences, is rarely accompanied by critical reflections on the experience that may be applied to other personal and professional settings. In Italy, in the 80s, the pioneers of psycho-oncology were undoubtedly helped by the writings of De Martino (1958) and Kuhl-Beross (1979), Le Shan (1982), Grof (1971), Ariès (1978), Elias (1985), as well as by the fiction and psychology classics. However, no tool was more valuable for the education and training of psychologists than the actual encounter with the individuals who, in the anguish of their illness, were so full of trust that they opened their heart and mind to share their past experiences and their own dying process as they were going through it, in the incessant evolution of psychic events that have personal resonances of meaning, until the moment of death, an instant that is impossible to experience and that we can just live by surrendering to the mystery.
Research Area: Professional Training and Licensure

Session Type: Papers

Should students enrolled on practitioner psychology programmes be subject to statutory regulation?

Carole Allan  
British Psychological Society, United Kingdom

Within the UK over 1.4 million workers, mainly within the healthcare domain are subject to statutory regulation. Analysis of complaints made against a wide range of practitioners indicates that the majority of fitness to practice hearings are related to breaches of ethics and professional conduct, rather than lack of competence. Robust supervision mechanisms are part of the process of protecting the public from novice practitioners. Traditionally students have not been regulated by the state but are subject to processes within the academic institution where they are studying or the workplace where clinical practice is undertaken. Because these tend to be two separate institutional settings, respective responsibilities are sometimes not clearly defined or fully appreciated, leading to occasional failures to address conduct issues. The Health Professions Council which regulates a range of practitioners including all applied Psychologists in the UK and is currently consulting on the feasibility of a voluntary Register for trainees. The case for introducing more secure arrangements will be discussed. This includes admissions procedures which apply selection and entry criteria which includes appropriate academic and professional entry standards, the objective measurement of student performance to ensure fitness to practice and requiring that Programmes are responsible for ensuring that trainees are fit to practice at the point of graduation.

Why register as an industrial psychologist in South Africa?

Fiona Donald  
University of the Witwatersrand, South Africa; Robin Bleekers  
University of the Witwatersrand, South Africa

The aim of this study was to compare the perceived status, prestige and job satisfaction of registered industrial psychologists with those of human resource practitioners. In South Africa, registration with the Health Professions Council of South Africa (HPCSA) is a statutory requirement which entitles one to call oneself an industrial or organizational psychologist, and to practice in certain areas. However, many personnel who are not registered psychologists also work in the field of human resources or people effectiveness and are not required to register with a statutory body. Despite differences in the minimum qualifications required and statutory registration requirements, there is a great deal of overlap between the roles of industrial psychologists and other human resources practitioners in organizations. This raises issues regarding the identity of these groups of personnel and the perceived benefits of registration. This research focuses on two potential intrinsic benefits of registration – perceptions of one’s status and prestige, and job satisfaction. The sample consisted of 46 participants who were registered with the HPCSA and 45 human resource practitioners who were not registered (N = 91). Participants completed questionnaires. Results found no significant difference between status, prestige or job satisfaction for registered and non registered participants. However, a strong positive relationship was found between job satisfaction, status and prestige. The findings are discussed in terms of the motivation to qualify and register as an industrial psychologist and implications for professional identity and practice.

How prepared for community service do newly qualified clinical psychologists feel?

Thembelihle Dube  
Fort Napier Hospital, South Africa

The study explored the experiences of recently qualified clinical psychologists during their community service year. Perceptions on whether their professional training adequately prepared them for the community service year are highlighted. Transformational learning serves as the study’s theoretical framework and helped elucidate how the participants created meaning from their experiences. A qualitative research methodology was utilised. Semi-structured research interviews were administered to eight recently qualified clinical psychologists. There were seven super-ordinate themes that came to the fore in the analysis of the data and they were distilled as follows: pre-placement; relocation; no understanding of the role of a clinical psychologist by residents; containment; being a scarce resource and the pressure that it engenders; the impact of the placement; and training. The community service placement was experienced as hard and challenging work but, for most, very rewarding. The isolation, traumatic nature of the cases, lack of containment, and supervision left some traumatised and eager to just get through it and leave. There is a need for more support for community service clinical psychologists in their placements. The profession needs to advocate to the Department of Health for basic support structures to be put in place on behalf of community service psychologists.

Balancing clinical and community training demands: The experiences of students at the University of the Western Cape

Kamal Kamaloodien  
University of the Western Cape, South Africa; Feroza Mohadien; Karen Killian; Wynnand Gerber; Lito Daniels; Erica Munnik; Ereene Brocker; Rashid Ahmed; Mohamed Adam; Rowan Smith

The literature on developing a relevant professional training programme for South Africa, has prompted a move to community psychology. However, while this call is well-articulated and strongly advocated by those responsible for training, far less is known about students’ experiences of, and responses to this call. This paper reports on the experiences of students from the University of the Western Cape’s psychology department. Drawing on both staff and student feedback, the paper identifies some of the key issues emerging from this call. The openness to community forms of intervention, perceived competence for community interventions, the emotional impact of community interventions and the challenge to existing worldviews, and professional boundaries, are identified as some of the key issues facing training programmes. The paper reports on both staff and student perceptions of these issues and it is argued that some of the challenges are not easily resolved. The paper concludes by identifying some of the areas for future engagement.

Transdisciplinary teams in private practice

Joanne Laskey  
Cornerstone Institute, South Africa

A qualitative study was conducted to capture professional practitioner’s perceptions on how to constitute a Transdisciplinary Team (TDT) in private practice. Part of the aim of the study was to encourage private practitioners to consider offering holistic, non fragmented care at a community level. A hospital by its nature is a team environment. However private practice is often an individual affair. Co-ordination of treatment often relies on referrals and the patients’ own discretion. Care therefore could be compromised post hospitalisation. The sample was conveniently and opportunistically selected from the population of health and allied health professionals practising independently in a wellness centre. Data collection was done in the form of a focus group. Data analysis was thematic and followed Braun and Clarke’s (2006) six phase guide. The professionals viewed TDT’s as multi-disciplinary team unifying around a common goal. Team work would only need to occur around joint projects but otherwise individual practice could continue. The practice would be client centred empowering the client to choose. Foundational to developing a TDT in private practice was creating a financially viable model. What was reflected in the study was the perceptions and struggles of health professionals who are engaged in the ‘trenches’ of private practice far removed from the ideals of academies and large scale funded institutions. The present study was limited to one focus group and could only capture the perceptions of how a TDT could operate. Future study could look at developing a comprehensive model for private practice.

Requirement of international monitoring in licensing foreign trained psychologists by a national psychology board

Mohammad Rahman  
Princess Marina Hospital, Bangladesh; Samiul Hossain

Psychology is an international discipline in today’s globalisation. The scope of psychology is no longer limited to the local needs of a particular country, as it crosses national boundaries. Often a psychologist trained in one country needs to be recognised to practice in another, in order to work as a practicing, licenced, applied psychologist. This is important after a natural disaster situation, and where there is severe scarcity of local or national psychologists, who are either unavailable, or not qualified to practice. The purpose of this paper is to explore the issues and complexity of granting licensing to foreign-trained applied psychologists from different cultures, and to suggest ways to create provision for psychologists to work beyond their national borders, and to be ready to treat people internationally. It is often difficult for foreign-trained psychologists to be licenced or registered in a foreign country, by a national body of psychology or health professionals. To meet the urgent psychological
service needs of a nation through promoting quality applied psychological services by foreign trained psychologists, to be employed in a different country, in a different culture, requires a standard procedure, and input from an international body of psychologists. Whether this is a recognised international body of psychology, such as IUPS or IAAP, who can play such a watchdog, or moderating role, to oversee the justified demands and requirements of a national board of psychology, is an important issue, which, although appearing to be controversial, is recommended and raised for discussion.

Psychology serving humanity: International education and training for applied child psychology

Michael Roberts University of Kansas, United States of America

Internationally, there are significant mental health problems and an immense need for services for children and adolescents. Examples illustrate this need, such as (a) infants born preterm, medically-ill or exposed to drugs, (b) youth with serious emotional disturbances such as schizophrenia and developmental disorders such as autism and mental retardation, (c) children with behavioural and psychological disorders such as Attention Deficit/Hyperactivity, Oppositional Defiant or Conduct, Anxiety, or Depression, (d) children coping with the trauma of disasters, war, terrorism, or community/family violence (including child physical and sexual abuse), (e) children adjusting to life changes such as divorce, death, relocation, or remarriage, (f) children living with physical illnesses, adhering to medical regimens, or coping with pain, (g) children with cognitive deficits and school performance problems, (h) adolescents with delinquency and high risk behaviours of substance abuse or sexual behaviour, and (i) children in poverty and without adequate health care. These and other mental and behavioural problems require specialty education and training and specialised services. However, children, adolescents and their families continue to be underserved because of lack of services availability and fragmented service delivery systems (private care systems, schools, juvenile justice, community mental health, medical systems), problems in financing services, differences in reimbursement systems, market forces present in the countries’ economic systems, political ideologies and country ‘heritage’ which create societal priorities, inadequacy of training programs in producing competent specialists, and relatively low numbers of specialty psychologists in applied child psychology, including clinical child and pediatric psychology—too low to meet needs and misdistributed internationally. This invited presentation will discuss education and training for applied child psychology as a research and practice specialty that seeks to investigate and remediate mental health problems for children, adolescents, and their families. Aspects of this applied and clinical research field are found in different countries with a broad range of populations, settings, problems, assessment, and intervention techniques. As a component of professional psychology, specialty education and training integrates clinical psychology with a comprehensive foundation in child, adolescent, and family development and developmental psychopathology. Many countries are in the process of developing their clinical child and adolescent psychology professionals. However, in some countries, specialists in child and adolescent mental health services are virtually nonexistent. The invited presentation will discuss several countries to improve the specialty education and training preparation of psychologists to assume leadership roles serving these diverse mental and behavioural needs through services and clinical research.

The reality we construct in training
Ilse Ruane University of Pretoria, South Africa

The purpose of training at a Masters level is to train psychologists so they will be capable of effective counselling with culturally different clients. This training philosophy cannot be more appropriate than in a country such as South Africa. Within the South African population, as in the case further afield, client needs are becoming more diverse and non-Western. A review of literature shows evidence of a number of studies illustrating the multicultural diversity of the South African society, but little has been researched in terms of universities and training institutions adequately preparing students to work within a culturally diverse country. Training programmes must produce graduates committed to a South African, not American, future. The focus of this paper is to explore some of the findings of my PhD research and to further engage with academics and professionals to contribute towards contextually relevant knowledge about the discourse around multicultural training at a Masters level at tertiary institutions. Through this research many challenges that exist with regards to multicultural training at South African universities have been highlighted. These include integrating multicultural training in counselling and clinical programmes, differences in defining multicultural competence, programme barriers, and a lack of agreement on effective teaching, and the study proposes to explore these. The paper hopes to explore suggestions, including addressing racism, expanding staff involvement and purposefully providing multicultural opportunities in practicum and internship.

Reflections on a professional training programme at a historically disadvantaged institution

Mario Smith University of the Western Cape, South Africa; Erica Munnik; Kamal Kamaloodien; Charl Davids; Umesh Bawa; Lynn Marks; Rashid Ahmed; Mohamed Adam; Mathinyane Tjelele

There is a relative paucity of data on professional training in South Africa and one of the gaps in the literature has been the extent to which training institutions face unique challenges. Drawing on the constraints and possibilities that students at one of the country’s few historically disadvantaged universities face unique challenges. Drawing on the findings of my PhD research and an Evaluation Process Form (EPF), 18 students at one of the country’s few historically disadvantaged universities were asked to respond to a questionnaire tapping, inter alia, prior awareness of the subject, access to psychology literature, knowledge of psychologists or psychological services in their communities, perceived relevance to or clashes with their culture, and parental awareness of the subject. The sample of 399 had a mean age of 22.4 years and was comprised of 72.2% women and 65.7% rural students. Almost half of the sample (48.1%) first heard about psychology on entering university, 75.7% had no access to books on the subject, and 54.1% had received no information from their school teachers about psychology as a career. Among those students with no prior knowledge of psychology, significantly more were from rural areas ($\chi^2 = 73.24$, $d.f. = 1$, $p = 0.0005$), and of those who received no information from school teachers about psychology as a career, significantly more were from rural communities ($\chi^2 = 90.25$, $d.f. = 1$, $p = 0.0005$). These and other findings are discussed in the context of the country’s history, along with their implications for student success and career development, considering especially the drastic shortage of black African psychologists in the country.

Rural South African students’ preparedness for the study of psychology

Jabulani Thwala University of Zululand, South Africa; Anthony Pillay

Considering the large under-served rural communities in South Africa, the present study investigated the extent to which first-year psychology students from these communities are prepared for this course of study. Newly-enrolled psychology students at one of the country’s few rural-based universities were asked to respond to a questionnaire tapping, inter alia, prior awareness of the subject, access to psychology literature, knowledge of psychologists or psychological services in their communities, perceived relevance to or clashes with their culture, and parental awareness of the subject. The sample of 399 had a mean age of 22.4 years and was comprised of 72.2% women and 65.7% rural students. Almost half of the sample (48.1%) first heard about psychology on entering university, 75.7% had no access to books on the subject, and 54.1% had received no information from their school teachers about psychology as a career. Among those students with no prior knowledge of psychology, significantly more were from rural areas ($\chi^2 = 73.24$, $d.f. = 1$, $p = 0.0005$), and of those who received no information from school teachers about psychology as a career, significantly more were from rural communities ($\chi^2 = 90.25$, $d.f. = 1$, $p = 0.0005$). These and other findings are discussed in the context of the country’s history, along with their implications for student success and career development, considering especially the drastic shortage of black African psychologists in the country.

Stress management program: Offering sources to face the stress

Samia Abreu Universidade de Brasilia, Brazil; Ana Carolina Concelo

The occupational stress is a source of productivity reducing and triggering physical and mental illness. Companies recent experiences indicate that interventions focused in improve coping strategies minimise negative impacts of working conditions and reduce the risk for disease. So that, a Brazilian health private health service, called Saude BRB, offered to its employees a stress management preventive intervention. The goal of the program was to decrease stress symptoms, prevent the onset of new symptoms and promote health coping. For that, was formed a psychoeducational group, with 8 sessions, lasting 1 hour and 30 minutes weekly. The discussed issues concerned to teach time management, assertiveness, decision making and relaxation techniques. The program was evaluated with pre- and post- testing, using the Inventory of Stress Symptoms for Adults (ISS) and an Evaluation Process Form (EPF). 18 people participated of complete intervention. According to ISS, the symptoms frequency had
a significant decrease, such as insomnia (50% decreases), constant tiredness (29% down), irritability (60% decrease) and hypersensitivity (less 48%). The EPF showed improvements on personal repertoire of coping strategies, such as changing compensatory or avoidance behaviour for seeking social support and stressors identification. Although, the program achieved the proposed goals, occupational and ergonomic changes would be a powerful toll for increasing mental health and life quality.

**Psychological peculiarities of university students’ professional adaptation**

*Elmira Kalymbetova* Kazakh National University, Kazakhstan; *Davlet None*

Professional adaptation embraces an important sphere of students’ socialisation in university. Professional activity starts in university and promotes self-actualisation of their personality features with ensuring complete performance of developing professional skills. Student’s internal position depends on professional skills increase. It may be expressed in their professional comprehension. That promotes beginning of their creative development and formation of positive attitude and emotional values connected with future profession. Former graduates witness that process of personality formation and professional adaptation continues for a long time. According to professional demands they need re-freshment procedures (master-classes and so on).

Students’ system of values and personality features are developing in tight inter-relation with professional adaptation. These properties couldn’t be analysed separately from each other. Important aspect of students’ adaptation is their subjective sense of his (or her) possibilities and abilities, comprehension of own self-peculiarities and level of individual self-esteem. Psychological observation, longitude study, differential-diagnostic questionnaires, professional case-study, focus-interview, and statistical means were used in the study. Students’ professional adaption period is tightly connected with an increase of their motivation. If a student forms higher level of values during university education he (or she) can certainly be successful in developing professional skills and ought to effective in future professional activity.

The Colombian College of Psychologists: History, characteristics and its role in the development of discipline and profession

*Claudia Sanín* Colegio Colombiano de Psicólogo, Colombia; *German Gutierrez*

The history of psychologists’ professional organisations in Colombia is briefly outlined. The Colombian College of Psychologists is currently the largest organisation of psychologists in the country. The main characteristics of its membership and its role in the development of both the discipline, and the profession, in Colombia are described. A historical analysis, showing the role of laws regulating psychological practice in the country, and their effect on the development of psychologists’ organisations, is also presented.

**Practice of clinical psychology in a medical setting in Sri Lanka: Trials and tribulations**

*Priyanjali De Zoysa* University of Colombo, Sri Lanka

In considering Sri Lanka’s mental health needs, compounded further by its decade’s long ethnic conflict, the number of mental health practitioners (MHP) in the country is woefully inadequate (about 20 clinical psychologists and 35 psychiatrists). The majority of clinical psychologists (CP) work autonomously in the non-state sector. Their clients are self-referrals and referrals by general practitioners and medical specialists, such as pediatricians and psychiatrists. In the state sector too, this situation prevailed. But in addition, state sector CP provided an expert evidence service to the state judiciary. A few months ago however, at the National Hospital of Sri Lanka, Sri Lanka’s premier teaching hospital, this long-standing practice was regressed, albeit verbally. At present, self-referrals, medical referrals, and referrals by non-psychiatry medical specialists to the CP is prevented and are instead directed to the psychiatry service. The stated reason being that clinical psychology is not an autonomous profession and hence a psychiatry service should decide if a referral is to indeed warranted. This new development has a significant impact in a country which already has very few MHP grappling with great mental health needs. Further, it unnecessarily subjects clients to a large number of assessments as they are forced to take a circuitous route in order to see a CP, lengthens the time taken for clients to consult a CP (with no guarantee of ever seeing one), increases the workload of an already overworked system, and is contrary to the international practice of clinical psychology.

Providing culturally congruent African/Black centered mental-health services and programming for victims of natural and man-made disasters

*Mary Elizabeth Hargrow* The Association of Black Psychologists, United States of America

The Association of Black Psychologists (ABPs) Disaster Relief Task Force’s (DRTF) mission is to partner with existing organisations and, where absent, provide leadership in the design and delivery of culturally congruent African centered mental health services and programming for African ancestry survivors of natural and man-made disasters worldwide. For over 40 years members of The ABPs have devoted their careers developing Black psychological theory, practice and skill sets. This body of work uniquely situates The ABPs and the field of African Centered/Black Psychology as a premier resource for providing leadership in the design and delivery of culturally congruent African centered mental health services and programming worldwide. Under the direction of the ABPs, the presenters have written three African Centered documents pertaining to culturally congruent African/Black mental health services and disaster recovery. The Master Document includes an introduction and overview of an African worldview with psychological underpinnings and theories, a discussion of African/Black Psychology’s recognition and respect for the historical experiences, cultural strengths, struggles, and disaster legacy of African ancestry people, an articulation of the need for Reclaiming Human Spiritness, and an explication of the African Centered Community Healing Model, OBI-DAN-BI (The Restoration of the Spirit). The Master document also includes a discussion of and need for Culturally Congruent Considerations, best practices guidelines, strategies and interventions and a selected Black Psychology bibliography. Two separate supplementary volumes are being written specific to the New Orleans Hurricane Katrina disaster and the 2010 Haiti Earthquake disaster. Despite universal responses to traumatic events across some societies and cultures, optimal recovery from trauma requires that psychologists and other service providers fully appreciate the historical experiences of the people traumatised (van der Kolk, et al, 1996). For people of African ancestry, the recovery process must include the experiences of colonialism, slavery, oppression and the global dehumanisation of African people. This symposium will offer an in-depth discussion of Black Psychology, the Obi-Dan Bi African centered recovery process and will demonstrate the utility of culturally congruent (African centered) treatment, intervention and development. The symposium will also provide an opportunity to review and critique the Association of Black Psychologists’ African centered restoration documents, other Black Psychology initiatives and explore possibilities for international replication.

Advancing the culture of competence in North America

*Emil Rodolfo* University of California Davis, United States of America

This program will describe the current North American definitions and components of competencies. It will provide a context by summarizing previous North American efforts to describe competence and will explore the assessment of professional competence during training and at the point of licensure. Problems in the assessment of competence will also be described and suggestions to enhance competency assessment will be provided. Future directions will be explored emphasizing the advancement of the culture of competence in North America. Specific goals include: (1) Participants will better understand the concept of competency within the United States and Canadian context. (2) Participants will gain a better understanding of the issues involved in the assessment of competence. (3) Participants will enhance their ability to develop methods to assess competency.

**Session Type: Invited Addresses**

**Symposium title: Current models of psychological competencies from around the world**

*Convenor: Sverre L Nielsen*

Psychological competencies with reference to south east asian nations

*Malavika Kapur* National Institute of Advanced Studies, India

The key issues in professional psychology is the competency of the professionals to meet the needs of the people. In the developing countries, majority of the population, especially disadvantaged groups, women and children have been neglected. To match the competencies and the needs of the people of a particular nation need to be calibrated to suit the particular cultural context. In most of the South East Asian countries, research, training and practice of
professional psychology in the developing countries have been rather slow to gain recognition at the country level. The impact of the profession with regard to most of the population is almost non-existent. In India, however, the profession of clinical has made its presence felt in the universities and in clinical practice at least in the metropolitan cities. The National Institute of Mental Health and Neurosciences, where the author was a faculty member has been providing quality training from 1986 onwards. However, traditionality, the various associations of psychology have maintained the code of conduct in an unofficial manner. As it stands at present there is no statutory body to mandate the various branches of professional psychologists / counsellors except Clinical Psychologists. Attempt is on at the national level to become part of the National Council for Health as a mandatory body. Could we have competency models with the lowest common denominator and could we have an International Statutory body offering foreign affiliate status to its members?

Symposium title: International trends in preparing clinical child and adolescent psychologists
Convenor: Michael Roberts

Training for licensing and credentialing in clinical Child and Adolescent Psychology in the United States
Barry Anton Rainier Behavioral Health, United States of America

This presentation will address challenges to licensing and credentialing for the professional preparation of delivery of clinical services by professionals in the speciality of clinical Child and Adolescent Psychology in the United States. Children are seriously under-served in the United States and the scientific knowledge base is evolving. However, there are significant barriers to practice that include licensing challenges and specialty credentialing for early career psychologists. This presentation will analyse the mental health needs of children and adolescents as well as the present state of licensing and credentialing. Implications for international professionals will be discussed.

Psycho-pharmacology applications in clinical Child and Adolescent Psychology and training
Ronald Brown Wayne State University, United States of America

This presentation will provide the latest updates on paediatric psycho-pharmacology for childhood mental health disorders including the most recent research on the safety and efficacy of many of the commonly used medications. In particular, information will be provided on the use of multi-modal therapies including the combination of psychotropic medication and psychotherapy for the management of both the internalising and externalising mental health disorders in children and adolescents.

Scientist-practitioner training in clinical child and pediatric psychology: International developments
Annette La Greca Miami University, United States of America

This paper will discuss professional preparation for delivery of evidence-based services by scientist-practitioner professionals in the specialty of pediatric psychology in the United States and other countries. Children are seriously under-served and the scientific knowledge base is developing to meet the needs affecting training. This presentation will analyze mental health needs of children and families as well as the present state of training and education specifically related to child health and pediatric psychology. Advances in the scientific literature and rising needs for qualified professionals in the United States require attention to sequences of predoctoral, internship and postdoctoral training. Implications for international professionalism will be discussed.

International trends in preparing clinical child and adolescent psychologists
Michael Roberts University of Kansas, United States of America

This symposium is intended to bring together different perspectives on developments in the training of the clinical child and adolescent psychology speciality field. This area of applied psychology has been growing worldwide in recognition of the immense unmet needs for improving the mental health of children and adolescents. Specialty training at different levels of application draws on evidence-based practice incorporating information from empirically-based assessment and treatment, clinician expertise, and client values. Different approaches are taken accommodating different countries’ educational structures and systems for mental health services. This symposium is intended to elucidate new developments and outline the future for specialty applications of clinical child and pediatric psychology worldwide. Presenters will discuss issues of licensure and credentialing faced in the United States, development of psychopharmacology training within psychology, applications and training in evidence-based practice in different countries and cultures, scientist-practitioner training in pediatric (child health) psychology, and Latin American developments for training professionals in applied child psychology.

Clinical psychology training and evidence based practice in Ireland
Michael Roberts University of Kansas, United States of America

An over-view of clinical psychology training in Ireland will be presented, emphasising the role of integrating knowledge of theory and research in child clinical practice. In addition, the blending of conducting clinically relevant research as a core part of clinical training will be illustrated.

Symposium title: Providing culturally congruent african/black centered mental-health services and programming for victims of natural and man-made disasters "The Restoration of Spirit"
Convenor: Mary Elizabeth Hargrow

Creating conditions for recovery from natural and man-made disasters
Mary Elizabeth Hargrow The Association of Black Psycho, United States of America

Two natural disasters, on the surface, Hurricane Katrina, New Orleans, 2005, and the Haiti Earthquake, 2010, affected and continue to affect large numbers of African ancestry people. The ABPsi was motivated by these disasters to come forward with its forty years of experience in psychological study, research, and treatment with people of African ancestry and provide international leadership by developing comprehensive culturally congruent black/African centred guidelines and interventions for services and programming to African ancestry victims of Natural and Man-Made Disasters. The ABPsi claims the leadership role in this endeavour based on a number of factors including the membersh ips fund of knowledge related to the trauma being suffered by the people affected: (1) direct experience with a history of untreated current and generational traumas, (2) ability to more likely to recognize and acknowledge the man-made responsibility in creating and supporting conditions that increased the levels of devastation, and (3) recognising the multiple roles of history, poverty and cultural alienation in the recovery process. An ABPsi Disaster Response Ideaogram has been developed illustrating the structural logic that informs the psychological impact of Natural and Man-Made disasters. The ideaogram began with Dr Lewis King recognising this need and offering the initial conceptual frame. The current ideaogram allows for interpreting psychosocial conditions in terms of shifting dimensions of need over time and the dimensions of spirit, incorporating the relationship between the psychological (spirit) and economic (material) conditions.

The African-centered communal health model: The restoration of spirit
Linda James Myers Ohio State University, United States of America

As we consider psychology serving humanity, it is important to be mindful of the influence of cultural worldviews on the production of psychological knowledge. This presentation will highlight how an African-centered, culturally syntonic psychology, requiring a new understanding of what it means to be human and of a fuller awareness of self, can provide the erudition necessary for the illumination, restoration, and elevation of the human spirit in the face of centuries of unprecedented trauma. Based on research examining the roots of the prevailing cultural worldview extant in Western psychology since its inception, as well as its significance in shaping the current global conditions for humans, the knowledge necessary to negotiate movement toward the highest stages of human development will be outlined. Examining classical African civilisation’s contributions to the cultural roots of all humanity and their implications for communal health and well-being in contemporary times, the resilience of non-immigrant Africans in the United States will be analysed to provide insight into the skills and tools necessary for human sustainability in the midst of catastrophe, translating science into practice.

International healing and collaboration structures
Gislene Mariett United States of America

The 2005 New Orleans Katrina Hurricane and the 2010 Haiti Earthquake galvanised Association of Black Psychologists intellectuals to critically identify conceptual models appropriate for responding to trau-
ma (natural and man-made) affecting persons of African ancestry. Black/African centred psychology paradigms and models of cultural competence and congruent disaster relief responses, interventions and treatment strategies were articulated, evolved and developed to address the immediate to long term needs of survivors of these types of disasters. The International Healing and Collaboration Structures presentation will introduce The Association of Black Psychologists guidelines for process, practice and paradigms used to formulate and operationalise The Association’s Disaster Relief Task Force Manual for effective, culturally congruent and competent work with persons of African ancestry anchored in African CENTRED Black Psychology theory and practice to improve outcomes related to trauma, natural or man-made disasters. The Associations’ efforts in Haiti offered its expertise in mental health and healing practices in a collaborative process as an example of and collaborative structures with Haitian healers, psychological community, government leadership and NGO organisations serving Haiti anchored in African-centred thought and practice. It is hoped that these foundation structures may serve as a guide to develop national and international models for work with persons of African ancestry from optimal theoretical perspectives.

Natural/man-made disaster and the derailment of the African world-view
Wade Nobles San Francisco State University, United States of America
This presentation will discuss the intentional derailment of Africa’s natural developmental trajectory and how colonialism was more than the political domination and exploitation of European empires over African land and resources. From the perspective of Black Psychology Dr Nobles will propose that colonialism and slavery are equivalent to psychological warfare and cultural genocide and should be understood as man-made disasters equal in death and destruction as any natural disaster. The change in African consciousness and Black Identity as a direct result of the derailment of the African worldview will also be explored in this critical discussion. In support of the other panelists, it will conclude with a recommendation for the culturally congruent (African centred) restoration of African spirit as the goal of any recovery treatment, intervention and development process as reflected in the ABPs’s Culturally Congruent African/Black Mental Health Services and Programming for Victims of Natural and Man-made Disasters.

Black psychology and the African Psychology Institute
Daryl Rowe United States of America
African/black psychology has a long and storied history. Black psychologists have redefined the approach to the provision of mental health services to people of African ancestry and have developed an African/black psychology that is consistent with and predictable from the cultural wisdom traditions of African and African American peoples. This presentation will provide a conceptual understanding for the more than forty-year history of efforts in creating an intellectual discipline, with a paradigm, episteme and a body of theories and knowledge about behaviour that is grounded in ancient wisdom traditions of African peoples. It will review key contributions in the development of African/black psychology, present an African-centred meta-theoretical context for thinking about human development, and present an institutional framework - The African Psychology Institute (API) - for coordinating and implementing various community-based and clinically oriented efforts that have as their emphases addressing and resolving conditions affecting persons of African ancestry in the United States and abroad. The overall mission of the API is to: (1) establish the parameters of a common fund of knowledge necessary for articulating African/black psychology; (2) offer a training programme in African/black psychology; and (3) to certify and/or credential psychologists to meet the psycho-cultural needs of peoples of African ancestry.

Session Type: Invited Workshop

Supervising trainee psychologist: Developing good practices for early career psychologists
Amie Frewen James Cook University, Singapore; Nenna Ndukwe
Early Career Psychologists (ECPs) are often called to act in a supervisory role whilst simultaneously developing their own knowledge and experiences of clinical practice. However, little training is available to offer guidance and direct the process of supervision for ECPs. The workshop will be facilitated by two ECPs who will reflect on their experiences of taking on a supervisory role in the UK, Australia and Singapore. A skills based workshop will: (a) Identifying the needs of ECPs (b) support for ECPs including newly qualified psychologist training, (c) key components of a successful supervisory relationship, (d) developing strategies for assessing trainee competency, (e) dealing with incompetence, and (f) adapting supervisory roles to match the trainee needs. The objectives are: (1) Enhance skills as a clinical supervisor in order to provide effective supervision for trainees, (2) to gain an awareness of theoretical models of clinical supervision to meet the developmental needs of trainees, (3) to gain practical experience of competency based supervision. Participants will be able to: (i) Share successes and pitfalls of ECP supervision, (ii) learn more about the theory and practice of clinical supervision, (iii) learn more about the practicalities of supervising trainee clinical psychologists, (iv) develop an awareness of the standards necessary to achieve good self care as an ECP, (v) develop an awareness of the standards necessary to achieve good practice in the supervision of clinical trainees. ECPs involved in the clinical supervision of trainee clinical psychologists.

Session Type: Symposium

Symposium title: A new national registration and accreditation scheme for psychology in Australia - the first 12 months of licensure
Convenor: Brin Grenyer
Challenges, solutions and future developments in implementing nationally consistent ethical standards
Alfred Allan Edith Cowan University, Australia
This presentation will consider the problems experienced in implementing nationally consistent ethical standards in a country with eight States and Territories which each has a unique legal system. Ethical and legal challenges arise when the jurisdiction of courts intersects with the legal regulation of health practitioners. Examples include disputed areas such as family court proceedings where the special role and status of psychologists as court appointed experts can also lead to notifications about their conduct. Further elaboration of the challenges within a national scheme will be done with specific reference to psychologists’ duty to report offending and other dangerous behaviour. Suggestions regarding how this problem can be overcome will be demonstrated.

Overview of Australia’s national registration and accreditation scheme
Brin Grenyer Psychology Board of Australia, Australia; Ann Stark Psychology Board of Australia, Australia; Alfred Allan Psychology Board of Australia, Australia; Sabine Hammond Psychology Board of Australia, Australia; Jillian Bull
On 1 July 2010 Australia implemented a new single unified licensing and registration scheme for the practice of psychology. All 29000 psychologists across the country are now listed on a publically accessible register that shows their registration status. In addition, psychologists now have title protection for practice in specific areas based on qualifications and supervised experience. The recognised areas of practice are organisational, clinical, clinical neuropsychology, educational and developmental, health, sport and exercise, community and counselling psychology. Unified educational standards for psychology have been established along with an integrated accreditation scheme across all 40 recognised higher education training providers. The scheme has incorporated mandatory, Professional development, obligations to report malpractice, indemnity insurance, criminal history checks, language competency, and advertising and ethical standards. A feature of the scheme is cross-disciplinary collaboration, with 13 other health professions being regulated within the same single national scheme. This presentation will outline the key features of the scheme and reflect upon the challenges of matching national with international psychology standards to promote mobility.

Dealing with individual psychologists applying for registration or managing malpractice complaints
Sabine Hammond Australian Catholic University, Australia
This presentation will consider the challenges of developing national consistency in decision making for regulators operating in a complex scheme involving 14 health professions and over half a million registered health practitioners. The paper reports on the first two years of implementation of the scheme from a regional board perspective. Key challenges have involved clarifying the working relationship and responsibilities between the National and Regional Psychology Board, and the Australian Health Practitioner Regulation Agency (AHPRA), unanticipated consequences of new policies, registration and complaint (notifications) mat-
Development of a single national framework for mandatory development and supervisor training

Ann Stark University of Tasmania, Australia

This presentation will review the experiences of Australian psychologists over the past two years in implementing a registration standard for continuing professional development. Prior to national registration and accreditation, in Australia, continuing professional development requirements had generally been overseen by professional societies rather than regulatory bodies. The requirement, under the National Law, for a registration standard relating to CPD has widened the application and sharpened the focus of CPD for psychologists. Current requirements and guidelines, and the rationale for their establishment will be outlined and a comparison with the CPD registration standards for the other 13 professions will be presented. In implementing this standard the Psychology Board of Australia has had the opportunity to draw upon the experiences of the New Zealand Psychologists Registration Board. Trans-Tasman learning will be explored and next steps identified. As the Australian CPD standard now mandates peer supervision or consultation for all registered psychologists, preliminary comment on the establishment of standards for the training of supervisors will be provided.

Can international agreement in psychology competencies help to address emerging global challenges?

Sverre L Nielsen Norwegian Psychological Association, Norway

Around the world there have been various efforts to describe and agree upon definitions of competencies that are needed for the psychologists practice in a number of fields. These descriptions vary from country to country, or between continents, both in level of formality and complexity, and regarding the qualifications to be able to practise. These differences in measures of competencies are obstacles to the mobility of psychologists between countries and/or continents. A conference in Stockholm July 2013, with participants from a number of international and national psychological associations, will make an effort to look at the possibilities for a global agreement on measures of psychologists’ competencies within various fields. These two symposia and the round table discussion are meant as starters for the conference next year.

Teaching and training: Professional identity and coherence, roles of international organisations

Jose Pérez University of Valencia, Spain

Professional identity has been defined as one’s professional self-concept based on attributes, beliefs, values, motives, and experiences (Ibarra, 1999; Schein, 1978). The socialisation of professionals in a discipline is a process which involves individuals and collectivities and aims for the development of professional identity of the individuals based on the process of identification with the profession. That professional identity will inspire and guide the professional practice and behaviours. Professions have been characterised by a number of features that contribute to their social identity.

Regulatory issues in psychology: International mobility

Carol Webb United States of America

This presentation will focus on the regulatory issues and barriers to professional mobility for psychologists between countries. As training in psychology moves towards an emphasis on the acquisition and assessment of competencies, and as there becomes more international agreement on how these competencies are acquired and assessed, the possibility of the ability to practise our profession internationally becomes more feasible. Additionally, as the development of electronic means of offering psychological services becomes more sophisticated and widely used, the necessity for internationally agreed upon methods for the regulation of psychology becomes more necessary. Examples of successful mobility efforts for psychologists between jurisdictions, and efforts to regulate the practice of telepsychology will be presented.

Symposium title: Can international agreement on competencies in psychology help to address emerging global challenges

Convenor: Stephen De Mers

Multiple accountabilities of competencies: Preparing psychologists to do what, when, for whom

Karen Cohen Herzlia High School, South Africa

This presentation will address the factors, conditions and considerations necessary to the determination and implementation of competencies for the practice of psychology. I will review what psychologists in Canada are trained to do, what kinds of service they go on to provide, what Canadians need when it comes to psychological service, and then consider the gaps and opportunities between these three important factors. Issues and initiatives relevant to need, demand and supply of psychologists in Canada, in the context of Canada’s health care environment, will be considered.

We need a major shift to bring about change

Tor Hofgaard Norwegian Psychological Association, Norway

In this talk I will focus on how psychology can become a part of the solution to the emerging global challenges. If we don’t find the answer, I will argue we will become a niche profession, interesting only to the very few who can afford it. We must start focusing on society, and the needs of the population. We need to present to the world why psychology is part of the solution, and not how we shall position ourselves to get international recognition. I will argue that to be able to deliver this message, and long before we start addressing stake holders, we need to get better organised. For an organisation to bring about change, it will need a certain representativeness within the group/profession, have the resources to enforce change and the internal structure to mandate the group organisation to work for change. It will also depend on the position in the society in general, the position, inside or outside, the formal structures of society and your competition for power and these competitors internal and external status. In my talk I will stress the need for leaders in the national and international organisations of psychology who have qualifications to build these kinds of organisations. And I will argue that they must integrate society’s needs into the very core of their organisation’s aims, strategies and actions. I will also argue that if they do that people will look to psychology when they address society’s challenges.

Clinical training in India

Ashraf Kagee Stellenbosch University, South Africa; Jason Bantjes; Chrisma Pretorius

South Africa’s National Health Insurance Green Paper and recently published regulations defining the scope of practice of psychologists have brought into sharp focus the need to examine the core competencies of the profession. While internationally the trend is towards the licensure of a single category of psychologist, South Africa has entrenched the division between clinical and counselling psychologists. The newly amended scope of practice is premised on an artificial divide
Clinical training in Australia

Analisé O’Donovan, Griffith University, Australia

The minimum level of training to practice as a fully registered psychologist in Australia is either a 4 year Honours degree plus a 2 year apprenticeship with an eligible clinical psychologist as a supervisor, or a postgraduate degree (either a masters, 2 year), professional doctorate (3-4 year) or a clinical PhD (5+ years) degrees. Currently there are 34 clinical programs in Australia, with at least 400 students graduating every year. In the last few years there have been a number of significant political and professional changes which have started to impact on clinical training. Some of these issues will be discussed to illustrate the changing Australian landscape in relation to clinical psychology training: the increasing push by the professional body towards registered psychologists being required to have postgraduate training; the debates in the profession regarding this push and possible workforce consequences; the limited number of places in postgraduate training courses; the changes to Australian Universities in 2012 with the Bradley reform affecting student numbers and thus university funding. Clinical programs are expensive to run and some universities have started closing postgraduate programs because of cost; the introduction of Medicare (health care) rebates for psychological interventions and the impact this has had on the profession and also on clinical training; the difficulty in getting enough clinical placements; and the potential impact on placements with the introduction of compulsory training for practica supervisors in Australia.

Overview of symposium

Analisé O’Donovan, Griffith University, Australia

Corresponding to the increasing demand for clinical training, there has been much debate about how this training should be conducted, what content should be included, and how the effectiveness of clinicians should be assessed. Although there are many similarities across training programs in different countries, this symposium will highlight the often marked differences with the aim of stimulating discussion of what the issues are facing clinical training, and what we may learn from different approaches to enhance training internationally. The symposium will cover four continents with presentations on training in: South Africa: Professor Ashraf Kagge, Dr Jason Bantjies, and Dr Christia Pretorius (skagge@sun.ac.za and jbatjies@sun.ac.za); USA: Professor Nancy Pachana (n.pachana@psy.uq.edu.au); UK: Dr Helen Beinart (Helen.beinart@chmex.ac.uk); and Australia: Associate Professor Analise O’Donovan (a.odonovan@griffith.edu.au) Discussent: Associate Professor Robert Schweitzer (r.schweitzer@qut.edu.au)

Clinical training in USA

Nancy Pachana, University of Queensland, Australia

The minimum level of training to practice as a psychologist in the USA is a doctoral degree requiring a 4 year undergraduate degree plus a 4 to 6 year doctorate program (either PsyD or PhD). (In Canada there is one province where only a Master’s degree is required, and no PsyD programs are offered by Canadian universities.) All North American graduates of clinical programs sit a national exam administered across USA and Canada in order to be eligible to apply for licensure. Entry into clinical psychology training programs is highly competitive (acceptance rates of 2-5% are not uncommon). Currently there are 217 clinical programs in North America. Main issues that will be considered: Mean debt related to doctoral education in clinical psychology currently exceeds $80,000, according to the 2011 APPIC match survey, and 44% of graduates accrue over $100,000 in debt. An internship year is required for all students. BEFORE the awarding of the postgraduate degree is finalised, and internship sites are not keeping up with demand – in 2011, 3,899 persons applied for clinical internships across the US and Canada and 804 (21%) of persons were unable to be matched to any internship Opportunities to specialise in the USA abound; diplomat status mirrors board certification for medical specialties and include neuropsychology, child psychology and (soon) geropsychology. Curricula competency and outcome based; graduates followed usually throughout their professional life to provide data to the graduating university/program.

Examination for professional practice in psychology: Assessing knowledge and critical thinking

Jacqueline Horn, University of California, Davis, United States of America

This will describe the psychology licensing examination for the United States and Canada and its focus on two important competencies - knowledge and critical thinking. The examination development process and important considerations in that process (practice analysis, standard setting, item development) will be presented.

Current assessment of competency in North America

Emil Rodolfa, University of California Davis, United States of America

This will provide an overview of the current mechanisms (testing, supervised experience, academic preparation) to assess competency for licensure in North America.

Continuing competency: A step to the future

Carol Webb, United States of America

This will explore how psychologists maintain and enhance their competency throughout their careers. This is a significant issue for professional psychology and for psychology licensing boards in order to fulfill their obligations to protect the public. The main focus of this presentation will be to present the empirical and professional basis for a substantially different model of continuing competence and will outline the specific activities that are proposed as a step towards ensuring the maintenance of competence through a professional’s career.

Symposium title: Collaborative efforts to define and assess competency

Convenor: Emil Rodolfa

Collaborative efforts to define foundational and professional competencies

Stephen De Mers, ASPB, United States of America

This will describe the association of psychology regulatory bodies throughout the United States and Canada to collaborate with relevant national and international organisations to identify and measure the foundational and professional competencies in the practice of psychology. This collaboration involves work with large professional associations of psychologists that set training and practice standards such as programme accreditation requirements and ethics codes as well as groups representing academic training councils.

Symposium title: Current models of psychological competencies from around the world

Convenor: Sverre L Nielsen

Development of competencies and competency-based training for psychologists in Australia

Lyn Littlefield, APS, Australia

In line with international trends, competency-based training and assessment of psychologists is gaining momentum in Australia. Models of education and training for psychologists based on the competencies required for general registration and areas of practice endorsement are under development. The Australian Psychological Society (APS) has nine specialist colleges aligned with the nine areas of practice endorsement and has made substantial progress on specifying the core and specialist competencies required for working in the areas of: Clinical, counselling, community, educational and developmental, forensic, health, neuropsychology, organisational and sport psychology. The APS is also developing competencies at various stages of the professional lifespan. This presentation will provide an outline of the progress in specifying competencies for the different categories of psychologists and the development of various education and training models for psychologists to achieve these competencies.
Assessing competence in North America: Problems, principles, procedures
Emil Rodolfa
University of California Davis, United States of America
This presentation will explore current problems in the assessment of competence in North America. It will offer basic principles in the assessment of competence and will describe specific procedures in the assessment of competence. The presentation will highlight the current assessment process used by jurisdictional licensing boards of psychology in the United States and Canada and will conclude by providing a summary of the steps needed to develop mechanisms to better assess competency. Participants will enhance their understanding of problems in assessing competency in the United States and Canadian context. Participants will enhance their understanding of the principles involved to develop an effective process to assess competence. Participants will enhance their understanding of current and future methods to assess competency.

Current modes of psychology competence in sub-Saharan Africa
Ann Watts
Entabeni Hospital, South Africa
Modes of psychology competence vary considerably in sub-Saharan African countries. Psychology benchmarking is generally better developed in English-speaking southern African countries, such as Namibia, South Africa and Zimbabwe, all of which have nationally determined levels of competence and which require a minimum of a Masters level of training. Furthermore, these countries have national regulatory/licensing bodies, and legislation protects the title psychologist and defines psychological acts. In contrast, in many other sub-Saharan African countries psychology is not regarded as an important priority in most universities given the challenges they face such as poverty, disease, natural disasters, civil wars and political unrest. There is thus a need to benchmark education, training, and licensing guidelines. This would assist many of these countries to attain the necessary statutory regulation/licensing for psychology. This will in turn facilitate the development of the discipline, enhance its stature and visibility on the sub-Saharan African continent, and increase its ability to assist underserved communities. Current modes of psychology competence in sub-Saharan Africa will be addressed within this context.

Symposium title: Psychology in Malaysia
Convenor: Chee-Leong Goh
Overview
Chee-Leong Goh
HELP University College, Malaysia
This paper provides an overview of the state of psychology in Malaysia as well as the role it is actively playing in the development of the country. The paper will explore four broad themes: Psychology education, the national psychology association, regulation of the psychology profession and the role of psychology in national development. Firstly, the paper will include data on the number and nature of psychology programs offered among tertiary institutions in Malaysia and the ongoing issues surrounding psychology education in Malaysia including the issue of accreditation and the problem of the "brain drain" on academic resources. Secondly, the paper will address the role played by the Malaysian Psychology Association in developing psychology in Malaysia and the current challenges and crossroads it faces. Thirdly, the paper will discuss efforts to regulate psychology in Malaysia and the various options and models being currently discussed. Lastly, the paper will examine whether psychology has played a significant and relevant role in the development of the country, in areas like human resource development, community development, empowering marginalised communities and the development of a national identity.

Symposium title: The state of psychology in Zimbabwe
Convenor: Gwadirera Javangwe
The practice of psychology in Zimbabwe
Gwadirera Javangwe
University of Zimbabwe, Zimbabwe
The paper documents the current status of psychological training, practice and regulation in Zimbabwe. Special emphasis will be placed on the gaps inherent in the teaching, training and licensing of psychologists in Zimbabwe. The paper concludes by illustrating the national road map, and how regional integration and international collaboration can instrumentally assist Zimbabwe in this field.

Human-technology interface: Impressions of the elderly
N.K. Chadha University of Delhi, India

The present study is a research oriented qualitative effort directed towards accomplishing an understand-
ing of an interface between man and technology, through the eyes and experiences of the elderly re-
siding in India. An attempt is made to explore the dimensions of availability, awareness and use of
technology among elderly males and females. For
the purpose of exploration, two focused group dis-
cussions were conducted (FG1 N=8 and FG2 N=10)
in separate sessions and videotaped for the purpose
of analysis and referencing. The content was analyzed
employing a deductive approach to thematic analysis,
where an effort was made to identify themes, revolv-
ing around the nucleus of human-technology inter-
face. Openness to the new, threats following misuse,
experience of vulnerability, cherished past and an
overload of present, functions associated with useabil-
ity and a positive outlook for change were the crucial
and critical themes captured in the study.

Personality and relational characteristics of elders, caregivers and family members and life satisfaction
Donata Francescato La Sapienza Rome Italy; Italy; Manuela Tomai; Tina Pezzuti; Maura Benedetti;
Minou Mebane

The enormous increase in the number of elderly people - in western nations, has stimulated much
discussion on how old people’s wellbeing can best be
promoted and how caregivers’ burdens can be
decreased. Some authors maintain that people over
70 have to remain mentally and physically active and
cultivate some specific personality characteristics such
as sense of humour, self-efficacy in dealing with both
positive and negative emotions and an appreciation of
the positive aspects of solitude. Other authors hypothesise that elders’ positive relationships with
family, friends and paid caregivers may play a major
role in promoting satisfaction with life for all people
involved. Few studies, however, have actually inves-
tigated both personality characteristics of elderly peo-
ple, paid caregivers and relatives, and how positive or
negative relationships affect their wellbeing. Our
study aims to explore the relative weight of person-
ality variables, and the quality of relationships among
caregivers, elderly people and relatives on their life
satisfaction and sense of empowerment. We have
given personality tests and interviewed 300 Italian
eiders aged 70 to 101, their 150 paid caregivers (aged
23 to 63), and of 450 relatives actively present in the
life of the target elders (aged 27 to 69), including 150
grandchildren (aged 17 to 50). Data analysis is under
way. Results will be presented at the conference.

Quality of life, depression and spirituality in older adults
Ana Gonzalez-Celis University National of Mexico, Mexico; Ruiz Edgardo; Tron Rocío; Chavez Marga-
rita

The quality of life (QoL) is an object of study of
psychology, as a central component of well-being.
The QoL in the elderly is especially relevant be-
cause as the years go by there are losses and gains,
including health, financial and family situation. The
purpose of this study was to evaluate the impact of
psychological variables associated with QoL of
elderly Mexicans. A sample of 75 elderly people
between 60 and 87 years (Mean = 65, SD= 9.41),
45 women and 30 men attendees at a health clinic.
CV was measured with the WHOQoL, three groups
were formed by the level of depressive symptoms
obtained with the GDS: (G1) absent (n1=42), (G2),
mild (n2 = 19) and (G3) moderate-severe (n3 = 14).
We found an acceptable correlation between QoL
and spirituality (r = 0.523, p <0.001). A negative
association between QoL and depression (r = -.482, p <0.001). The QoL showed differences be-
tween groups with different levels of depressive
symptoms (F 2,72 = 15.212, p <0.001). The QoL
showed differences between diseased subjects (QoL = 61.19) and healthy subjects (QoL = 66.61) (t =0.205, p <046). There were differences in spiritu-
tality (S) among elderly patients(S=64.77) and
non-ill elderly (S = 75.0) (t = 2.37, df = 97, p <0.2).
The QoL in the elderly can improve with psycho-
logical interventions to reduce depression, where
spirituality can be a resource and coping strategy
to strengthen other areas of aging.

Psychosocial experiences of coloured grand-
mothers who care for their grandchildren:
Implications for intergenerational relations
Herman Grobler North-West University, South Afri-
ca; Vera Roos

Due to major social changes like migration, HIV
and AIDS grandmothers take on the role of primary
caregivers of grandchildren. The goal of this study
was to explore the psychosocial experiences of
colored grandmothers who care for their grandchild-
dren. Twelve participants from the Groenheuwel
community in Paarl, South Africa, were selected
and participated in a reflective group discussion
during which the Mmogo-methodTM was applied.
The meanings of the visual representations were
used as textual data, and both the textual and the
visual data were analysed through thematic analy-
sis. Three main themes emerged from the findings:
Challenges associated with caring for grandchild-
dren, coping with challenges associated with caring
for grandchildren and implications for intergenera-
tional relationships. Grandmothers experienced sig-
nificant stress, either emotionally or physically in
raising their grandchildren. The support they re-
cieve from community members and peers and the
existential meaning that they give to their respon-
sibility of caring for their grandchildren, provide
them with intra- and interpersonal coping strategies
to deal with the challenges. Grandmothers experi-
ence the relationship with their grandchildren amb-
vivalently. On the one hand they have positive
emotions in relation to their grandchildren, but on
the other hand they expressed negative perceptions
towards their grandchildren. The current intergen-
erational relationships compared with previous in-
tergenerational relationships and the nostalgia they
experience in relation to the previous relationships
inform the intergenerational relational context.
The ambivalent nature of the intergenera-
tional relationships have implications for the con-
tinuous interactions between grandmothers and
grandchildren and for future supportive relation-
ships.

Intergenerational relationships in South Afri-
ca: Differential gazes and negotiated spaces.
Jaco Hoffman University of Oxford, United Kingdom

With more than 5.4 million people living with
AIDS in South Africa, and an estimated 1.2 million
HIV/AIDS orphans – a figure predicted to rise to
2.3 million by 2020 - many grandparents act as
carers for their infected children and/or as surrogate
parents to their (orphaned) grandchildren. An esti-
imated 60% of HIV/AIDS-orphaned children live in
such grandparent-headed multi-generational net-
works. Based on 58 narratives of different genera-
tions (generational sequential approach) in 20
multi-generational networks, this contribution qual-
atively explores the ambiguous nature of these
relationships in Mpumalanga, South Africa. Al-
though the distinctive historical and genealogical
positioning of these respective generations has the
potential to bring them in outright opposition to
each other, it also presents the possibility for nego-
tiation and learning from each other. Such a possi-
bility to continuously re-conceptualise, reconfigure
and regenerate these relationships is dependent on
the differential positions and subsequent “gazes” of
the respective generations. It is found that older
generations are motivated from the prescribed norm
of duty, in spite of the limited capacity available.
Juxtaposed to this, younger generations, on their
part, are strongly guided by the pragmatics of a
hierarchy of priorities and available capacity.

Exploring older people’s experiences of lone-
liness in institutional settings: The impor-
tance of context for effective interpersonal
relations
Lelanie Malan (Kriek) North-West University, South Afri-
ca; Vera Roos

Existing literature confirms that older persons who
experience loneliness are more prone to depression
when living in institutional facilities. The purpose
of this study is to explore older people’s experi-
ences of loneliness in the context of an institutional
setting. Data were gathered by means of the
Mmogo-method which assisted an exploration of
the underlying subjective experiences of loneliness
and Graphic Family Sculpting, which was used to
explore the interpersonal interactions among 10
white male (3) and female (7) South African older
people, aged between 62 and 82 years. The data
were analysed by using thematic and visual analy-
ysis, as well as key words in context. Preliminary
results indicated most of the findings about loneli-
ness of older people in institutionalised settings are
confirmed in literature. However, in this particular
context, it was found that the social contexts, where
interactions are taking place, are experi-
enced as unsafe, due to sensitive information being
revealed to management, which prevents effective
and meaningful interactions between people who
are functioning in close proximity to one another.
Participants’ fear to become transparent, and they
do not receive unconditional acceptance, empathy,
and confirmation, and they cannot express their
needs to have meaningful interactions with co-
residents. The context in which interpersonal inter-

actions takes place, determines the quality of the interactions and if loneliness has to be addressed effectively, more emphasis should be placed on creating a social context in institutions that will promote more effective interactions among the older people in the institutionalised setting.

The elderly and technology: Perceptions and potential barriers
Shraddha Mathur University of Delhi, India

The research problem was: (1) to study the perceptions of technology and explore the differences, if any, among the various criterion groups of the elderly and (2) to study the barriers to technology and explore the differences, if any, among the various criterion groups of the elderly. The sample was 750 elderly participants from the National Capital Region of India. The pilot study was conducted and interviews with the elderly participants were undertaken. The findings from the pilot study were used to create a questionnaire regarding the perceptions and barriers on technology on a five-point rating scale. Criterion groups of elderly were classified on the basis of age, gender and living arrangement. Descriptive statistics, t test and F test (one way ANOVA) were calculated. Significant differences were observed between criterion groups on their perception towards technology in the areas relating to usefulness/assistance of technology, stress as an outcome of modern technology and on the role of education in promoting technology use. Significant differences were observed between criterion groups with regard to the barriers that they experience in the areas relating to complex/difficult everyday life, the challenges of using sophisticated technological appliances and growing age affecting technology use. The elderly perceive technology as difficult to use; however, they also find it useful. They were also observed being sensitive to the role education plays in making individuals aware and adapt in using technology. The elderly are seen as receptive to new technology and aware of the challenges of constant technological change.

Prevalence incidence and symptom severity of mental disorders in the elderly in Europe
Manuel Munoz Universidad Complutense Madrid, Spain

Reliable data on the prevalence and incidence of mental disorders in older people are currently lacking for the European Union. Furthermore, there are no cross-national studies investigating the interaction of mental disorders, the impairment and the utilisation of services of older people in Europe. The objectives of the present study are to (1) develop, respectively to adapt existing instruments and (2) to collect data on the prevalence, the incidence and on the natural course and prognosis of mental disorders, across different European countries and the use of services by the older population in Europe. The present communication exposes the methodology of a multi-centre epidemiological survey in selected catchment areas in different European countries and associated states (Germany, Switzerland, Italy, Spain, Great Britain and Israel). The study includes a pilot phase and two sampling waves. For the study some mental health and functioning assessment instruments will be adapted to older people (e.g. a new CIDH version). The lifetime and 1-year cross-sectional prevalence of mental disorders, the level of utilisation of services and their associated factors such as symptom severity and prior course, quality of life and the degree of impairment of activities and participation will be assessed. The study includes a 1-year follow-up in order to examine the incidence and to describe the 1-year natural course. Results will help to change health care in direct contact with people, and beyond this, they offer starting points for structural changes initiated on the level of health politics.

Marital idealisation between older husbands and wives over time
Norm O’Rourke Simon Fraser University, Canada

Marital idealisation is defined as an interpersonal mode of self-deception by which one conveys an exceedingly positive portrayal of his/her spouse and marriage. This phenomenon entails a propensity to discount negative interpersonal perceptions and experience (e.g., ‘If my spouse has any faults, I am not aware of them’, ‘My spouse has never made me angry’). Marital idealisation is not significantly associated with purposeful distortion (i.e., impression management). In other words, these spouses credibly hold idealised beliefs and perceptions however implausible to the outside observer. In previous research, marital idealisation has emerged as a predictor of marital satisfaction among spouses undergoing treatment for alcoholism and as a significant buffer to distress among caregivers of persons with Alzheimer disease. Also, idealised depictions of deceased husbands are associated with adaptation to widowhood, and marital idealisation predicts the physical well-being of older married adults in both cross-sectional and longitudinal studies. The current study examines this construct within older couples at four points over a three year period. Over three months, cross-legged effects are noted; more precisely, idealization by husbands predicts their wives’ idealisation of them and vice versa (controlling for marital idealisation previously measured). Also of note, wives’ idealisation predicts their husbands’ idealization two years later; the corollary was not observed for husbands. These findings may explain why older men appear to garner more emotional sustenance from marriage than their wives. Future research should attempt to replicate these findings with younger and same-sex couples to ascertain if this is a sex-specific or cohort effect.

Comparison of happiness and its components in different levels of religious attitude
Elita Peymanfar Payame Noor University, Islamic Republic of Iran; Mahnaz Aliakbari Dehkordi

Research has shown that religious influences reduce the problems of the elderly, but few studies have discussed the role of religion and religious attitudes on positive emotions such as happiness, especially during aging. This study investigates the role of happiness and religious components in the lives of the elderly. The study used a comparative research design, and the sample consisted of 221 persons (81 women and 140 men) over 60 years of age. A random cluster sampling method was used. The Oxford’s Happiness Questionnaire and Khodayari Fard’s Religious Attitude questionnaires were used as instruments in this study. The results of multivariate analysis of variance and the LSD following method showed that elderly people with stronger levels of religious attitude felt happier (p<0.05). Also, there is significant difference between levels of religious attitudes in the three components of happiness; life satisfaction, self-esteem and self-satisfaction (p<0.05). Since the religious attitude of positive emotions has a positive role in the elderly, we recommend that authorities do proper planning to strengthen religious beliefs of the elderly. Additionally, the results of this study suggest that the medical communities, as well as psychiatrists, pay special attention to the issue of religion in the mental and physical health of the elderly.

Physical and psychological profile of the aged and their coping strategies
Bir Priya University of Delhi, India

While population aging represents a human success story, it also poses myriad challenges to the individual and the social institutions that must adapt to a changing age structure. Old age poses a particular moment in one’s life when not only physical and sensory-motor conditions decline but more specifically one is confronted with multiple social and psychological challenges. Questions as to the possibility of a healthy and enjoyable old age often involve successful meeting of psychological demands and adjustment to different and difficult conditions of living. In spite of wide spread interest in studying the coping behavior of the elderly, the main focus has been to study the quantitative changes in strategies utilized by the elderly. The present study aims to make a physical and psychological profile of the aged and understand the various coping strategies used by them. The variables studied are health ailments, perceived health (self-rated), mental health, social support, attitude towards old age, and household decision making-powers.

The therapeutic benefits of an indoor garden installation in residential aged-care facilities
Theresa Scott University of Queensland, Australia; Nancy Pachana; Barbara Masser

Plants and gardens are vital elements in human wellbeing – they meet an essential human need. According to biophilia theory (Wilson, 1984), people have an innate bond with the natural world and an in-built positive response to nature. Prior research has demonstrated that mere observation of nature has physiological and psychological healing benefits (Ulrich, 1984). This study aimed to determine whether implementing positive changes (related to nature) to the physical environment of aged-care facilities, had an impact upon the wellbeing of the residents. Specifically this research examined the effect of an indoor simulated garden installation, which included visual, auditory and olfactory stimuli and seating, on the emotional and social well-being of residents, compared to a reminiscence-based installation and a control no installation condition. A quasi-experimental, ABA design was used; two intervention conditions, plus a wait-list control condition. A questionnaire was administered to residents pre-, during- and post-intervention, which included several standardised scales related to mood, health, and social interaction adapted for the study; a measure of social engagement, and observational measurement of use of
space. Additionally staff reports were collected. It was found that being around plants led to increased well-being for residents because of the plants’ aesthetic appeal and by providing opportunities for shared reminiscence and social exchange. An indoor garden installation is a relatively inexpensive way to transform a disused indoor area of an aged-care facility for the benefit of residents.

A qualitative study on the adjustment to ageing through the eyes of older adults
Sofia Von Humboldt; Isabel Leal
This research aims to analyse the main contributors that older adults recognised as being a determinant of their adjustment to ageing. Information was gathered by a research tool composed of two parts: (a) a demographic questionnaire and (b) a qualitative semi-structured interview in which subjects replied to open-ended questions about their adjustment to ageing in one specific period in their lives: today. Interview transcripts were subjected to content analysis. The research sample comprised thirty-three elderly people between the ages of 74–100, from eight different nationalities and distinct cultural backgrounds. Results yielded a set of seven descriptive categories that captured the distinct ways older adults acknowledged life satisfaction and that reflected the individual’s attitudes towards successful ageing. Adjustment to ageing was found to be associated with an increased likelihood of reporting specific themes in its definition. Recommendations for future research on older adults’ life satisfaction and clinical practice are also presented.

Session Type: Posters

Personalty and cognitive level in patients at an early stage of Alzheimer’s disease
Pocnet Cornelia; Jérôme Rossiur; Jean-Philippe Antoniett; Armin von Gunten
In this cross-sectional study, we explored the relationship between premorbid personality and its changes over five years as well as cognitive deterioration in patients with mild Alzheimer’s disease. The cognitive level of 54 patients was compared with that of 64 control subjects using the Mini Mental State (MMSE). Family members completed the NEO-PI-R (form R) twice, once to evaluate the participants’ current personality and again to assess personality traits as they were remembered to be five years earlier. Furthermore, the family filled in the Informant Questionnaire on Cognitive Decline (IQCDE), the Activities of Daily Living (ADL), and the Instrumental Activities of Daily Living (IADL) scales to assess their proxies’ cognitive level and daily living functioning. Regarding the relationship between personality characteristics and cognitive status, we observed trends for premorbid personality and significant links for personality changes in the clinical group. Thus, changes in neuroticism and conscientiousness were associated with cognitive deterioration, whereas decreased openness to experience and conscientiousness over time predicted a loss of independence in daily functioning in the clinical group. Our study suggests that premorbid features can be considered as latent traits linked to the neuropathology underlying the disease process, while personality changes are probably the consequences of the pathologica process.

Life quality, well-being and spirituality of rural and urban senior citizens
Adriana Correia; Isabel Leal
The main objective of this research was to compare the quality of life, well-being and spirituality of senior citizens from both rural and urban areas, while trying to find out how the presented variables would relate to each other. In this study, which compared two groups, 62 participants (31 were from the village of Arelio while the other 31 were from Lisbon), who were about 60 years old or older, were evaluated using the following measures: Sample Characterisation Questionnaire, WHOQOL-bref, Philadelphia Geriatric Morale Scale and Spirituality in Health Contexts Scale. There were no significant differences found, in the evaluated variables, between the rural and urban groups except in two domains which referred to the quality of life: The rural group is more satisfied with their surroundings and with their personal relationships than the urban group. These data can be explained by the specific characteristics of the rural area, which this study considered as more facilitating than those of the urban area. These characteristics favour a stronger interaction and contact between the populations of the rural community, which can explain their greater satisfaction with their personal relationships. There were correlations found between the quality of life, well-being and spirituality. It was observed that spirituality could influence positively the quality of life and well-being, fomenting positive thoughts like hope and optimism. Simultaneously, the more life is perceived as being good and pleasant, the better the well-being of the elderly.

Exploring quality of life of older persons: A relational perspective
Lizanle De Jager; Vera Roos
Many studies concerned with Quality of Life (QoL) for older people have found that relationships, among many other constructs, have an influence on the way older people perceive the quality of their lives. The purpose of this study was to explore to the QoL of older persons in terms of their relational experiences. QoL refers to the livability of an environment, the life-ability of a person, the utility of life and the appreciation of life measured against life changes. This falls within the positive psychological framework. The relational network of older persons seems to get smaller as people age. It is, however, not clear how older persons’ relational experiences shape their subjective experiences of their quality of life. The study was qualitative in design, allowing the researcher to gather information and investigate the phenomenon within the actual environment in which the older person resides. An inductive exploratory study was conducted to gather information on specific relationships of importance to older persons and the roles fulfilled by these relationships and how this contributed to experiencing QoL. Data were analysed through content analysis allowing the researcher to determine specific themes. Qualitative data was gathered by means of individuals interviews, focus groups, journals and by making use of the Mnogo-method. Provisional trends and findings will be discussed highlighting the importance of positive relations in promoting the QoL of older persons.

Quality of life in different age cohorts of older persons in South Africa
Lizanle De Jager; Vera Roos
Evidence exists that a person’s construction of Quality of Life (QoL) changes as the older person becomes. Limited resources were found with a specific focus on QoL and how it is subjectively experienced by older persons of various ages. The purpose of this qualitative inquiry was to explore how QoL is subjectively experienced in ‘younger’ and ‘older’ old people and to describe the different components that construct QoL for them. Qualitative data was gathered by means of individual interviews, focus groups, journals and the Mnogo-method. The research problem was addressed from a positive and developmental psychology perspective. A qualitative exploratory and comparative design was used; comparative studies focus on the similarities and differences between groups. Interpretative Phenomenological Analysis (IPA) was used for analysis. Line-by-line analysis occurred; a dialogue was developed, followed by the construction of themes. Provisional findings will be discussed. This study forms part of a PhD. Comprehensive results will be available in March 2012. Based on analysis of individual interviews, dissimilar value systems seem to have an impact on the way QoL is constructed for individuals. Decreases in energy and health for the ‘older’ cohort, have an influence on the way they construct QoL. Financial concerns and social constraints were prominent indicators having an influence on QoL in both cohorts.

Aging: Pain or pleasure?
Brenda Hattingh
Our quality of life is a conscious choice. This research was done in five retirement centres in South Africa in order to determine the factors that influence the quality of life of our aging population. Three retirement centres in financially affluent suburbs and two centres situated in less affluent areas were included in the research. The research comprised personal interviews and questionnaires used in group sessions. Approximately 280 persons aged 65 to 93 took part. The following five factors were found to be common amongst all aging people, irrespective of their age, financial income, area or retirement centre they lived in: boredom, negativity, insecurity, ignorance and fear. The alternative choices of: adventure, productivity, faith, love and freedom, were introduced through workshops and follow up discussions. The outcome revealed that those aged persons who had a positive disposition towards life, were open to new suggestions and development programs. It was also found that those persons with inherent negativity and unresolved psychological issues, found it more difficult to heal these issues while their negativity became more acute. Life expectancy is increasing and our demographics will be including more senior citizens in the future. However, the subject of psychogerontology does not yet receive the recognition it deserves. This is creating new personal, professional and
community challenges while a wide variety of untapped potential is being lost. This calls for a new awareness and intervention on a global scale.

The effectiveness of a community-based life goal pursuit programme for preventing depression in older adults

Nahoko Kusaka, Doshisha Women’s College, Japan; Shinko Tokutsu

A goal-directed programme, based on cognitive-behavioural therapy, was offered to older adults with the objective of improving their psychological well-being and preventing depression. The participants, aged 65 to 80, were assigned to an intervention group (n=13) and a control group (n=20).

Assessments were performed both before and after the intervention, along with a follow-up comparison six months later using the Meaning in Life Questionnaire (MLQ), the Herth Hope Scale (HHS), Ryff’s psychological well-being indicators, the SDS (Zung Self-Rating Depression Scale, 1965) and the Self-efficacy in preventing depression test (pre-test, post-test, and follow-up test, respectively). In order to analyse our hypothesis, which predicted that the intervention groups would improve more than the control group, mixed-effects models, fixed for treatment time and groups, were fitted to assessment scores. The intervention groups had significant improvement with regard to time as compared to those in the control group on all subscales in MLQ, HHS, Ryff’s psychological well-being indicators, SDS, and the self-efficacy in preventing depression test. Single-effects analyses with the Bonferroni Test indicated that there were no changes between each testing point in the control group. There were significant differences between the pre- and post-test results in the intervention group. The findings of this study showed that the programmes improved the levels of psychological well-being and self-efficacy in preventing depression. Implications for the effectiveness of the programme on making participants’ lives “wonderful” will be discussed.

Older adults in isolation in Madrid: Six years’ experience of support

Manuel Munoz, Universidad Complutense Madrid, Spain

This study presents the service of psychological support to fragile elders with social isolation in Madrid (SPS). The aim of this service is to acquire an approach of persons with clear risk of social isolation, which allows leading these situations to normalisation, assigning social opportunite resources in every case, and even facilitating involuntary internment, and considering the legal incapacitation at the end. The SPS follows a strategy of outreach, home-based, community interventions and case management, in order to link this isolated population with social and health services. Engagement, assessment and intervention protocols are used. Of the total of 165 old people in social isolation who have been attended by SPS in the past 6 years, 123 cases were closed by the intervention of SPS. Most are women, single or widowed, childless, living alone and with a mean age of 81.01 years. Mental disorder is detected in more than half of this population. They have a very high number of unmet needs and very difficult living conditions. The present applied investigation has revealed the need to have professionals trained in psychological strategies of outreach, engagement and treatment that should allow an approach, with certain guarantees, to the problems of this group. The information indicates that interventions with this type of population need a long duration, with interventions to medium and long term (between 1 and 43 months).

Bidirectional causality between contact between grandparents with grandchildren and grandparents’ identity

Jun Nakahara, Osaka University, Japan

The causal relationship between the contact between grandparents with grandchildren and grandparents’ identity has been interpreted from the perspective of symbolic interaction theory (SIT). SIT suggests the following implications: First, when a person internalises a positional designation, owing to the interactions in role relationships, a role identity is formed. Second, the maintenance of positive role identity is an important motive for an individual selecting an action. In other words, SIT hypothesises bidirectional causality between contact of grandparents with grandchildren and grandparents’ identity. This study aims to explore the bidirectional causality. Two surveys were conducted with elderly people (n=311) over 60 years of age, belonging to the center for lifetime study. The 2nd wave (7-8/2011) was conducted around one year after the 1st wave (7-8/2010). The participants who had grandchildren and responded to both the surveys were included in this study. The result of the modeling analysis of the cross-lagged effects was conducted using the longitudinal data in the 1st and 2nd waves. This showed that while the frequency of contact with grandchildren in the 1st wave determined grandparent identity in the 2nd wave, grandparent identity in the 1st wave did not determine the frequency of contact with grandchildren in the 2nd wave. This result confirms the first implication, but not the second one. The finding indicates that the more there is interaction between grandparent and their grandchildren, the more positive is the grandparents’ identity, but that positive grandparent identity might not be a motive for role-related interactions.

Subjective age and well-being among the Japanese elderly

Aya Toyoshima, Osaka University, Japan; Yuki Obara, Hirohiko Hirono, Kiyoshi Hibiya, Yasuyuki Gondo, Taketo Furuna, Shinichi Sato, Aki Shimanouchi, Shuichiro Watanabe

Formerly, “Self-youth” phenomenon, that the subjective age is younger than chronological age, has been picked up in the field of social gerontology. Especially, the tendency of “Self-youth” among elderly people has been considered, in particular that it was influenced by negative stereotype about ageing. (Markides & Boldt 1983). However, we think that younger self identification among them is more an adaptive phenomenon to maintain their everyday life. In this study, we measured 3 kinds of subjective ages on the middle aged and the elderly, such as Feel Age, Physical Age and Brain Age. We hypothesised that these subjective ages would have some relationships with their well-being. We conducted a questionnaire including WHO-5 as a scale measuring well-being and 3 variables of subjective ages for Japanese, 244 middle-aged, 263 young-old and 104 old-old people. Correlations of these 3 variables of subjective ages with WHO-5 were significant. Feel Age and Physical Age showed a medium level of correlations with WHO-5. But the correlation between Brain Age and WHO-5 was lower than Feel Age and Physical Age. A result of multiple regression analysis for WHO-5 as a dependent variable showed that Feel Age and Physical Age had significant regression coefficients. However, Brain Age had significant but only low level effects. These results may indicate that Feel Age is related to Physical Age more than Brain Age. We think that physical strength may be a more important factor than a cognitive factor for peoples’ feeling of younger identity and well-being.

An auto-ethnographic study of a young woman’s relational experiences of older persons

Janine Van Aardt, North West University, South Africa

People are embedded in social networks, including family, friends and the broader community. The aim of this study is to explore the relational experiences of a young woman and older persons in the different social networks in which she functions. An auto-ethnographic research design was used, which is a self-narrative method focusing on the understanding of the self, others and the culture. The participant is a 22-year-old female and her social networks can be described as multi-racial (Indian, White and Coloured) and multi-lingual (Afrikaans, English and Hindi). Data were gathered by means of a personal journal as well as the Mmogo-method™. The journal was completed by means of open-ended questions reflecting the experiences of the younger woman’s relationship with older persons. The Mmogo-method™ is regarded as a visual data gathering method, consisting of clay, beads and straws which are used to make visual constructions, which are regarded as projections. Data were analysed by means of thematic analysis. The findings revealed that the young woman’s community networks which consist of different social networks, varying in their levels of closeness and with different motivations for their involvement with one another, formed her understanding of relationships. In these diverse relational networks she developed respect for diversity irrespective of race and age. She developed sensitivity and adaptability towards older persons in various social and cultural contexts. In conclusion, being exposed to diverse relational networks contributed to her ability to interact empathetically to people across different cultures.

Nonagenarian longitudinal study of active ageing

Maria Dolores Zamarron, Autonoma University of Madrid, Spain; Rocío Schettini; Angeles Molina; Maria Lopez; Marina Munoz

The objective of this study was to analyse the main determinants of active nonagenarian ageing. A sample of 188 independent individuals older than 90 years (mean age: 92.9; 67 men and 121 women) living in “the community” (N=76) or in residences (N=112), were assessed through the European Survey on Aging Protocol (ESAP) by collecting an-
thropometric, health, life styles, psychological and social data. A year after the baseline evaluation 104 individuals were re-assessed (42 men and 62 women). Mean age 93.3 (range: 91–103). Active Ageing classifying criteria was as follow: Satisfied or very satisfied with life, have a good or very good perception of health, functional and cognitive capacities preserved. A regression analysis was carried out to predict which factor, evaluated on the baseline, explain a year later subject active ageing. Hearing capacity, associative learning and productive activity, were the active ageing nonagenarian strongest determinants. Physical, cognitive and productive factors predict active ageing in the very old individuals.
Research Area: Psychopharmacology

Session Type: Papers

The association between the oxytocin receptor gene (OXTR) polymorphism and trait empathy, as measured by the Interpersonal Reactivity Index (IRI)
Zhi Li Peking University, China; Nan Wu; Yanjie Su
Oxytocin exerts well accepted effects on one of the key social process: empathy. Previous researchers have demonstrated that oxytocin promotes emotional and cognitive aspects of empathy, by exogenous administration as well as on gene level. However, the effect of diverse gene locus haplotypes of oxytocin receptor gene (OXTR) on trait empathy lacks reliable evidence. The current research aimed at manifesting the OXTR effect on trait empathy on several gene locus haplotypes. Participants consisted of 101 genetically unrelated, non-clinical Chinese college students (46 males and 55 females). Interpersonal Reactivity Index was applied to measure the trait empathy from four dimensions: empathy concern, personal distress, perspective taking and fantasy. Fantasy and perspective taking measured cognitive aspects of empathy. Four single tagging SNPs on OXTR, rs237887, rs4686302, rs53576 and rs1042778 were tested. Genotype difference on perspective taking was found on rs237887 and rs4686302 whereas personal distress varied between rs237887 homozygous and variant carriers. On cognitive aspects, there is a genotype difference on rs4686302. The findings demonstrate that natural variants of OXTR are associated with trait empathy.

Meeting the underserved psychopharmacological needs of children and adolescents in the United States
Mary Sa Cambridge Medical Center, United States of America
There is a shortage of psychiatrists available in the United States to meet the mental health needs of children and adolescents. The under-supply of practitioners has resulted in children receiving inadequate care from mental health professionals and primary care physicians who lack the necessary training. There are about 7,000 pediatric psychiatrists practicing in the U.S. (AMA, 2009). However, according to the Surgeon General’s report from 1999, there were approximately 15 million children in the U.S. with mental health disorders and about 20 percent of them were receiving mental health services. Of that 20 percent, only a small portion were receiving care by pediatric psychiatrists. The population of children in the U.S. is projected to grow by more than 40 percent in the next 50 years to more than 100 million (U.S. Bureau of the Census, 2000). The demand for child and adolescent psychiatry is projected to increase by 100 percent by 2020 (U.S. Bureau of Health Professions, DHHS, 2000). One effective solution is to train psychologists to bridge the children’s mental health service gap by (1) providing consultation to primary care physicians and pediatricians and (2) licensing appropriately trained psychologists to prescribe psychotropics directly. This presentation will discuss both models taken from the presenter’s personal experience of practicing as a licensed prescribing psychologist and in collaborative practice with pediatrics and primary care providers. The future role of prescribing psychologists (RxP) as part of a new model of care will be discussed.

Prescribing psychologists in primary care
Steven Tulkin CA School of Professional Psychology, United States of America
The integration of mental and behavioural health into primary care has the potential to bring about significant improvement in primary, secondary and tertiary prevention. From the basic issue of how to increase acceptance and adherence to medical and behavioral protocols to the more complex issues of diagnosis and treatment of mental disorders, the integration of psychologists on primary care treatment teams represents a paradigm shift in health care. For psychologists to provide comprehensive care, they should be trained in the full range of biopsychosocial assessments and treatments, including prescription authority. Shortages of psychiatrists are increasing and primary care physicians do not have training in differential diagnosis of mental and behavioral disorders, or in the motivational interviewing techniques that can increase behavioral adherence. This presentation will provide examples of the work of prescribing psychologists in primary care settings, describing the scope of their work, along with illustrative clinical cases. Issues related to the process of system change and impediments to acceptance of prescribing psychologists will also be discussed.

Session Type: Posters

A common allele in the oxytocin receptor gene contribute to empathy and prosocial behaviour
Nan Wu Peking University, China; Zhi Li; Yanjie Su
The prosocial neuropeptides Oxytocin (OT) has an increasingly accepted relationship with personal generosity and charitable giving. A common variant (rs53576) in the Oxytocin receptor gene (OXTR) has been implicated in various social-behavioural phenotypes. However, the mechanism of Oxytocin promoting prosocial behaviour as well as Oxytocin situational specific effect remains unclear. We hypothesised that the empathy serves as mediator between Oxytocin and prosocial behaviours in diverse social situations. Therefore we manipulated the ingroup/outgroup contexts by priming Chinese and Japanese cultures and figures, both of which are collectivist. The current study aimed to examine how rs53576 variance contributes to empathy and prosocial behavior in different social contexts. 101 college students (46 males, 55 females, M=22.50y, SD=2.279) were genotyped of OXTR rs53576 and assessed with Reading the Mind in the Eyes Task (RMET), which assesses capability of affective mental inferences. The Public Good Games measure reciprocating cooperation of participants. We found a significant two-way interaction of priming context and genotype on RMET, such that individual with GG genotype under Japanese culture priming performed better with regard to empathy ability. The same interaction of genotype and priming contexts also existed in Public Good games, data analysis showed individuals with GG genotype contributed more in Public Good games than individuals with AA/AG genotype only in a Chinese culture priming context. The present finding provides further evidence that Oxytocin motivates in-group favouritism only for people with a certain genotype.

Session Type: Invited Addresses

Psychopharmacology and the evolution of primary care psychology
Morgan Sammons CA School of Professional Psychology, United States of America
This presentation will discuss the acquisition of prescriptive authority for psychologists as an integral component of the evolution of psychology into a primary care specialty. A history of the movement to obtain prescriptive authority by psychologists will be provided, along with a history and current status of psychologists’ involvement in primary care. The presenter will then outline specific competencies required for the successful integration of psychology into the primary care arena, and will suggest changes to the educational curriculum for doctoral level psychologists, including more specific training in psycho-pharmacology, to enable psychologists to prepare for new roles in the primary care environment. The presenter will also reference his experience as a prescribing psychologist who has worked in the primary care environment for a number of years. He is responsible for devising curricula needed to train psychologists in both psycho-pharmacology and the primary care environment. He has established training protocols for psychologists entering the primary care environment. He lectures and writes extensively on the issues of prescriptive authority and primary care psychology. Learning objectives (1) Attendees will understand the history of prescriptive authority for psychologists. (2) Attendees will gain an appreciation of the need for the integration of education in psycho-pharmacology in order to prepare psychologists for work in the primary care environment. (3) Attendees will understand specific knowledge-based and training competencies required for work in the primary care environment.

Session Type: Invited Symposium

Symposium title: Alcohol use disorders and behaviour change: Research advances from behavioural neuroscience to public health
Convener: J. Bruce Overmier
Brain-body mechanisms of emotional regulation and a novel approach to increase behavioural flexibility towards alcohol
Marsha E. Bates Rutgers University, United States of America
The desire to enhance positive emotion and reduce negative emotion is a primary motivation for alcohol use. Persons who are less efficient at regulating emotional arousal are vulnerable to the coping use of alcohol. Alcohol intoxication then further interrupts neurophysiological connections that support emotional regulation, and impairs the cognitive control of alcohol use behaviours. This presentation describes a brain-body system that helps regulate
emotional response to challenges and behavioural flexibility. This system’s function can be enhanced through empirically-supported biofeedback techniques that could be implemented cost-effectively on broad scale to enhance physiological modulation of arousal and reduce emotion-focused coping use.

Brain mechanisms of behavioural changes promoting relapse in alcohol dependent individuals with repeated detoxifications

Theodora Duka University of Sussex, United Kingdom

This presentation describes how alcoholic patients, as they experience more detoxifications and their alcohol dependence increases, show withdrawal-induced impairment in prefrontal subfields and inability to perform a task that captures two of the basic features of addictive behaviour – cue-induced motivation to seek a reward, and failure to inhibit such motivation when reward seeking is inappropriate. Furthermore, under emotional challenge, multiple detoxified alcoholics show an increase in integration of neural networks in sub-cortical regions, underlying a bottom up emotional input. These changes may confer inability in conflict resolution and increased sensitivity to stress, both of which may contribute to relapse.

Cognitive capacity and its impact on behaviour in alcoholics

Sara Jo Nixon University of Florida, United States of America

Detoxified alcoholics often exhibit deficits across a wide-range of cognitive tasks, ranging from neurophysiological aberrations to the inability to solve impersonal and interpersonal problems in real-world settings. These deficits are typically subtle and therefore often unrecognised and/or underappreciated by employers, primary care/mental health providers, friends and family. The failure to recognise these problems may increase work-place frustration and complicate familial adjustment and establishing appropriate peers. This presentation (a) provides an overview of these deficits and their neurobehavioural underpinnings, (b) explores how these deficits interfere with positive behavioral change, and (c) proposes opportunities for improving behavioural outcomes.

Alcohol use disorders and behaviour change: Research advances from behavioural neuroscience to public health

J. Bruce Overmyer University of Minnesota, United States of America

Current scientific consensus is that biological, behavioural, and environmental components of functioning are dynamically intertwined in complex adaptive systems that serve to promote health or illness. Highly prevalent health problems like alcohol misuse are resistant to interventions based on reductionist models of illness and require research and application from disparate knowledge domains. To promote public health, we need to understand how functional neurobiological and psychosocial mechanisms give rise to human behaviour that is integrated and flexible. Health across the lifespan is thus conceived as the dynamic outcome of interrelated functional systems spanning the micro level of the genome to the macro level of the global environment. This symposium on alcohol misuse spans adjacent levels of organised behavioural regulation from neurobiological to behavioural economic mechanisms and real-world dissemination of evidence-based interventions that are applicable to large numbers of people.

Screening and brief interventions for alcohol misuse among tuberculosis patients attending primary care clinics

Karl Peltzer South Africa

The aim of this cluster randomised controlled trial is to provide screening for alcohol misuse and to test the efficacy of brief interventions in reducing alcohol intake in patients with active TB (N = 462) found to be misusing alcohol in 42 primary health care clinics in 3 provinces in South Africa. At the clinic level systematic sampling is used to recruit newly diagnosed TB patients. Patients who screen positive for alcohol misuse over a 6-month period were given either a brief intervention based on the Information-Motivation-Behavioural Skills (IMB) Model or an alcohol use health education leaflet. Results and discussion will be presented.

Behavioural economics and strategies based on choice architecture to reduce alcohol-related problems

Jalie Tucker University of Alabama at Birmingham, United States of America

Behavioural economic research has robustly demonstrated that investment activities in humans and animals are vulnerable to delay discounting, wherein shorter term outcomes are weighed more heavily than delayed outcomes even when the latter have higher overall value. Choices depend on the available commodity set, and behaviour change strategies based on “choice architecture” frame options to help people make choices in their best interests (e.g., by making the default option the more beneficial choice). The implications for change strategies at individual, public health, and public policy levels to reduce alcohol-related problems are discussed, with emphasis on applications in lower resource environments.

Session Type: Symposium

Symposium title: History and evolution of training programs in psychopharmacology in the United States and Europe

Convenor: Steven Tulkin

The Southwestern Institute for the Advancement of Psychotherapy/New Mexico State University programme

Elaine LeVine New Mexico State University, United States of America

This presentation will discuss the unique aspects of the New Mexico State University (in collaboration with the Southwestern Institute for the Advancement of Psychotherapy) post-doctoral program in psychopharmacology leading to an interdiscipliary Master’s degree. Graduates of the program qualify to apply for a New Mexico license of Prescriptive Authority. Classes are taught in eight-hour modules with open book exams. Many of the classes are taught live in Las Cruces, New Mexico, on weekends. However, students may take a number of classes via a distant education format. The SIAP/NMSU Programme provides extensive hands-on training in conducting a physical exam as part of a pathophysiological assessment. Training in anatomy and physiology includes live brain dissections. The SIAP/NMSU Programme is presently the only programme designated by the APA that is supported by a major public university. The presenter will also summarise data about the number of students who have completed the programme who are prescribing and their locations throughout New Mexico and the United States.

Brief history of psychopharmacology training: Curriculum, politics, and progress

Morgan Sammons CA School of Professional Psychology, United States of America

Professor Sammons will review the history of training in psychopharmacology for prescription authority (RxP). He will include the rationale for approval of prescription authority for psychologists, significant steps in curriculum development, role of the American Psychological Association, politics regarding RxP, both within psychology as well as from other professions, and the current status of RxP in the US, noting the role of RxP in the evolution of models of health care.

Postdoctoral master of science program at the California school of professional psychology

Steven Tulkin CA School of Professional Psychology, United States of America

The Postdoctoral Master of Science Program in Clinical Psychopharmacology at the California School of Professional Psychology is the first and the largest postdoctoral psychopharmacology masters program in the United States. Our first class began in 1998 with 35 psychologists in the state of Louisiana, followed shortly by cohorts in California, Texas, Maryland, Oregon, and several other states. We have now graduated over 400 psychologists, with close to 80 of them authorised to prescribe. Some of our major accomplishments over the 14 years of the program are: (1) Being selected by APA Division 18 (Psychologists in Public Service) to partner with them on a nationwide initiative to train public service psychologists to prescribe. (2) Working with the Indian Health Service to provide training in psychopharmacology to psychologists working with Native Americans. (3) Graduating the first psychologist in the territory of Guam to receive postdoctoral in psychopharmacology training. (4) Having students from several countries including Qatar and Taiwan.

The European psychopharmacology training program, SIAP and the New Mexico State University

Huibert Van Dis University of Amsterdam, Netherlands

New Mexico State University (in collaboration with the Southwestern Institute for the Advancement of Psychotherapy) offers an interdisciplinary Master’s degree in psychopharmacology to psychologists in Europe. Many of the classes are online and discussions are presented in a synchronous fashion. A number of classes are taught live in the Netherlands so that students can obtain extensive experience in physiology (through dissection of a brain nervous...
A prescribing psychologist’s approach to treating the seriously mentally ill

Elaine LeVine New Mexico State University, United States of America

Research has indicated that the seriously mentally ill die, on the average, twenty years earlier than others without serious mental illness. We know that this population is more susceptible to a variety of illnesses that can lead to their early demise. In addition to their biological predisposition, the lack of sufficient care creates a great vulnerability among this population. This paper will talk about how the integrated care of psychotherapy and medication management provided by prescribing psychologists can help address the lack of services for this population. In addition, because of the close monitoring by the prescribing psychologist, as well as the use of cognitive and behavioural interventions, serious metabolic side effects can be more carefully monitored and managed. These principles will be illustrated with case material.

The extent and effectiveness of prescribing psychologists in the Indian Health Service

Kevin McGuinness U.S. Public Health Service, United States of America

The author of this presentation spearheaded the prescribing authority movement in the state of New Mexico with the purpose of improving access to care for the very many underserved mentally ill within the state. Since obtaining her prescriptive authority certificate, she has worked in an impoverished community near the Mexican border in a combined role as medication manager and clinical supervisor. With case material, her presentation will demonstrate how the poor and minority groups often receive improper medication or are overmedicated with untoward side effects when less intrusive measures might be effective. She will then explain how the prescribing psychologists “Psychobiosocial Model of Care” fosters social justice among such populations through the emphasis on patient education, extensive informed consent, as well as reducing multiple medications and implementing effective psychological techniques.

Consulting as a prescribing psychologist enhances primary care psychology in the Netherlands

Jan Derksen Raboud University Nijmegen, Netherlands

For thirty years clinical psychologists have practiced in primary care in close cooperation with family physicians in the Netherlands. Their short term psychological help is reimbursed by health insurance companies. In their assessment of the treatment of psychological disorders they are confronted more and more with patients that have been prescribed psychotropic medications, most of the time, by the family doctor. The psychologist trained in psychopharmacology has the advantage of seeing patients for 45 minutes and on a weekly basis instead of 10 minutes and with irregular frequency with the physician. The psychologist in contrast to the physician, is trained in assessment and has psychological techniques that enable him or her to get a good understanding of the psychological, social and biological contributions to, for instance, a mood disorder. This background results in a strong capacity to combine psychological treatment with medications but also to stop medication and switch to psychological treatment if necessary. In this lecture the psychological help available in primary care and the benefits of psychopharmacological contributions by psychologists will be explained and discussed.

Prescriptive authority for psychologists can foster social justice

Elaine LeVine New Mexico State University, United States of America

The author of this presentation spearheaded the prescriptive authority movement in the state of New Mexico with the purpose of improving access to care for the very many underserved mentally ill within the state. Since obtaining her prescriptive authority certificate, she has worked in an impoverished community near the Mexican border in a combined role as medication manager and clinical supervisor. With case material, her presentation will demonstrate how the poor and minority groups often receive improper medication or are overmedicated with untoward side effects when less intrusive measures might be effective. She will then explain how the prescribing psychologists “Psychobiosocial Model of Care” fosters social justice among such populations through the emphasis on patient education, extensive informed consent, as well as reducing multiple medications and implementing effective psychological techniques.

The extent and effectiveness of prescribing psychologists in the Indian Health Service

Kevin McGuinness U.S. Public Health Service, United States of America

This presentation will begin with a brief overview of the training and work of the original ten psychologists trained in psychopharmacology through the Department of Defense Demonstration Project. Then the numbers and venues of present-day military prescribing psychologists and prescribing psychologists in the Indian Health Service will be overviewed. The way the prescribing psychologists can interface with physician will be illustrated by this prescriber who is a Captain in the Public Health Service and who has been stationed at a federally qualified health center in rural New Mexico.
Discourses of xenophobia: A South African study
Nicola Graham; Rhodes University, South Africa

Since South Africa’s transition to democratic rule in 1994, extremely high levels of xenophobic attitudes and practices have been documented within the country (Crush et al., 2008). This rising xenophobic tide has attracted much scholarly attention, but to date there do not appear to be many published studies of this phenomenon from a social psychological perspective. This exploratory study examines how four employed South African women and men from varied racial and income groups talk about xenophobia. Individual semi-structured interviews were conducted, and the generated material was analysed using Foucauldian discourse analytic methods (Willig, 2008) in conjunction with positioning theory (Bamberg, 2004; Davies & Harré, 1990). The focus of the analysis was an examination of the ways in which black African foreigners are discursively constructed by South African citi-
Race, sex and class in psychology: Vision of hope for a fair and just South Africa
Hester Gertrude Pretorius University of Johannesburg, South Africa

The purpose of this paper is (1) to present a philosophical debate on the exigency for the profession of psychology in South Africa to adapt to the transforming society it purports to serve through reformatory thinking and (2) to provide recommendations on how the profession can transcend erstwhile discriminatory practices in race, sex and class. The discussion commences with an analysis of the current state of the profession of psychology in South Africa in relation to the selection of students for training as professionals in psychology, the current training model for professionals in psychology and the practice of psychometric assessment and test development. The author then argues that the current state of psychology practice in South Africa is experiencing a moral dilemma because the practice framework has not yet transformed to allow psychologists to address psychological services. Based on this dilemma, the author argues that there is a need to create a post-conventional moral consciousness in the profession to bring the practice of psychology in-line with the needs of all people in South Africa. The paper concludes with a discussion of a preferred scenario for the practice of psychology in South Africa and engages a debate on an initial step toward developing a theory of implementation. This debate is considered from an ethical and moral viewpoint, with consideration given to transformation and legislation.

Everyday anti-racism in interpersonal contexts
Rob Ranzijn University of South Australia, Australia; Margaret Mitchell; Danielle Every

Everyday conversations among non-Indigenous Australians are a significant site in which racism towards Indigenous Australians is reproduced and maintained. This study explores the possibilities of everyday antiracism by asking how people negotiate racist discourses in interpersonal contexts. 12 first year psychology students (10 female, 2 male, aged 18–50) who had completed a compulsory Indigenous studies course were recruited as participants. Semi-structured interviews were thematically analysed for the constraints and facilitators in responding to racism in everyday contexts. As constraints against speaking up, participants offered “social expectations to fit in,” “fear of provoking aggression and conflict”, assessments of “the type of relationship”, whether they “could make a difference” and the “type of racism”. As a facilitator for speaking up, participants reported they were confident in challenging erroneous statements when they felt well-informed and authoritative about the facts. The research suggests that everyday anti-racism requires a preparedness to deal with possible discomfort and “bad feeling” which participants reported avoiding. The paper concludes with suggestions for stimulating critical thinking and intergroup dialogue in relation to everyday anti-racism.

The legacy of racism continues to permeate and destabilise South Africa. However, Durrheim et al. (2011) argues that existing theories of racism are no longer sufficient for understanding this complex issue within the context of post-apartheid South Africa. They suggest that “Social change can only be informed by analyses of ongoing racial practices that are undertaken by people as they go about their ordinary lives: As people participate in forms of social life arranged around ideas about race, they are constituted as racial subjects in more complex and nuanced ways than can be captured by labels such as ‘racist’ or even ‘modern racist’.”

Nightclubs and clubbing have become international social and cultural phenomena, yet have received little attention from local academics. Likewise, there has been limited research into ethnicity and race in club culture abroad. Accordingly, this mixed-methods, multimodal qualitative study roots its analysis of social life in South Africa in the “ordinary lives of club goers, aiming to paint a rich ethnographic portrait of club culture while simultaneously building a scholarly analysis of the architecture and choreography of racialised practices and identities within club spaces. Drawing primarily on poststructuralist authors such as Judith Butler and Michel Foucault, the aim is to explore the ways in which racial subjects are constituted in clubs. The “vibe” is appropriated as a theoretical and analytic device for exploring how, as “a repeatability of materiality” and discursive process, it reinscribes ideas about race in clubs and mediates racial performativity.

Who’s the victim? Post-Apartheid racism, identity and discourse
Suntosh Pillay University of KwaZulu-Natal, South Africa

When an 18 year old white man went on a shooting spree in the Skierlik informal settlement in the North West province, the media labelled this a racist attack. Four black residents were killed and others traumatised. The media outrage that followed, in early 2008, reared a discourse of “small town racism” and post-Apartheid race-relations were again being debated. Residents of the town of Swartruge gens were interviewed, in order to investigate how place-identity is constructed in the context of racialised violence. A critical discourse analysis was used to argue that a discourse of victimhood emerged from all “race” groups in the town. White citizens claim they were all unfairly stereotyped by the media; black citizens claim that this is in fact a racist town as exemplified by the Skierlik incident; and Indian residents claim that their peaceful small town life has been disrupted by the black-white tension. Has Post-Apartheid life become a struggle for claiming victim status, and if so, what purpose do these discursive constructions of victimhood serve?

It’s the vibe*: Race, space, practice and subjectivity in South African nightclubs
Clinton Rautenbach University of KwaZulu-Natal, South Africa

The research suggests that everyday anti-racism requires a preparedness to deal with possible discomfort and “bad feeling” which participants reported avoiding. The paper concludes with suggestions for stimulating critical thinking and intergroup dialogue in relation to everyday anti-racism.

Race and Racism

How racism impacts the development of postpartum depression symptoms in Hispanic women
Kelly Doyle Nova Southeastern University, United States of America; John Lewis; William Dorfman; Iriny Boules; Josie Augustin

In recent literature, researchers have examined how Postpartum Depression (PPD) impacts women in the general population and what variables can serve as protective/risk factors for these individuals such as socioeconomic status (SES), social support, marital satisfaction, and access to resources. Though research on the origin of disparities between racial groups exists, the literature fails to discuss how racism and discrimination impact the development of PPD in minority groups. Given that the literature reports Hispanic women as being more likely to report PPD symptoms in comparison to other ethnic group members, we will collect a sample of Hispanic women and non-Hispanic women reporting symptoms of PPD. To examine the differences in how racism impacts the development of PPD symptoms in Hispanic mothers and mothers of other ethnic/racial groups, the perceived effects of racism will be measured by structured interviews and racism/discrimination scales. We will assess this effect by constructing a hierarchical regression model in which the effects of racism are evaluated over and above the effects of the other predictor variables. We anticipate that Hispanic mothers perceiving higher levels of racism are at a higher risk of developing PPD symptoms than those who perceive little to no racism. Conducting this study will provide evidence for the potential impact of perceived racism.
racism on the development of PPD and allow us to identify pertinent risk factors for minority groups, thus paving the way for preventative measures and appropriate clinical, culturally-sensitive interventions.

How would you label me: Stereotypical behaviour of students at a South African higher education institution

Cebile Tebele University of South Africa, South Africa; Kathryn Nel University of the Western Cape, South Africa;

The study investigated stereotypical attitudes held by students at a South African higher education institution. The sample comprised 288 students with a mean age of 22.19 years (SD=3.103 years). The history of racism in South Africa is briefly described to contextualise the stereotypes and discourses that are found in the contemporary context. This study was deemed relevant due to the increasing reports of racist attacks and xenophobia at tertiary institutions in South Africa (Barton, 2003). The study objectives were two-fold, firstly to determine whether students at the institution showed stereotypical behaviour towards people from the same racial group as theirs and those from different racial groups. Questionnaires adopted from Durheim (2007) were utilised for data collection as they seek to identify stereotypes that students have about other racial groups. Discourse analysis was used to unpack the underlying discourses from the qualitative responses given by participants. These discourses were related to the prevailing paradigm at the time, which was more patriarchal and oppressive (April, 2008). The stereotypical observations made by the respondents in describing how they feel about, for instance, Afrikaner Whites, indicate that there are feelings of racial tension towards this group. Findings also confirm that stereotypes exist within the same racial group, alluding to Black-on-Black racism in this instance. As a university can be considered the workplace of students, it is likely that these findings will be mirrored in the broader workplace. This assumption is underpinned by the outbreak of xenophobic violence in South Africa during 2008.

Session Type: Invited Address

Racial identity conceptual frameworks rather than racial/ethnic categories

Janet Helms Boston College, United States of America

Until the advent of racial identity theories and related measures in the 1980s, most empirical research in psychology had erroneously treated socially ascribed racial or ethnic categories as though they were conceptual frameworks that could be used to explain human behaviour scientifically. However, in an attempt to replace factitious racial-ethnic categories in psychological research, racial identity theorists contend that being socialised as if one is a member of a disadvantaged or advantaged socially-constructed racial-ethnic group has implications for how one perceives oneself, as well as one’s related mental health, health, and other behavioural consequences. In this presentation, I review relevant literature and make recommendations for future directions.

Session Type: Invited Symposia

Symposium title: The Apartheid Archive project: Remembering and social transformation in post-apartheid South Africa

Convenor: Christopher Sonn

The Apartheid Archive: Lieu de memoire

Norman Duncan University of the Witwatersrand, South Africa

This presentation is partly based on an empirical analysis of 150 narratives collected as part of the Apartheid Archive Project. A salient feature of these narratives is the difficulty experienced by the narrators (as reported in the narratives) when they were initially invited to recount their earliest significant experiences with racism during the Apartheid years. The aims of this presentation are: (a) to explore some of the key reasons for this manifest difficulty in speaking about past experiences on the part of narrators who had contributed to the Apartheid Archive and (b) to examine the implications of this apparent reticence in dealing with the past for the growth and the strengthening of the Apartheid Archive Project narrative database. The research and publications produced thus far on the basis of the narratives contained in the database as well as recent writings on the emancipatory potential of memory work in societies recovering from widespread social trauma underline the potential utility of Apartheid Archive Project in understanding past and current social dynamics. Consequently, it may be of value to explore ways of broadening and strengthening the Apartheid Archive Project. The presentation will provide a series of recommendations in this regard by way of conclusion.

Reflections on past and present racist discourse on sexuality in South Africa

Tamara Shefer University of the Western Cape, South Africa

As part of a larger memory project: The Apartheid Archive Project, this paper reflects on intersections of gender, sexuality and racism in the narratives of a group of diverse South Africans. Applying a Fanonian psychoanalytic lens, the paper is concerned in particular with unpacking the power of fantasy in the reproduction of racist discourse and racialised regulatory practices around sexual intimacy. The paper elaborates on the power of imagined hostility and violent threat as well as fantasies of and desires for the ‘other’ in both troubling and regulating interpersonal relationships between South Africans as emerges in stories on apartheid. The paper further reflects on the long history of racialised surveillance of sexuality in colonial and apartheid South Africa, and interrogates the extent to which the proliferation of contemporary work in relation to HIV, gender and sexuality may be reproducing practices of ‘othering’, including the demonisation of male black sexuality in particular, that characterised the apartheid regime. Focusing also on public responses to a recent research report on men and rape in South Africa, and juxtaposed with the narratives on apartheid, the paper attempts to unpack the continued patterns of apartheid sexualisation (Ratele, 2001) in their contemporary articulations.

Speaking unspoken memories: Voices about Apartheid racism from the South African diaspora in Australia

Christopher Sonn Victoria University, Australia

There is a growing recognition of the importance of storytelling and autobiographical work in critical approaches to social inquiry. This approach is central to liberation psychology that emphasises the importance of deconstructing ideologies of race as part of the process of empowerment. In this article I draw on this approach to discuss themes that have emerged in research in Australia with South African immigrants about identity construction following relocation, as well as the stories immigrants wrote for the broader project. The themes within the stories highlight the public spaces in which different groups interacted and the strategies of surveillance (petit apartheid) white people used to control black people. Narrators wrote about the effects of as well as the ways in which they resisted petit apartheid. The stories also suggest that participants continue reconstructing memories in the new context. It is within this new context that past narratives felt free to pursue personal, economic, and professional aspirations. It is also in this context that participants developed deeper understandings of the effects of racism on their subjectivities, and began deconstructing cultural mistrust rooted in Apartheid oppression. I discuss these ideas with reference to liberation psychology and the role of memory projects, such as the Apartheid Archive Project, for providing a space for collective remembering and for telling stories about the past and constructing new stories and subjectivities.

Apartheid archive project: Remembering and social transformation in post-apartheid South Africa

Christopher Sonn Victoria University, Australia

The apartheid archive project was launched in 2009 and was developed as a means to explore contemporary intergroup relations in South Africa. The project is premised on the idea that ever since the demise of formal apartheid, the ongoing effects of the ideology on memory, identity, intergroup relations, and social inequity continue to hamper a post-apartheid South Africa. Situated within a qualitative framework, the project initially targeted collecting 5000 narratives from ordinary South Africans about their experiences of racism and living under apartheid, and the ongoing effects on individual and group functioning. The project is thus also a repository for people’s stories as well as a means for exploring the methodological, interpretative and praxis possibilities of engaging with history from a psychological standpoint. In this symposium we offer a selection of papers by researchers engaged in the apartheid archive project. The first paper provides an overview of the project including its genesis and subsequent development. The second paper delves into methodological, interpretative, and political possibilities and tensions based in and flowing from the project. The final three papers offer exemplars of the different theoretical and conceptual lenses researchers have utilised to work with the narratives deposited and in related projects as they engage with understanding the ongoing impacts in the lives of individuals of racialised domination, and its intersections with dimensions of gender and class.
The Apartheid archive: Memory, voice, and narrative as liberatory practice
Garth Stevens University of the Witwatersrand, South Africa; Norman Duncan

This presentation explores the socio-political imperative and psychosocial value of re-engaging and expanding the apartheid archive in contemporary South Africa. It suggests that this archive’s entanglement with de facto official histories of South Africa has resulted in certain elisions about the historical content of this archive, but also compromises our ability to examine the ongoing effects of our racialised past. It argues that the archive needs to be liberated from these socio-political constraints, expanded, re-appropriated and reclaimed, if we are to more fully apprehend and comprehend the impact of this history. Utilising the Apartheid Archive Project (AAP) as an exemplar, the paper highlights the value of retrieving personal memories in countering the totalising effects of official histories, argues for the relationship between such memories and the articulation of voice for those marginalised groups and subalterns that have been excluded from official histories and the archive. It suggests that the narrative is a liminal mnemonic technique that allows for the expression of these memories as fragments and traces of the past that are re-constituted in the present, but also allows for a future imaginary.

Breaking the ignorance contract: White South Africans’ recollections of complicity with Apartheid
Melissa Steyn University of Cape Town, South Africa

It has become a commonplace joke in South Africa that one cannot find any white South African who admits to having voted for the Apartheid government. White South Africans tend to produce accounts of their past in ways that present innocence, or at least ignorance, of how their privilege was premised upon the disadvantage of black South Africans. The paper explores some of the complexities of dealing with the shame and continued self-interest that inhibits the admission of complicity. Drawing on the emergent field of epistemologies of ignorance, and based both on focus groups with white South Africans on the topic of “what we knew,” and on the narratives collected in the Apartheid Archives, the paper investigates the costs and rewards of breaking faith with the ignorance contract that holds white collusion with racial privilege in place.

Session Type: Symposia

Symposium title: Engaging with issues of race in everyday and organizational contexts in South Africa and Australia
Convenor: Christopher Sonn

White people’s constructions of political violence in apartheid and post-apartheid South Africa
Danilo Caforio Wits University, South Africa

There appears to be limited literature in South Africa examining the social constructions of political violence in colonial and post-colonial times, from the perspectives of white people. The aims of this research were to explore constructions of political violence that occurred during the apartheid era and the post-apartheid period and how these constructions of political violence intersect with white people’s constructions of the self and other. Data that was gathered from six white South Africans using interviews were analysed to address these questions using Critical Race Theory and whiteness studies as a framework. Based on the findings, it is argued that constructions of political violence in contemporary South Africa are mediated in significant ways by ‘race’ and racial identities. Specifically, it is argued that different identities of whiteness strongly shape constructions of apartheid and post-apartheid political violence, as well as constructions of the Self and ‘Other’. It is also argued that apartheid seems to have fostered a particular view of ‘otherness’ that is in very stark contrast to the multiracial tolerance fostered in South African society today. The findings of this study add to a growing body of literature centering on critical race studies and are discussed in terms of anti-racism practices and social transformation in South Africa.

Examining barriers to employment equity: The complexities of gender and race solidarities in a bank’s empowerment discourses
Hugo Canham University of the Witwatersrand, South Africa

This paper examines what enhances and what detracts from empowerment initiatives in banks by looking at the empowerment discourses operating within a South African bank as it seeks to implement its employment equity policy. The Act requires all employers with a staff complement of more than fifty to plan for demographic representation in relation to race, gender and disability. The focus of the paper is on the intersections between gender and race as these are key social asymmetries which the policy seeks to address. Pheterson (1986) called for authentic gender-based solidarity which comes from a place of being conscious of internalized dominance, internalized oppression (Fanon, 1963) and an understanding of relative oppression arising from patriarchy and racism. In line with this call, this paper draws on interview data with professional level employees in a bank in order to examine alliances between “black” and “white” women in the banks empowerment drive. The emerging picture is one of complexity where racialized solidarities often trump gendered alliances. Key barriers include a deficit approach to employment equity in relation to notions of merit, and deeply entrenched historical and mutually reinforcing alliances for the maintenance of privilege. While these are firmly rooted in South Africa’s history of race-based politics, it does not bode well for black women empowerment and leaves the dominant hegemony unshaken and whiteness firmly ensconced at the centre of power.

Reproducing privilege and disadvantage: Making visible racialisation in everyday talk about barriers to aboriginal and non-aboriginal partnerships
Amy Quayle Victoria University, Australia

While more recent events in Australia’s history represent a significant departure from direct violence, exclusion and control, more subtle forms of racialised oppression continue to shape the lives of indigenous people in post-colonial Australia, as well as relations between indigenous and non-indigenous Australians. Guided by writing from a decolonising standpoint, this study explores the everyday ways that race is reinscribed and unequal relations of power expressed, constituted and legitimised in a context marked by colonial dispossession. Using discourse analysis, I examined explanations of barriers to indigenous and non-indigenous partnerships in the context of the Community Art Network Western Australia’s Strategic Partnership Initiative. Semi-structured interviews were conducted with a total of seven non-indigenous local government representatives across four shires. Participants were four male CEOs and three female Community Development Officers, recruited through CANWA. Data analysis distinguished three interrelated discourses in local government explanations: Abstract liberalism, culture blame and silencing and forgetting the past. These hegemonic discourses reflect and reproduce Aboriginal marginality as well as the power and invisibility of whiteness. Resetting relationships between indigenous and non-indigenous Australia as part of the broader project of liberation necessitates critical engagement with whiteness or the deconstruction of normativity, as a means of creating new listening positions, forging new subjectivities and ultimately, in establishing more receptive social environments. Creating more receptive social environments is posted as an essential prerequisite in moving toward true reconciliation and in transforming the domain of Aboriginality, in post-colonial Australia.

Race in organisations: Examining continuities, responses and strategies for change
Rejone Williams WITS University, South Africa

Confronting racism remains a complex and complicit task. Emphasis for addressing racism has primarily been on changes in legislation, structures, policies and practices with some attention paid to changing attitudes and behaviours of those not at the receiving end of racism. The experiences, behaviour and agency of those at the receiving end of racism have largely been unsupported and overlooked as a factor in the continuing dynamics of racism. Guided by writing in the psychology of oppression and liberation, this paper examines the psychosocial and personal manifestations of racism for “black” individuals and the multiple ways they are challenged by and respond to racism in organisations. Archival data gathered as part of systematic diagnostics for and evaluations of anti-racism workshops and semi-structured interviews with individuals for a larger study are analysed using narrative analysis. The analysis shows that there are policy and other structural responses that have been implemented to address racism. However, there remains a lack of knowledge about the continuity of racism in different settings and the ways in which people respond. The data shows diverse responses and also the multiple individual and group level resources required for negotiating and disrupting racism. It is argued that greater attention has to be paid to “black” agency and how it is supported in theory and practice as a factor in ending the destructive impact and cycle of racism in organisations.
Why study race and resilience? What we can learn from examining blacks in South African and US contexts

Tabbye Chavous University of Michigan, United States of America; Robert Sellers

Our symposium will examine resilience processes among Black youth in South African and US contexts. The study of risk and resilience between and among these populations is appropriate given parallels in historical experiences related to race and oppression in the two settings. This introductory paper will present the construct of resilience, overviews of psychological frameworks on resilience, and highlight the utility of studying Blacks’ experiences in different social, ecological, and national contexts to understand the nature of resilience and use this understanding to promote youths’ positive development. Across every spectrum of life in both American and South African contexts (education, income, well-being), there are significant racial differences in success indicators. Despite significant racial stratification in these societies, there are numerous examples of individuals from disadvantaged racial/ethnic groups who overcome tremendous obstacles and become successful, or show resilience. Although considerable research from various disciplines attempts to explain racial group inequalities, relatively little has investigated resilience among individuals in disadvantaged groups from a psychological perspective. Past research examining racial group differences only as outcomes, is important but vulnerable to promoting a deficit approach to inequalities that blames the victims by conceptualising racial inequality in terms of inherent genetic, psychological, or cultural deficits within disadvantaged groups, or essentialising racial group differences and over-emphasising between-group differences at the expense of within-group variation. A resilience approach provides an important alternative conceptual framework for understanding racial inequalities, focusing on strengths rather than deficits and on understanding healthy development in spite of risk exposure.

Racial identity matters: The role of race, risk, and resilience in the psychological wellbeing of African American youth

Tabbye Chavous University of Michigan, United States of America; Robert Sellers

African American youth face myriad challenges to their healthy development in a society that has traditionally devalued them because of their race. Chief among these challenges is the continued exposure to racially discriminatory events. Research findings have consistently indicated that African American youth experience racial discrimination at non-trivial levels. Research has also consistently linked African American youth’s experiences with racial discrimination to a variety of deleterious academic, social, and well-being outcomes. At the same time, there is also evidence that many African American youth are resilient in the face of these racial challenges. African American adolescents’ racial identity attitudes seem to be a particularly important source of resilience. Racial identity refers to individuals’ attitudes and beliefs regarding the significance and meaning of race in individuals’ lives. This paper will review some of our latest research findings related to the interplay among racial identity attitudes, racial discrimination, and well-being outcomes in African American adolescents. The talk will conclude with a discussion of the implications of our research for the healthy development of African American youth and prescriptions for future research.

Race-class intersections as interactional resources in post-apartheid South Africa

Kevin Whitehead University of the Witwatersrand, South Africa

A prominent line of social scientific research, employing the concept of “intersectionality” (Crenshaw, 1989), examines relationships of inequality among categorically-based social groups – and in particular the ways in which these relationships are changing over time and across contexts (McCay, 2005). South Africa represents an important site for the investigation of such changes, as the collapse of the apartheid system gave rise to a dynamic period with respect to the country’s previously rigidly racialised class structure. In this paper, I examine how common-sense knowledge of South Africa’s complex post-apartheid race-class intersections is displayed and mobilised in ordinary episodes of interaction. I begin by providing a brief overview of the historical origins and current patterns of these race-class intersections, describing some ways in which they can be seen as both legacies of and departures from those of the apartheid system. I then present some findings from an ethnographically-informed, conversation analytic investigation of audio-recorded data drawn from interactional South African radio broadcasts. In my analysis, I demonstrate some ways in which taken-for-granted, common-sense knowledge about race-class intersections can be used and resisted in everyday interactions. This analysis reveals some ways in which continuities and discontinuities in common-sense knowledge of race and class between the apartheid and post-apartheid periods are both reflected and reproduced at the level of everyday interactions.
End of preview.
SCi. High road traffic accidents and crime were contributing factors to SCi and PTSD. This study supports the view that significant neurocognitive deficits is a sequela of traumatic SCi and that high levels of PTSD impacts negatively on cognitive functioning in patients with SCi. The authors proposed that these factors be seriously considered in post SCi treatment and rehabilitation.

Applying a systems approach to job placement with special populations

Chrisann Schiro-Geist University of Memphis, United States of America; Chrisann Schiro-Geist

The presentation will focus on a systems approach to the job placement of persons with disabilities. An instrument which has been created to assess placeability of clients will be presented. Research on the validity and reliability of the instrument will be presented. History of the instrument and its development as a functional tool to create individual placement plans will be noted. The eight subsystems will be explored. Finally, the extended use of the instrument on populations of persons who are incarcerated will be presented, along with data on a special program existing in Memphis, Tennessee, which uses the systems approach with prisoners who are about to be released from prison.

Session Type: Posters

The influence of the Malamulele Onward Intervention Model on caregivers of children with cerebral palsy

Marilyn Adan South Africa; Gillian Saloojee; Patricia McInerney

The study explores the influence of the Malamulele Onward Intervention Model on the lives of caregivers of children with cerebral palsy who attend cerebral palsy clinics at the Butterworth and Taflofe in the Eastern Cape. The model provides intensive therapy for the children as well as education and home programme training for their caregivers. It aims to improve treatment available to these children as well as to lighten the burden of care on their caregivers. Data was collected during focus group discussions between caregivers and trained facilitators who were fluent in English and isiXhosa. The discussions were audio-taped and transcribed and then translated into English. The transcripts will be analysed using thematic coding techniques and the results will be presented.

Equine assisted therapy: A multidisciplinary, holistic approach in psychological well-being

Alexa Brand UNISA, South Africa

The present study examines the value of equine assisted therapy as a holistic approach to anger management in a sample of 6 girls from a children’s home in South Africa. The purpose of this presentation is to demonstrate the applicability of equine related therapy on trauma and anger in the context of rehabilitation, healing and confidence building. The study is ongoing at the time of writing this abstract. Qualitative data is being obtained by conducting participant observation and semi-structured interviews with participants. The aim is to identify themes pertaining to rehabilitative value of horse interaction, by means of content analysis. Results will be presented in poster format, utilising photographic images to demonstrate the therapeutic process. The researcher aims to demonstrate that the process of holistic equine therapy may be an innovative line of therapeutic psychology, applied to anger management, with global relevance.

Children and adolescents in family rehabilitation – what works in Finland

Pirjo Lehtoranta Rehabilitation Foundation, Finland; Ritva Linnekangas; Asko Sukkainen; Alla Jarvikoski

We investigate the factors explaining success in multidisciplinary psychiatric family rehabilitation for children and adolescents and their families. We surveyed 440 children between 5 and 16 years, their parents and the rehabilitation providers before and after the rehabilitation. The pre and post rehabilitation parent questionnaires included Goodman’s (1997) SDQ on their children’s symptoms. We analysed the children’s and parents’ perception of receiving help, and reduction in the SDQ scores using logistic regression. The duration of rehabilitation, family coherence, and parents’ concern over the well-being of their child predict reduction in symptoms measured using the SDQ. The duration and the form of rehabilitation (focusing on family therapy and group activity) and the social support received from the family and acquaintances predict parents’ perception of having gained resources from rehabilitation. The duration and the form of rehabilitation (focusing on individual and family orientated rehabilitation), and the resources parents receive from rehabilitation predict children’s perception of having gained help from rehabilitation. Family rehabilitation should concentrate on the needs of both the children and their parents. As the challenges faced by the children and parents differ, the availability of different forms of family rehabilitation is needed.

The chronic renal patients’ psychological rehabilitation: Strategies

Aymara Reyes Oriente University, Cuba; Edelsys Hernandez; Miguel Roca

In Cuba, there is an insufficient development in psychological intervention with End-Stage Renal Disease (ESRD) patients. For this reason, a strategy of psychological intervention is developed with the psychological rehabilitation in the ESRD patients, family and health staff, through the use of psychotherapeutic and educational methods. The design of the strategy was developed using qualitative methods, discussion groups with 15 patients and family, including interviews with the health staff (2 nephrologists, 3 nurses and 1 psychologist). The rehabilitation indicators identified were: Adaptation to the illness, family functionalization, social support, free time activities and insertion to activities of social nature. The application of these adaptations conforms to psychological intervention in four ways: patients’ group intervention, family orientation groups, mutual help duets, and the training of health staff. Partial and pilot applications have been carried out, with preliminary results that indicate the effectiveness of the strategy to improve adaptation to illness, emotional coping with the disease consequences, social support and more collaborative relations between the family and health staff to conduct the rehabilitation of renal disease patients.

Memphis city schools: College campus transition programme (CTTP)

Chrisann Schiro-Geist University of Memphis, United States of America; Ryan Cox

This poster presents a pilot customised employment program led by Memphis City Schools’ (MCS) Exceptional Children and Health Services, in collaboration with The University of Memphis Institute on Disability (UMID), The University of Memphis’ College of Education, and the Memphis Tourism Education Foundation (MTEF), and the department of Vocational Rehabilitation of Greater Memphis. Through this collaboration, students will have received customised employment training from which they will have developed job readiness skills to prepare them for employment in demand occupations with emphasis on the hospitality and tourism industry. This training will have culminated in the receipt of a certificate of programme completion issued by the University of Memphis’ University College. There are four stated goals of this programme. One is to provide students with mild/moderate disabilities a transitional linkage to post secondary educational environments and experiences while training for employment options that offer a living wage upon graduation from high school. Second is to develop and support internships during the transition from school to work process, along with our third goal of providing each student with “a seamless transition” to employment facilitated by The University of Memphis Center for Rehabilitation and Employment Research Employment Network Programme. Eligible students will be recruited to participate in the Social Security Ticket-to-Work Initiative. Last, we hope to connect each student to same-age peers through encouraging participation in post secondary sponsored activities.

Self-ratings and observer-ratings within the measurement of social competencies among young apprentices with learning disabilities

Burkhard Vollmers University Of Hamburg, Germany

This paper presents results of measurements of social competencies within a project of vocational rehabilitation in Germany called “VAMB” (www.vamb-projekt.de). A role-play was constructed in order to examine the social competencies of young adults with learning disabilities during their apprenticeship in companies. Members of staff were trained in order to observe the young adults. In a pre-post design of 143 young adults, mean of age was 19.6 years, were examined twice – at the starting-point of their apprenticeship and about 15 months later. Research questions were: (1) Do the ratings of trained observers correspond with the self-ratings of the apprentices? (2) Do our results differ from the extent of accordance of self-ratings of supervisors and ratings of members of staff in business companies? (Research literature of social psychologists was used.) Results of our study show that the extent of similarity of self-ratings and observer-ratings is rather equivalent to the analogical relation of self-ratings of executives and observer-ratings of members of staff in business companies. That means.
little correspondence of correlation-coefficients (less than .4) and a higher numerical level of self-ratings. In our study among young apprentices in Germany the range of correlations of self- and observer-ratings was .0 to .4 (Spearman’s Rho) within 14 items of observation. On average self-ratings were 0.5 points higher than observer-ratings (using a 5-point-scale).

The transformation of vocational rehabilitation in Germany: Results of a survey among disabled persons

Burkhard Vollmers University of Hamburg, Germany; Jasmin Saidie

The United Nations Convention on the Rights of Persons with Disabilities obligated all states to "promote vocational and professional rehabilitation, job retention and return-to-work programmes for persons with disabilities" (Article 27). Therefore, in Germany, the system of vocational rehabilitation was transformed. The ARGE (http://www.arge-bfw.de) is an association of 28 Vocational Training Centres for disabled people throughout Germany. During the last three years the ARGE has changed completely the processes of vocational education and integration. The new leitmotiv is this: Not only domain specific knowledge is essential in vocational rehabilitation, but also the education of health literacy and social competences. Therefore the ARGE has launched two new features to support the disabled persons in order to facilitate their vocational reintegration. These two new elements are: (1) A new form of monitoring the process of vocational training by systematic self and observer ratings. (2) A new management tool to promote quick reintegration of disabled persons into the labour market. In autumn 2011 an online survey was conducted. 3105 persons, who got their vocational training within the ARGE, evaluated the new structure of vocational education. Methods of exploratory data analysis (EDA) were used to describe principal trends within the data. Main results are that the participants look upon the new organisation of their vocational training very favourably. They often however suffer from a lack of information concerning details of the process of vocational education within their own institution.

Session Type: Invited Symposia

Symposium title: Disability studies and psychology: Current and future directions
Convener: Leslie Swartz

Disability and psychoanalysis

Leslie Swartz Stellenbosch University, South Africa; Brian Watermeyer

This contribution to the disability studies symposium will discuss the complex interface between disability studies and psychoanalytic thinking. Psychoanalysis has been complicit in the pathologising of disability for a long time; recent work in the field however has helped develop an understanding of interpersonal processes at play in how different people respond to issues of disability. This understanding may be helpful in supporting movements for social change.

Programmes for individuals with autism and their families in United Arabic Emirates

Muna Bagh United States of America; Paul Probst; Allam Woel

The Sharjah Autism Centre (SAC) serves a total of 60 individuals with autism and their families. This paper aims at evaluating the outcomes of programmes running at this centre on a pilot-study level. The measures used for evaluation include video-based behavioural observation, standardised questionnaires and tests as well as semi-structured interviews and written therapist and teacher notes. The programmes to be evaluated include (a) a centre- and home-based early intervention programme for 20 children, aged 3–5 (b) a centre-based four-full day (per week) classroom programme, with some inclusion components, for 30 learners, aged 5–15 and (c) a short-term home-based parent-child and family counselling intervention programme for multiple needs families, and (d) a workshop-related programme for 10 adults. All programmes focus on strategies based on the TEACCH approach (Treatment and Education of Autistic and Communication handicapped Children) and related behavioural methods. In addition, in the multiple needs family programme, the “Solution Focused Brief Therapy (SFBT)”, which is orientated on cognitive-behavioural and systemic principles, has been used. Overall, the outcomes indicate tentative evidence for effectiveness in terms of child, parent/ family and teacher measures. Data from case studies will be presented that demonstrate how both the application of TEACCH strategies and the family support by SFBT has led to clinically significant decreases in challenging behaviours (e.g. compulsory symptoms), improvements in developmental domains, and relevant improvements in parent-child, sibling-child and teacher-child relationships.

Challenges of implementing ASD specific programmes in Namibia

Petra Dillmann United States of America

After a brief explanation on the history of the Namibian education system and the current efforts being undertaken by the Education and the Health / Social Services Sector, this paper will describe and evaluate efforts, challenges and successes of ASD intervention in Namibia. The methods used for this evaluation include (a) an analysis of a questionnaire sent to parents, teachers and service providers of children with ASD; (b) personal notes made from phone calls with parents and professionals; (c) protocols from relevant meetings and training sessions; (d) personal experience as a parent of a 23-year-old man with autism. Programmes, methods and treatments used include TEACCH (Treatment and Education of Autistic and Communication Handicapped Children), PCS (Picture Communication Systems), behavioural therapies, alternative and augmentative communication systems, ecletic home based programmes, and occupational therapy, physiotherapy and speech therapy.

Outcomes of a sexual education programme for children with autism spectrum disorders

Jacob Christina Lombard UnicaSchool, South Africa; Xavier Knox

With the prevalence of 1:100 for Autism Spectrum Disorders, there should be an estimated 490000 individuals on this spectrum living in South Africa. AIDS has emerged as one of the biggest social and health problems worldwide. Due to the large number of AIDS infections in South Africa, a huge responsibility has been placed on schools and other institutions to provide adequate education as a primary safeguard against the pandemic. One of the key features of Autism Spectrum Disorders is not necessarily sexual activity but rather social ineptness. Subsequently, our learners are particularly vulnerable to abuse. As a result, it is our obligation to educate these learners to practise socially acceptable sexual behaviour. The purpose of this programme was to initiate change, rather than to create knowledge. The 20 participants were students at Unica School for children with Autism ranging from 12 to 17 years of age. Data were collected through clinical observation and field notes. In addition, a questionnaire was sent out to the 4 educators as well as to the respective parents/caregivers, consisting of open ended questions and Likert scale questions, enquiring about changes in previously observed inappropriate sexual behaviour. Subsequently this paper would fall in the cadre of action research. Feedback received from participants’ care givers and educators reflected that this visually based programme has had positive influential outcomes in terms of improved practice and awareness socially, hygienically, and socially.

Synthesis of six related TEACCH-based outcome studies for Autism Spectrum Disorders

Paul Probst University of Hamburg, Germany

While TEACCH (Treatment and Education of Autistic and Communication-handicapped Children) has shown promising evidence for clinical validity there is still a lack of international outcome studies. In this presentation, a synthesis of six TEACCH-based outcome studies for children and adults with ASD conducted by author in Germany is provided. Study 1 describes the outcomes of a controlled single-subject design with a 7-year-old girl in a residential setting. Study 2 analyses the outcomes of a 3-year TEACCH-based intervention in a vocational setting with 3 adults. Study 3 includes the outcomes of a 3-month-follow-up parent group training with 23 parents of 24 children. Study 4 reports the 3-month follow-up outcomes of a teacher training with 10 special teachers of 10 children. Study 5 describes the outcomes of a centre-based social communication programme with 2 older children and a young adult conducted by 3 facilitators, including a parent tutorial.

Rehabilitation
component. Study 6 (descriptive) reports the outcomes of a home-based child-parent programme with a 5-year-old boy. The outcome measures of the six studies embrace standardised questionnaires, behavioural observation instruments, and semi-structured interviews. Overall, the synthesis of these six studies provides support for the effectiveness and social validity of TEACCH-based interventions across different subjects, ages and clinical settings. The results are consistent with outcome studies from North America and Europe. Cross-cultural implications for the educational and health sectors are discussed.

Symposium title: Improving quality of life for people with disabilities
Convenor: Ishbel McWha

Access to mental health services for people with psychiatric disabilities living in a poor, rural community in the Eastern Cape Province, South Africa
Stine Braathen Stellenbosch University, South Africa; Leslie Swartz

People with psychiatric disabilities are among the most vulnerable and marginalised groups of any population. Despite their increased vulnerability to physical illness, they often lack access to medical, psychological and social services. There is a pervasive relationship between culture and psychiatric disability, but we know little about actual experiences at the interface between psychiatric disability, culture and accessibility to health services. This project uses qualitative, in-depth research methods to examine factors influencing access to mental healthcare among Xhosa speaking people with psychiatric disabilities in Madwaleni, South Africa. The results are based on in-depth interviews with people with psychiatric disabilities, as well as health care providers from both the professional sector (biomedicine) and the folk sector (healers and indigenous practices of various kinds). The results show that the availability of mental health care is limited in this community, and even where services are available, there is limited use of and access to them. The reasons for this are complex, varying from lack of awareness of mental health and mental health services, conceptualisation of mental health, living conditions of the users to working conditions for health professionals. The relationship between these factors will be described and discussed. This study shows that there is a need to raise awareness among health providers as well as the community on issues of psychiatric disabilities, such as causes and triggers, treatment possibilities, how to get help, referral and living with a psychiatric disability.

EquivFrame: Analysis of equity for people with disabilities in 51 health policies from Sudan, Malawi, South Africa and Namibia
Joanne McVeigh Ireland; Leslie Swartz; Mutamad Amin; Hasheem Mannan; Amani El Khatim; Alister Munthali; Gert Van Rooy; Malcolm MacLachlan; Shahla El Tayeb

While many health services strive to be equitable, accessible and inclusive, the right to health of people with disabilities often goes unrealised, particularly in low-income countries. A policy analytical framework was developed: EquiFrame, to evaluate (1) the extent to which 21 Core Concepts of human rights were addressed in policy documents, (2) coverage of 12 Vulnerable Groups, including people with disabilities, (3) Core Concept Quality (reflecting commitment to monitoring), and (4) Overall Summary Ranking (a composite). Literature searches and consultation workshops, with over one hundred stakeholders, practitioners and policy makers in Africa, contributed to identifying key issues for human rights and social inclusion. In each country two raters independently applied EquiFrame to policies that sought to address their major health challenges. 51 policies, ranging from disability policies to national health policies from Malawi, Namibia, South Africa and Sudan were assessed. In general, policies did not reflect the particular health challenges within each of the four countries. Our analysis highlighted some strong policies, serious shortcomings in others, as well as country-specific patterns. EquiFrame facilitates policy analysis and benchmarking, and provides a means for evaluating policy revision and development with regard to the promotion of human rights and social inclusion. If social inclusion and human rights do not underpin policy formation, it is unlikely they will be inculcated in service delivery. We call for a programme of health policy revision - across low and high-income countries - to promote the inclusion of people with disabilities.

A disability inclusive workforce: Evaluating a just-in-time toolkit for managers
Ishbel McWha Cornell University, United States of America; Hannah Rudstam

Managers are often the key gatekeepers of those employment decisions that most impact on disability inclusiveness in the workplace. Practical disability-focused training for this group is critical. However, traditional methods have had little success in reaching mid-level managers, perhaps because of their lack of time to invest in training, and rapid rates of turnover. In response to the need for non-traditional training approaches, the Northeast ADA Centre developed an innovative “Just in Time” programme; an online toolkit featuring ten quick and easy-to-use tools to address typical disability-related workplace situations faced by managers. In addition, the programme actively builds the capacity of each organisation’s affinity (“core”) group, who promote the toolkit and disability inclusiveness amongst their coworkers. This presentation will introduce the toolkit, and will outline the results of ongoing impact evaluation across a range of US organisations. An in-depth pilot of the toolkit with two organisations (one public and one private) has recently been completed. Data suggest a positive impact on core group capacity, including a significant increase in knowledge and behavioural intent. Interviews with managers indicate a potential for the toolkit to positively impact long-term disability-inclusive behaviour. Ongoing evaluation utilises a longitudinal approach, gathering data from managers at multiple time-points, while concurrently engaging the core group to provide insights on observed changes within their workplace. This research demonstrates the positive impact of a relatively low-cost intervention that can have on disability inclusiveness at work.

Access to healthcare for disabled persons in rural community in South Africa
Richard Vergunst United States of America

The study looked at the challenges that people with disability present to achieving access to healthcare in a poor rural community in South Africa. There is international evidence that people with disabilities face barriers when accessing health care services and that there is “inadequate specific information” available about effective interventions that work to improve the lives of people with disabilities. These findings call for “urgent attention to the issue of access to appropriate health care for people with disabilities especially in low income and middle income countries” (Tomlinson et al., 2009:1857). Disability and access to health care among the poor rural populations has received less attention. There is scarce data on their health needs (Lisher et al., 1996:45). While poor rural residents generally experience barriers to access to primary health care, these problems are further exacerbated for people with disabilities. Meeting the health care needs of rural residents with disabilities will require interventions beyond health care, involving access more broadly (Tezoni et al., 2006). This study used qualitative interviews in addressing access issues to health facilities for disabled persons in Madwaleni, a poor rural Xhosa community in South Africa. Health service users and providers were interviewed. Findings identified facilitators and barriers for disabled persons to access healthcare in the rural community.

Symposium title: Survivorship qualities with trauma
Convenor: Elias Mpofu

Social support mediated survivorship in Pakistani women with post-earthquake trauma
Elias Mpofu University of Sydney-Cumberland, Australia; Kaye Brock; Jasim Anwar

This study investigated social support effects on experiences of post-traumatic stress disorder (PTSD). Participants were 425 Pakistani women of reproductive age and with recent earthquake experience. The cross-sectional design study used data collected from the women using the Centers for Disease Control (CDC) reproductive health assessment toolkit. PTSD was measured using the Harvard Trauma Questionnaire (HTQ). A score of ≥ 2.5 from the HTQ indicated experience of PTSD. The survivor women had superior coping post-earthquake with supportive family and particularly spouses. Survivorship was also higher with continuity in housing arrangements, and gender sensitive health care services. Social support in the context of conservative community norms enhances survivorship in women of reproductive age and recent earthquake experience.
A neural network predictive model to estimate future transfer of knowledge to the work environment
Eduardo Cascallar Katholieke Universiteit Leuven, Belgium; Carla Quesada; Pilar Pineda

Given the level of importance and investment that personnel training has in a modern corporation, it is a central concern that the training provided to employees results in tangible changes in their work and has a measurable effect on the organisation. We offer a new approach to understanding the concept of statistical relationships in psychological research, which provides a method of multiple comparison for quantile splittings of data sets (objects) for each measured psychological parameter. Thus, it is necessary to refuse a preliminary promotion of a hypothesis about the form of the dependence (linear or any other concrete non-linear dependence). That is, the method allows us to determine, for an investigated matrix of the data, both the form of dependences, and a degree of their expressiveness with regards to various pieces of test scales, in a unified system of measurement. This system has achievable norms for coefficients of connection strengths, resulting in the analogues of individual correlations accepting values close or equal to a unit. We will consider the programme-realised method of classification of dependences (for the author’s method of the studying of statistical dependences). Classification are defined kinds of dependences: 11 for triads, and 28 for quarters. The basic types of dependences: dependence with a maximum and a minimum, increasing and decreasing, but not linear fluctuations max-min and min-max. In each type we include various quantities (from 2 to 9) of kinds of dependences (for fewer triads, as they have more than quarters), which are defined by symmetry, as well as the general increasing or decreasing tendency, shift to the left or to the right, and uniformity of change. Criteria for such automatic classification are defined.

Utilising evaluation research as mechanism for empowerment, knowledge and skills diffusion
Hester-Louise Henderson UNISA, South Africa

The context in which the majority of smaller not-for-profit (NPO) and community based organisations operate in Africa does not always lend itself to the easy implementation of sophisticated evaluations as required by their funding organisations. Furthermore, funding agencies and the community based organisations - the recipients of this funding, do not always define the parameters indicating the success of a project similarly, resulting in both parties being left frustrated by the results the evaluation methods produced. It is therefore pertinent that evaluation studies, especially those conducted in low or under resourced areas and smaller organisations in Africa, be approached with more than merely the primary goal of outcomes measurement. It is suggested that evaluation methodology incorporate mechanisms through which the process of evaluation creates opportunities for both the empowerment of target organisations and the transfer and diffusion of knowledge and skills to and within these organisations and their service beneficiaries. Secondly it should allow for the collection of data in formats that are meaningful and functional for both the funding and target organisations and their beneficiaries.

Enabling active participation of hospitalised children through the use of participatory techniques
Coyne Imelda Trinity College Dublin, Ireland; Ana Martins

The aim of the study is to share our experiences of using participatory techniques to enable children and young people (aged 8 to 16 years) to express their views on decision-making. There has been a methodological shift in research methods, from approaches that view children as ‘passive actors’ to methods which engage children as ‘active participants’ in the representation of data. Participatory techniques help to reduce the power differential in researcher-child relations. The successful use of participatory techniques lies in the process of information-sharing, discussion, and action rather than simply on the type of tools used. Children represented one group of participants from a larger qualitative research project which sought multiple perspectives (parents, doctors, nurses and allied healthcare professionals) on triadic decision-making in a children’s hospital in Dublin, Ireland. Data were collected through single interviews, focus groups, participatory observation and participatory techniques. The first phase involved participatory observation and individual interviews with children (n=10), their parents and healthcare providers. The second phase involved probing questions on data from phase one, with the purpose of understanding rationale for behaviour, which could be challenging. Therefore participatory techniques were used with individual interviews and focus group discussions to enable dialogue about abstract aspects of decision-making. We used photovoice, sorting cards and diamond ranking exercises which are a visual representation of ideas designed to work with children of different ages with varied literacy skills. Participatory techniques relaxed the children, encouraged active participation, promoted dialogue, facilitated explanations and enriched the data.

The development and validation of an adja-cency segregation analyzer
Nicola Jacobs University of KwaZulu-Natal, South Africa; Michael Quaye; Emmanuel Dufourq; Kevin Durheim

A number of different methods are available to quantify segregation at the macro-ecological level of cities, towns, and neighbourhoods. While this level of analysis offers a valuable understanding of broader political and economic issues, it neglects to investigate how interactions on an individual level can constitute or sustain segregation. With the exception of the seating adjacency index of Camp-
bell, Kruskal and Wallace (1966), there is a notable dearth of measures of segregation at the micro-ecological level of face-to-face contact. We propose a new way of quantifying micro-ecological segregation that has a number of advantages over the Campbell, Kruskal and Wallace I-index. Our alternative, entitled the Adjacency Segregation Analyzer, computes individuals’ segregation scores across three different levels of intimacy, and then aggregates these scores to provide a segregation score for the space as a whole. In addition to these observed statistics, the Adjacency Segregation Analyzer uses bootstrapping to calculate segregation z-scores, to determine whether these observed scores deviate from those expected under an assumption of randomness. The Adjacency Segregation Analyzer has performed well in validity tests and has been found to address the limitations in the Campbell, Kruskal and Wallace I-index. We thus propose that the Adjacency Segregation Analyzer is a viable alternative to the CKW-A index and provides a useful tool for the quantification of segregation.

The efficacy of the Parenting Education Program
Irwan Nuryana Kurniawan Freie Universität Berlin, Indonesia

The Parenting Education Program is designed to help parents acquire and internalize foundational parenting skills, knowledge regarding school-aged child development, and a basic spiritual approach to parenting. This will assist them to raise their children effectively, leading to positive outcomes for both parents and children. The purpose of this study is to evaluate the efficacy of the parenting education program as indicated by the knowledge, skill, and behavior changes reported by participants. A retrospective post/pre rating survey was administered to 29 participants from 3 experimental groups (ages 6-10; n =11) after they completed all sessions of the parenting education program. The sample consisted of 29 participants (27 women and 2 men), each parent with at least one child at elementary school. Participants’ ages ranged from 29 to 52 (M=37.94, SD=5.20). Mean scores and the paired sample t-test were used to determine the significance level of changes. The results provided preliminary support for efficacy of the parenting education program. Participants reported statistically significant improvement in their ability to use the five foundational parenting skills, their confidence in parenting, and their satisfaction within their family. Parents reported a significantly increased ability to try different approaches and deal with challenging situations. The implications of the current findings and the limitations of current study are discussed.

Applying fuzzy set theory principles to analyse Likert scaled data
Natale Le Roux University of the Free State, South Africa

Likert scales or Likert type items are commonly used in questionnaire design to collect psychological and educational data (Gob, McCollin & Ramahoto, 2007). Responses to the Likert items are generally viewed as ordered categorical observed variables in which the underlying trait is latent or unobserved. In practice, parametric and non-parametric statistical methods are used to analyse Likert scaled data with varying success. The “permissible statistics” controversy has divided social scientists into two opposing groups, namely the pragmatists and the fundamentalists. The debate about which is the most appropriate statistical method to analyse Likert scaled data are the focal point for this research. Baillie (1993) asserts that psychological concepts are vague and imprecise and their boundaries are not clearly defined. The principles of Fuzzy Set Theory have been proposed to analyse imprecise and vague data. The objective of this research is therefore to apply the principles of fuzzy set theory to analyse Likert scaled data and secondly to compare the results to a non parametric and a parametric statistical method. A comparative analysis will be conducted between the fuzzy conjoint model, the proportional odds model and analysis of variance (ANOVA).

The visual image as discussion point: Increasing validity in boundary crossing research
Linda Liebenberg Resilience Research Centre, Canada

This presentation is based on a larger study exploring the use of visual methods as a communication tool in research where the researcher crosses boundaries such as culture, context, age and so forth. To illustrate the value of this methodology, particularly in instances where power imbalances are heightened in the research context, a case study was conducted with five teenage mothers from a sub-economic community outside Cape Town, South Africa. This presentation will explore how the use of visual methods contributes to increased validity of data. Specifically, this discussion will consider how the use of images as a communication tool increase participant control over the research process, and incorporates participant self-representation via a period of self-exploration, improving contextual accuracy and relevance of data.

Research as human elevation
Helena Marujo University of Lisbon, Portugal; Luis Neto

Transformatively, appreciatively, phenomenological and systemic (TAPS) research refers to investigations that are framed by a fundamental appreciation of what works in a given context, and that strive to respect phenomenological experiences, uphold, and improve life in relation to the myriad potentialities and solutions already present, involving dialogues and communion between all the systems that interact in a particular setting. This type of research has an immediate practical orientation, where addressing social justice, changing power issues, implementing critical pedagogy and activating participatory actions are vital, but is also for the sake of scrupulous methodology and perceptive theory. The model is supported by the idea that questioning is always intervening, and that there is a moral obligation to use research as a way to improve human lives, transform social realities, and mobilize people and community’s recognition of resources and strengths as outcomes of investigation. The TAPS research processes involve (a) qualitative methods that give an active voice to all the participants; (b) appreciative and positive inquiry; (c) systemic, collective and dialogic dialogues involving all the stakeholders; (d) the three temporal dimensions (past, present, future); (e) different languages (poetry, photographs, drawings...) complementary to verbal methods of gathering data, enrolling right and left brain hemisphere strategies; (f) the researcher’s perspectives and feelings during the recollection of data and its analysis. The model defends, nevertheless, that it is mostly through meticulous description and compelling explanation that the findings can lead to constructive, actionable implications. This type of research follows a dialectical path to make it meaningful and significant in terms of realism, responsiveness, practicability and effectiveness. As Paulo Freire described it, the dialectics of research is a praxis, considering that a research study that is not aimed to transform risks is an exercise in futility. We would also add that a research process focused on the problems and needs, in individuals per se, and in pre-determined inquiry, also risks being detrimental – it risks drawing attention to what is not functioning in a person’s life, reinforcing isolation of individuals from their contexts, histories and collective endeavors, and risks passivity and distance towards science and its mechanisms. Supported on the TAPS model, examples and data from several research processes coordinated by the authors will be detailed, including domain areas as diverse as community actions, health programs and clinical work, exemplified in research projects on (1) well-being in populations living in poverty, (2) post-traumatic growth processes in children with terminal diseases, their families and health professionals, and (3) micro-analysis of communication processes between therapists and clients in positive clinical psychology. In all the cases presented there will be a focus on the processes, factors and hermeneutics involved, as much as on how research infused the participants with their creative presence and empowered them and their communities by means of the positive, appreciative and innovative dialogues that transcended a fusion of understandings, creating emancipatory conversations in practice.

Determinants of risk behaviours among adolescents: Implications for educational policy in Latin America
Hugo Morales Pontificia Universidad Católica, Peru

The education system in Latin America typically does not stimulate non-cognitive learning outcomes. Empirical evidence suggests that non-cognitive achievements can act as a protective factor in future risky behavior when these consist as part of the educational goals. These outcomes are relevant for the promotion of a healthy lifestyle during the life course. According to the Pan American Health Organization (2008), the problems of public health and safety originate at school age, especially during adolescence. There is empirical evidence for the influence of the school in preventing risky behavior among adolescents (Rutter, 2005). The aim of this study is to identify the causal factors that act as determinants in different behaviors such as delinquency, drug use, unprotected sex and gang membership in a sample of 1,000 students of secondary education last year in Peru. We evaluated a taxonomy of risk behavior and risk-protection variables reported by the international literature through an anonymous survey. The results showed that student, family and school variables act as predictors of...
risks behaviors such as delinquency, drug use and unprotected sex. Similarly, school protective factors were associated to such risk behaviors. The attachment between teachers and their students were significant outcomes. A probit causal model with ‘random effects’ was estimated in order to analyze comparatively the school effects in comparison to the student variable effects and their families on risky behavior. Finally we discuss the relevance of these findings for the design of educational policies (based on evidence) that contribute to the promotion of healthy lifestyles.

Psychological research: In theory and praxis

Carlos Rivera University of Puerto Rico, Puerto Rico; David Fryer

From our community’s critical psychology standpoint, we regard it as essential to engage with critical methodology, radical reflexivity, ethical-ideological-political considerations and institutional power in relation to the manufacture and legitimation of knowledge through psychological research, and to do so not just in theory, but to enact research practically in radically different ways. Whilst community psychologists, radical psychologists, critical psychologists, critical social psychologists, feminist psychologists and others have called for years for a reconstruction of research in psychology, problematising areas such as the conceptualisation of subjectivity, the ontology of the subject, relational and recursive knowledge construction in research, institutional power fluctuations from dispositions that transcend research, etc., the transition in practice from traditional ways of doing research in psychology to less problematic ways, has seldom actually been achieved. We call for the rethinking of the ‘reviewing’ of literature, the obliteration of differences between theory and practice, the explication of links between methodological and theoretical aspects of research, the uncovering and critiquing of ethical-ideological-political positions taken up, implicitly or explicitly, by researchers and the reconstitution of knowledge from a critical standpoint. We call for reflection on questions such as: What impediments and impositions inhibit the development of new ideologically progressive, theoretically sophisticated, effectively emancipatory research? What would constitute resistance to such impediments and impositions? And, crucially, how can such resistance be facilitated?

Deconstructing the focus group as a transformative methodology and potential intervention

Mario Smith University of the Western Cape, South Africa; Maryam Papadaki; Ronelle Carolissen

Focus groups have traditionally been conceptualised as having advantages such as, increased number of participants, observable dynamic interactions, and cost-effectiveness when compared to other qualitative methodologies. An aspect of focus groups that has been referred to in process comments, but has not been optimally explored from a methodological point of view is the transformative nature of focus groups. It is thought that this transformation comes about as a result of participants needing to qualify and even sometimes defend their beliefs and opinions. As mentioned before, this often happens as an aside, rather than an intentional consideration on the part of the researcher. the aim of this paper is to report on a study where the transformative nature of a focus group was intentionally investigated. the paper reports on a study where three focus groups were facilitated with 9 health professionals who work in the area of sexual abuse and/or intellectual disability to explore their familiarity with the statutes regarding sexual offences. Findings indicated that the category of registration and place of employment largely determined both familiarity with statutes and general stance towards knowledge of legislation. Clear shifts in perception took place among the participants underscoring the transformative power of the focus group methodology. Participants reflected on the need to effect behavioural and attitudinal change as a result of having participated in the focus group.

My first Bayes: How to run your first Bayesian model using MLWIN/AMOS/MPLUS

Rens Van De Schoot Utrecht University, Netherlands

Did you ever encounter one of the following problems: (1) A data set too small for your complex model? (2) Non-normally distributed variables? (3) Negative variances? Or did you ever want to compute: (1) The probability that your hypothesis is true after observing the data? (Note that this is not the interpretation of the classical p-value.) (2) A 95% probability that your estimate (e.g. mean, regression coefficient) is in between two values. (Note that, again, this is not the interpretation of the classical confidence interval.) During this workshop you will be introduced to Bayesian statistics. This includes: Bayes theorem, why and when to use Bayesian statistics, P(H|data) versus P(data|H), choosing prior distributions, interpreting posterior distributions and how to do with posterior estimates. The emphasis will be on applying the methodology to solve the issues mentioned above.

Multidimensional item factor analysis with optimal ridge maximum likelihood estimator

Rulin Wu Beihang University, China

Multidimensional Item Factor Analysis (MIFA) is a popular topic in recently research of mathematical and statistical psychology. The limited information estimation method for ordinal data based structural equation modelling framework is strength of less time consume. However, when it is employed more non-converging results and Heywood cases are incurred, especially when the Maximum Likelihood (ML) estimator is used. Ridge ML method (or Tikhonov regularisation), which performs better than ML in terms of convergence rate and convergence speed, has been developed (Yuan, Wu, & Bentler, 2011). The current study extends the ridge ML method, and proposes an approach for choosing optimal value of regularisation parameter. The Monte Carlo simulations about MIFA are conducted. Results show the optimal regularisation approach based on minimum of mean square error of estimates offers more accurate estimates.

Using different single-case designs to illustrate academic procrastination interventions

Fan Wu University of Houston, China

The purpose of this study is to illustrate the advantages and disadvantages of different single-case designs using an intervention for academic procrastination as an example. Single-case research has played a crucial role in evaluating interventions designed for behaviour modification (Kazdin, 2011). Four single-case designs will be discussed: A-B-A design, multiple-baseline design, A-B-C design, and changing-criterion design. Academic procrastination is common among students and adults; it also influences learning and achievement negatively (Clark & Hill, 1994; Harriott & Ferrari, 1996; Solomon & Rothblum, 1984; Wesley, 1994). About half of the college students procrastinate consistently (Day, Mensink, & O’Sullivan, 2000). Possible associations of procrastination include depression, anxiety, and low self-esteem (Lay, 1992; Lay & Schouwenburg, 1993; Lay & Silverman, 1996; Martin, Flett, Hewitt, Krames, & Szanto, 1996; Saddler & Sacks, 1993; Senecal et al., 1995; Solomon & Rothblum, 1984). Cognitive and behavioural interventions have been used with students who procrastinate. Five interventions will be discussed: strategies for achievement - a web-based course, task management groups, brief cognitive-behavioural coaching, time management training, and a study skill course intervention. An academic procrastination workshop which integrates the content of the five interventions will be offered to students and adults. Four single-case designs will be used to illustrate this intervention. Hypothetical examples and graphs will be used to demonstrate how each design will work. Advantages and disadvantages will be discussed.

Session Type: Posters

New methodology: Are computer and paper and pencil based tests equivalent?

Marta Boinski University of Gdańsk, Poland; Paweł Atrozsko University of Gdańsk, Poland; Janina Nowak University of Gdańsk, Poland

Technological progress has enabled new possibilities in the field of psychological studies. Currently, it is common to conduct computer based research via the internet. However, to date there are no systematic studies which would demonstrate equivalence between measurement of psychological variables with paper and pencil, and computer based versions of questionnaires. There seems to be a shared implicit assumption among psychologists that there are no differences between the results obtained through these two methods of measurement. In order to empirically test this presupposition, our research team has begun a research project, the aim of which is to identify possible sources of inequivalences between these two types of measurement in psychological studies. The methodology incorporates different testing sequences, a wide spectrum of psychological traits which may vary according to their stability in time, systematically modified testing interfaces, and different samples of subjects varying in important demographic characteristics: age, education, sex. The preliminary results suggest notable differences of correlation coefficients between two versions of scales for different measured variables.

The exploration of context in intergenerational relationships

Monique Fourie NWU Potchefstroom Kampus, South Africa

The goal is to explore how different contexts in which people grow up have an effect on intergen-
erational relationships. A collective case study was adopted as research design. The theoretical framework used was the theory that events early in life affect your current behaviour thus, also your social relationships with people around you. We also looked at how things we pick up subconsciously can affect our outlook on life and how we perceive others. Data were collected using the Mnemo-method® (Roos, 2008; Roos, 2012.). The participants were 18 students and 15 elderly people (60+ years old). Data were collected from observations, reflections, visual information, transcriptions and group discussions, and were analysed using thematic analysis. Before the study, we wanted to know whether context has an effect, and if so, in what way. It was found that context, specifically cultural, values, religious background, and experiential contexts do have a marked influence on intergenerational relationships, because the differences in these fundamental aspects of life affect the way older and younger people interact, which in turn, has an effect on intergenerational relationships. The findings have promise in helping future researchers to uncover a way of making it easier to find common grounds for people from different generations to connect, relate and form better relationships.

An interdisciplinary challenge: Method triangulation in the field of educational neuroscience

Danilo Jagenow; Free University Berlin, Germany; Frances Gottwald; Diana Raufelder; Aimee Ferreira

There is an ongoing debate about the relationship between the disciplines of education and neuroscience, which are characterised as “a bridge too far.” We show how these disciplines can profit from each other. Based on a methodological technique that directly links quantitative, experimental and qualitative data, an interdisciplinary study was designed, to bridge the gap between neuroscience and education by using method triangulation. In our SELF-study[1], the methodological procedure (1st step) starts with a quantitative survey (N=1000 students), investigating educational and psychological aspects of socio-emotional factors and motivation in school. By using latent class analysis four different learner types could be identified: (1) teacher-dependent learner, (2) peer-dependent learner, (3) peer- and teacher-dependent learner, (4) independent learner. In experimental studies (2nd step), the variables (socio-emotional factors) will be evaluated in terms of their effectiveness with maximal accuracy by using neuroscience procedures. In an event-related fMRI study, differences in striatal activation between the different learning types using a probabilistic learning task (Remijnse, Nielen, Uylings, & Veltman, 2005) will be tested. Qualitative guided interviews with the 48 students from the fMRI study will be used (3rd step) to gain a closer description of the four different learning types and the empirical reality of social relationship and the daily learning processes in school. We expect to identify basic principles of the interaction between learning-processes, motivation and socio-emotional aspects of adolescents by applying a behavioural, cognitive as well as the biological (neuronal) approach. [1] SELF = socio-emotional learning factors.

New methodology: Are computer and paper and pencil tests equivalent?

Nowak Janina University of Gdansk, Poland; Marta Boiniska University of Gdansk, Poland; Pawel Atroszko University of Gdansk, Poland

Technological progress has enabled new possibilities in the field of psychological studies. Currently, it is common to conduct computer based research via the internet. However, to date there are no systematic studies which would demonstrate equivalence between measurement of psychological variables with paper and pencil, and computer based versions of questionnaires. There seems to be a shared implicit assumption among psychologists that there are no differences between the results obtained through these two methods of measurement. In order to empirically test this presupposition, our research team has begun a research project, the aim of which is to identify possible sources of inequivalences between these two types of measurement in psychological studies. We have explored different testing sequences, a wide spectrum of psychological traits which may vary according to their stability in time, systematically modified testing interfaces, and different samples of subjects varying in important demographic characteristics: age, education, sex. The preliminary results suggest notable differences of correlation coefficients between two versions of scales for different measured variables.

The identification of desirable and undesirable processing strategies by fixed-links models in repeated measures data

Karl Schweizer Goethe University Frankfurt, Germany

Fixed-links models are useful tools for the identification of all kinds of method effects and also of processing strategies that are chosen by participants in completing the items of a cognitive measure. The precondition for the identification of processing strategies is that they incorporate different testing sequences, a wide spectrum of psychological traits which may vary according to their stability in time, systematically modified testing interfaces, and different samples of subjects varying in important demographic characteristics: age, education, sex. The preliminary results suggest notable differences of correlation coefficients between two versions of scales for different measured variables.

A review of integrative data analysis using across independent longitudinal studies

Wenqing Tang South China Normal University, China; Mingqiang Zhang; Jieting Zhang

Metal-analysis is a noteworthy method that fosters the development and maintenance of cumulative psychological science. In development psychology, though it is essential to develop cumulative and innovative development psychological science, usage of meta-analysis limited by the amount of published information on particular research issue, the complexity of longitudinal designs, the sophistication of analyses, and practical limits on full reporting of results. Integrative data analysis (IDA) has been considered and proved by several studies to be necessary and effective in the pursuit of cumulative psychological science, as well as in a cumulative development psychological science, when raw data are available. IDA is defined as an emerging set of methodological techniques that involves the simultaneous analysis of multiple independent samples? it was characterised by a host of advantages, but also some challenges in development psychology. There are also some practical explorations in analysis of pooling longitudinal studies. The article drops the focus on a review of IDA using in pooling longitudinal studies under the combinational framework. We described the theoretical foundation of IDA and its procedure in analysing multiple longitudinal studies; especially discussing the psychometric models that dealing with different kinds of heterogeneity in pooling data analysis. In summary, the authors concluded with a discussion of potential limitations and directions for future research on IDA in longitudinal studies.

Reliability and validity of essay tests under different testing and scoring designs: A simulation study

Satoshi Usami Tokyo Institute of Technology, Japan

In Japan, essay-type tests have been widely used in university entrance examinations and national surveys, as a result of strong needs among teachers, and examiners, to assess, not only knowledge and understanding abilities, but higher-level abilities in educational assessment. However, in essay test scoring, rater disagreements generally arise in practice, and this often leads to a serious influence on test quality (i.e. reliability and validity). Additionally, testing designs such as scoring methods, the number of rating points, the number of raters and items and resolution methods (i.e. how to adjudicate (also referred to as "arbitrate" and "moderate", see Penny and Johnson, 2011) the rater disagreements to report a single item score), are also important keys for reliability and validity of essay tests. In the present research, we performed two wide simulation studies to provide the answers for a question: what factors have the strongest impact on the reliability and validity of essay tests, and what is the best way to improve the reliability and validity of essay tests in practice? In simulation 1, we compared the results of reliability and validity based on reliability coefficient (i.e. correlation between true scores and actual test scores) and accurate pass/fail rates, under different testing and scoring designs. In simulation 2, we comprehensively evaluated the impact of different resolution methods (i.e. rater mean, parity, tertium quid, and expert) on reliability and validity of essay tests.
Functional principal component analysis in ERP
Min-Qiang Zhang South China Normal University, China; Min-Ping Xiong
Event-related potentials are collected by placing electrodes on the surface of the scalp. These studies produce millions of datapoints every few seconds, and the points are correlated in time. These data thus consist of highly intercorrelated observations. However, traditional statistical methods ignore the obvious autocorrelation between successive points and cannot analyze these high-dimensionality points. Nevertheless, functional data analysis makes up for these shortcomings, and in addition, functional principal component analysis can reduce dimensionality and reveal latent structure in the relations between variables. Consequently, this study firstly analyze ERP signal with the functional principal component analysis method. These three principal components extracted with a functional principal component analysis method are fully consistent with cognitive outcomes. The good conclusions powerfully support the analysis of ERP signal.

The development and theoretical underpinnings of the Mmogo-method
Vera Roos North-West University, South Africa
Existing data-gathering methods mostly neglect the contextual dynamics in which meanings emerge and within which they continue to exist. The aim of the presentation is to discuss the theoretical underpinnings as the rationale for the development of the Mmogo-method that can provide social researchers with a deeper understanding of the personal, relational as well as the collective experiences, perceptions and meanings of people in cross-cultural and intergenerational research contexts. In this method, people create their own data by making visual representations that project meanings on different levels and which is jointly explored in a participatory manner. The Mmogo-method is regarded as a visual research method which is used to access unconscious meanings of participants’ lived experiences. Participants are asked to place themselves in a circle comprising eight to ten people. They are then asked to make a visual representation based on an open-ended prompt by using malleable clay, colourful beads and straws. The visual representations are regarded as external narratives and data are obtained by exploring the visual representations of each of the participants individually as well as the informal group discussions that emerged spontaneously from the group about the topic. Case studies of different research contexts will be discussed to illustrate the process of how deepened complex interpretations were derived at. A practical demonstration of the application of the method will also be included in the presentation.

Critical discussion of the papers in the symposium
Catherine Ann Cameron University of British Columbia, Canada
Prof Ann Cameron from the Psychology Department, University of British Columbia, Vancouver, B.C., will critically discuss the papers presented in the symposium: "The Mmogo-methodTM: Gaining a deeper understanding of personal, relational and collective meanings in people in different contexts".

Applying the Mmogo-method: Experiences of loneliness among Batswana older people
Carlien Kahl South Africa
Ageing in Africa and the world is an all-encompassing phenomenon that affects individuals and societies. An expanding older population (people aged 60+) in South Africa led to this research, which represents an attempt to explore the experiences of loneliness from an African perspective. The aim is to gain some understanding of the subjective experiences of loneliness in specific socio-cultural contexts as the existing literature’s applicability to these contexts is uncertain. Qualitative research was used together with a convenience sampling method whereby Setswana-speaking older people (16 women and two men) from Ikageng, Potchefstroom, South Africa were selected. Data were collected by using multiple qualitative data gathering methods: in-depth individual interviews, the Mnogo-method, group discussions, reflexive notes and observation. Multiple data analyses included phenomenological analysis, key-words-in-context and strategies stipulated by the Mmogo-method. These analyses enhanced trustworthiness through crystallisation. The results showed that loneliness in this context is experienced as a lack of meaningful interactions with other people and coping with loneliness is primarily to connect with other people – to be with them, through daily conversations and to initiate contact by engaging in shared activities. Loneliness is also managed by maintaining intergenerational relationships and to interact with significant people at traditional ceremonies. The Mnogo-method is regarded as a qualitative data gathering method that assisted researchers to obtain data in a culturally-sensitive manner, because it is a method in which personal, relational and collective meanings can be expressed.

The value of the Mnogo-method in a participatory community-embedded project with rural Sotho adolescents
Linda Theron NWU, South Africa
The value of the Mnogo-method in a participatory community-embedded project with rural Seseho adolescents will be discussed. The aim of this paper is to comment critically on the methodological value of this method with rural youth who have limited English and who are typically bound by cultural conventions when interacting with adults. The broader context of the study is the five country Pathways to Resilience study which is a mixed methods study that is investigating the formal and informal pathways of youth resilience. South Africa is one of the five participating countries and our research site is located in the rural Eastern Free State. Most of our participants are growing up in traditional Africentric ecologies. One consequence of this context was the need to include qualitative methods that resonated with the culture of our participants and so we included the Mnogo-methodTM. Drawing on these lived experiences with rural, Seseho-speaking adolescents, we report benefits of this method (i.e., Africentric cultural alignment, generation of rich data, serendipitous therapeutic potential), and considerations for future use (i.e., smaller group size, presence of culturally competent researchers, collective Mnogo-building towards closure, and ethical imperatives).

Applying the Mnogo-method to older women to explore loneliness and quality of life
Vera Roos North-West University, South Africa
The aim of this presentation is to illustrate the use of the Mnogo-method together with focus groups and diaries to explore the subjective experiences of women regarding loneliness and quality of life. Loneliness is associated with and chronic conditions, anxiety and depression exist which impairs quality of life (QoL). In the study on loneliness, 15 older women voluntarily participated at a service centre for the older persons in Potchefstroom, North West Province, and 10 older women at a residential care facility in Bloemfontein, Free State Province of South Africa participated in research about their quality of life. The visual data obtained from the Mnogo-method was analysed by means of semiology and the textual data obtained from discussions about each visual representation were analysed by means of thematic analysis. The Mnogo-method contributed to access rich data from the participants which were supported by the data obtained from the focus groups and diaries. The projections that were elicited through the Mnogo-method provided a forum for the group to share experiences in a non-threatening manner. The manner in which the research is conducted also seems to facilitate a trusting relationship among the participants, including the researcher. In both cases of data collection it was found that the projections were used by individuals as a medium through which they could communicate feelings and experiences that was not obtained in the individual interviews or the diaries.

My first Bayes: How to run your first Bayesian model using MLWIN/AMOS/MPLUS
Rens Van De Schoot Utrecht University, Netherlands
Did you ever encounter one of the following problems: (1) A data set too small for your complex model? (2) Non-normally distributed variables? (3) Negative variances? Or did you ever want to compute: (1) The probability that your hypothesis is true after observing the data? (Note that this is not the interpretation of the classical p-value.) (2) A 95% probability that your estimate (e.g. mean, regression coefficient) is in between two values. (Note that, again, this is not the interpretation of the classical
During this workshop you will be introduced to Bayesian statistics. This includes: Bayes theorem, why and when to use Bayesian statistics, P(H|data) versus P(data|H), choosing prior distributions, interpreting posterior distributions and what to do with posterior estimates. The emphasis will be on applying the methodology to solve the issues mentioned above.

The German national educational panel study: A new database for psychologists interested in empirical educational research

Thomas Baeumer NEPS, University Bamberg, Germany; Hans-Peter Blossfeld; Hans-Guenther Rossbach; Sabine Weintert; Jutta von Maurice NEPS, University Bamberg, Germany

The German National Educational Panel Study (NEPS) provides access to a huge data base on educational processes and decisions, learning opportunities, competence development and returns to education. In addition, the special situation of migrants in Germany is focused on. The samples cover the whole lifespan from birth to retirement and beyond. To make information about relevant educational processes over the entire life course available as quickly as possible, a multi cohort sequence design is utilised. Starting in 2009, the data of the first wave of a starting cohort of adults aged 23 to 64 years is already open to the scientific community. Data collection of four additional starting cohorts (kindergarteners, fifth-graders, ninth-graders and college freshmen) began in winter 2010/2011 and data will soon be released by the NEPS Data Center. Finally, a birth cohort (seven-month-olds) will start in 2012. Overall, the sample size approaches 60,000 target persons as well as 40,000 context persons (parents, childminders, educators, teachers and principals), making the NEPS one of the greatest scientific endeavours in social sciences. In this presentation, we will give an overview of the conceptual and theoretical bases of the panel study and the constructs and variables that are implemented in the assessments so far. We will focus on two areas that may be of special interest for psychological analyses: measurement of competencies and competence development over the lifespan as well as educational processes and opportunities in formal, non-formal, informal and family learning environments.

The survey of health ageing and retirement in Europe: A European research infrastructure on aging

Frederic Malter Germany; Ivo Noci

Turning the challenges of population ageing into chances is a top priority for Europe and many countries around the world. The Survey of Health, Ageing and Retirement in Europe (SHARE) helps to understand individual and societal ageing. It is an infrastructure that collects micro data on health, socio-economic status and social and family networks of more than 40,000 individuals aged 50 or over. The third wave of data collection in 2008/2009 (SHARELIFE) focuses on the life histories of the participants and allows to assess the effects of welfare state interventions through the linkage of individual micro data over the respondents’ entire life with institutional macro data on the welfare state. Currently (Nov. 2011), the fourth wave is being finalized in 18 countries, with Estonia, Hungary, Portugal and Slovenia as new additions. The current wave brought new cutting-edge innovations to SHARE. An extended module on social networks was added to the instrument, allowing a detailed assessment of respondents’ social embeddings and satisfaction with social connections. This new module will enable us to explore critically under-researched aspects of older people’s life, e.g. relationships between retirement and social connectedness. Further, in the German subsample, experiments are being conducted regarding interviewer training and respondent incentives, as well as the highly innovative collection of dried blood spots that will enable researchers to examine a whole new dimension of relationships between objective biomarkers and socio-economic characteristics.

The multiple-cohort longitudinal study SOEP as a rich data source for psychological research

David Richter Socio-Economic Panel Study, Germany; Juergen Schupp; Gert Wagner

The German Socio-Economic Panel Study (SOEP) is a wide-ranging representative longitudinal study of private households. Every year, nearly 11,000 households and more than 20,000 individuals are interviewed. Data provide information on all household members, including Germans living in the states of both the former East and West Germany, foreign citizens, and recent immigrants to Germany. The panel was started in 1984. The SOEP sampling framework allows for longitudinal analysis of the entire life course within the household context. Initially, the survey focused primarily on questions informed by concepts from economics and sociology as well as political science. Psychologists have discovered the SOEP data in recent years as well, mainly for longitudinal measurement of life satisfaction. The SOEP has included particular psychological concepts (i.e. locus of control), however, since as early as the 1990s. Additional concepts such as personality, reciprocity, subjectively rated justice, tendency to forgive, affect and mood, as well as cognitive competencies have been added since then. Correspondingly, the number of SOEP-based publications in high-impact psychological journals is increasing steadily, partly due to the fact that the SOEP data are freely available for scientific research purposes. The presentation will give a brief overview of the SOEP and the psychological concepts measured. In addition, we will lay out the possibilities for researchers to influence and shape the SOEP survey programme. In particular, the recently launched “Innovation Sample” will offer unique opportunities to introduce new survey concepts and engage in interdisciplin ary collaboration.
International research on addiction and mental health: Fostering collaborations

Merry Bullock
American Psychological Association, United States of America

The United Nations Office on Drugs and Crime (UNODC) and the World Health Organisation (WHO), report that illicit drug use is 1 of the top 20 health risk factors globally. In fact, drug use disorders are associated with an increased risk of HIV/AIDS, hepatitis, tuberculosis, suicide, overdose deaths, and cardiovascular diseases. According to the 2011 UNODC World Drug Report, nearly one-fifth (17.9%) of the world’s injection drug users have HIV; more than half (50.3%) have hepatitis C; and nearly one-quarter (22%) have hepatitis B.

As part of the National Institutes of Health (NIH), the National Institute on Drug Abuse (NIDA) encourages international collaborative research applications on drug abuse and addiction that take advantage of special opportunities that exist outside the United States including access to unusual talent, resources, populations, or environmental conditions in other countries that will speed scientific discovery.

This presentation will highlight the mission of NIDA and its scientific priority areas including: linkages between HIV/AIDS and drug abuse, and prevention, initiation, and treatment of nicotine and tobacco use (especially among vulnerable populations such as children, adolescents, pregnant women, and those with co-morbid mental disorders). Innovative research funded by NIDA include all areas of science addressing drug addiction including but not limited to prevention, basic science, epidemiology, treatment and health services. Other NIH international programmes, research training, and funding opportunities, including the NIH Fogarty International Center, will also be highlighted.
Research Area: Sexuality

Session Type: Papers

Facilitating intergroup contact to reduce sexual prejudice: A contact hypothesis intervention
Clinton Anderson American Psychological Association, United States of America

This presentation describes an intervention to facilitate interpersonal contact that reduces sexual prejudice and to buffer lesbian, gay, and bisexual people and their allies who undertake the intergroup contact from the negative mental health effects that may result from the stress of the contact. The Michigan (US State) Psychological Association developed the intervention for use by psychologists and other mental health professionals with grant funding from the Arcus Foundation. Extensive research on the contact hypothesis has shown that intergroup contact between majority and minority group members reduces prejudice against the minority group among the members of the majority group, including reductions of sexual prejudice from contact between sexual minorities and heterosexual people. Further, research on resilience and minority stress suggests that sexual minorities may combat minority stress by engaging in various forms of coping, including socio-political activism and seeking out social support. Five skills are the core of the intervention: (1) evaluating the risks and rewards of initiating prejudice-reducing intergroup contact; (2) identifying people who are appropriate targets of prejudice reduction; (3) reducing the target’s anxiety in the contact; (4) using helpful language and body language; (5) recognising possible negative feelings and emotions that may be experienced during or after intergroup contact and addressing them through self-care, stress management and professional help, if indicated. The presentation will include evaluation results from the use of the intervention. Participants will guided through a process of identifying potential settings in which they might provide the intervention and provided information about how to obtain the materials.

Conflicts between same-sex sexual orientation and religion: A framework for affirmative psychotherapy
Clinton Anderson American Psychological Association, United States of America

This presentation aims to increase participants’ knowledge of and ability to apply, a framework for affirmative therapeutic practice with adults seeking sexual orientation change. The American Psychological Association Task Force on Appropriate Therapeutic Responses to Sexual Orientation developed and published the framework in their 2009 report. The Task Force report provides a scholarly, evidence-supported framework for responding to clients who seek to change their sexual orientation, their behavioral expression of the sexual orientation, or both. A brief overview of the report will include the systematic review of the research literature on sexual orientation change efforts, but the bulk of the presentation will focus on the recommended psychotherapeutic framework, in which the emphasis is on ethical and evidence-based intervention that supports the integration of religious and sexual orientation identities in conflicted clients. The framework aims to counteract the either-or understanding of conflicts between same-sex sexuality and religious beliefs that have characterised much of the popular and professional discourse. The framework affirms the importance of science as the basis for psychology’s application to improving human well-being, while respecting religion as an important aspect of human diversity. The affirmative therapeutic framework includes five elements: (1) acceptance and support; (2) comprehensive assessment; (3) active coping; (4) social support; and (5) identity exploration and development. The presentation will also provide a brief experience of active consideration by the participants of barriers and opportunities to the application of the framework in their practice, research, and training activities.

Stigma and identity in the light of homosexual territories
Rafael Barreto UNIRIO, Brazil; Francisco Farias

Currently the theme of diversity, respect for differences and the fight against discrimination has been widely discussed in various academic fields in Brazil and worldwide. In this sense the present paper reports on homosexuality, with an emphasis on male homosexuality, which over the years has been gaining more visibility in society, to form a group that, based on factors such as collective memory can be seen as capable of composing identity(ies) and define territories often made as a means of refuge from the discrimination faced by this group. Thus, this paper presents part of work developed during a Master’s degree in demography which has described the dynamics of some spaces of sociability of homosexuals in the city of Rio de Janeiro - Brazil. In this study we analyzed some territories occupied by this group, understanding the symbolic field created by it, which was realized through elements such as distinctive dress and vocabulary, for example. It also made a brief analysis of how to give the relations between the members of this group as well as the relationship between them and individuals external to it. During the investigation it was possible to perceive the relationship between the trauma of homophobia and the formation of identity(ies). Finally a discussion is proposed about the conflicts in which these individuals are, the process of stigmatization (including participating in its formation as an individual and group), among other issues, leading the reader to ponder the question of respect for differences.

The sexual identities of high-income female sex workers in Johannesburg, South Africa
Shannon Bell University of the Witwatersrand, South Africa; Lynlee Howard-Payne

There is a vast amount of empirical research exploring the physical health of female sex workers and their risk of contracting and spreading sexually transmitted infections. Also, a number of studies have been dedicated to the dangers of sex work, such as physical violence, rape and the social implications of stigmatisation of these women. There is, however, little empirical evidence exploring the negotiation between female sex workers’ professional and personal sexual identities. This research aims to qualitatively explore and understand the sexual identities of high-income female sex workers from the northern suburbs of Johannesburg, South Africa. It was found, after conducting semi-structured interviews with six high-income female sex workers, that the social stigmas that exist in society regarding sex work and sex workers influence various identity- facets of the high-income female sex worker’s personal life, professional life and self. Through the use of narrative analysis, various narrative categories emerged such as change in perception of self and others, “othering”, issues surrounding males, contradictory defences of the social stigmatisation, sex as “work”, personal relationships, and management of personal versus professional sexual identities. It was found that the sexual identities between the high-income female sex worker’s personal and professional lives are different from each other. Therefore, various psychological mechanisms are put into place to negotiate the differences in order for the female sex workers to manage the different roles they have to occupy, as well as adequately function in their daily lives.

Constructing sexuality following a voluntary termination of pregnancy
Catriona Boffard University of the Witwatersrand, South Africa; Nkululeko Nkomo

The consequences of having a termination of pregnancy on women’s sexuality are somewhat underresearched and unknown. In addition, very few studies examine the interplay between discourses on sexuality and construction of sexuality after a voluntary termination of pregnancy. This presentation discusses the findings of a recent study that explores this relation. Seven women from private termination clinics in Johannesburg were interviewed, using a semi-structured and open-ended interview schedule. The data was analysed using both discursive and critical discourse analytic methods. The findings indicate that women engage with sexuality following a termination of pregnancy in very complex ways. Sexuality following a termination of pregnancy is mediated by a number of discourses on sexuality. However, it is clear that these discourses are intricate and multifaceted, and that within one particular discourse lie further sub-discourses. Prescriptive notions of women and their bodies within a patriarchal framework are particularly relevant, as are discourses of women’s sexuality in line with heteronormativity. Furthermore, the discursive techniques which participants’ employed, such as justification and validation, ultimately support the emerging discourses and further strengthened the participants’ way of speaking about sexuality following a termination of pregnancy. In light of these findings, the implications of how women construct their sexuality following a termination of pregnancy will be discussed.

Rape is newsworthy: Discourses of attribution in news media reports of sexual violence
Werner Bohmke Rhodes University, South Africa

Social explanations for incidences of sexual violence frequently take the form of accounts of the event which facilitate the attribution of blame and responsibility between the individuals involved in...
certain ways. It has frequently been the case that such attributions provide discursive and rhetorical support for the perpetuation of rape myths and victim-blaming practices (Anderson & Doherty, 2008) and which, in turn, become the discursive resources that undergird rape-supportive cultural attitudes and practices (Gavey, 2005). Drawing on a feminist and discursive theoretical framework, this paper argues in line with Anderson and Doherty (2008) that the aforementioned attributional features of social accounts for sexual violence are not restricted solely to the interactional context of individuals discussing events in isolation, but due to their social and discursive nature, have become regularly repeated features of public domain discussions and reporting of incidences of sexual violence. The paper presents a discourse analysis (Parker, 1994; 2005) of short newspaper articles reporting on cases of sexual violence in South Africa that critically examines the manner in which implicit and explicit attributions of responsibility and blame are reproduced and circulated in public discourse and texts in manners that often inadvertently repeat rape-supportive attitudes and understandings of sexual violence.

Prison inmates with a heterosexual romantic partner inside the same prison: Loneliness, sexual satisfaction, and quality of life
Rodrigo Carcedo University of Salamanca, Spain; Maria Oroz; Daniel Perlman; Felix Lopez; Noelia Fernandez-Rouco; Richard Faldowski
This work has focused on the differences in loneliness, sexual satisfaction, and quality of life among three groups of prison inmates: inmates with a heterosexual romantic partner inside the same prison, i.e. a fellow prisoner, inmates with a partner outside the prison, and inmates without a partner. In-person interviews with 70 male and 70 female inmates from the Topas Penitentiary (Spain) were conducted. These inmates lived in the same facility, but in gender-segregated modules. After controlling for age, nationality, total time in prison, actual sentence time served, and estimated time to parole, the results showed a lower level of romantic loneliness, and a higher level of sexual satisfaction and global, psychological, and environment quality of life for the group of inmates with a heterosexual partner inside prison. These findings highlight the positive attributes associated with heterosexual romantic relationships between inmates inside the same prison.

Weapons, ornaments, and female choice
Lei Chang Chinese University of Hong Kong, China
According to evolutionary psychology, specific perceptual and cognitive response systems have been fashioned by the ancestral environment to solve specific and recurrent survival and reproductive challenges. Because ancestral men and women have faced drastically different reproductive issues, the processing of mating information should evoke gender differential perceptual and cognitive response. I will present a series of experiments to illustrate this evolutionary psychological principle. In a similar research paradigm, these experiments manipulated mating motivation by exposing participants to attractive opposite-sex stimuli while examining the expected cognitive and perceptual response to different experimental tasks. Drawn from three separate studies that have been carried out at the Chinese University of Hong Kong, these tasks included processing war scenes and war-related words, responding to high risk sports, and performing creativity tasks for men and, for women, evaluating voice pitch and completing romance-related lexical tasks and explicit mate evaluations. By testing various hypotheses about human mating behaviour that are derived from Dawin’s sexual selection theory, these experiments also serve to illustrate how empirical and, specifically, experimental studies can be conducted to test evolutionary theories.

Heterosexuals’ attitudes toward same-sex parenting: The case of Portugal
Pedro Costa UIPES, Portugal; Claudia Rita; Inês Fernandes; Sara Caldeira; Henrique Pereira; Isabel Leal
During the last decade in Portugal, there have been political changes regarding the rights of gay, lesbian, bisexual and transgender individuals, such as the right to marry. However, parenting by same-sex couples is not legally recognized, and there are legal impediments for same-sex parents to adopt a child. The purpose of this study was to assess Portuguese heterosexuals’ attitudes toward same-sex parenting and the reasoning behind them. 993 participants (266 males and 727 females), aged between 18 and 69 years with a mean age of 34, responded to one of three online questionnaires using a quasi-experimental methodology: Each questionnaire included a case vignette depicting a heterosexual, a gay, or a lesbian couple wishing to adopt a child. Participants were then asked to evaluate if the couple would be fit to adopt and if they anticipated any social and emotional problems with the child. Results revealed that participants evaluated more favourably the heterosexual couple than did the same-sex couples. Furthermore, participants consistently anticipated more child’s social and emotional problems if they were adopted by a gay or a lesbian couple. Group differences revealed that men evaluated less favourably gay and lesbian couples than women did. Religious affiliation also revealed that Catholic people were less favourable toward gay and lesbian adoption than atheist people were. Implications of these findings will be discussed.

Discourse analysis of hypersexual disorder diagnosis
Roshan Das Nair University of Nottingham, United Kingdom
There has been considerable media hype about prominent public figures claiming to have ‘sex addiction’. The diagnosis of ‘hypersexual disorder’ (one framing of ‘sex addiction’) has been proposed for inclusion in the DSM-5, but there is debate about the validity, utility, and implications of such a diagnosis. There is concern whether this is another way in which sexuality can be controlled by some social actors. This study adds to this debate by using discourse analysis (DA) to highlight issues about this diagnosis and the rationale offered for its inclusion in diagnostic systems. DA is an interdisciplinary approach which closely reads texts (e.g., diagnostic criteria) to examine the role of language and power in framing an issue/problem. From a theoretical perspective, there appears to be limited consensus whether the issues should be framed as addictions, obsessive compulsive disorders, or impulse control disorders. DA of the rationale for the diagnosis revealed how legitimization of the construct relied on a selective representation and reading of extant literature, silencing dissent, establishing the discourse of science and empiricism as ‘regimes of truth’, and reproducing discourse of monogamy and fidelity to pathologize transgressive sexualities. This study exposes the inherent power dynamics in the language used to frame diagnostic criteria for hypersexual disorder, highlights the lack of consensus in framing the diagnosis, and problematizes the issue without having to subscribe to either end of a moral panic-libertarian continuum.

"Not into the scene": Gay men’s narratives of gay social norm negotiation in New York City
Brian Davis The Graduate Center, CUNY, United States of America
Whereas past research has found a strong association between negative mental health outcomes and weak identification with gay social groups, increasingly affirmative attitudes toward gay men within U.S. urban culture over the past decade, suggest the possibility of expanded opportunities for gay men to explore social identities that may include, but are not necessarily limited to, gay social groups. In the present study, prospective participants completed an online screening survey, where inclusion criteria consisted of: a) high self-esteem, b) low internalised homonegativity, c) lack of characteristics marginalised in the larger gay culture (e.g., older age, larger body size), and d) low level of involvement in gay social activities (e.g., pride parades, bars). Ten white gay men aged 20-50 residing in New York City then participated in semi-structured one-on-one interviews. Analysis of latent themes indicated that the men maintained positive gay self-identities while negotiating perceived gay social norms when those norms came into conflict with prioritised aspects of self-concept. This negotiation involved two distinct strategies of dissent (challenging group norms to better the group) and disengagement (eschewing gay social groups in favor of alternative, sexually affirmative social groups). These results suggest that gay men’s participation in gay-related activities and identification with gay social groups may constitute one of many viable and sexually affirmative routes of socialisation. Implications for developmental models of sexual orientation and the coming out process are also discussed.

"Because we’re not straight": Interpretative repertoires of the valueless and compromising lesbian woman
Natalie Donaldson Rhodes University, South Africa; Lindy Wilbraham
With the inclusion of sexual orientation in the Equality clause of our post-Apartheid Constitution, which demands equal rights and protection for all individuals regardless of sexual orientation, South Africa has been praised as one of the most liberal countries in the world. However, discriminatory discourses such as homosexuality as ‘un-African’ and unnatural, which often result in brutal hate crimes against LGBTIQ individuals (such as cor-
Determinants of elderly sexual behaviour in Ille-Ife, Nigeria
Opeyemi Ekundayo Obafemi Awolowo University, Ile-Ife, Nigeria
Aging has become an issue of growing research interest, especially as the average life span in the world has grown longer. However, relatively little is known about the sexual behaviour of the elderly compared to adolescents and younger adults, especially in Nigeria. The study examines the determinants of sexual behaviour among the elderly in Ille-Ife. The study was a cross-sectional survey that collected data from the elderly in Ile Central local government area using a multi-stage sampling technique. The sample consisted of 375 adults comprising 170 middle adults (45.3%) and 205 older adults (54.7%). A standardized psychological instrument and interviews were used to collect data from the respondents. The analysis of the questionnaires showed that the pattern of sexual behaviour, that is, holding hands (53.2%), hugging (52.1%), kissing (50.9%), fondling 58.0%, caressing (60.1%), vaginal sex (51.5%), use of condom with spouse (72.5%), use of condom with someone other than spouse (90.9%), and transactional sex (61.1%) are more prevalent among middle adults than older adults. Sex, religion, educational level, occupation, and marital status do have a significant influence on the sexual behaviour of middle and older adults. Analysis of the interviews revealed that female older adults are significantly influenced by family type. As against the notion that sexuality does not have a place in the lives of the elderly, this study concludes that sexuality is integral in their lives.

Sexual epistemic plurality, or provincialising sexuality
Kirk Fiereck Columbia University, United States of America
This paper explores how "the sexual" is culturally and historically constituted in contemporary South African society. The categories of psychology that are used to order and understand sexual expression and experience, such as heterosexual, homosexual, and transgender, among others, are historically specific, non-universal constructs. During the course of its past and present global circulation, the discipline of psychology, along with its categories, has encountered and encroached upon other cultures that enact their own concepts and categories to organise sexual life, albeit cultures that do not bear the designation "scientific." In the South African context, this encounter has produced, what I term here, "sexual epistemic plurality." This analysis draws upon a diverse set of ethnographic and historical data in order to trace the circulation, dissemination, emergence and dialectical entwining of psychological and non-scientific epistemises within the multicultural context of South Africa. Consideration is limited primarily to those categories that delimit and describe same-sex desire (i.e., homosexuality, gay and lesbian, etc.), but necessarily engages with concepts related to sex and gender. In large part, the history of sexuality in South Africa has been written with reference to the concepts and categories of a psychological epistememe, despite the existence and relevance of non-scientific sexual epistemises in the everyday lives of South Africans. This examination troubles those mono-epistemic readings of "the sexual" and argues for the perspective of epistemic plurality in order to contribute to a more adequate theory of sex, gender and sexuality in contemporary South African public culture.

Experiences of homophobia at institutions of higher education among a group of gay men in Cape Town, South Africa
Neil Henderson University of the Western Cape, South Africa; Tamara Shefer
Homophobia and hate crimes against the LGBTI community have been widely documented in South Africa notwithstanding the huge advances that have been made to protect the right of sexual orientation since post-1994. Studies conducted at universities have also highlighted that these remain sites that reflect a heteronormative society and in which gay and lesbian students continue to experience homophobia and hate crimes (Ellis, 2009). This paper draws on a larger qualitative study on how gay men construct a gay identity and negotiate their relationships within contemporary South African contexts, following constitutional and legal changes in this respect. The paper reports on one of the key findings that of participants’ reported experiences of homophobic, rejection and ‘othering’ of their desires and sexual practices, as it manifests in their experiences of being students. It recommends that men and women who engage in ‘hate speech’ and crimes, and homophobia in general on the campuses should be disciplined, that inter-disciplinary gender and sexualities studies should be promoted at Faculty level and that queer groups should be encouraged with a focus on facilitating space for alternative sexualities. A qualitative study based on in-depth interviews with 15 participants, a sample of self-identified gay men, aged 20 to 46 years, drawn from a local university and through snow-balling in the larger Cape Town Metropole, was conducted. Interviews were audio-recorded, transcribed verbatim and analyzed through qualitative thematic and narrative analysis, drawing on the listening guide of Gilligan and co-authors (2003).

The mental health implications of anti-LGBT policies: Global perspectives
Sharon Horne University of Massachusetts Boston, United States of America; Ronald Schilltler; Alyssa Jacaruso; Raphael Apter
Drawing on an emerging body of research documenting the negative psychological impact on LGBT individuals and family members during anti-LGBT legislative campaigns and movements (e.g., Horne et al., 2010; Horne, Rostosky, & Riggle, 2011; Riggle, Rostosky, & Horne, 2010; Rostosky, et. al., 2009; Rostosky et al., 2010; Russell, 2000), this presentation extends the discussion to the role of global psychology in the prevention of legislative-related stress during political movements aimed at limiting LGBT rights. For example, recent proposed legislation in Russia and other post-communist countries has increased the visibility of sexual minorities in these areas, but there are few psychological resources in place to support LGBT individuals. Similarly, research suggests that LGBT individuals who lack legal status due to the lack of inclusion of same-sex relationships in immigration laws, experience greater LGBT minority stress. We will highlight current policies that are potentially harmful to LGBT individuals and families (e.g., St. Petersburg, Russia; U.S. states, etc.) and describe steps that LGBT psychologists, allies and psychological associations can take to reduce the debilitating effects of anti-LGBT policies. Debates related to the rights of sexual and gender minorities are highly polemic; concerns that will continue to attract legislative and judicial attention in countries around the world. A brief overview of the international human rights context and growing LGBT rights advocacy within which this is being played out will be provided. Our discussion will include social justice perspectives that enlist psychologists in the mission to reduce human suffering and inequity.

Sexual experiences of a group of young, low socio-economic, South African females
Kim Howard University of Witwatersrand, South Africa; Peace Kiguwa
Current psychological research on HIV, sexual violence and other ‘perils’ associated with female sexuality highlight discourses of female sexuality that often fail to acknowledge and engage with social practices of sex, sexuality and desire that are agentic and emphasize pleasure. These public discourses tend to emphasize the problems of danger, disease, abuse, population explosion and disempowerment. Absent from these dominant accounts of perilous sex are alternate constructs of sex as pleasure, desire, arousal, connectivity and fun. Through qualitative interviews with five women between 19 and 26 years of age, this study aimed to get insight into how a group of young women from a low socio-economic cohort interpret their experiences and negotiations of sexual relationships. The personal and social motivations underlying the different sexual experiences of these young women were diverse and varied. All participants, to a greater or lesser extent, engaged in sex in order to secure a long-term mate to ‘have and hold’ and with whom to procreate. Some had been forced, coerced and motivated by money and material goods, yet all participants described times
What questions do young people have about sexuality? Perspectives of urban Indian adolescents
Jahnvee Joshi Nirmaia Niketan College of Home, India; Kiran Parab; Anuradha Bakshi

The aims of this research were (a) to examine the sexuality-related questions of urban Indian adolescents, (b) to compare these questions by age and gender of adolescent, and (c) to explore whether parents were aware of the sexuality-related questions of their adolescents. Judgemental sampling was used to select 100 participants from socioeconomically-privileged, two-parent Hindu families residing in Mumbai—40 adolescents (14-year-old and 18-year-old girls and boys), their mothers, and a subset of 20 fathers. Data were collected using individually administered interviews. Quantitative and qualitative data analytic strategies were used. Younger adolescents had a significantly higher number of questions than older adolescents. While for all the adolescents most questions related to biological aspects of human sexuality, many younger adolescents also asked culturally-relevant questions such as, “Is it okay to have a girlfriend?” The most frequently asked question by girls was “What do people do when they have sex?” versus boys who asked “What measures can be used to have safe sex?” Not surprisingly, many parents either did not know what questions their child had asked or stated that there were no unanswered questions. The findings are interpreted using a cultural framework including a cultural psychology theory of mind (Shweder et al., 2006). Implications for sexuality education in urban India are also discussed.

Attitudes of Nigerian professionals towards lesbians and gay men: Implications for counselling
Joseph Kinanee Rivers State University of Education, Nigeria; Jessica Ezekiel-Hart

It is widely reported that many African governments are not favourably disposed towards the concept and practice of homosexuality, due to their value system. Late last year, the Nigerian Senate passed a bill criminalising gay marriage and any same sex “amorous relationship”, with a 14-year imprisonment for anyone found guilty of such relations as well as similar punishments for individuals/groups campaigning for the rights of LGBT. Presently, Sharia law in the northern part of the country already prohibits homosexual relationships, spelling out very drastic punishments for LGBTIs. In the light of the above, these researchers investigated the attitude of 200 Nigerian professionals living in a University community towards lesbians and gay men, with a view to ascertaining possible factors underlying such attitudes. An adapted version of the Attitudes towards Lesbians and Gay Men Scale (ATLG) was used for data collection. The respondents were mainly teachers, civil servants, lawyers, medical doctors, engineers/ technicians. The study revealed generally negative attitudes towards homosexuals and lesbians, due to cultural, religious and other social factors, irrespective of the respondents’ professions. Over 90% of them called for more stringent homophobic laws to be put in place. These results have great implications for counselling and the defence of human rights in Nigeria, which are discussed in the paper.

Profiling the female sex offender: An initial proposal
Sheranne Kramer University of the Witwatersrand, South Africa

The female sex offender has recently become the subject of increased academic, legal and medical attention. While this interest is gradually strengthening, currently available information concerning female sex offenders is somewhat limited. Most of this information is based on single case studies or larger studies limited to the American population. Furthermore, this work is, for the most part, focused on a singular aspect of female sexual offending such as cognitive distortions or childhood histories of abuse or the offender’s self-knowledge systems. While these studies are obviously valuable, they do not help us to identify a comprehensive and holistic profile for the female sexual offender. As a result, we currently understand female sexual offenders as a heterogeneous group and we are therefore unable to develop generalised assessment devices and rehabilitation services. Accordingly this paper forms the initial part of a larger study that aims to profile the female sexual offender according to various sets of both qualitative and quantitative data. This initial part will focus on a review of the available and current literature in order to identify both the information that we do have concerning female sexual perpetration as well as the gaps in current knowledge. This review will then inform the latter part of the study which will involve the surveillance and interviewing of both victims and perpetrators of female sex crimes as a means to develop a profile of the female sex offender. The profiling of the female sex offender will become a significant source of information for test developers, rehabilitation services, clinicians and policy makers in the field.

A discourse analysis of gay mens’ identity constructions in a same-sex marriage
Bruce Leing University of Johannesburg, South Africa

This study, which is located in a social constructionist epistemology, offers an exploration of how gay men in a same-sex marriage construct their identity. Recent studies on same-sex marriage have focused on the celebratory aspects of the institution and utilised phenomenological methodologies whereas this study employs a critical psychology framework and incorporates both Foucauldian and queer theory to gain a critical perspective of the identity of the gay married subject. Four men who self identify as gay and had been married for at least a year were used as the participants of this research and Parker’s discourse analytic guidelines were applied to analyse the interview texts. This research approach explores the influence of language in the shaping of identity and the effect of institutional and ideological power. The analysis found that the discourse employed by the participants entrenches heteronormativity as a moral and sexual authority and reinforces homophobic attitudes. The married gay man positions himself as a ‘decent’ sexual subject and locates the single gay man as amoral and ‘deviant’. The study found that ‘decent’ married gay man assumes the heterosexual sexual subject and locates the single gay man as amoral and ‘deviant’. The study found that ‘decent’ married gay man assumes the heterosexual sexual subject and locates the single gay man as amoral and ‘deviant’.
Sex, sexuality, relationships and love in South African media
Caretha Laubscher UNISA - UCAP, South Africa
The pervasive, accessible and popular nature of media makes it an excellent instructor, offering an opportune way to learn about sensitive and taboo issues. However, the media can be harmfully limiting, stereotypical and one-dimensional. In most societies and cultures it is acceptable to use “sex” to sell products. It is also acceptable to genderise relationships and to typecast love, but to negotiate satisfying sex and sexuality is a “tabooed” story. I explored why popular South African media talk about sex, sexuality, relationships and love and explore the way general society prefer to talk about these topics. The study incorporated a qualitative method of enquiry and adopts a social constructionist view on the themes as they emerge. Popular media is seen as the voice of society and the media makes it an excellent instructor, offering an educative function. The analysis identifies the discourses in 66 media articles that impact on participants and are predictable from the circumstances in which invisibility is associated with homosexual visibility in the 21st century post-Apartheid context. The paper presents a narrative account of initial successes in advocating for an LGBT-affirmative psychology in the Philippines. I will talk about the development and adoption of the official policy statement by the Psychological Association of the Philippines (PAP) against anti-LGBT discrimination in October 2011, possibly the first of its kind in South-east Asia. I will also discuss ongoing localized efforts in professional organizing, teaching, and offering of LGBT-affirmative psychological practice for Filipinos. Opportunities and challenges facing Filipino LGBT psychologists will also be analyzed within the context of Philippine psychology and the LGBT rights situation in this developing, post-colonial nation.

The real world is the cruellest world: The politics of homosexual visibility in the 21st century post-Apartheid context
Jacqueline Marx UFH, South Africa
This paper is taken from research that analyses the politics of homosexual visibility in dressing-up, cross-dressing and drag performances that take place in a small city in South Africa. The study draws on Butler’s notion of performative resistance and adopts a Foucauldian genealogy to examine the conditions that make visibility possible and through which particular representations of homosexuality are articulated and read, or remain unread or mis-read. Information about dressing-up, cross-dressing and drag performance was obtained in interviews, from documentary evidence, and from audio-visual recordings of drag shows and gay and lesbian beauty pageant competitions. Semiotics and a Foucauldian approach to analysing discourse were used to interpret the written, spoken, and visual texts. This paper focuses on the potential for harm that is associated with homosexual visibility in the 21st century post-Apartheid context and consideration is given to the circumstances in which invisibility is desirable.

Integrating an in-depth analysis of the discourses of South African bisexual women
Ingrid Lynch University of Pretoria, South Africa; David Maree
The discipline of psychology has typically upheld a monosexual binary, with heterosexuality and homosexuality positioned as the only legitimate categories of sexual identification. Within such a structure bisexuality is not considered a viable sexual identity. In public discourses female bisexuality is generally constructed in delegitimising ways, such as through constructions that equate bisexuality with promiscuity, describe it as an eroticised male fantasy or as a strategy to retain heterosexual privilege. This feminist poststructuralist study explores the discourses drawn on by a group of South African women who self-identify as bisexual. Data collection entailed conducting interviews with 13 bisexual women. The discourse analysis focused on how the various constructions of bisexuality identified in the text function. The analysis identifies a number of discourses that impact on participants’ positioning as bisexual. In a post-Apartheid context, participants regard fixing their identity along strictly defined lines of difference as oppressive and resist bisexuality as primary to their identity. The analysis further indicates that in claiming a bisexual identity, participants risk marginalisation in the face of delegitimising discourses that construct them in negative terms of promiscuity, hypersexuality and sexual decadence. Silencing discourses further construct same-sex attraction as un-African and as sinful. The analysis concludes with a discussion of participants’ strategies to normalise bisexuality. This study contributes to accounts that explore diversity in sexual identification. It has implications for how female sexual identities are theorised and contributes to the visibility of bisexual women in South African discourses of sexuality.

LGBT psychology in the Philippines: Initial inroads
Eric Manalastas University of the Philippines, Philippines
This paper presents a narrative account of initial successes in advocating for an LGBT-affirmative psychology in the Philippines. I will talk about the development and adoption of the official policy statement by the Psychological Association of the Philippines (PAP) against anti-LGBT discrimination in October 2011, possibly the first of its kind in South-east Asia. I will also discuss ongoing localized efforts in professional organizing, teaching, and offering of LGBT-affirmative psychological practice for Filipinos. Opportunities and challenges facing Filipino LGBT psychologists will also be analyzed within the context of Philippine psychology and the LGBT rights situation in this developing, post-colonial nation.

Self-objectification and the desiring subject: Being a blind man in a sighted world
Kharnita Mohamed University of South Africa, South Africa
Derived from an ethnographic study in 2006 conducted with visually impaired male students at the University of the Western Cape in Cape Town, South Africa, this paper reveals how the students utilised oculocentric discourse strategically in their interactions with the sighted. During the study, it emerged that visual criteria and experiences were fundamental in crafting masculinity. The paper addresses the formation of masculinity when the visual is not embodied and yet the visual has primacy in shaping interactions. To be a desired and desiring subject requires policing gendered boundaries through a presumed normative subject. The absence of sight does not necessarily mean one is outside of a visual episteme as the male students ascribed to a form of visuality to properly display masculine desires and demonstrates the modalities of self-objectification in the quest to be desired. The disconnection between sensory experience and its discursive use informs us about the ontological power of the visual episteme in creating meaning and generating social relations and elucidates the pressures of visual signifiers and practices in the formation of masculinity.

The influence of religiosity and spirituality on sexual behaviour and sociosexuality among African undergraduates
Simon Moripe University of Limpopo, South Africa; Solomon Mashegoane University of Limpopo, South Africa
The influence of religious motivations on sexual attitudes and behaviour has been established using Western samples. The purpose of the present study was to examine the association of religiosity, and spirituality, to sexual attitudes and behaviour in an African context. Three hundred single, African undergraduate students completed questionnaires assessing socio-demographics, religiosity, spirituality, sexual behaviour and attitudes. Both religiosity and spirituality were measured as multidimensional constructs, and sexual attitudes were conceptualized as sociosexuality. Data was collected at one point only. Scores of sexually experienced and inexperienced students differed on intrinsic religiosity and belief in the afterlife measures, and did not differ on almost all the aspects of spirituality measured.
Sociosexuality was related to intrinsic and extrinsic religiosity, but was not related to almost all the spirituality facets. Furthermore, gender and intrinsic religiosity predicted sociosexuality with consistency. The results are discussed in the context of the planning of prevention programmes for sexual risk among African students.

Mapping the mindsets of rural youth in an emerging lesbian, gay and bisexual community
Juan Nel; UNISA Centre for Applied Psychology, South Africa; Theo Sandfort; Louise Polders
Lesbian, gay and bisexual (LGB) youth are diverse in psychological profile. Segmenting LGB youth based on mindsets, allows for the identification of key target groups on which research could focus, and that might best benefit from interventions supporting their well-being. The research that informed this presentation aimed to both identify and profile the various segments (mindsets) among rural LGB youth in the North-West Province, South Africa. Past research into LGB South African youth has focused primarily on urban contexts while rural youth are typically excluded. Data were collected using convenience sampling and multiple methods of recruitment. Participants comprised 275 self-identified LGB youth between the ages of 16 and 34 years. Rim weights were applied to the data to ensure an accurate representation of the youth across age, sex and racial lines. Cluster analysis was used to segment the LGB youth. The four composite cluster variables defining the mindsets were: gender non-conformity, mental distress, internalised homonegativity and active hiding of sexual orientation. Hierarchical cluster analysis results found a 3-cluster solution to be the most stable and meaningful data collection at step two was aimed at discovering the differences among the clusters. Experiences of social discrimination were significantly more prevalent among the well-adjusted segment, while sexual abuse and rape were more common among the conflicted and hidden group. The gender non-confirming and distressed group displayed significantly more drinking problems. The needs profile of each segment will inform future interventions and optimal allocation of resources.

Influence of television on adolescent girls’ sexual attitudes and behaviour
Tebogo Nganase; University of Limpopo (Medunsa), South Africa
This study explored how television influences the sexual attitudes and behaviour of adolescent girls in Mabopane, a black township in Gauteng, South Africa. Qualitative research was used as it allowed the author to obtain rich data from the participants who were between the ages of 16 and 17 and enrolled for grades 11 and 12. Although the area of adolescent sexual behaviour has been widely researched, there appears to be a lack of information concerning adolescents’ sexual behaviour and attitudes relating to Africa, especially South Africa. The author investigated adolescent girls’ experiences using in-depth individual interviews, and did a thematic content analysis of the textual data she gathered from the participants. The results of this study indicated that adolescent girls from Mabopane feel that television does influence their sexual attitudes and behaviour, and that television does not display the consequences of sex, thus influencing adolescents to engage in such behaviour. Furthermore, the participants indicated that television is not the only influence in their lives; other factors, such as parental guidance and peer pressure, also contribute to shaping their sexual attitudes and behaviour. Frequent television viewing was mentioned as resulting in adolescents changing their sexual beliefs and adopting behaviours seen on television.

An exploratory study of homosexual Xhosa men’s experience of traditional circumcision (ulwaluko) in the Eastern Cape, South Africa
Anathi Ntizini; University of Fort Hare, South Africa; Hlonelwa Nqangweni
This study investigated perceptions of homosexual traditionally circumcised Xhosa men about their ulwaluko experience. This is also an initiation into manhood and the pain that an initiate experiences in this transition to manhood plays a vital role in validating his masculinity and bravery. The ritual also establishes contact with the sacred realm and constructs future social identities. While homosexuality emerges in multiple sites to reproduce inequality and abuse, especially in the virulent strains found in South Africa and the African continent, ulwaluko could surely be construed as the most threatening, to a young Xhosa man’s self esteem, of such sites. Respondents were nine (9) Xhosa men aged eighteen (18) to twenty-six (26) from the Eastern Cape who were recruited using snowball sampling. A thematic analysis revealed that their reasons for undergoing ulwaluko ranged from wanting to validate their ‘manhood’ to being forced to undergo the ritual in an attempt to convert them to heterosexuality and adopt the traditional roles associated with a post-ulwaluko experience.

Meaning of human sexuality and sexuality education: Perspectives of urban Indian adolescent boys and their parents
Kiran Parab; Muktangan, India; Anuradha Bakhshi; Jahnvee Joshi
In India, there has been some resistance from parents to sexuality education programs for adolescents. A misconception is that sexuality education programs incite promiscuity. Given this background, this study was designed to elicit the definitions of human sexuality and sexuality education from adolescents and their parents. Importantly, reflexive data collection at step two was aimed at facilitating expansions in the participants’ conceptualisation of sexuality and sexuality education. Hundred participants were selected from Mumbai using judgmental sampling (i.e., forty 14- and 18-year old girls and boys, their mothers, and 20 fathers). All participating families were two-parent, Hindu and privileged. Individual interviews were conducted using reflexive data collection as a qualitative strategy; data were analyzed using quantitative and qualitative methods. As expected, at step 1 most of the participants attributed biological meanings to human sexuality and sexuality education. At step 2 when the participants were facilitated through the use of specially constructed concept cards, there was a shift seen for most of the participants from biological (e.g., sexual act, reproduction) to comprehensive meanings of the terms sexuality and sexuality education (e.g., emotional, cognitive, behavioral, and cultural dimensions). Dyadic and triadic congruence regarding the perspectives of members of a family was established. Low degree of congruence was observed in the spontaneous responses whereas a high degree of congruence was observed following facilitation with concept cards. Findings are discussed using the theory of cultural psychology.

Czech lesbian family study: Negotiating family identity during transition to parenthood
Eva Polaskova; Masaryk University, Czech Republic
The main research aim was to contribute to understanding of parenting experience of Czech lesbian women who have decided to become parents within a same-sex relationship in planned lesbian families. In particular, it was to identify and examine the specifics of the transition to parenthood with a special regard to its partial aspects (key moments and events) of the decision-making process lining the couple’s path to parenthood. The qualitative study was designed as an exploratory-descriptive type of research. The sample consisted of 10 planned lesbian families represented by the parental couple. The criterion for sample inclusion was lesbian identity of the respondents, fact that all women were engaged in a same-sex relationship and were raising in a shared household only children that were born within the context of the current relationship. All couples were subjected to a joint in-depth semi-structured interview followed by an individual interview (both with the biological and social mother). Consequently, a focus group was run with a part of the respondents. The acquired data were processed on the grounds of the principles of qualitative methodology (interpretative phenomenological analysis) and the analysis was supported by the qualitative data software package Atlas.ti. Descriptive processional model of transition to parenthood in lesbian couples is presented. Its individual components represent key moments and events that gradually "emerge" with the transition to parenthood and that involve specific psychosocial tasks.

The role of sexual sensation seeking and attitude toward condom use in risky sexual behavior of the heterosexual single male
Wahyu Rahardjo; Gunadarma University, Indonesia; Matrisya Hermita; Gunadarma University, Indonesia
Risky sexual behavior is known as a world-wide sociosexual phenomenon, and sexual sensation seeking as well attitude toward condom use have been chosen as factors to be investigated in this study. The study is one of proactive efforts to overcome the phenomenon, which occurs despite of the increase of HIV/AIDS cases. The heterosexual single male, figured as the sexual initiator and holding the important role of sexual decision maker, was chosen as the subject of this study. The aim of this study is to investigate the contribution of sexual sensation seeking and the attitude toward condom use in risky sexual behavior. Seventy-eight heterosexual single males living in Jakarta, Indonesia, were selected using the snowball sampling tech-
nique. Participants were questioned, and gathered data were analyzed using multiple regression. The results showed that sexual sensation seeking contributed highly to all kinds of risky sexual behavior. Additionally, the attitude toward condom use is that it is not too desirable in the number of vaginal intercourse. These findings show that sexual sensation seeking plays an important role in risky sexual behavior, while some differentiation appeared in sexual seeking sensation based on participants’ first vaginal sexual intercourse and blood test status. Research findings in Asia related to risky sexual behavior focusing on other variables, including substance use in China and Hong Kong (He et al., 2007; Ngai et al., 2006), and male to male sexual intercourse in Vietnam and Cambodia (Colby et al., 2004; Girault et al., 2004) have been used as references in this study, and gave other views in understanding the phenomenon of risky sexual behavior.

Homosexuality: The disclosure process during adolescence
Veronica Lee Robertson Stellenbosch University, South Africa; Marcia Johnson; Anna Rieckmann; Matthew Johnson; Veronica Robertson; Fischer Hakan; Charmaine Louw

During no other time in history have lesbians, gays and bisexuals been the recipients of so much attention, scrutiny and unprecedented acceptance and inclusion into mainstream culture. However, many individuals with alternative sexual orientations remain fearful of disclosing their sexuality. Adolescents with alternative sexual orientations face unique challenges, such as the coming out process, during which they must recognize, explore, and disclose their orientations in a way that heterosexual individuals need not. Disclosure of sexual orientation is a struggle for most lesbian, gay and bisexual youth due to fears of discrimination, ostracism and violence from others. Despite a growing body of scientific literature on homosexuality, in general little is known about the coming out process and its impact on an adolescent. This study seeks to help fill the gaps by giving voice to the adolescent by exploring their experiences of coming-out and will provide insight and knowledge to clinicians to aid adolescent clients throughout the coming out process. This qualitative research study was embedded within an interpretive/constructivist paradigm. Purposeful sampling was used to select five male and five female participants. Semi-structured individual interviews and reflective notes were employed. The findings suggest that male and female participants experienced a similar trajectory to coming out. Reactions of parents ranged from extreme outrage and expulsion from the home to support and acceptance. The participants’ parents were initially ill-prepared and unable to support their child during his/her disclosure.

Troubling South African masculinities and male sexualities
Tamara Shefer University of the Western Cape, South Africa

The imperatives of HIV together with the challenges of violence against women in South Africa has seen an increase in research focusing on gender and sexuality as well as more recently on boys, men and masculinities. While welcomed, this paper argues a deterministic discourse on men’s sexuality and masculinity in general, is inherent in many of the current understandings of heterosexual practices which have tended to focus on girls’ and women’s vulnerabilities. Researchers appear to ‘buy’ into normative assumptions of the male sexual drive discourse, that men are driven primarily by an inherent sexual drive. Such assumptions are also arguably underpinned by racist and classist discourses, in which African masculinities have been ‘othered’ through racialised and colonial discourse that have historically represented Black men as hypersexual and hypermasculine (thus removing the gaze from white men), resulting in blaming, stigmatising and othering practices. Arguably, any efforts at challenging normative gender roles and power relations between men and women need to acknowledge and unpack the complexity of the male position especially as intersected with social inequalities of class, ‘race’, sexuality, health, status, geographical location and many others. The paper argues for a critical reflexive lens that is sensitive to the impact of knowledge production on cultural representations of masculinities and that attempts to explore sexual relations between men and women as a negotiation of power and practices, rather than a simplistic reflection of patriarchal power.

The experience of homophobia of young South African homosexual men belonging to ACTIVATE
Thulisile Shelemba University of the Witwatersrand, South Africa; Noleen Pillay

This research is set against the backdrop of a country that endorses equal human rights to see if changes in legislation have had an effect on the publics’ attitudes towards homosexuals. With the new constitution in South Africa that prohibits homophobia and encourages equality on the grounds of sex, gender and race, this research aims to bring to the fore the experiences of young South African homosexual men in contemporary South Africa. A qualitative research design was used wherein a focus group was conducted with eight young South African homosexual men who belong to ACTIVATE: a lesbian, gay, bisexual and transgender organisation at the University of the Witwatersrand. Using thematic content analysis, it was found that the patterns of religion, culture, race and gender have an effect on their experiences of identifying as homosexual men. Furthermore, a social constructionist framework was employed in this study which guided us in delineating their experiences. It served to inform us that its tenets of language, interaction and knowledge have a bearing on their lived experiences. Although there have been changes in legislation, the participants’ responses were mixed, but the perception was that attitudes towards homosexual men are gradually changing. According to the participants there were decreased homophobic attitudes from heterosexuals who knew of homosexual people.

Policies and practices: A review of sex education in the USA, United Kingdom and Australia
Precious Sipuka UNISA, South Africa

Early sexual activity and teenage pregnancy is a global health problem. Early sexual activity does not only result in teenage pregnancy but also exposure to HIV, STI and the inevitable interruptions in young people’s education. Sex education should not only be limited to the influence of parents and society but also educational institutions. In a recent effort to combat the increasing problem of teenage pregnancies, the South African Minister of Health embarked on a campaign of introducing sex education in primary schools in the near future. The aim of this paper is to review the sex education programs and policies in four different regions. This will serve as an example and an aid to South Africa as it attempts to introduce similar sex educational programs in its primary schools. A literature review will be conducted on programmes in the United States, United Kingdom, and Australia in order to understand the state of sex education in these settings. Sex educational policies and practices will be reviewed. The review appraises positive changes sex education has brought about as well as the challenges thereof. Guidelines for the composition of a comprehensive South African sex education programme for primary schools will be discussed along with a possible research plan on testing it.

An intersectional analysis of the experiences of black lesbian women in Cape Town
Angeline Stephens UCT, South Africa; Fiorello Boonzaier

A current multi-site qualitative study explores the discursive constructions of gendered subjectivities of women in intimate lesbian relationships in South Africa, with a specific focus on the issues of power and abusive practices. Recent lesbian scholarship recognises the multiplicity and complexity of sites of power that extend beyond patriarchy. The current study employs focus groups and depth interviews with lesbian women from KwaZulu-Natal, Gauteng and the Western Cape in an attempt to unveil and better understand these complexities. This paper presents two themes that have emerged from a preliminary analysis of the data generated from the Cape Town group. More specifically, it explores the extent to which race and locality intersects with lesbian identity, subjectivities and gendered power among black women. It does this by firstly examining the challenges associated with constructing alternate gender identities in a society that maintains heteronormative practices. It illustrates how the current South African context simultaneously liberates and constrains black women in their attempts to establish relationships that are free of power imbalances. Secondly, it explores the concept of race and the experiences of racism within the lives of these women. It explores how subtle forms of racial inequalities, whether perceived or real, serve to alienate and marginalise black women within the lesbian community. The paper concludes by considering the possible permutations for power imbalances within lesbian relationships due to perceived racial inequalities within the lesbian community.

Homophobia in schools in Pietermaritzburg, South Africa
Angeline Stephens UCT, South Africa

The pervasiveness of homophobia in schools is well documented in international scholarship. Although there is a growing body of schol-
arship in the area of homophobia in South Africa, the focus tends to be guided by policy issues at a macro level and located within the discourse of ‘democracy and rights’. Significantly less research is directed at exploring homophobia within schools. This paper presents the key findings of a recent questionnaire survey that aimed to explore levels of homophobia in secondary schools in Pietermaritzburg. The Homophobia Scale, developed by Wright, Adams and Bernat (1999) was administered to 1301 learners from seven ordinary, public, co-educational schools in Pietermaritzburg. Key findings suggest that significant differences exist across gender and race. More specifically female learners scored significantly lower than their male counterparts in all three sub-categories of the Homophobia Scale: Negative affect, behavioural aggression, and cognitive negativism. Indian learners were found to have the highest levels of cognitive negativism in comparison to learners from other race groups. The findings are discussed in the context of two broad themes: Firstly, the changing South African political, historical and social landscape and the accompanying contradictions contained in all levels, and secondly, schools as institutions of power that control access to information. The paper concludes by suggesting the need for multi-levelled, inter-disciplinary interventions that consider the unique South African landscape.

Taxi queens: Transactional sex and risk behaviour among young girls and taxi drivers in the Western Cape, South Africa
Anna Strebel South Africa; Nokuthula Shabalala; Cheryl Potgieter; Claire Wagner; Tamara Shefer
The phenomenon of transactional sex and its possible consequences, which include teenage pregnancy, gender-based violence and HIV, have been widely documented. Some information has begun to emerge, mainly anecdotal and in the media, about young girls who ride with older taxi drivers, and are thought to have sex with them in exchange for gifts and money. This study aimed to explore issues of gendered sexuality in the relationships between ‘taxi queens’ and taxi drivers in the Western Cape, South Africa. Thirteen focus groups were held with youth in local communities, 25 individual interviews were conducted with young girls identified as taxi queens, and 225 questionnaires were administered to taxi drivers, in order to explore perceptions and experiences of young girls’ and attitudes of drivers. It was found that there was widespread recognition of transactional relationships between young girls and older taxi drivers, which were regarded as largely exploitative and stigmatising, especially for the girls, although they also reflected complex power relations. Substance abuse, risky sexual practices and physical coercion were commonly reported. The findings confirm the importance of considering this particular phenomenon within broader interventions focussing on gender, sexuality and HIV among youth, families and in the public transport sector.

Understanding the partners of masculine identifying trans people
Liesl Theron Gender Dynamix, South Africa
Becoming the partner of a transgender person radically complicates the partner’s experience of their sexual orientation. It challenges gender norms and sexual identity expectations and queering both heterosexual and homosexual spaces. This presentation draws on a digital story-telling DVD clip I produced and on my scholar research. I interviewed eight female partners of masculine identifying trans persons from different ethnic groups and varied in income and age. The message in the video aims to inform the viewer about the unspoken choices, courage and support given by partners of trans persons. Secondly it illuminates the need for counseling, guidance and support for couples. The presentation will share information about different experiences by heterosexual, bisexual and lesbian partners, and how each of them dealt with intimacy and relationship situations. Transitioning is central in their relationships and consumes prime energy from both persons. Partners need time to adjust. Many partners find it hard to ‘pay attention to their own personal and relationship issues’. Due to the overwhelmingly heteronormative world the couples are bound to function in, I am of opinion that there is indeed a solemn need for debriefing, counseling, therapy and guidance. By no means is this because of one person in the relationship being trans per se, but rather as a result of a transphobic, heteronormative and homonormative society. The partners of trans persons are functioning as much on the margins of society as their trans partners.

Markers of well-being among Hijras, the male to female transsexuals
Seemantini Tumkur Shivakumar S.D.M. College, India; Manjula M.Y. S.D.M. College, India
People often assess well-being based on their own criteria for evaluating the quality of life. Generally physical, psychological, socioeconomic conditions, family relationships and community acceptance contribute holistically to the level of satisfaction and happiness one experiences. The current research has taken a qualitative approach to understand the determinants of well-being among Hijras - male to female Transsexuals. The participants were selected from the Bangalore district, Karnataka, India. They were selected based on cut-off scores obtained on the Subjective Well-being Inventory. Among 100 participants, four fell under the category of high subjective well-being and 22 under the category of low subjective well-being. Out of this, three from the high well-being category and five from the low well-being category volunteered as participants for in-depth interview. The eight in-depth interviews were analysed thematically. Some of the markers that emerged are the nirvana — castration ceremony, acceptance by the general population, support they get from the Hijra community, job profile, violence towards them, positive and negative emotions experienced and sense of control over the same, perceptions and attributions about their condition.

Lesbian parenthood in South Africa: Perceptions and experiences of significant role-players
Sjouke Ummels linked to UvA and UP, Netherlands; Carien Lubbe-de Beer; Henny Bos The Netherlands
This paper reports on lesbian parenthood and the perceptions of significant role-players who have had contact with lesbian parent families mainly in the education, legal and medical systems. South Africa has come a long way in this relatively short time after apartheid, characterised by a liberal legislation. However, stigmatisation still takes place against people with a homosexual sexual orientation. The homo-negativity, being two female parents and the support system give shape to the way lesbian parents experience parenthood. In this study nine semi-structured interviews were conducted with people who have experience with lesbian parent families in their professional life. The interviews were transcribed and analysed using Interpretative Phenomenological Analysis (IPA). Two super-ordinate themes emerged from the transcriptions, namely Homonegativity in South Africa and Lesbian parenthood.

Binaries and boxes, or not: Unpacking a health care provider sensitisation training model
Delene Van Dyk OUT Wellbeing, South Africa
Lesbian, Gay, Bisexual, Transgender and Intersex (LGBTI) people, as a sexual minority group, often experience challenges in the uptake of psychosocial services. High levels of homonegativity and ignorance, as well as heteronormativity, increase the discrimination and stigmatisation experienced in healthcare settings. The Binaries and Boxes model of sensitisation training was developed through a reflective process over a period of more than four years and is based on a human rights- and sex-positive approach. Informed by social psychology and the principles of experiential and adult learning, this psycho-educative workshop is interactive and participatory - a non-threatening one-day training – in which the aim is to deconstruct fixed and linear notions of identity and behaviour and assist in stereotype reduction and the debunking of myths. Also, it empowers psychologists and other health-care providers to understand the unique health challenges faced by LGBTI persons and the importance of LGBTI-affirmative stances in healthcare. The model, its theoretical approach and feedback of participants, will be briefly outlined during the presentation. The model consists of a four quarter grid, covering the main areas of human sexuality. It includes sex (biological concept), gender (social construct), sexual orientation and sexual practices (behaviour plus meaning). Heteronormativity and internalised homonegativity are introduced during the discussion on sexual orientation. The content may not be new to the trainees, but the style in which it is presented, is new, fresh and insightful.

Disinhibited sexual behaviour in dementia
Susan Van Hooren Open University, Netherlands; Monique Bakhuizen-Pons; Luk Gijls; Wim Waterink
Dementia is a degenerative disorder that is characterized by cognitive decline and behavioural problems. Disinhibited sexual behaviour is one of the behavioural problems resulting in serious distress and discomfort among family, health care professionals, and other residents. The aim of this study was to examine the prevalence and frequency of a large range of sexual behaviours among elderly with dementia and to investigate their association with demographic and clinical characteristics. The study sample consisted of 56 patients with dementia. The results
Sexuality

showed that a broad range of sexual behaviours is prevalent among one third of the present study sample. These behaviours were present in men and women, but men uttered more verbal sexual comments and exposing behaviour. Specific behaviours were also more prevalent in patients with a partner or patients with a dementia diagnosis other than Alzheimer’s disease. These findings on disinhibited sexual behaviour have theoretical implications, diagnostic value and offer new ideas for dementia care.

Session Type: Posters

Moderating effect of having a heterosexual romantic partner inside a prison on the relationship between interpersonal needs and quality of life

Rodrigo Carcedo; University of Salamanca, Spain; Maria Ramos; Daniel Perlman; Maria Orgaz; Felix Lopez

The main focus of this study was to investigate the moderating effect of having vs. not having a heterosexual romantic partner inside the prison, on the relationship between interpersonal needs and quality of life. In-person interviews were conducted with 55 male and 64 female inmates from the Topas Penitentiary (Spain). Higher levels of social loneliness and lower levels of sexual satisfaction were associated with lower levels of quality of life. In addition, the interaction between sexual satisfaction and romantic partner status was significant. Higher levels of sexual satisfaction were associated with higher levels of quality of life for only the group without a partner. These findings indicate the detrimental aspects that can be associated with not having a satisfactory sexual life while incarcerated.

Moderation effect of enforced sexual abstinence on the relationship between sexual satisfaction and psychological health of prison inmates

Rodrigo Carcedo; University of Salamanca, Spain; Maria Ramos; Daniel Perlman; Noelia Fernandez-Rouco; Felix Lopez; Maria Orgaz

The purpose of this study was to investigate, in a sample of prison inmates, (a) the relationship between sexual satisfaction and psychological health and (b) the moderating effects of heterosexual activity level (abstinent vs. non-abstinent) and gender on the relationship between these two variables. In-person interviews were conducted with 82 male and 91 female inmates from Spain’s Topas Penitentiary. These inmates lived in separate modules within the same facility. Sexual satisfaction was a significant predictor of psychological health but only for members of the sexually abstinent group. These findings point to the positive effect of sexual satisfaction on psychological health, especially for inmates in a less favourable sexual situation (i.e., sexual abstinence).

Sex education in Spain: Training, attitudes and involvement of school teachers

Rodrigo Carcedo; University of Salamanca, Spain; Isabel Vicario-Molina; Paola Ilabaca; Jose Luis Martinez; Eva Gonzalez

Sex education in Spain is considered to be a cross-curricular issue, however, school-teachers often fail to integrate sex education contents in their teaching practice. Since it is essential that teachers have appropriate knowledge, skills and attitudes with regard to sexuality and sex education, in order be effective sex educators, this study aims to examine the relationships between involvement in sex education, attitudes and training. A total of 3760 pre-school, primary and high school teachers throughout Spain completed an on-line questionnaire that gathered information on the above mentioned variables as well as other socio-demographic and professional factors (sex, age, educational stage, type of centre, academic training, and years of teaching experience). Analyses show that teachers who are trained in sexuality and sex education are more likely to have positive attitudes towards sex education. Data also indicate that trained teachers are more likely to implement sex education in their teaching practice. Finally, differences in attitudes towards sex education according to type of school, educational stage and involvement in sex education, have been found. Consistent with previous findings, sexuality and sex education training seems to encourage school teachers’ adoption of positive attitudes toward sex education and involvement in sex education. Therefore, suggestions for improvement of this training both in the field of university education and continuous training are offered.

Sexual differences and predictors of psychological health and quality of life in transsexuals

Rodrigo Carcedo; University of Salamanca, Spain; Felix Lopez

Until now, psychological studies on transsexualism have been essentially focused on diagnostic, individual and personality aspects (Michel & Mornont, 2003; Pauly, 1990). The aim of this study was to investigate personal (body image, coping skills and self-esteem), and interpersonal aspects of the transsexual population (social and emotional loneliness and sexual satisfaction), and their relationship with their quality of life and mental health. Also, the study analyses the sexual differences between male (female-to-male) and female (male-to-female) transsexuals. One hundred and twenty persons were interviewed face to face, 60 male and 60 female transsexuals from all over (Spain). Mean differences (t-tests) and hierarchical regressions were utilised to study the relationship between personal and interpersonal variables with psychological health and quality of life. On the one hand, the results showed that lower social loneliness is consistently the best predictor of an improved state of anxiety, lower social loneliness and higher avoidant coping skills the best predictors of depression, and lower self-esteem and social support coping, the best predictors for quality of life. On the other hand, the study showed no statistically significant differences in all the variables included in this study between male and female transsexuals. These findings suggest the importance of working on improving social loneliness, self-esteem, and coping skills to reduce levels of anxiety, depression, and to increase quality of life for transsexuals, both male and female.

Preliminary findings of a study of the female’s relationship with her gynaecologist

Caroll Hermann; University of Zululand, South Africa

The objective of this study was to investigate the attitudes of gynaecologists and their patients regarding female sexuality, with special focus on discussing intimate problems experienced by the patients. The focus of this paper is on the dysfunctional perception of the male gynaecologist of female sexuality in spite of his medical background. Convenience random sampling of patients and doctors completed a semi-structured questionnaire and unstructured interview. Content analysis was used to quantify and analyse the presence, frequency and relationships of scripts and concepts. Inferences were made about the messages within the scripts and shared amongst the women. Results showed that a significant number of the participants had similar complaints and agreed that it appeared as if the doctors are unsympathetic towards women’s intimate queries and there is a perception that a female’s sexuality is secondary to that of males. Very few women felt that they could address these issues with their doctors and that there is a lack of support and understanding from the male dominated medical world. This study was based on numerous consulting room stories and supported the notion that psychology should focus more on educating males and how their perception of female sexuality can or would impact on the sexual experiences of females.

Legal recognition of same-sex partners and sexual minorities’ physical health

Ethan Mereish; Boston College, United States of America; Paul Poteat

Lesbian, gay, and bisexual individuals (i.e., sexual minorities) are at risk for greater physical health disparities than heterosexuals. Most of this research, however, is limited to U.S. studies, with a dearth of international research. Prevalence of psychiatric disorders is higher among sexual minorities living in the U.S. states with discriminatory policies (e.g.,
The social construction of young women's identity and sexual decisions

Neo Pule South Africa

The identity, sexual identity, and sexual decisions of young women have been explored from a social constructionist perspective in this text. The three concepts are therefore explored in terms of the reality of each of the participants. The work of Gilligan (1982), Bowen (1978) as well as other research carried out regarding sexuality, sexual issues and identity, particularly of young women, has been used as a theoretical background, as well as to gain a better understanding of the sexual lives of young people. The participants, who were all students at a South African higher education institution, were gathered by means of a volunteering system to participate in two focus groups. The focus group discussions included creative or artistic expressions as well as an application of the nominal group technique. The stories of the young women were recorded. The researcher obtained some understanding of these by means of the feminist post-structural discourse analysis. The participants reported that a relationship context, specifically connectedness, is essential to the social construction of the identity of young women. Furthermore, the participants indicated that an exchange of knowledge together with debate and negotiation, facilitates the social construction of female sexual identity. They finally reported that their own intra-personal script, generally informed by socialisation, context (family, friends, religion, beliefs, etc.), and past experience, as well as their need to care and nurture appears to inform the sexual decisions of young women.

Survey on the perception of discrimination in the workplace by Italian homosexuals

Riccardo Sartori Verona University, Italy; Angelo Benozzo

Italy is considered the second most homophobic Country in the European Union (European Union Agency for Fundamental Rights, 2011). It has no law against homophobia and no equality body covering sexual orientation discrimination in the workplace. The aim of this survey, carried out with 774 Italian homosexual employees, was to put in relation such variables as gender, education, work and coming out with the assessment of 8 discrimination behaviours (self- and other-directed) and 3 support behaviors (rating scale from 0 = never to 4 = always). Results show low frequencies of perceived discrimination behaviours. However males, people who are out at work, people with diplomas, people working in private sectors and people with temporary and part-time jobs declare more discriminations than females, people who are not out at work, graduates, people working in public sectors and people with regular and full-time jobs. As for the social support, people who are out at work, graduates and people with regular jobs declare more support than people who are not out at work, have diplomas, and/or have temporary jobs.
Session Type: Invited Symposium

Symposium title: PANEL: Medical male circumcision for HIV prevention: What it means to women
Convenor: Cheryl Potgieter

Medical male circumcision for HIV prevention: What it means to women
Cheryl Potgieter University of KwaZulu-Natal, South Africa

Persons in conversation will be Thando Mgqolozana, the acclaimed author of A Man Who is Not A Man (2009), a novel that deals with traditional male circumcision and other social issues such as sexuality and the manhood initiation tradition as practised by amaXhosa in the Eastern Cape Province, South Africa; Cheryl Potgieter, feminist professor of psychology and University Dean of Research at the University of KwaZulu-Natal; she is working on a project with Mgqolozana, which is on Zulu women's perception of the implementation of Medical Male Circumcision (MMC) in KwaZulu-Natal; and Dr. Kay Govender, School of Psychology, and HEARD at UKZN who is currently working on a project on MMC, geared to assess the perceived behavioural impact (risk disinhibition behaviours) - MMC on young men in a community site in KwaZulu-Natal. The panellists will, first and foremost, contest the term Medical Male Circumcision. They will talk to the issue of women's involvement (or lack thereof) in the role out of MMC for HIV prevention, the neglect of the social and cultural aspects of male circumcision in prevailing research on MMC - which has implications for women-, the dominance of heterosexuality in relation to MMC and various other important and controversial aspects of this phenomenon in relation to the reduction of HIV transmission. They will also share information about the projects they are involved in, which are directly related to the topic.

Session Type: Invited Workshop

Perspectives on guidelines for LGBTI-affirmative practice: Global and local experience
Juan Nel UNISA Centre for Applied Psychology, South Africa

This two-hour symposium, hosted under the auspices of the International Network on Lesbian, Gay and Bisexual Concerns and Transgender Issues in Psychology (INET), will provide perspectives on global and local experiences of the International Network on Lesbian, Gay and Bisexual Concerns and Transgender Issues in Psychology (INET), will provide perspectives on and Bisexual Concerns and Transgender Issues in Psychology (INET), will provide perspectives on the concept of LGBTI-Affirmative practice guidelines for the African context will provide a report on that session. This will be followed by a discussion of the relevancy of guidelines elsewhere, and how such processes may be initiated in other contexts.

Symposium title: Diversity among lesbian and gay parent families on four continents
Convenor: Charlotte Patterson

Diversity among adolescents in planned lesbian mother families in the Netherlands
Henny Bos United States of America

This paper is focused on the psychological adjustment of adolescents in planned lesbian mother families living in the Netherlands. Based on longitudinal data from 100 Dutch families studied since 2002, this paper will compare lesbian and heterosexual parent families and also explore diversity among adolescents growing up with lesbian mothers. Does it matter whether there is a known or unknown donor, whether youth have or have not experienced stigmatisation and discrimination, or whether the youth employ coping styles of different kinds? These questions will be addressed with standardised data about adolescent adjustment. This is the first such study of youth in the Netherlands, a nation known for its tolerant attitudes, so the results will make a unique contribution to research in this area.

Lesbian parent families in South Africa
Carien Lubbe-De Beer University of Pretoria, South Africa

This paper reports from a meta-analysis on six studies of life in lesbian families in South Africa. Three of the six studies explore experiences of parents in creating families via donor insemination or in vitro fertilisation. Two focus on children reared in lesbian mother homes, and another explores adoptive family experiences in the context of children’s schools. The meta-analysis is framed within a positive psychology framework, and highlights both risk and protective factors among lesbian parent families.

Sexuality

Symposium title: Intersectionality: Disentangling multiple identities related to sexuality
Convenor: Damien Riggs

Intersectionality: Disentangling multiple identities related to sexuality
Rashan Das Nair University of Nottingham, United Kingdom; Melanie Jeffens; Jhon Moreno

Intersectionality is a framework that enables us to explore multiple identities simultaneously, and how they interact with each other, causing disruptions and creating possibilities. In lesbian, gay, bisexual, and trans (LGBT) literature, much attention has previously been paid to viewing sexuality as the primary identity for individuals who subscribe to these sexual minority identity labels, to the exclusion of the existence of other identities they may have and their interactions regarding psychological outcomes. In this symposium, we examine how sexuality, sexual practice, race/ethnicity, disability, rehabilitation, and sexual identity are experienced by those who hold other minority positions in society, through four papers which focus on people labelled as ‘migrants’, racial and ethnic minorities, and survivors with disabilities caused by traumatic brain injuries (TBIs). Although each paper focuses on a specific aspect of LGBT life, using different historical changes in the experiences of gay fathers in the USA.

Experiences of exclusion within schools amongst a sample of south Australian lesbian-mother families
Damien Riggs Flinders University, Australia

Research continues to find that despite facing ongoing discrimination, lesbian mother families continue to thrive. This is perhaps nowhere more evident than in the educational system. The research reported here sought to explore the educational experiences of lesbian mothers and their children in the context of South Australian schools, through an online questionnaire comprised of rating scales related to experiences of discrimination and degree of comfort in the school setting. The findings suggest that a minority of the sample of mothers and a minority of the children reported experiencing discrimination within their children’s schools. Experiences of discrimination amongst mothers were statistically significantly related to the age of the child, outness of the mother, and the socio-economic rating of the school. The research also assessed the degree to which both mothers and children had heard the words ‘lesbian’ or ‘gay’ used pejoratively. A large proportion of children had reported hearing such negative usage, as had a minority of mothers. Having heard the words used negatively was statistically significantly predicted by the age and gender of the child for the children, and for mothers, the socio-economic rating of the school. Degree of comfort within school spaces amongst mothers was also assessed, with comfort negatively influenced by experiences of discrimination and the socio-economic rating of the school. The findings highlight some of the explicit and more subtle ways in which marginalisation occurs within schools and the pressures this places upon lesbian mother families.
methodologies, they all drive home one point: there isn’t one monolithic notion of an LGB or T individual or community, and that there is much diversity within these groups. The specific challenges and opportunities presented by having multiple identities and positions in society are illustrated through these papers. It is hoped that through these presentations, we are able to develop a more nuanced and comprehensive notion of what it means to be a sexual minority without homogenising experiences or ignoring differences. Recognising the diversity within the diversity is a strategy aimed at the identification of the dynamics of human development.

**Exploring hyphenated identities: The intersections of race/ethnicity and sexuality**

**Roshan Das Nair**
University of Nottingham, United Kingdom

Within some lesbian, gay, and bisexual (LGB) research and activism, the primacy of the sexual identity over other identities has been observed. This is problematic for ‘metamminorities’ (who may have multiple minority identities, e.g., Black and Minority Ethnic [BME] LGB), and fosters the notion of stasis of identities. While such primacy of sexuality identities over others is advantageous for the creation of a unitary voice to create positive change for sexual minorities, it also has the potential to create a hegemonic homo/bisexuality, which silences those who challenge the orthodoxies of such sexuality identities. In order to advance our knowledge for clinical practice, research, and policy, we need to tease out these ‘differences in diversity’, to examine how people form, develop, maintain, and update their sexual identities within a matrix of other identities, and not in isolation; the conflicts and contradictions between multiple identities and how these are experienced and dealt with; the challenges and opportunities that these multiple identities afford; and how to be still seen as a ‘group’ to continue our fight for positive change.

**Unraveling the complexity of sexuality after traumatic brain injury**

Jhon Moreno University of Montreal, Canada; Michelle McKerrall; Caron Gan

Sexuality is a complex and integrative function that encompasses cognitive, physical, and psychosocial components. Because humans are sexual beings throughout the life span, the expression of sexuality is linked to the overall health of individuals. Therefore, sexuality can be altered by disabilities, and adjustment to disease can transform a person’s sexual life. Sexual difficulties have been described in many medical conditions such as diabetes, cancer, spina bifida, neuromuscular diseases, arthritis, cardiovascular and pulmonary disease, epilepsy, stroke, cerebrovascular accidents, multiple sclerosis, Parkinson’s disease, and traumatic brain injury (TBI). Sexual problems in neurological diseases, including TBI, affect both the individual and his/her relationship with his/her partner. Epidemiological studies have shown that the incidence of sexual difficulties following TBI ranges from 50 to 60%. Specifically, TBI can limit sexuality by affecting the processing of sexual stimuli, the quantity of sexual desire, the expression and communication of affect, and sexual intercourse. A biopsychosocial approach to disentangle the variables implicated in sexuality after TBI is presented, including three interacting domains: a) Neuropsychological and psychological effects, b) medical and physical issues, c) relationship factors. For TBI survivors, sexuality needs to be addressed as part of the rehabilitation process in order to prevent the development of sexual dysfunction, to improve quality of life, and to provide a holistic treatment approach.

**Sexual diversity and disability: Future directions in traumatic brain injury rehabilitation**

Jhон Moreno University of Montreal, Canada; Michelle McKerrall

Sexuality in patients with chronic disease or physical handicaps deserves consideration because many clinicians and rehabilitation professionals show a lack of information/education on sexuality and disability, which is a major contributing factor towards the stigma attached to them. Following traumatic brain injury (TBI), survivors experience cognitive, psychiatric/behavioural and physical functional sequelae that impact sexuality. TBI survivors thus represent a group in need of multidisciplinary rehabilitation, including sexual and couples’ relationship issues. However, sexuality in TBI rehabilitation is often neglected because many professionals do not feel comfortable discussing sexual issues. Particularly, there is a literature gap concerning TBI, sexuality and lesbian, gay, bisexual, transgender and intersex (LGBTI) issues. In the rehabilitation process, LGBTI TBI survivors are exposed to both the disability and the sexual minority social stigmas because being in a sexual minority can place a person at risk of being socially discriminated against in the course of assessment, education, examination or treatment. Context-sensitive issues such as sexual orientation disclosure, fear about including partners in the treatment programme, heterosexual-centric attitudes, and homophobia are a reality in many cultures and settings, including healthcare. Neuropsychological issues in TBI, such as cognitive deficits, diminished self-awareness, anosognosia, the presence of psychiatric symptoms, and neurological comorbidities, as well as the psychosocial aspects impacting the family system make the treatment of sexual issues more challenging. A comprehensive approach in research and rehabilitation is required to address sexual and gender orientation of LGBTI TBI survivors since they have special medical, legal, psychological, and education needs.

**Lesbian and gay migrants: When, and how, does minority stress provoke negative outcomes?**

Melanie Steffens Friedrich Schiller University, Germany; Brea Burger

The minority stress model postulates that distal and proximal stigma-related stressors affect minority members’ mental health outcomes. More specifically, the psychological mediation framework proposes intra and interpersonal processes mediating the effects of stigma on health outcomes. Lesbian and gay migrants may experience stigma based on ethnicity and based on sexual orientation (the latter, both in the host society and in their ethnic communities). We posed the question under which conditions it is possible to cope with this multitude of minority stressors, investigating a diverse sample of lesbian and gay migrants in Germany (N = 137) and a lesbian and gay control group (N = 106). Whereas health or self-esteem did not differ on average between samples, migrants reported lower life satisfaction and less social support than their peers. Group differences in distal stressors concerned discrimination within families and ethnicity-based discrimination. Group differences in proximal stressors were more negative perceived attitudes in migrant communities, more internalised homonegativity, and more hiding of sexual orientation. Analyses within the migrant sample showed that social support and self-esteem were the main mediators through which stressors (stigma consciousness, internalised homonegativity, and hiding of sexual orientation) affected outcome variables (life satisfaction and psychosomatic symptoms). Overall, our findings show both who is endangered by multiple sources of minority stress and what are key factors for overcoming minority stress.

**Symposium title: Perspectives on guidelines for LGBT-affirmative practice: Global and local experience**

Convenor: Juan Nel

**Development and application of LGBT practice guidelines at American Psychological Association**

Juan Nel
UNISA Centre for Applied Psychology, South Africa

In 2000 the American Psychological Association (APA) adopted guidelines for psychotherapy with LGBT clients. The guidelines have proven to be a useful tool for providers of mental health services to LGBTI persons, for consumers seeking appropriate care from the mental health system, for advocates for LGBT equality, and for researchers and educators. The guidelines have also been translated into other languages and other national psychological associations are developing or have adopted LGBT practice guidelines. There were many challenges faced and met that are relevant to others who may wish to consider, or who are considering, a similar effort. For example, psychologists questioned the adoption of practice guidelines per se. Many argued the Ethics Code was sufficient to ensure appropriate care for LGBT clients. Other concerns involved issues of inclusion, e.g., whether to include transgender concerns. (They were not.) This portion of the programme will discuss the sixteen-year history from conception to adoption of LGBT practice guidelines at the American Psychological Association. It will examine: Types of guidelines (i.e., practice vs. treatment guidelines), the bi-partite internal structure of each guideline, (i.e., rationale and application), their relationship to the Ethics Code, the professional and scientific criteria for guidelines, and the importance of other minorities to the integrity of the guidelines. Finally, it will make recommendations for developing guidelines. For example, guidelines must not only reflect professional consensus and scientific evidence, they need to be culturally relevant and sensitive. Indeed, that is a primary motive for developing practice guidelines.
Guidelines for working therapeutically with sexual and gender minority clients: The British experience
Juan Nel UNISA Centre for Applied Psychology, South Africa

In 2007 a Working Party was constituted to develop a set of guidelines to help clinicians and practitioners in applied psychology work in an affirmative way when seeing lesbian, gay, bisexual, or trans (LGBT) people therapeutically. This resulted in a document Guidelines for Working Therapeutically with Sexual and Gender Minority Clients. The guidelines were submitted in 2009 to the Professional Practice Board of the British Psychological Society to consider and approve the practice statements and draft guidance. Following several iterations, the guidelines had not yet been approved as of November 2011. Various issues had arisen between the Working Party and organisations which represent psychologists and healthcare regulatory bodies. There are country and culture-specific challenges when writing any guidelines which deal with complex and “controversial” topics, such as sexuality, which are not only limited to individual attitudes and beliefs, but also organisational and societal perspectives. This session will deal with some of these issues in detail. By sharing our experiences, it is hoped that parties writing similar guidelines in the future can pre-empt such challenges and find local and culturally specific ways of dealing with them.

Ongoing ethical guidelines for Australian Psychological Society for gender diverse people
Juan Nel UNISA Centre for Applied Psychology, South Africa

Ethical guidelines developed by and for mental health professionals represent a public safety measure that Registration Boards refer to when required to investigate complaints of professional misconduct or unprofessional conduct. Ethical Guidelines amplify a profession’s Code of Ethics and are often informed by research evidence, consumer advocacy and human rights principles. Perhaps nowhere are the latter two sources of information more pertinent than in the case of marginalised groups, and in the context of issues related to gender and sexuality; this is especially true for sex and gender diverse people. This presentation will briefly outline the ongoing development of Ethical Guidelines for the Australian Psychological Society, for psychologists working with sex and gender diverse people. Emphasis is placed upon the principles that underpin the Guidelines, namely the right to autonomy and justice, and to respectful and competent provision of psychological services.

Perspectives from East, North and West Africa
Juan Nel UNISA Centre for Applied Psychology, South Africa

Africa is a continent of great historical, cultural and religious diversity. The diversity impacts on the legal and social position of LGBTI people, as well as provision of mental health services in the various regions or countries. Presenters and participants from the Pre-Conference Workshop introducing the concept of LGBTI-Affirmative practice guidelines for the African context will discuss the unique circumstances they have identified as pertinent to their parts of the continent and reflect on the discussions initiated in the pre-conference workshop.

Update on SA development of African psychological guidelines for LGBTI-affirmative practice
Niel Victor University of South Africa, South Africa

South Africa has a unique recent history in its inclusion of non-discrimination on the basis of sexual orientation in the 1996 Constitution. Non-discrimination was seen as part of the larger struggle for human rights. Yet, the struggle against the dominance of heteronormativity remains active and LGBTI individuals are exposed to continued significant risk and vulnerability to stigmatisation, discrimination and victimisation. This is unfortunately reflected in the current practice in mainstream mental healthcare in South Africa, which includes a lack of respect for differences and secondary victimisation. It stems in part due to the lack of localised guidelines and training to sensitize practitioners to issues of non-discrimination, awareness of LGBTI issues, and their own heteronormative beliefs and attitudes. There has been an increased call for LGBTI affirmative therapists, and the need has been expressed for clear guidelines in South Africa with regards to LGBTI affirmative therapies. Some of the potential areas for applications are touched on. The development of draft guidelines for LGBTI Affirmative Practice has followed a two-pronged approach thus far. In the first case, recent research among South African LGBT users of psychotherapy and counselling services highlights some of the areas of concern that would need to be included in the guidelines. Secondly a working group has been convened to design and fine-tune the draft guidelines. The outline for the guidelines is discussed and a way forward is suggested.

Symposium title: Sexuality in context
Convenor: Jacques Van Lankveld

Childhood sexual abuse and its impacts on sexual dysfunction in women with Borderline Personality Disorder
Zeynep Gunay Kadikoy Belediyesi KCRSM, Turkey; Jacques van Lankveld

Childhood sexual abuse (CSA) is traumatic, and creates numerous difficulties which affect the way the victim perceives herself, her attitudes toward her body, and her relationships with others. Today, sexual dysfunction (SD) and impairment is commonly observed in women with Borderline Personality Disorder (BPD). The primary purpose of this study was to examine whether CSA victims suffering from BPD have higher levels of sexual dysfunction and Post Traumatic Stress Disorder (PTSD) symptoms than those subjects without CSA, but having BPD, and those in the healthy control group (CG). Sixty six women with BPD were divided into two groups; a sexually abused BPD group (BPD+CSA; N=31) and a non-abused BPD group (BPD-CSA; N=35). The results showed that although BPD+CSA and BPD-CSA group do not differ significantly regarding SD and PTSD symptoms, BPD+CSA group exhibited high levels of SD compared to both BPD-CSA group and the CG. Together, these findings indicate that the experience of CSA has a large impact on sexual dysfunction and PTSD levels in patients with BPD.

Does it take two to tango? The effects of partner presence on sexual arousal in the sex lab
Jacques Van Lankveld Open University, Netherlands; Marieke Dewitte; Dave Rubben; Jet Dinges; Charlotte den Butter; Andrea Grauvogl

Research into psychological factors in the etiology of sexual arousal disorder has often failed to include relevant partner cues in sex lab research. A study was performed in healthy female (N=12) and male (N=12) heterosexual volunteers in the psychophysiological laboratory. All participants underwent six different experimental conditions. They watched 5-minute erotic film fragments separated by neutral film fragments. Erotic stimuli were delivered either without further manipulation, while participants were confronted with their own mirror image (private self-focus), or while being observed through a video camera (public self-focus). This was performed either with or without their own partner being seated at the opposite side of the table with the computer screen on which the erotic stimuli were presented. Genital data were standardized using ipsilateral z-score transformation to make female and male data comparable, and to reduce intersubject variation in overall genital responsiveness. Partner presence resulted in increased levels of state self-focused attention, and in reduced genital responses, compared with the situation in which the partner was absent. Subjective sexual arousal was not affected. Moreover, a significant three-way interaction effect was found. Compared with erotic film alone, induction of state self-focus in the presence of the partner had a stronger inhibiting effect on genital arousal in men, compared to women. In contrast, increased state self-focus was found to produce stronger disinhibition of genital arousal in men, compared to women, when their own partner was not present.

Sexuality in context
Jacques Van Lankveld Open University, Netherlands

Sexuality is an important aspect of life throughout the life span. It contributes substantially to quality of life. Loss of sexual health, sexual function, or sexual well-being greatly impairs quality of life. Sexuality is optimally considered from a multifactorial or biopsychosocial perspective. In this symposium, three contributions (2, 3, and 4) focus on sexuality in groups of medical and psychiatric patients, respectively with Alzheimer dementia, non-Alzheimer dementia, and borderline personality disorder with and without childhood sexual abuse background. Sexual behaviour and sexual functioning in these groups have been studied from a biopsychosocial perspective, and quantitative data on sexual behaviour and functioning will be presented, highlighting the relative contribution of biological, psychological, and contextual factors. Another presentation (1) will focus on recent empirical data from the psychophysiological sex laboratory. Specifically, the impact was studied of partner presence vs. absence on genital and psychological sexual responses to erotic stimulation in healthy female and male volunteers. The research that will be
Sexual disinhibited behaviour in relation to Alzheimer dementia

Wim Waterink Open University of the Netherlands, Netherlands; Susan van Hooren

In nursing homes, sexual disinhibited behaviour (SDB) is recognized as a behavioral symptom of dementia. SDB can result in distress and discomfort among health care professionals and other residents. SDB can be expressed on different dimensions: verbal, non-contact, exposure and physical. Brain damage related to dementia type is seen as the primary cause. In one nursing home it was examined whether patients suffering from dementia showed sexual disinhibited behavior more often than or differently to patients suffering from somatic complaints. 21 Alzheimer, 10 non-Alzheimer and 17 somatic patients were included in the study. Analysis of covariance with gender showed that in general demented patients more often showed SDB than somatic patients. More specifically, concerning the verbal and exposure dimensions, there were no significant differences between Alzheimer patients, non-Alzheimer patients and somatic patients. However, with regard to the non-contact dimension, non-Alzheimer patients more often showed SDB than Alzheimer patients and somatic patients. In addition, Alzheimer patients showed no significant differences compared to somatic patients. The same pattern just failed to reach significance for the physical dimension. The findings indicate that SDB is due to dementia and SDB on a non-contact and physical dimension is probably due to damage to sub-cortical and frontal brain regions.
Can party affiliation be predicted from personality? An examination of the predictive influence of authoritarianism and locus of control on party affiliation

Reyhane Bilgic Middle East Technical University, Turkey; Bengi Oner-Ozkam

This study aimed to reveal the relationship between party affiliation and personality variables, namely, authoritarianism and locus of control. The reason for utilizing authoritarianism as a personality variable is the fact that it is the foremost concept used as a causal factor in party affiliation. In addition to authoritarianism, the personality trait of locus of control was included in this study due to the fact that this concept is widely used in political settings. The externally-oriented individuals are expected to be relatively passive in any attempt to change the world; therefore, they are more likely to be affiliated with autocratic political activities and ideological conservatism, while internally oriented individuals are expected to be more inclined towards social and political change. In order to examine the relationship between the aforementioned personality variables and party affiliation, 167 party members of all contemporary parties in Turkey were given a Turkish translation of Rotter’s (1966) External-Internal Locus of Control scale and Adorno’s right wing scale (1950). The parties that people are affiliated with were grouped in terms of extreme left, middle of the left, middle of the right, and finally, extreme right. The results of the multi-nominal logistic regression indicated that party affiliation could be reliably predicted solely from variables of authoritarianism and locus of control. Possible explanations for the findings and directions for future studies were discussed.

Unpacking intergroup anxiety

Huseyn Cakal University of Oxford, United Kingdom

In three studies (Study 1, South Africa, n=220 and Studies 2 and 3, Turkey, n=420), we tested the reliability of Stephan and Stephan’s (1985). We used structural equation modelling and analysed the data through a series of exploratory and confirmatory factor analyses. Results suggest that across all three studies Stephan & Stephan’s anxiety measure presented a three factor structure, rather than one as reported by earlier research. We also asked the participants to report their intergroup anxiety to using West, Gausel, & Turner’s anxiety measures. The results confirmed the three factor structure of Stephan & Stephan’s construct. These three factors reveal that intergroup anxiety can be unpacked into three different types of anxiety, as (a) concern about behaving inappropriately, (b) concern about being rejected by the out-group and (c) concern about being rejected by the in-group. Overall the findings point toward the multidimensional structure of the current intergroup anxiety measure, as incompetence anxiety, out-group anxiety and in-group anxiety.

United States policy towards trafficking in persons: Why psychology matters

Angel Colon-Rivera University of Puerto Rico, Puerto Rico

Trafficking in persons has become a pandemic problem that transcends borders and affects an estimated 27 million people around the world. Thousands are trafficked into the United States. Trafficking victims are largely under-identified and experience severe trauma and its perpetrators demonstrate utter lack of compassion for the people they enslave. From victim assistance and rehabilitation to program evaluation and best research practices, psychology has much to contribute to this emerging field. Yet the psychological community has been mostly absent from the research literature or policy discussions on the matter. The William Wilberforce Trafficking Victims Protection Act (TVPA) stands as the lone piece of comprehensive legislation designed to address the needs of victims and punish traffickers in the United States. Despite its strengths, the US legislation still suffers from severe gaps which psychologist can help to fill. Among these gaps are: Critical protections and services for victims, a need for the operationalisation of the crime in ways that capture its uniqueness and thus increase prosecutions, a lack of program evaluation in its mandate, and more comprehensive data gathering. This article aims to describe the current psychological literature on trafficking in persons. It also discusses some of the current ways psychologist can become involved in the current debates. Recommendations for improving the last reiteration of the TVPA based on this research are included.

Psychology and refugee studies

Giorgia Dona University of East London, United Kingdom

This presentation traces the historical development of the relationship between psychology and refugee studies and it discusses their engagement with those who are simultaneously insiders and outsiders to local and global communities. The contribution of psychology to refugee studies is visible in the mainstreaming of the psychological concepts of trauma, mental health, psychological acculturation, psycho-social needs and psycho-social interventions within refugee studies where they are used as a metaphor of the refugee experience to symbolize forced migrants’ journeys and to inform humanitarian practice. The integration of these concepts interro-gates disciplinary boundaries and calls for the contextualisation of psychological representations alongside interdisciplinary ones like social suffering, belonging or social bridging. The paper also examines the tension between psychology and refugee studies. Forced migrants’ core predicament is one of mobility that challenges psychological theories premised on human rootedness. Psychology’s historical advancement situated within Western modernity is confronted with the appearance of multiple psychologies that emerge from violence and involuntary migration. Refugees’ communal experiences of conflict, displacement and transnationalism question individually oriented psychological explanations that take place in an increasingly networked world. The paper concludes with a discussion of how to strengthen synergies between psychology and refugee studies so that forced migrants’ lives can be improved and their roles in enhancing and enriching the societies we live in can be better appreciated.

Replay the past: Narratives of the “born-free generation” in South Africa

Tarryn Frankish University of the Witwatersrand, South Africa

Pumla Gobodo-Madikizela (2007) quotes an eight year old girl from Mlungisi township: ‘Let’s play a game’. The young girl has gathered together a group of her peers and orchestrates the re-enactment of a ‘necklacing’ in play, despite never having directly witnessed an actual necklace killing in the course of her own lifetime. This story suggests the importance for thinking about second generation memory in a post-Apartheid South Africa: How do young South Africans (‘the born-free generation’) make sense of and process a history that they were never a part of? This paper looks at stories told by adolescents in different geographical locations around KwaZulu-Natal: urban, township and rural communities. Cut through by gender, race and class divisions, their stories offer insight into the specific histories and realities of their different communities as well as the politics and psychology of second generation memory more broadly. In particular this paper explores a concept of ‘play’ in the machinations of identity making among the youth of South Africa. As alluded to by Gobodo-Madikizela (2007), the concept of ‘play’ tackles questions about how the next generation attempt to overcome social and psychological legacies of violence and trauma. Bringing together theories on child development and (inter)generational trauma this paper asks into the ways young South Africans ‘play’ with an indirect knowledge of an Apartheid past as they try to navigate their present and future.

Emotional climate in an Ecuadorian city: The influence of community belonging

Jose Luis Gonzalez-Castro University of Burgos, Spain; Carrera Darwin

A community’s, or country’s, emotional climate refers to a series of emotions perceived by a society in relation to its socio-political context (DeRivera, 1992). They are dominant emotions in a collective emotional state during a certain period of time. This concept of emotional climate is of importance in political and social studies since it allows us to envisage how a society is experiencing their individual and group interactions. Our study was conducted with 455 participants in Ambato, a middle sized city in Ecuador. We analysed through descriptive analyses (correlations, mean scores), factor analyses, and multiple regression how different variables influenced the perception of the community’s positive and negative emotional climate. Results show that socio-demographic variables (age, sex, income, etc.) did not predict either emotional climate. The most relevant explanatory factors were psychological well-being (Ryff, 1989), expectations about how things were going to be in a year’s time, and trust in institutional organizations (police, political parties, church). With regard to positive emotional climate, the most important factor was participating in community affairs and ac-
Predictors of a diagnosis of post-traumatic stress disorder in community-based asylum-seekers
Debbie Hocking Victoria University, Australia; Suresh Sundram; Gerard Kennedy
It is widely accepted that forced migrant populations have high rates of Post Traumatic Stress Disorder (PTSD), and prevalence of PTSD exceeds that of migrant populations and the general community (Silove et al., 1998). However, compared to accepted refugees, evidence of psychiatric morbidity is sparse for asylum-seekers. In forced migrant populations, torture and cumulative exposure to traumatic experiences have emerged as the strongest predictors of PTSD (Steel et al., 2009). The present study aimed to examine the prevalence, and predictors, of PTSD in a community-based population of asylum-seekers (A-S) and refugees (PR). The analysis examined the relationship between psychiatric morbidity and both numbers of traumatic events and torture reported by participants. 131 adult refugees (n=33) and A-S (n=98) were recruited through the Asylum Seeker Resource Centre (Melbourne, Australia) for a prospective study. Demographic information and data via self-report measures for depression, anxiety and PTSD was gathered, which included a checklist for Traumatic Events (TEs) and Torture History. PR and A-S groups did not differ on incidence of TEs and torture, although A-S had higher rates of PTSD (52%) than PR (27%). Regression analyses found that the number of TEs was a predictor of PTSD but torture was not. However, when residency status (A-S vs PR) was included, the number of TEs no longer made a unique contribution. Undergoing the refugee determination process may be a more significant predictor of PTSD in A-S than pre-migration traumas.

Participation of South Africans with lived experience of mental illness in public mental health policy-making
Sharon Kleintjes University of Cape Town, South Africa; Leslie Swartz; Crick Lund
Participation of people with lived experience of mental illness (PLEMI) in policy-related decision-making can benefit their recovery. Policy participation of PLEMI has been limited during the 17 years of democracy in South Africa. This paper suggests strategies for improving participation of PLEMI in policy decisions which impact on their recovery within the South African context. A systematic literature review on strategies for participation in policy decision-making was conducted. 96 semi-structured interviews with 56 purposefully selected South African policy-makers, service providers and civil society organisations, and 40 urban and rural PLEMI was conducted. 12 key informant interviews were conducted with PLEMI involved in mental health advocacy initiatives elsewhere in Africa. A framework analysis approach [1] was used to analyse interview data, data sources were triangulated, and participant verification obtained for derived strategies for improving participation. Respondents identified five participation barriers: Stigmatization and low priority of mental health, poverty and poor access to social assistance, ineffective treatment and recovery services, lack of fora for involvement, and insufficient capacity of PLEMI for involvement in policy-making. Strategies to create a supportive environment for participation include stigma-reduction and advocacy for acceptance of PLEMI as policy participants, a supportive regulatory framework to promote participation, equipping providers and policy-makers to support inclusion and promote recovery of PLEMI. Development of self help initiatives and capacity-development of PLEMI for policy participation can also provide impetus to PLEMI voicing their priorities in policy processes.

Trans-generational transmission of war-related knowledge in post-conflict northern Uganda
Grace Lapwoch University of Ulster, United Kingdom; Ed Cairns
The recently ended war in northern Uganda lasted for over two decades. Most studies conducted in this region have focused on the impact of the war on mental health. No research has attempted to find out what the next generation is learning about the war. This study therefore set out to explore trans-generational transmission of war-related knowledge from mother to child in northern Uganda, in particular in the districts of Gulu. In January 2012 a total of 3 villages were visited and 9 Focus Group Discussions were conducted (3 in each village). The focus groups were conducted in Luo (the local language) by native speakers of Luo. A total of 71 mothers aged 20-60 years old took part, approximately 24 mothers from each village. The majority (45.7%) had not been themselves abducted nor had their children. 34.3% were formerly abducted mothers and 20% were mothers who had not been abducted but whose children had been abducted. Content analysis suggests personal experience of the war did not appear to influence mothers' opinions. The majority agreed that their children should be told about the war so they grow up to denounce war, understanding it does not solve problems, or so that knowledge of their suffering would be passed on to the next generation or to help counter the anti-social behaviours that some youth developed in the IDP camps. Those not in favour of telling children said the memories were too painful to recount.

Immigrants’ representations of their receiving society: The French Republican model
Romain Lebreuilly Université de Caen, France; Manuel Tostain; Joelle Lebreuilly
The present study set out to analyse how immigrants perceive their receiving country’s willingness to promote integration, looking specifically at the French Republican model of integration. We sought to set the ideals of this Republican model (separation of public and private spheres, secularism) against immigrants’ perceptions of French society. We surveyed 300 first-and second-generation non-European immigrants via a questionnaire probing the following three areas: (1) The French Government’s integration policies, (2) French people’s attitudes and behaviour towards immigrants, (3) the values of the Republican model. Results highlighted how attitudes towards immigrants within French society and highly contrasting perceptions of the French Republican model. The authors discuss the link between the immigrant acculturation process and the receiving country’s integration policy (French Republican model vs. politics of recognition).

Experimental support for dual path model of collective action participation intention
Jia Luihan Central China Normal University, China; Hongyu Ma
This study was aimed to construct a dual path model of collective action to explain why people engaged in collective action. The dual path model contained two paths, which were the cognitive path and the emotion path. There were 288 university students, 88 males and 200 females, sampled in the experiment. The experiment situation was the increase of the food price in one university dinner. The experiment had two conditions - one was procedural justice, which was to offer a voice to students in the process of food price inflation, and the other was procedural injustice, which was depriving the students of a voice in the process of food price inflation. A questionnaire survey followed the experiment. The independent variable was procedural justice of two levels, which were justice and injustice, the dependent variable was collective action participation intention. The standard of the cognitive and emotion paths were collective efficacy and anger respectively. Then we used SPSS to process the data by reliability analysis and regression analysis. Results suggest that procedural justice had a positive effect on collective action participation intention and that collective efficacy and anger had a partly mediate effect between procedural justice and collective action participation intention. The experiment supported the dual path model of collective action: the procedural injustice had a positive influence on collective action through cognitive path (which was collective efficacy) and through the emotion path (which was anger to influence collective action). The cognitive path and emotion path can motivate the collective action participation intention combined or separately.

The psychological aspects of terrorism: Dealing with and treating actual acts of terrorism effectively
Ludwig Lowenstein Southern England Psychological, United Kingdom
What follows seeks to describe the most recent research into the causes, manifestation, and the remedying of the destruction caused by suicide (homicide) bombers. Efforts are made to consider the causes as well as the personalities of such perpetrators. The author provides a description of such individuals favouring that terrorists have ingredients in the psychotic and psychopathic areas. They are deluded, suggestible and lack empathy towards the humanity they seek to destroy. Most important is the role of religious leaders
Predictors of relative deprivation in the Serbian and Indian contexts
Nebojša Petrović University of Belgrade, Serbia and Montenegro; Huseyn Cakal; Waheede Khan
In three separate studies, we investigated the role of social identity and inter-group contact on intergroup trust and perspective-taking. In Study 1, 400 Hindu and Muslim Indian university students completed a survey on intergroup attitudes. Intergroup contact and identification with the in-group were entered as predictors, and trust and perspective-taking as criterion variables. The predicted model was estimated using structural equation modelling and the results revealed that intergroup contact predicted trust positively, and significantly in both groups. Although positive, the association between perspective-taking and contact failed to reach the level of significance, contrary to our expectation. Additionally, in-group identification predicted both trust and perspective-taking negatively. In Study 2, using Bosnians as the target out-group, 100 Serbian students completed an omnibus survey on intergroup attitudes and were randomly allocated to control and experimental groups. Participants who were in the experimental group, who experienced vicarious contact with the out-group Bosnians through biographies, demonstrated higher levels of collective guilt, trust, and perspective-taking, than participants in the no-contact group. We then performed a regression analysis, where we tested the predictive role of in-group identification on trust and perspective-taking in both control and experimental groups. In-group identification predicted trust negatively, in both conditions, whereas it failed to predict perspective-taking in the experimental group. Results confirmed that positive intergroup contact has a direct positive influence on intergroup trust and perspective-taking indirectly. In line with earlier research we demonstrated the positive impact of contact on trust and perspective-taking.

Psychosocial dynamics of protest: The case of the Jan Lokpal Bill movement in India
Ravi Shankar Ravi Bhim Rao Ambedkar College, India; Girishwar Misra
Notwithstanding the fact that protest against societal problems has a long history, the individualistic bias of the mainstream social psychology has marginalised its study as a relevant phenomenon. Also, collective behaviour has traditionally been treated as irrational, illegitimate and regressive. The protesters were looked at as deficient/disturbed. Mahatma Gandhi championed Satyagarah as a protest in South Africa and subsequently in the Indian freedom struggle. Recent research reveals that protest behaviours could also be rational, legitimate, and progressive. Such behaviours are triggered not just by encroachment into one’s psychological space or by infringement on values or by usurping on one’s rights but are also exhibited as proactive/responding philanthropic activism for societal progress and development. This study explores the psycho-social dynamics involved in the recent protest movement led by a Gandhian Anna Hazare against the official tactics of delaying the creation of necessary legal provisions. The demand for a strong anti-corruption law (Janlokpal) got support across different regions of India and the parliament had to take cognisance of the public voice. Following a grounded theoretical perspective this study examined the processes through which the protest took shape and got mobilised. The psycho-dynamics of the movement are analysed using the texts from newspapers during the period of protest. The emerging grounded theory offers insights into the dialogical process of sharing and transformation of group behaviour as an emergent reality. The implications for understanding group level functioning are discussed.

When do people protest? Insights from anti-corruption protests in India
Ravi Shankar Ravi Bhim Rao Ambedkar College, India; Girishwar Misra
Protesting against official policies has a long history as a major source of social change in various parts of the world. Mainstream social psychology has not given it much attention as it goes beyond the range of normal social phenomena. Also, it is difficult to deal with the proto-typical linear model of individual social behaviour which often considers collective behaviour as irrational and regressive. The protesters, being part of minority, are often treated as deficient/disturbed. This paper explores the socio-psychological dynamics of protest behaviour by documenting an analysis of recent anti-corruption protest movements in the Republic of India. The nation-wide protest movement to bring legal provisions to eliminate corruption from the public domain was analysed. To this end the reports published in the national daily media during the period of protests, were qualitatively analysed using grounded theory. The analysis provides a conceptual model of the underlying psycho-dynamics in a temporal perspective. The emerging grounded theory offers insights into the dialogical
process of sharing, play of emotions, accentuated perception of anomalies, and transformation of values and behaviours at group level. It shows that protest behaviours are rational, legitimate, and progressive. They are triggered, not merely as reactions to encroachment of psychological space or the infringement of values, or by infringement on one’s rights but are also pro-active, constructive responses for controlling the future, and philanthropic activism for societal progress and development. The implications of protest behaviour for understanding emergent social processes are discussed.

Surviving gross human rights violations - exploring survivors’ experience of justice and reparation
Nora Sveaas
Department of Psychology UiO, Norway; Peter Elsass; Inger Agger; Brandon Hamber

The system of international criminal justice has taken long steps in order provide justice to persons subjected to gross human rights violations and accountability for the perpetrators of such acts. But there are numerous issues involved that need further engagement. The situation of the survivors, the rights for those who are testifying, the preparation and support needed to present complaints, etc. are all questions that need research as well as action. For those who have experienced severe abuses and loss of loved ones, the path to justice is often a long one, and seldom lives up to the expectations for justice. Most people today will probably never experience any form of legal process, but some may have been engaged in truth commissions, or have been presented for possible acts of reparation, including symbolic reparation. Some may have received therapeutic assistance and even rehabilitation, while others have struggled or coped without professional support.

Others again have been part of a community that has struggled or coped without professional support. The results indicate that the percentage of females in parliament does not correlate significantly with health \((r = 0.046, n = 44, p = 0.765)\), education \((r = 0.098, n = 38, p = 0.558)\), or military expenditure \((r = 0.137, n = 46, p = 0.346)\). These findings seem to inveigh against the cognitive dissonance theory and the hypothesis that the percentage of female parliamentarians influences the amount of money spent towards female agendas. It also seems as if the female agenda, which may be deemed to be pro-social, is not advanced by the women elected to parliament. With such empirical evidence, seemingly at odds with theory and the professed ideology of a socialised ideal, female parliamentarians should be urged to increase their advocacy of those issues that directly - and indirectly - affect women.

Organised psychology in Latin America: Reflections of the past, present and future
Marcelo Urra UARICS, Chile; Raymond Mar; Cornelia Mueller; Hermann Kappelhoff; Adele Goldberg

Psychology in Latin American countries has made its appearance in recent times and new institutions like the Latin American Union of the Entities of Psychology and the Ibero-American Federation of Psychology Associations have joined the Interamerican Society of Psychology (Sociedad Interamericana de Psicología), which has become the most important group of psychologists of the region. The work intends to analyse the past, present and future of organised psychology (OP) in Latin America. The concept of organised psychology is not common in the region and it is possible that this is not due to chance. The relations of OP to other actors of the society and its stability within the science field is analysed. The different activities in which organised psychology is involved - congresses, journals and task forces - are considered too. Finally a proposal is made to merge the concept of organised psychology in the field of that science in Latin America, based on the concept of psychology as an international endeavour, with global, regional and local institutions involved. This effort is needed for the progress of the discipline and for its relations with the society, and to increase the social relevance of this science in all fields of activity and learning.

Piloting the hate and bias crime monitoring form in South Africa: Preliminary findings
Hanlie Van Wyk UNISA, South Africa; Juan Nel UNISA, South Africa

Hate crime data is currently gathered in South Africa by different organisations to address their unique needs. Unfortunately such a disparate approach impacts the presentation of coherent and conclusive data to Government. To address this shortcoming the Hate Crime Working Group (HCWG) developed a multi-sectoral report and monitoring form to capture data across several hate crime categories, including nationality, sexual orientation, race and ethnicity. By collecting information about the nature and impact of hate crime across sectors the Working Group aims to ameliorate a major criticism of similar forms used in the UK, EU, Canada and USA, and hopes to contribute to combating hate crime. The research aims to inform the development of current legislation and policy is South Africa, demonstrating not only the need for policy and legislative change to effectively address hate crimes in South Africa but, most importantly, to highlight the significance of attending to the impact of hate crime on the individual, the community and society. A mixed method approach was used to collect secondary data in five provinces, as pilot qualitative data thematically analysed, while quantitative data analysis provided descriptive information.

The validation of the monitoring form would provide an accepted means of collecting and in time hate crime information and trends countrywide. It would also serve as a basis for training various CSO’s and government divisions in issues relating to hate crime. The preliminary findings demonstrate complications brought about by lack of conceptual clarity, absence of an accepted legal definition and often competing agendas.

Effects of authority trust, social justice, and outcome favourability on policy acceptability
Er-Ping Wang Institute of Psychology, CAS, China; Iie Zhou; Kuan-No Wu

Mass incidents, which increment, accompanied with China’s economic reform during the past three decades, refer to the conflicts between certain civili ans and local officials. Our field and laboratory research indicated that public policy failures and improper administrations were the root causes of mass incidents, and authority trust, social justice, and outcome favourability of public policies influence the policy acceptability of civilians. Although the Social Attitudes Survey of China (SAS-C) annually conducted since 2004 effectively predicted the regional possibilities of mass incidents, the relationships among the attitudinal variables of the surveys are not so clear. The purpose of this study is to replicate the analysis of the relationships. Data from the SAS-C of 2011 were analysed. The independent variables are local authority trust (3 items for general, intentional, and competence), social justice (2 items for procedural and distributive), and outcomes favourability (1 item). The dependent variable is policy acceptability (1 item). ANOVA results indicated that all main effects are significant, authority trust and procedural justice interaction and 3-way interactions are statistically significant. Hierarchical regression analysis shows similar results to the laboratory and field research, all main effects are significant; 3-way interactions are significant, with higher trust in authority intention condition, the interaction of procedural justice and outcome favourability being significant, there was no such interaction in lower trust conditions. These findings indicate that, with higher trust in authority intention, procedural justice may compensate unfavourable outcomes caused by certain policies, but there is no such compensation in lower trust conditions.

Moral education and educational ideologies in Mexican political transition
Roberto Anaya-Rodriguez Universidad Autónoma de Ciudad Juárez, Mexico; Alicia Cedillos Universi dad Autónoma de Ciudad Juárez, Mexico

This work considers the process of citizenship formation and education for democracy in the context of democratic transition that Mexico is dealing with. It establishes the study of two important elements that
control the behaviour of future elementary school teachers, moral reasoning (Kohlberg, 1992; Rest, 1993), and the educative ideology (O’Neill, 1981). As far as capacity, or thought structure, is concerned along with ideas or relative beliefs to the common goal of education. Elements that will allow them to truly choose between different paths of action, beyond accomplishments in a certain time and context. The project questions if the civic and ethic challenges developed among children and teenagers through the integral programme of civic and ethic formation for elementary education, are able to be verified in a potential way in the future teachers of the elementary education subsystem. It adopts a quantitative investigation model and an investigation design quasi-experimental, descriptively transactional, and correlative (Campbell y Stanley, 1966; Lopez & Perez, L.Llantada, 2005). A sample directed by critiques (Hernandez, Fernandez, & Bautista, 2006) concerning 495 students coursing the last semesters in seven professor institutions in the state of Chihuahua, Mexico, was configured. Profiles for moral and educative ideology for institutions were elaborated, considerable statistic differences with test "r" and ANOVA were obtained, "r" of Pearson for both two central elements, and they were thoughtful to the civic and ethic challenges to develop among elementary school children.

Introducing international psychology to U.S. professional psychology trainees

Susan Hawes Antioch University New England, United States of America

Professional psychology training at the doctoral level has made moderate progress in integrating issues of multicultural diversity in their curricula, exceeding that of Research-Practitioner training programs. In these programmes, some gains have been made in attention to issues of social justice. However, there is minimal, if any, attention given to issues of global mental health, and much less to issues of globalization, global poverty, HIV/AIDS in the southern hemisphere, problems of brain-drain in African nations, and so on. There are no training opportunities offered in the U.S., which would involve clinical psychology trainees serving the underserved in countries where there are insufficient numbers of practitioners to meet the mental health needs of their citizens. This poster will present an annual international assessment practicum offered to our students. The programme serves HIV positive children living in Soweto who are receiving home-based care services from a local Johannesburg NGO. The assessment model has attempted to integrate concerns about Western Psychology hegemony and to provide services that have direct pragmatic benefits for the children’s education. How well we are doing at attaining our goals for the children is a work in progress, as we adapt ourselves to practice-based needs every year. The benefits our doctoral trainees receive are without number. Input from attendees on our efforts will be very greatly appreciated.

 Worries as determinants for preference of presidential candidates in Uganda

Grace Wangasira Makerere University, Uganda; John Munene Makerere University, Uganda

The study examined the influence of worries in the determination of preference for the presidential candidates in the February 2011 Ugandan elections. Boehnke, Schwartz, Stromberg and Sagar’s (1998) measure of worries was administered to 705 (300 male, 405 female) Makerere University students in early February 2011 just before the 18th February presidential elections. Of these, 32.9% preferred the incumbent president, 40.7% an opposition presidential candidate, and 26.4% had no preference. Results showed that worries influenced the preference for presidential candidates. There was a significant difference between students who preferred the incumbent president and those that did not in their ratings for ‘worries in health and safety’ and ‘worries in social relations and meaning in life’. The former had the highest mean ratings for these worries. The major reason for preference of the incumbent president was to maintain peace in the country; and that for preference of an opposition leader was to bring change in the country’s leadership. Overall results showed that one’s worries about ‘health and safety’ influence his/her preference for a particular leader. It is therefore important for current and aspirant leaders to realise that issues of ‘health and safety’ over ride all other issues and significantly influence one’s evaluation and preference for a potential leader.

Factors that influence the treatment of children in penal systems: An international comparison

Jean Kubecck NYC College of Technology, CUNY, United States of America; Jesse Lyon; Vera Albrecht

At what age can a child be held responsible for a criminal act? This question invokes additional questions of the competency, autonomy, and culpability of children. This study presents a search of penal codes pertaining to the treatment of children (under 18 years) in countries around the world. Based on available data, the median minimum age at which a child can be transferred to adult court (MAT) is Oceania (10), North/Central America (12), Africa (13), Europe (14), and South America (14.5). The median minimum age at which a child can be charged for criminal responsibility (MACR) is lowest for Asia (9.5 years) followed by Oceania (10), North/Central America (12), Africa (13), Europe (14), and South America (14.5). The state of the United States vary widely and in common law states, no minimum age for criminal responsibility or the age at which a child can be tried in an adult court has been set. For states that have set minimums, the lowest age for MACR and MAT appears to be 10 years. Moderators are presented and discussed. Variables included: MACR, MAT, religion, GDP, adult literacy rate, constitutional authority, per capita income, and intentional homicide rate. Note worthy was the finding that lower literacy rates were associated with lower MACR. Similarly, type of constitutional authority was also related to MACR. We were surprised, however, to find that religion (Christian, Muslim, Other), income (GDP or per Capita) and homicide rate were not associated with MACR. Implications are discussed.

Attitudes towards regional diversity in Ukraine

Lyubov Naydonova Institute of Psychology, Ukraine

Regional differences in Ukraine have historical, cultural and economic origins. The idea of regional diversity was used by electoral political technologists in a negative separating context, introducing the idea of two poles existing in the country. We assume that some abnormally negative attitudes may arise in current political circumstances. The main goal of our research is to evaluate the attitude of young and adult people towards regional diversity. We used a new version of IAT (Greenwald, 1998) proposed for evaluating the regional diversity attitudes. Cities of the regions represented categories for East-West division, while words with positive and negative sense were chosen for the other dimension. A sample of inhabitants of Eastern, Western and Central regions of Ukraine was investigated (n=178). As a result we encountered some of the initially expected attitudes. The youth of each region tended to have positive views on people from their native region and negative ones on people from other regions, but there were some abnormal tendencies of negative attitude in the Central region. There was a discrepancy in the results of direct and implicit methods as well. Our findings allow us to propose specially organised group discussions aimed at attitude change in difficult cases. The possibility of using IAT for measuring attitude towards regional diversity was confirmed. The situation with the attitude towards regional diversity in Ukraine needs psychologists’ attention, as the dynamics of the attitude towards: regional diversity is an important indicator of efficiency and correctness of political electoral technology in Ukraine.

The relationship between locus of control and the South African national political environment

Charles Van Wijk South Africa

Locus of control refers to the prediction of how reinforcements change expectations. An internal locus of control was previously reported to be associated with access to political and economic power in ‘Apartheid’ South Africa. The democratization of South Africa gave equal access to political power to all its citizens. This study sets out to investigate whether post-apartheid political changes have altered the way a group of technical engineers in the public service perceive their own ability to influence their personal lives and political environment. A total of 297 male participants with a mean age of 30 years, comprising Black, Mixed-race, and White sailors, completed Rotter’s Internality-Externality Scale. This was scored using Ferguson’s (1993) two-factor solution, which comprise of a personal and a political control factor. The scores of the three race groups were then compared. Results indicate that there were no significant differences between the groups on the total score and scores on the Personal Control factor. All participants believed in an equal internal control over their personal lives. However, Black respondents scored more external than the other race groups on the Political Control factor, indicating a perception of lesser influence over political affairs. The results suggest that the effects of the shift in political power have not fully filtered down to ordinary citizens yet.
be appeals both at a national and sometimes at an international level. There is also the possibility of pardons or other legislative changes. People affected by human rights violations have several different roles, both formal and informal, in court trials. There is a need to address these roles in order to enable better support for people during, in between and after trials. This paper discusses some of these challenges involved in trials related to past human rights violations. The paper is based on a study on victims’ experiences of transitional justice in Argentina and Peru.

Coping with political suppression interviews with Buddhist lamas about how to survive Chinese terror

Peter Elsass United States of America

How to combine politics with spirituality and religion is a debated subject. The Tibetans have solved it in a unique way; symptoms related to stressful injury are rare among Tibetan survivors. This resilience may be a result of having a Buddhist point of view. Some, however, have argued that there might be an incentive in minimising distress in that this can attract much-needed political and financial support from Western admirers of Tibetan Buddhism. An example of Western romanticisation is the use of so-called ‘Mindfulness’, as a meditative method to make one more resilient towards daily stress. The Tibetan refugees also use mindfulness to cope spiritually with political terror. But for them spirituality is much more than being mindful. Video examples are given about how Buddhist Lamas orientated approaches to dealing with the needs of affected people. Without ethical and political considerations spiritual methods such as Mindfulness are just a tool and can be misused to create a sense of psychological wellness - even in a Chinese torturer.

Healing political wounds: The role of macro interventions in assisting victims of political violence

Brandon Hamber INCORE, University of Ulster, United Kingdom

Using personal experience from engagement with victims and survivors of political violence during the South African Truth and Reconciliation Commission, and peacebuilding work in Northern Ireland, the paper will delve into the complex interplay between individual psychological processes and macro political interventions. The paper will highlight the limits of narrow mental health and medical orientated approaches to dealing with the needs of victims of political violence. Specifically, the paper will explore the role of different macro-interventions and transitional justice mechanisms such as reparations, "doing justice", and truth recovery in assisting victims of political violence.

Court trials after gross human rights violations: Reflections on the roles of people affected by state violence

Nora Sveass Department of Psychology UiO, Norway

Court trials related to past human rights violations are important in many aspects, both for persons affected by human rights violations, and for society at large. Yet, such trials present several challenges for those involved. There are practical and economic as well as emotional challenges when going through such trials, and often a lack of support for people who have been affected by state violence. There is also a time aspect to such trials: Not only will they be of a long duration, there will also often

Disability studies and psychology: Current and future directions

Leslie Swartz Stellenbosch University, South Africa

Psychology has for a long time made contributions to how people think about and respond to disability. The disability rights movement has not always found this contribution helpful, however, and along with other disciplines in the health field, psychology has been accused of subscribing to a medical model of disability which disallows the experiences of people with disabilities. Along with other liberation movements, the disability rights movement foregrounds the expertise and participation of insiders and the importance of the insider voice. A key slogan for the movement is ‘Nothing about us without us’. This slogan is to some extent in contrast to moves within psychology and related disciplines towards what are termed more objective approaches to the work of psychology, to de-focus from subjectivity. The field of disability studies as it intersects with psychology offers interesting challenges to psychology and psychologists, requiring us to rethink many aspects of our discipline, from the methods we use, to the partnerships we make, to the ways in which we disseminate what we know. The papers in this session will illuminate various challenges we face and suggest ways in which they can be addressed. There will be a particular emphasis on the challenges experienced in southern Africa.

Training disabled people’s organisation members in southern Africa in basic research skills

Leslie Swartz Stellenbosch University, South Africa

It is well established that until comparatively recently most writing about disability and about the issues disabled people face in their daily lives has been produced by non-disabled people, often professionals providing health or welfare services. Disability activists, alongside activists in other fields such as women’s liberation and black liberation, have for some time insisted that it is important for disabled people to speak for themselves, to produce and disseminate their own knowledge about themselves. The politics of othering of disabled people is exacerbated in contexts like southern Africa, where most disabled people are poor and black and have not had access to high quality education. Most formal knowledge we have about disability worldwide is produced by well educated, mainly white able-bodied people from higher income countries. In recognition of these and other issues, the South African Federation of the Disabled (SAFOD), an umbrella organisation representing disabled people’s organisations (DPOs), obtained funding to launch a research plan designed both to collect information on disability in the region and to build
the research capacity of the national DPOs making up SAFOD. I was fortunate to be appointed Lead Research Partner to this project with a particular portfolio of training representatives of DPOs in basic research skills. The trainees were a very diverse group with respect to previous education and training, ranging from people ready to undertake masters degrees to some who have not completed high school. The training took place within a broader context of disability politics within which solidarity, loyalty and activism are highly valued, and in which there is widespread disillusionment with and scepticism about able-bodied researchers. I am an outsider to the trainee group in multiple ways, including the fact that I am white, Jewish, by birth, atheist, and an academic. One of the primary aims of the research training is to assist trainees to look critically at data and at issues of evidence. A recurring theme during the informal breaks in the training, however, and during often humorous asides, is the question of faith in relation to disability. Failure to take adequate account of more spiritual, affective and relational aspects of disability politics and identity in trainings like these may, paradoxically, inhibit opportunities for development of empirical research skills.

Claiming loss in disability
Brian Watermeyer
South Africa
Pervasive representations of disability carry associations with the idea of loss. These have been strongly rejected by the social model movement as stereotyping, which may perpetuate views of disabled people as incomplete, vulnerable or needing rehabilitation. Discourses of loss, acceptance and denial remain a lens through which disabled persons are misknown. It is posited that ascribed notions of loss serve to maintain feelings of control and mastery within the observer, quieting the destabilising psychic threat which disability poses. Further, disabled people positioned as having to deny imputed loss may be at risk of suffering self- alienation relating to a mode of being which is (necessarily, understandably) preoccupied with not being the personification of stereotype, at the expense of exploring aspects of identity and self. Such an orientation embodies unstable foundations for an entitled, articulate disability movement. Conceptual ideas are based on the author’s experience as a disabled group psychotherapist working with severely physically impaired adults.

Utilising leadership positions to model, encourage, and empower others
Gwendolyn Keita
American Psychological Association, United States of America
This presentation will focus on utilising the leadership positions to model, encourage, and empower others to broaden their focus of attention and seek greater opportunities to make a difference, and to see their roles as change agents. Leaders often follow in the footsteps of others who held the position before them. This often leaves a great deal of room to establish programmes and projects that can really make a difference in improving people’s lives. For example, while Director of the APA Women’s Programs Office, I spearheaded three Women’s Health Conferences to highlight the importance of Behavioural and psychosocial factors in women’s health, and health more broadly. There will be discussion on ways to get others to see their leadership positions as providing important platforms to facilitate, and convene others in ways that make a critical difference in solving social problems. The presenter is the Executive Director of the American Psychological Association’s Public Interest Directorate.

Effective development of leadership skills: Unlocking your leadership potential to effect a change within your community
Jennifer Kelly
Independent Practice, United States of America; Rosie Phillips Bingham Independent Practice, United States of America; Melba Vasquez; Gwendolyn Keita
Independent Practice, United States of America
This presentation on leadership development and effective use of our special skills and talents will be presented by four women of colour leaders within the United States psychological community. The four dynamic presenters will describe key strategies and components for leadership development, and what to do with that special talent in making a difference within your community—the psychological community and the community at large. The four presenters have all served in leadership positions within the American Psychological Association (President and Member-at-Large of Board of Directors, and Executive Director of the Public Interest Directorate) and their respective communities. They each bring unique perspectives to leadership development that will be shared with the audience. There are leadership characteristices and qualities that psychologists possess that can make a difference in the community. That includes making a difference at the grassroots level (bottom up) to policy change (top down). There will be focus on strategies to utilise our unique skills to make positive changes. In addition, techniques to further develop these skills will be provided.

Key principles in attaining and achieving leadership positions in psychology
Melba Vasquez
Independent Practice, United States of America
This presentation will provide information and principles involved in attaining and achieving leadership positions in various areas of careers in psychology. The path to leadership for this woman of colour in the United States will be described. The presenter is the first Latina/o and first woman of colour president of the American Psychological Association (APA), out of 120 APA presidencies. Basic leadership principles as well as the presenter’s “lessons learned” and personal experiences will be shared as strategies for a successful, healthy and productive process in attaining and maintaining leadership positions. "Choosing the high road" in the application of feminist and multicultural ethics and principles will be shared. Entering a world that requires navigating "microaggressions", stereotypes, and one’s own issues such as the "imposter syndrome" will be reviewed. Strategies to cope with adversity, e.g. engaging in productive work while balancing family and other aspects of self care, will be identified.

Symposium title: Psychological services and humanity approach in the process of transition from state to private sectors in East Europe
Convener: Miloslaw Solc

Attitudes toward democracy in post-communist states and their psychosocial determinants: The example of Poland
Urszula Jakubowska
Polish Academy of Sciences, Poland; Krys Kaniasty
Since 1989 Poland underwent a transformation from communism to democracy. Studies from the 1990s documented that Poles’ understanding of democracy deviated from the normative meaning of it. Poles envisioned democracy as a wealthy welfare state and had many unrealistic expectations for the future. This study examined (1) the current understanding of democracy in Poland, (2) attitudes toward democracy in general, as well as specifically in Poland, and (3) the relationship between these attitudes and various political actions. This research included both a convenience pilot study sample (N = 62, a phase completed) and a probability national sample of 400 adults interviewed by phone (a phase currently being conducted). The one-hour long phone interviews incorporated a host of scales measuring political attitudes, beliefs and behaviours. Perceptions of stressful political and personal events and psychosocial resources were also assessed. Analyses based on pilot data documented that many of the instruments purposefully constructed by authors had adequate psychometric properties. Political interest and sophistication mea-
sures showed reliable relations with assessments of an understanding of democracy, the importance of democracy for contemporary Poland, and engagement in political activities and descent. Political attitudes also correlated with social support, and personal and community efficacy specifically related to political behaviors. Erroneous understanding of democracy, disapproval of democratic changes and initiatives in Poland, continuous sense of anomic and political frustrations are relevant predictors of political behaviors. These factors may particularly be relevant for understanding contrarian behaviors such as political extremism or political indifference.

Psychology of democracy and democratisation: Experience from Central and Eastern Europe
Martina Klicperova Academy of Sciences, Czech Republic
Presentation focuses on a) psychological predispositions to democracy and b) the observed evidence of significant attitudes and representative mentalities in the region. Civic political culture, civic patriotism and civility are considered the three basic prerequisites for democracy (the Feierabend triad). Civility (civic ethos, morality of civil society) in particular is the key element, inevitable for negotiations and peaceful conflict resolution within democracy, a regime based on dialogue and balance of disparities. As citizens of the region cope with democracy, free market and economic challenge, several distinct mentalities can be identified by social surveys and cluster analyses: Progressive social liberalism, traditional morality, post-totalitarian mentalities, immoral opportunism, and risk-taking hedonism, among others. Their incidence in various countries and periods of transition will be presented. The post-totalitarian syndrome calls for particular concern as it includes specific immorality (intolerance to diversity, acceptance of corruption and cheating) and negative passivity, authoritarianism or parochialism. Psychologists can help by intervention (e.g., guidance for citizens used to state paternalism) and involvement in education and fostering of democratic citizenship.

Symposium title: Psychologies of occupation: The Palestinian family context
Convenor: Judy Roth

When ongoing trauma becomes normal: Compassion fatigue and collective healing
Laila Atshan United States of America
This presentation will explore the idea of secondary traumatic stress, also known as "compassion fatigue", in the Palestinian context. In contrast to the more familiar situation of professionals developing secondary trauma through merely hearing about traumatic events, the Palestinian professional is also subject to the subtle collective trauma that is an ongoing and ubiquitous stressor in Palestinian so-

Soldiers and children, soldiers as children: What enables dissociation?
Efrat Even-Tzur "PsychoActive", Israel
This paper focuses on psychological mechanisms of dissociation, dehumanisation and renouncement of subject position, and their relationship to the carrying out of violence. Its context is the violent towards children and families in the West bank, executed regularly by the Israeli military, as reported by human rights organisations, media sources and Ex-soldiers’ testimonies. The soldiers are usually normative citizens, expecting eventually to be parents. What brings them to take part in physical and psychological abuse of children? Based on my experience as a student and as a soldier-teacher in Israeli schools, and on research by education and psychology scholars, I will claim that the answer lies partly in the Israeli education system. Ex-soldiers report retroactively on the psychological state that enabled them to take part in violence against minors, contrary to their own basic values. Their accounts testify to a de-humanisation mechanism that leads to perceiving Palestinians, including children, as enemies rather than humans. This de-humanisation, affected by the messages of certain elements of Israeli education, allows the dissociation that enables the violent acts. I will further use my own research, to claim that soldiers’ testimonies reveal the effort Israeli army put into the infantilisation of young recruits, depriving them of their agency and subjectivity. Ex-soldiers tend to talk about themselves as “children” who were brainwashed. I will suggest a relation between the impaired subject position of the soldiers, the de-humanisation mechanism, and the deprivation of subjectivity from Palestinians, and the consequence of violence.

Controlling the population across generations: Mechanics of long-term military occupation
Gerard Horton United States of America
This paper considers some of the methods used to maintain control over a civilian population during prolonged military occupation. The paper primarily focuses on the arrest, detention and military prosecution of Palestinian children, and some of the effects this has on both children and families. The paper also contrasts the situation of Israeli children living in settlements, who are prosecuted in civilian, not military courts. Annually, around 500-700 Palestinian children from the West Bank are incarcerated in this military detention system. Credible reports of torture, ill-treatment and trauma have persisted for years. The majority of the children are charged with throwing stones. The ill-treatment starts at the moment of arrest when many children report experiencing terrifying night time raids on the family home, before being tied and blindfolded. The children are then transferred to interrogation centres where they are questioned alone and reports of threats and assaults are common. Most children confess and are imprisoned inside Israel, far from their parents, making visits difficult. By way of contrast, Israeli children living in the settlements are subject to civilian law. For the same offence, an Israeli child will see a lawyer before being questioned and is entitled to have a parent present at all times. This child will almost certainly be granted bail and is unlikely to serve a custodial sentence if convicted. Upon release, parents of Palestinian ex-child detainees report that their children experience nightmares, bedwetting, role playing, isolation, reduced academic performance and a general sense of hopelessness.

Psychologies of occupation: The Palestinian family context
Judy Roth City University of New York, United States of America
Under long term occupations both occupants and occupied develop a justified fear that they are living
in a sphere of danger. Perpetual occupation begets abnormal societies of traumatisation, where seething hostilities prevail. This panel focuses on psychological dimensions of the situation of Palestinian youth arrested, interrogated and incarcerated by the Israeli military in the Palestinian occupied territories of the West Bank and East Jerusalem. After presenting data on the particulars of arrest and contrast between treatment of Palestinian and Israeli youth arrested for similar offences (Paper 1), we turn to three psychological dimensions of this situation: the effect on Palestinian families of the dangers faced by their children, as evidenced in extensive interviews with mothers (Paper 2); The effect on Palestinian health professionals attempting to relieve traumatisation of a given arrest, when they share the whole society’s “normalised” condition of abnormal perpetual danger (Paper 3); the psychological processes of young Israeli soldiers perpetuating violence against young Palestinians. (Paper 4). We believe these topics to be of relevance to parties attempting to work towards justice for Israeli and Palestinian peoples, and to psychologists from other nations struggling with legacies and current conditions of colonial and ethnic occupations.

Symposium title: Race, risk, and resilience among black youth in the United States and South Africa: Conceptual, methodological, and application considerations
Convenor: Tabbye Chavous

Understanding sociopolitical development: Profiles of ideological beliefs among black adolescents and young adults
Elan Hope University of Michigan, United States of America

This paper focuses on Black youth resilience through examination of sociopolitical beliefs and orientations linked to youth agency and empowerment. Civic engagement, community involvement, and political empowerment are critical to promotion of well-being and positive development among minority youth, particularly those from historically oppressed groups. Watts and colleagues proposed a model of sociopolitical development (SPD) positing individual and contextual factors that influence how adolescents understand and become involved in society. SPD is an evolving understanding of cultural, economic, and political systems, how these systems define society, and how societal definitions impact one’s own status with the society while giving specific attention to oppression and injustices. SPD contends that critical analysis of authority and power, critical ideological beliefs, sense of agency, and opportunity structures are key factors related to increased societal involvement and positive development among youth. The current study examined critical ideological beliefs of 635 Black American youth (ages 15-25) and implications for political beliefs and behaviors. Participants were from the Black Youth Project by Cohen and colleagues. Cluster analysis of Black youth’s perceptions of fairness, government trust, and citizenship beliefs resulted in five cluster profiles of ideological beliefs. Youth’s demographic characteristics (age, income, father’s education) were related to cluster membership. Additionally, cluster group membership predicted political efficacy, political talk, political action (e.g. petitioning), and violence behavior. The study highlights heterogeneity of ideological beliefs among Black youth and helps extend current literatures on adolescent sociopolitical attitudes and positive development.

The youth research collaborative: Prospects and challenges for a youth participatory action research initiative
Robert Jagers United States of America

This paper describes a participatory action research approach to promoting youth agency for social change among Black adolescents from diverse urban and suburban community contexts. The Youth Research Collaborative (YRC) was developed by researchers at the University of Michigan’s Center for the Study of Black Youth in Context (CSBYC). YRC is a youth participatory action research initiative for African American secondary school students. Participatory action research is a methodological approach based in community psychology around collecting and documenting information that honors, centers, and reflects the experiences of people most directly affected by issues in their communities. That is, researchers and stakeholders collaborate to design and conduct all phases of research (e.g., formulating research questions, research design, data collection, data analysis, dissemination, and utilisation). The ultimate goal is increasing the likelihood that the products resulting from research will solve the problems that stakeholders define and experience. The UM-YRC programme was developed based on basic theory and research on adolescent development and sociopolitical development. The programme engages students in a critical analysis of their lived experiences and facilitates their use of social science research skills to design, implement and evaluate their efforts to address identified, actionable concerns in their schools and communities. This paper presentation will provide examples and an overview of findings from several youth-developed and youth-led projects. Findings will be used to discuss the intersections among education, adolescent development, and sociopolitical development, especially among African American boys and young men.

Using basic research to inform the development and evaluation of psycho-educational interventions and community development programs in South African contexts
Sibusiso Ntsangase United States of America

This paper describes examples of basic and applied psychological research (from community and developmental psychology) within South African contexts related to education, poverty, and HIV/AIDS. As a primary example, the author will focus a documented area of academic and social risk - learners with disabilities in South Africa schools and ways that black special needs learners are viewed and responded to in the South African context. First, the author will present research on self-esteem among special needs and non-special needs learners in Johannesburg, South Africa using an ecologically and culturally specific measure as well as traditional measure (Rosenberg’s Global Self-Esteem measure). The findings – counter to prevalent cultural views of special needs learners - indicate the utility of considering culture in the assessment of self-esteem. Furthermore, there were no significant self-esteem differences using the culturally-based measure between special needs and non-special needs learners in inclusive, mainstreamed classrooms. The findings indicate potential benefits of inclusion and also highlight the potential value of culturally-based self-esteem interventions as an important part of implementing inclusion of special needs learners in South African schools. Second, the author considers and describes how basic psychological research with special needs learners can be used in the development and evaluation of psycho-educational intervention and community development programs. Using the prior basic research example, the author will discuss programmatic approaches to influencing educators’ attitudes and beliefs about educational/classroom inclusion of special needs learners in Johannesburg, South Africa schools.

Symposium title: Surviving gross human rights violations - exploring survivors’ experience of justice and reparation
Convenor: Nora Sveaas

Culturally adapted approaches to healing of trauma for survivors of Khmer Rouge in Cambodia
Inger Agger ICT, Denmark

The objective of this study is to explore different forms of individual and collective symbolic reparations, which victims of the Khmer Rouge genocide may encounter in Cambodia, which is presently in a transitional justice process. The Khmer Rouge Tribunal (ECCC) started its proceedings in 2007, thirty years after the devastating events happening under the Khmer Rouge regime (1975-1979). The Tribunal, which is a hybrid UN/Cambodian court, is meant to be “restorative" and “ease the burden of the survivors”. However, it cannot award individual or material reparations, only "collective" or "moral" reparations. Therefore, the Tribunal has recommended the development of "non-judicial" forms of reparations such as memorial and remembrance activities, rehabilitation (psychosocial support for traumatised individuals and communities), and documentation and education. The study is based on six months of fieldwork in Cambodia which included qualitative and open-ended interviews with individual Khmer Rouge survivors and members of victim organisations, interviews with members of the indigenous healing system (monks, nuns, traditional healers), and with NGOs, mental health professionals, and staff from the Khmer Rouge Tribunal. The study also included observation of community activities aimed at healing, religious rituals and ceremonies concerned with improving the relationship to the dead, as well as proceedings of the Khmer Rouge Tribunal. The study seeks to contribute to the understanding of healing after violence-related trauma in low-income countries, which are transitioning from conflict towards peace and democracy.

Court trials after gross human rights violations: Reflections on the roles of people affected by state violence
Anne Margrethe Sonneland Diakonhjemmet University, Norway

Court trials related to past human rights violations are important in many aspects, both for persons affected by human rights violations, and for society at large. Yet, such trials present several challenges for those
involved. There are practical and economic, as well as emotional challenges when going through such trials, and often a lack of support for people who have been affected by state violence. There is also a time aspect to such trials: Not only will they be of a long duration, there will also often be appeals both at a national and sometimes at an international level. There is also the possibility of pardons or other legislative changes. People affected by human rights violations have several different roles – both formal and informal – in court trials. There is a need to address these roles in order to enable better support for people during, in between and after trials. This paper discusses some of these challenges involved in trials related to past human rights violations. The paper is based on a study on victims’ experiences of transitional justice in Argentina and Peru.

Symposium title: The facets and faces of human trafficking: The psychological and public health crisis of the 21st century
Convenor: Nancy Sidun

Human trafficking: Psychology’s role in prevention and intervention
Jill Bloom Massachusetts School of Professional Psychology, United States of America

Despite the increased public awareness of trafficking victims internationally, the knowledge base remains weak. Research on trafficking has moved minimally beyond estimating the scale of the problem, mapping routes between countries of origin, transit, and destinations and reviewing legal frameworks and policy responses. There is little reliable data on the number of trafficking cases and the characteristics of victims and perpetrators. In order to develop effective methods and programs for both prevention and intervention, a more nuanced understanding of trafficking survivors’ experiences is called for. Rigorous ethnographic and sociological studies based in-depth interviews with trafficking survivors are beginning to provide baseline data on trafficking victims. Too often victims of trafficking remain one-dimensional figures whose stories are condensed and simplified, limiting the development of culturally appropriate services. In order to develop appropriate assistance and treatment programs for trafficking survivors, increased attention must be paid to the expertise and practical knowledge of NGOs, and to programs serving victims of trafficking. Attention also, to the evaluation of well-designed studies, can help identify effective policies and best practice approaches. In focusing more specifically on issues related to mental health interventions, diagnosis and screening, it is essential that approaches help providers develop culturally sensitive and informed interventions. Working with other systems, who come into contact with trafficking victims is, also, an important role for differentiating between perceptions and treatment of trafficked survivors as victims versus criminals.

Symposium title: The social psychology of religion: Understanding religious prejudice
Convenor: Constantin Klein

Religious anti-gay prejudice: Physical aggression measured with hot sauce allocation paradigm
Joanna Błagowska Belgium; Vassilis Saroglou

The relationship between religiosity and prejudice against targets threatening traditional values is already well established but there is no evidence on whether such prejudice may lead to physical aggression. This is an interesting question. In general, aggression can be one of the consequences of prejudice. However, religious prosociality (even if limited to proximal and in-group targets) could prevent religious people from explicitly showing aggression towards their targets of prejudice. In an experiment with 130 participants (students), we used the hot sauce allocation paradigm as a measure of physical aggression towards (1) a gay target who presumably had written a text praising society’s progress in protecting gay civil rights (experimental condition), or (2) a neutral target who had written a text praising society’s technological progress (control condition). Religious fundamentalism, but also mere religiosity, predicted physical aggression towards the gay target. The results highlight the problematic behavioural consequences of religious prejudice.

Psychological impact of trafficking on women and girls
Cynthia De Los Fuentes Independent Practice, United States of America

Traffickers use a variety of coercive methods designed to destroy their hostages’ psychological defenses, create dependency, and limit chances for escape. These methods include physical, sexual, and psychological violence, isolation, relocation to areas where cultures and languages are unknown to their victims, forced dependence on alcohol or drugs, control of access to food, water, and sleep, and close supervision. As a result of these circumstances, trafficked women and girls face numerous negative consequences to their psychological welfare. This talk will address the psychological consequences of trafficking for women and girls. Victims of trafficking frequently experience psychological trauma that includes disassociated ego states, shame, grief, fear, distrust, hatred of men, self-blame and self-hatred, suicide, suicidal thoughts, and PTSD. PTSD develops in those trafficked women and girls who experience greater stressor magnitude and intensity, unpredictability, uncontrollability, and physical and sexual victimisation. Judith Herman’s (1992) definition of Complex PTSD “…prolonged, repeated trauma can occur only where the victim is in a state of captivity, unable to flee, and under the control of the perpetrator” will be presented as it is an appropriate frame for understanding the psychological sequelae of trafficking in women and girls. (Please note: this is to be apart of the symposium: “The Facets and Faces of Human Trafficking: The Psychological and Public Health Crisis of the 21st Century”).

Health HIV and human trafficking in women and girls
Raman Durvasula CSU Los Angeles, United States of America

Human trafficking places women at risk for numerous deleterious health outcomes, yet relatively little systematic attention has been given to the larger relationship between health and trafficking, particularly HIV infection. The major categories of health risk facing this population include: (a) Greater risk of acquiring HIV and other sexually transmitted infections, (b) physical violence, (c) substance use, (d) psychiatric disorders, (e) nutritional deprivation, (f) severe psychological stress, (g) poverty, and (g) lack of access to health care (Spice, 2007; Vijeyara et al., 2010). Past and ongoing histories of poly-trauma magnify the consequences of these health risks. HIV is of particular importance, with estimates that 25-80% of trafficked women and girls will become infected with HIV (Gupta et al., 2009), with higher risk of morbidity and mortality. This presentation will focus specifically on HIV/AIDS in trafficked women and girls and address: (a) The heightened risk factors for acquisition of infection in this population, (b) the specific types of clinical complications that this population of women and girls are more likely to experience, and (c) specific HIV prevention and treatment considerations that must be tailored for this population within the context of the unique psychological, economic, cultural, and social issues faced by these women. HIV/AIDS is one of many health risks faced by trafficked women and girls, however, better understanding of prevention/treatment of HIV and its sequelae becomes a model by which to address the myriad health risks raised by trafficking.

Modern day epidemic: Human trafficking
Nancy Sidun Kaiser Permanente-Hawaii, United States of America

After drug dealing, human trafficking, our modern day slavery, is the second largest criminal industry in today’s world and is the fastest growing. According to the U.S. Department of State, 600,000 to 800,000 victims are trafficked annually across international borders. These figures do not account for those trafficked within their home country. This symposium will highlight the structural and proximate forces involved in the maintenance of human trafficking, while paying special attention to how this phenomenon disproportionally affects tradition disenfranchised populations. For example, among those who are trafficked, estimates are that 80% are women and 50% are children. Additionally, a growing amount of research has indicated that socioeconomic factors, such as poverty and globalisation, are important factors leading to vulnerability. Traffickers target vulnerable individuals for exploitation, often exposing them to chronic stressful. Therefore, survivors of human trafficking are in need of the type of trauma-informed services. The role of psychologists in providing evaluations and writing psychological affidavits for victims of trafficking will be addressed. (Please note this is to be apart of the symposium entitled "The Facets and Faces of Human Trafficking: The Psychological and Public Health Crisis of the 21st Century".)

Does hetero-religious priming increase pro-sociality? Depends on the religion
Magali Clobert Université catholique de Louvain, Belgium; Vassilis Saroglou

Series of priming studies have shown that implicit activation of religious concepts leads to prosocial effects (activation of prosocial concepts, willingness to volunteer, cooperation, low retaliation). All these studies used Christian religious primes among participants of Christian background. What if priming participants with concepts from another than (Christian) background? In a study with 130 participants (students), we used the hot sauce allocation paradigm as a measure of physical aggression towards (1) a gay target who presumably had written a text praising society’s progress in protecting gay civil rights (experimental condition), or (2) a neutral target who had written a text praising society’s technological progress (control condition). Religious fundamentalism, but also mere religiosity, predicted physical aggression towards the gay target. The results highlight the problematic behavioural consequences of religious prejudice.
with a Buddhist version of the Golden Rule (Vilaythong et al., 2010). We argue that the other religion’s effects depend on the positive valence attributed to another’s own religion rather than on a general "outgrip" effect. In the present experiment, 117 Belgian students of Christian tradition were randomly assigned to three conditions: Buddhist prime, Muslim prime, and control (no prime). Primes were pictures that decorated the experimental room. Afterwards, participants’ prosociality was measured through a task of sharing hypothetical gains. Primes of a positively seen “other” religion, i.e. Buddhism, but not of a negatively seen other religion, i.e. Islam, implicitly increased prosociality. Social context moderates effects of religious priming on social behaviour.

Fuelling religious conflict - studies on the interaction between ideological beliefs and religious identification
Anne-Katrin Henseler Bielefeld University, Germany; Hector Carvacho; Andreas Zick
Many scholars have found evidence for the relation between in-group identification and out-group derogation. Also identification with religious in-groups has been proved to predict prejudice towards religious, ethnic and cultural out-groups (Hunsberger, 1995). However, some moderators have been suggested to indicate under which conditions in-group identification leads to prejudice (Brewer, 1999). This paper tests the content of the identity and ideological beliefs as moderators of this relation. Four experimental and correlational studies were conducted. In the first experiment we manipulated the level of religious identification in a sample of Christian students. We expected to find an interactive relationship between in-group identification and different beliefs (such as religious belief styles and ideological attitudes like social dominance orientation) to predict prejudice towards Muslims, Jews and non believers. In the second study, the Group Focused Enmity (GFE, Zick et al., 2008) survey was reanalysed looking for the same patterns, this time using the interaction between superiority beliefs and strength of religiosity to predict GFE. The third study was conducted to combine the relationships between social dominance orientation, religious belief style, and identification as predictors of prejudice. We expected to find support for a mediated moderation: the joint effect of social dominance orientation and religious identification leads to religious fundamentalism, which in turn enhances prejudice towards religious out-groups. In study four, longitudinal data of the GFE panel study were used to test underlying causal assumptions. The paper will sketch basic results and propose a new approach to understand why religious people become prejudiced.
Research Area: Social Psychology

Session Type: Papers

The role of historical collective memory and group identity in paradigm and behaviour change

Riyanti Abriyani Universitas Indonesia, Indonesia

The research explored and discovered the roles of historical collective memory and group identity in paradigm and behaviour change. The research is interdisciplinary (Social Psychology and Political Psychology) and aims to understand the roles of historical collective memory and group identity in paradigm and behaviour change. The research focused and worked on paradigm and behaviour change in the TNI (Indonesian National Army) Reformation process. Research participants are 2 generals (architect of TNI Reformation - reformulation of armed forces), 3 retired generals (pro-reform), 3 retired generals (cons-reformation), 6 generals, 6 colonels, and 6 captains. The result is a theoretical model of paradigm and behaviour change generated from a qualitative method Grounded Theory. Research results showed contested historical collective memory inhibits paradigm change, but not behavior change. Negotiated collective memory and group identity, together, make way for paradigm and behavior change. Contested historical collective memory and group identity, together, inhibit paradigm change but not behaviour change. Keywords: Historical collective memory, group identity, paradigm change, behavior change.

The role of historical collective memory and social identity in intergroup forgiveness process

Riyanti Abriyani Universitas Indonesia, Indonesia

Intergroup forgiveness researches have been emerging lately, though it has long been recognised that the human behave differently in groups. The difference is caused by the occurrence of a change in personal identity to a social identity (Tajfel & Turner, 1979) and more emphasis is placed on in-group rather than oneself. The research is a Social Psychology research that aims to understand the role of the historical collective memory and social identity in intergroup forgiveness. The empirical context of the research is intergroup forgiveness between Indonesia and Timor-Leste people. Participants of the research are 6 Indonesians and 6 Timor-Leste residents who live in the border areas of both countries. Data collection is done by means of interviews (in-depth interview and focus group interview). The result of this research is a theoretical model of intergroup forgiveness generated from a qualitative method Grounded Theory. Results show contested historical collective memory strengthens the in-group’s social identity and derogates the out-group’s social identity. The fulfillment of basic needs determines social identity choice, the forced separation from the people who formerly was in-group raises social identity confusion, social identity confusion persists even though people already had the desired national identity, social identity confusion increases motivation to forgive, intergroup forgiveness at society level is perceived as the most ideal intergroup forgiveness for both groups, but not at the political level.

Mate or hate: Exploring the automaticity of in-group bias in Australian males

Joel Anderson Australian Catholic University, Australia; Leah Kaufmann

In Australia, there is an assumption of male mate-ship. This implies in-group preference along the social dimension of gender. However, homophobic attitudes are empirically reported as highest when both the target and perpetrator are men. This reveals out-group bias toward the same target if the salient social dimension is sexual orientation. The juxtaposition of clashing social categories complicates the already under-researched male in-group bias. This study examined the influence of self-reported religious affiliation, sexual orientation and individual differences in religiosity on implicit and explicit homophobic attitudes among Australian males. 60 females (M=26.89 years, SD=10.18 years; 43.30% Heterosexual; 51.70% Christian) participants completed a battery of religiosity measures, the Attitudes Towards Gay Men and Lesbians scale, and the Go/No-Go Association Task. The sample reported relatively positive explicit attitudes, but differences existed as a function of sexual orientation and religious affiliation. Specifically, straight participants reported more negative attitudes towards gay men than lesbians. This pattern did not exist for gay male participants. Christian participants reported more negative attitudes towards both gay men and lesbians than non-Christians. Implicit results revealed a females/positive and males/negative pattern for heterosexual targets. This pattern was reversed for homosexual targets. There was no interaction with the participants’ sexual orientation. These findings were interpreted as evidence that heterosexual, but not homosexual participants lack the mechanism that stimulates automatic own-group preferences consistent with Rudman and Goodwin’s (2003) proposition and that this is associated with sexuality-based prejudice.

Radio broadcast to increase couples intimacy

Fernando Arias-Galicia Morelos State University, Mexico; Mónica Mónica Páez Martínez

It has been said that radio programmes may have an educational impact. For instance, Boily (2004) refers to radio as a didactic support tool in teaching. Therefore, an experiment was launched in order to help couples to increase intimacy: sexual-ity, acceptance, and satisfactory interaction. 25 couples were assigned to the experimental group and 25 to the control group. They were married from 4 months to 36 years. Average age was 37 years. Average time of marriage: 11 years. Couples in the experimental group were instructed to listen to a series of six radio programmes designed specifically to increase intimacy; these were broadcast by a commercial radio station. Couples in the control group were asked not to listen. The instrument was administered both at the beginning and the end of the experiment to both groups. The Likert type Intimacy scale (Osanya, 2003) was administered before and after intervention. It has shown good reliability (.85). The T-test showed significant differences in the before and after scores in the experimental group. No significant change was observed in the control group. Radio broadcasts have shown a very important potential role to educate adults. Intimacy between couples may be an important factor to increase quality of life. More experiments in another settings and themes are mandatory.

Encountering politicisation: Group and intergroup dynamics at a public broadcaster

Corinna Arndt University of Oxford, United Kingdom

This paper uses the South African Broadcasting Corporation as a case study to explore how group dynamics and inter-group processes relate to a public broadcaster’s susceptibility to politicisation from outside. The analysis rests on specific sub-groups of journalists and editors that have formed around ethnicity/race, time of employment, political affiliation, age, skills level, and shared role perceptions. It reflects on individually held and collective attitudes, values and beliefs, about the resulting inter-group communication patterns and practices in the newsroom. Findings suggest that intra- and inter-group dynamics have a significant impact on (1) how the news and current affairs division as a whole perceives and performs its role vis-a-vis the political sphere; (2) how identity and value conflicts are managed within the organisation; and (3) the organisation’s widely acknowledged and documented resistance to change and professionalisation. The research is qualitative and largely exploratory in nature. Findings are based on extensive ethnographic fieldwork conducted between 2005 and 2011, including in-depth interviews with more than 100 current and former journalists and more than six months full-time participant observation in seven SABC newsrooms. The approach is interdisciplinary. It draws on group relations theory and contemporary theories of the systems psychodynamics of organisations; sociology (organisational culture, sociology of news production), and political science (the politicisation of institutions). It is work in progress based on ongoing doctoral research.

House of mirrors: National stereotypes in Iran, China, Canada and the United States

Fatemeh Bagherian Shahid Beheshti University, Islamic Republic of Iran

How do stereotypes of people in other nations compare with the stereotypes the people hold of themselves? University students from Iran, China, Canada and the United States listed up to five words or phrases that first came to mind when thinking about each others’ countries. They then rated their attitudes towards the words/phrases they listed. Americans generally received negative ratings, especially from Canadians. Canadians and Chinese generally received positive ratings, and Iranians received positive ratings from everyone except Americans. Predictions about in-group bias were not supported in that respondents did not generally hold more favorable stereotypes of themselves than of other nationalities. Predictions about out-group homogeneity were supported. Most participants showed more variability in ratings of their own nationality than in ratings of the other three. Several exceptions were found, suggesting that in-group and out-group phenomena shift with nationality and culture.
Lay theories and poverty-related social cognition in a hierarchical society: Philippine research

Allan B. I. Bernardo De La Salle University, Philippines

In many parts of the world, modern democratic social institutions co-exist with social practices that reflect historical social hierarchies and inequities. The Philippines is an example of a democracy where socio-economic and political power is concentrated in the elite, and social processes are characterised by transactions between the elite and the masses. The hierarchical nature of Philippine society has been traced to its pre-colonial history, through the colonial periods under Spain and the United states, and is maintained to this day. Social psychologists have proposed that social inequalities and hierarchies are perpetuated in part by specific aspects of social relationships that influence how people distribute resources across the different groups within a society. For example, research and theory has suggested that lay theories representing beliefs about how people control social outcomes (e.g., the Protestant work ethic) and about the essential qualities of human beings (e.g., incremental vs. entitative theories) are related to various types of intergroup behaviour, including some subtle forms of prejudice. Much of the work on lay theories has been done in relation to group-based hierarchies that are important in the West (e.g., gender, race, sexual orientation). In this paper, I present a series of studies in a research programme that inquires into various poverty-related social cognitions among the Filipinos from the higher and lower socio-economic groups. The studies refer to negative stereotypes about the poor, empathy for the poor, subtle forms of prejudice like dehumanisation, and behavioural asymmetries between upper and lower socio-economic groups in intergroup behaviours (i.e., conflict resolution, helping, and language attitudes), among others. The studies explore how poverty-related cognitions are shaped and propagated by lay theories and beliefs. The investigations focus mainly on the two meanings of the Protestant work ethic, but also inquire into other lay theories. The findings are discussed in relation to how lay theories shape intergroup behaviour even when the markers of in-group and out-group membership (and therefore of social identity) are not explicitly defined (in contrast to how membership in gender- or race-related groups is explicitly defined). These lay theories may be appropriated and given very specific meanings within the egalitarian discourses of democratic institutions in ways that perpetuate social inequalities and hierarchies. Finally, research on the development and activation of lay theories is discussed to point to possible social interventions that could transform the functioning of specific lay theories in the hope of transforming poverty-related social cognitions and inter-group behaviours.

Online study with 578 participants we looked for factors that influence the perception of such aggressive acts. In preparation we collected data about aggressive acts on subway stations as well as eyewitness reports. Using these we created a list of important situations, environment and person factors. Nine factors were chosen for a facet study. We wrote 64 short descriptions of possible aggressive situations from the view of an eyewitness. As we used a fractional factorial design each participant had to rate only a subset of four stories for the perceived dangerousness, for their emotions and for their behaviour in the imagined situation. Results of the mixed linear models showed strong effects for the factors ‘type of aggression’ (verbal or physical) and ‘number of aggressors’. Different aspects of the cognitive, emotional and behavioural measurements were influenced by the factors describing the culprit. ‘Gender of victim’ and ‘reaction of the victim’ (defence or withdrawal) did not reach significance for the cognitive judgements, but were significant for the emotional ones. ‘Presence of others’ and ‘video surveillance’ had an effect on all ratings. Only small differences could be found between the subsamples of men and women as well as younger and older participants.

The unconscious process of anchoring effects: Subliminal anchoring effects

Li Bin Central China Normal University, China; Wang Wei; Hongyu Ma; Yongyu GUO; Fuming Xu

Subliminal anchoring effects refer to a phenomenon that, even if anchor values are presented, subliminally could still make anchoring effects occurred. This study tries to explore the mechanisms of subliminal anchoring effects. A total of 270 undergraduate students were recruited. Experiment 1 demonstrated subliminal anchoring effects by a 2 (Anchor Types: High VS Low) × 2 (Presence or Absence of Subliminal Anchor) × 2 (Word Types: Summer VS Winter) × 2 (Time Pressure: Present VS Absent) between subject design. Experiments 2 and 3 demonstrated the interaction effects between subliminal-anchor and experimenter-provided-anchor, subliminal-anchor and self-generated-anchor. Experiment 4 explored the mechanism of subliminal anchoring effects by a 2 (Anchor Types: High VS Low) × 2 (Word Types: Summer VS Winter) mixed factorial design. The results in Experiment 1 showed that only under time pressure, Experiments 2 and 3 showed that only without experimenter-provided-anchors or self-generated-anchors, did subliminal anchoring effects happen. The results in Experiment 4 showed that participants were faster in recognizing anchor-consistent rather than anchor-inconsistent target words in the lexical decision task. This implies that the accessibility of the proposition property in numerical anchors may be the mechanisms of subliminal anchoring effects.

Relationships between various sources of social identification in South Africa

Elirea Borman University of South Africa, South Africa

Social identity theory holds that membership of social groups is integrated into the social component of our self-concepts which is – at least partially – defined by our membership of social groups. Although most analysts agree that individuals can identify with more than one group simultaneously, most research has focused on single ingroup-outgroup categorizations. However, researchers are becoming more and more interested in the dynamics of multiple group identification. Current theories such as optimal distinctiveness theory have been refined to include potential relationships between various group identities, while social identity complexity theory also emerged. Other researchers give attention to levels of social identification as well as the contextual cues that can activate particular identities. This paper focuses on the potential of multiple group identification in the diverse South African society and the relationships between various sources of social identification. The results of a countrywide random sample of 2,530 respondents representative of all population groups, provinces and regions of South Africa conducted in 2001 will be discussed. References will also be made to the results of follow-up surveys. Correlational and factor analyses were conducted to investigate the relationships between various forms of social identification. The results confirm the existence of subnational, national, supra-national and global levels of identification and the existence of complex identities, but contradict theory and common assumptions of the relationship between other identities such as racial and ethnic identities. Conclusions are drawn with regard to the implications for both intragroup and intergroup relations in South Africa.

Anthropomorphism for social change

Max Butterfield Texas Christian University, United States of America

Anthropomorphic thinking about non-human animals and objects, influences both cognition and behaviour. The present studies demonstrate how this phenomenon can be used to influence behavioural intentions and potentially achieve public good in two distinct domains: public health and environmental protection. In Study 1, undergraduate students (N=69) at a private university in the United States were randomly assigned to think anthropomorphically or non-anthropomorphically about viruses. Participants in the anthropomorphising condition were more willing to engage in disease-preventing behaviours (e.g., handwashing, vaccinations, preventative medical care, etc.) than were participants in the control condition. In Study 2, a new group of undergraduates at the same university (N=75) were randomly assigned to anthropomorphise trees or not. Those in the anthropomorphism condition showed more positive attitudes toward trees and more willingness to engage in environmental conservation than did those in the control condition. Mediation analyses demonstrated that participant’s attitudes toward trees fully mediated the relationship between anthropomorphism and pro-environment behaviour. The adaptive relevance of anthropomorphism in light of recent kin-selection and group-selection research is discussed, as is the potential for using anthropomorphism as a tool for promoting human welfare.

An exploratory study of the metaperceptions of white females who adopt transracially in South Africa

Cherilee Camara University of the Witwatersrand, South Africa

Metaperceptions and transracial adoption (TRA) have been investigated separately, although no research has investigated the metaperceptions of
White mothers involved in transracial adoption. Additionally, little research into transracial adoption has focused on the mothers’ experiences, as the focus has been on the child. It is therefore interesting to examine metaperceptions regarding transracial adoption in the South African context, as well as from the mothers’ perspective. The study aimed to explore how the metaperceptions of White mothers are constructed in relation to their transracial adoption. To do this, this study conducted a focus group discussion with five White mothers who had all transracially adopted Black and Coloured children through The Love of Christ Ministries (TLC), an organisation caring for orphaned children. The data from the study was analysed using thematic content analysis. The findings demonstrated the many challenges that are presented in transracial adoption for the mother, the child and the family. Such challenges included racial identity formation, parenting, family structure, cultures, boundaries and racism. From the results it was evident that the mothers’ experiences substantially affect the construction of their metaperceptions of their TRA. It is hoped that context specific interventions and support programmes will be developed to aid mothers involved in transracial adoption. Such interventions would improve their understandings and coping mechanisms used in response to their experiences of their TRA and their metaperceptions.

**Effects of bullying on stuttering**

*Susana Carvalho Universidade Federal de Sergipe, Brazil; Lucas Souza; Claudia Santos; Arion Oliveira*

Socially, the fluency of speech is a highly valued skill and people who stutter are potential targets for bullying. However, there are few studies that investigate the frequency and characteristics of bullying with this specific group. The aim of this study is to describe the relationship between bullying and stuttering and its effects. Participants (n=27) are patients at the Laboratory of Voice, Speech and Fluency at Universidade Federal de Sergipe, with diagnosis of stuttering and ranging in age between 14 and 64 years (IM: 27). All of them were invited to answer open-ended questions based on the topic of this research and agreed that the interviews were recorded on audio. Data were analysed through content analysis. The majority of participants (88% - n=24) has already been target of intimidation and, among these, 79% (n=19) does not react. Most of them believe that, from the moment they don’t care about what is said or done, will be no longer targets of bullying. This could explain the reasons for not reacting to attacks, but can also indicate their conformity to social stereotypes. For most participants, a worsening of the stuttering occurs in these situations. As effects on behaviour, bullying reinforces the avoidance of communication activities and social isolation.

**Imaginary, symbolic and real in the analysis of Albert Munyau's "Heaven does not fall"**

*Maria Carvalho University of Witwatersrand, South Africa*

The aim of this paper is to present a reading of the work of art by Albert Munyau, namely, “Heaven does not fall” through the three Lacanian categories: Imaginary, Symbolic and Real. A work of art can be described as an object that is considered by its creator as deserving to be exhibited to others. For the artist, a work of art might fulfill the role of trying to symbolise experience. A posteriori this artwork may indicate associations with the specific context in which it was created. Some of the questions that will be considered in this presentation is what makes a work of art attractive to the viewer and is it possible to view an image as a discourse? Identifying the meanings that may possibly be attributed to “Heaven does not fall” brings up issues that go beyond these meanings. The presentation will finally consider how art may translate the experience of dealing with what is impossible to represent not only to the artist, but also to those who are invited to engage with his work.

**Social identity related differential helping intentions of Chinese toward Japanese after 3.11 Japanese earthquake**

*Yong-Yuen Chen School of Psychology, BNU, China; Fang Wong; Yan Xu*

After a 3.11 Japanese earthquake, opinion polls on the Internet indicated that some Chinese people identified themselves as global citizens while others still held onto their Chinese citizenship identity. To test the hypotheses that social identity plays a vital role in shaping individuals’ helping intentions, the present research conducted three studies. Participants were 446 Chinese university students aged from 18 to 30. Study 1, a survey taken shortly after the disaster, confirms that there is a social identity divide among Chinese people, finding that participants with more salient global citizen identities expressed stronger intentions in helping Japanese people than those with more salient Chinese citizen identities. Study 2 replicated the results in a laboratory experiment and shows that when participants spontaneously identify themselves as global citizens more than Chinese citizens, evoking an overarching identity as human beings instead of a national identity, it strengthens their helping intentions, while a reverse pattern occurs if participants originally identify themselves as Chinese citizens more than global citizens. Study 3 further reveals that participants are more willing to help Japanese people when helping is considered as a means to defend their social identity, and less willing to help if it is seen as a threat to their social identity. The theoretical and practical implications of these findings for assistance between nations are discussed.

**Do cultural orientations facilitate better performances?**

*Lau Chi Yuen The Hong Kong Polytechnic University, Hong Kong*

Previous research has shown that self-constriasts affect individuals’ self-presentation style for impression management and goal attainment. However, less is known about how cultural orientations shape this goal-directed process and facilitate performance outcomes. In two studies, these relationships were examined among seven hundred secondary school students in Hong Kong. In study 1, bicultural identity integration (BII) was found to be correlated positively with assertiveness, individuation and modest behaviour. In study 2, some of these Chinese students were sampled to study their presentation performances in English and Chinese oral examinations which were graded by their teachers. BII predicted their presentation performances positively. More importantly, individuation mediated the link between BII and the presentation performances.

**African migrants’ acculturation experiences in South Africa: Reflections on context and interpersonal styles**

*Shingairai Chigeza North-West University Potchefstroom, South Africa; Vero Roos*

This article aims to explore the acculturation experiences of African migrants in a new context as well as their interpersonal styles that facilitated or limited their acculturation in South Africa. The study on which the article is based is part of a larger international research project on the commonalities and differences in the way that intergenerational relations, citizenship and belonging play out in three countries: The United Kingdom, France and South Africa. 10 families and 24 individual participants (men and women in the age range 18-59) from different African countries who had migrated to South Africa were selected through purposive sampling. The data were obtained through narrative inquiry and in-depth individual interviews that were thematically analysed using a secondary data analysis approach. Themes that emerged from the study were that the migrants used interpersonal styles that ranged from over-flexible to rigid. The relational processes involved in the acculturation of the migrants were the socialising role of the parents, concern about the absence of communal involvement and the lack of exposure to cultural rituals and traditions. It seemed that the migrants with a flexible interpersonal style could associate themselves with the new cultural context and expand their behavioural repertoire. The migrants in the study with a rigid interpersonal style often experienced disillusionment and discord. The study findings can be used to inform future research and support the adjustment of migrants in South Africa.

**Self efficacy, self-esteem and the intention to practice safe sex among Botswana adolescents**

*Rapaleng Chilisa University of Botswana, Botswana; Thlabano Kagiso; Cedric Vista*

Despite the existence of many notable HIV/AIDS programmes in Botswana, HIV spread and prevalence is still a concern in the country. For example, there is still a tendency among adolescents to have more than one sexual partner. Also, condom use is still not at 100% as indicated by the results from the 2008 Botswana Aids Impact Study (BIAS) III which showed that only 78% of 15- to 24-year-olds consistently used condoms. This study investigated the self efficacy and self esteem of Botswana adolescent males and females and how these predict their intention to practice safe sex through abstinence, consistent use of condoms if they engage in sex, sticking to one partner and resisting negative pressure from partners. An anonymous self administered questionnaire collected data from 286 adolescents (34.9% boys & 65.1% girls) of 10–19 (mean age 15.02, SD 1.02) years of age in Junior secondary schools. Multivariate regression analysis was used to evaluate the predictive power of self efficacy, self esteem and the intention to practice
safe sex. The findings of the study showed that adolescents who scored high in the self efficacy and self esteem scales, more likely had the intention to practice safe sex through either abstinence, consistent use of condoms if they engage in sex, sticking to one partner and resisted negative pressure from their boyfriend or girlfriend. Boys generally had significantly higher self esteem compared to girls.

Identity development as a function of self-regulation and social comparison
Renee Clarke Howard University, United States of America; Jamie Barden
The current research explores the impact of self-regulation (Kelperman, 1997) and social comparison (Festinger, 1954) on cognitive construals and short-term racial and academic identity seeking behaviours. Participants were 99 (21 male and 78 female) Howard University introduction to psychology students who self-identified as Black. These participants completed either a racial identity measure or a problem-solving measure and were given social comparison feedback. In the next step, they indicated whether they endorsed more ideal construals (hopes and aspirations) or ought construals (duties and obligations). According to self-discrepancy research (Higgins, 1987; Lee et al., 2000), the racial condition was expected to lead to endorsement of ought construals, as it involved viewing the self as a group member, while the problem-solving condition was expected to lead to endorsement of ideal construals, as it involved viewing the self as an individual. ANOVA analyses resulted in partial support for a self-regulatory process, as participants in the racial condition were likely to report ought construals, while those in the problem-solving condition were not likely to report ideal construals. Additionally, ANOVA analyses revealed support for the impact of social comparison on racial identity developing behaviours; those who performed well on a race-relevant assessment indicated more intent to engage in race-related activities. This finding was particularly true for those participants who measured high in racial centrality, which is a measure of the extent to which an individual defines him- or herself with regard to race (Luhtane & Crocker, 1992).

Interracial intimacy and hate crime: Examining possible connections
Kellina Craig-Henderson NSF/Howard University, United States of America
In the past two decades, a large volume of social science research has considered the meanings and manifestations of ethnic and racial status. Some of this work has also suggested that intimate interracial relationships serve as an important barometer of the quality of race relations in society. In the U.S., rates of involvement in interracial marriages have consistently increased during the last decades of the previous century, and data garnered from the previous century, and data garnered from the most recent 2010 Census are likely to be consistent with this trend. In step with these trends in interracial intimacy, there is another form of intergroup behavior with implications for the quality of race relations. According to the U.S. Department of Justice, there were more than 8,000 victims of hate offenses in 2009 in the U.S. Hate crimes represent a unique form of illegal, aggressive behavior perpetrated primarily because of what the intended target represents. This paper explores the possible connections between interracial intimacy and hate crime. Perpetrators of racist hate crime are likely to find certain forms of interracial intimacy and portrayals of it to be provocative. This discussion begins with close examination of several incidents involving hate crimes targeting an interracial couple. An analysis of the perpetrators, their motives, the victims and the circumstances of the incidents is presented. This is followed by a consideration of the way in which broader trends in interracial intimacy may be associated with certain types of hate crime. The paper concludes with discussion of the implications for the quality of race relations.

Cultural leadership related to emotions at work: The role of age, gender and cultural origin
Antonio De Pascali Italy; Carmen Tabernero
The higher presence of immigrant students in classrooms has become a significant fact of the educative system during the last decades in many countries. Such demanding working conditions elicit particular competencies in cultural leadership. This paper, in dealing with the current topic of multiculturalism, examines the perceived cultural leadership (task oriented and relationship oriented) in relation to the emotions experienced by teachers at work. In addition, we evaluate the effects of socio-professional variables (age, gender, seniority) on leadership style. The study sample comprised 600 teachers from different countries (Spain, Portugal, Venezuela). Results revealed that feeling positive emotions is related to a leadership style focus in both task and relationship oriented leadership. Female teachers presented a stronger cultural task and relationship oriented leadership than male teachers, while the youngest teachers showed stronger cultural relationship oriented leadership than the oldest teachers.

Psychological and biological mechanisms underlying control over anger and aggression
Thomas Denson University of New South Wales, Australia
Aggressive people are often characterized as socially reckless, not caring about control over anger-driven impulses. We investigated psychobiological mechanisms by which at risk individuals can exert improved control over anger and aggression. Aggressive participants who completed two weeks of self-control training showed reduced anger and aggression when exposed to a laboratory provocation (Study 1). Acute sugar consumption reduced aggression among those high in trait aggressiveness but had no effect on anger (Study 2). Consuming sugar helped those low in working memory overcome reliance on automatic determinants of aggression (Study 3). During induced anger control, individuals low in endogenous cortisol and high in testosterone showed the highest levels of activation in brain regions implicated in emotion regulation (Study 4). The studies suggest that those high in trait aggressiveness, low in working memory, or hormonally at risk do try to exert control over anger and aggression, but sometimes lack the ability.

Social mobility: A meta-analysis
Kitty Dumont South Africa
Social mobility is conceptualised by Social Identity Theory as social belief (versus social change) and individual behaviour (versus collective). Even though social mobility is theoretically part and parcel of the social identity approach and had been assumed by Tajfel and Turner (1979, 1986) to present a prepotent strategy to gain positive social identity, it has attracted less empirical attention and conceptual consideration than social change and intergroup behaviour. The studies that addressed social mobility and its correlates, however, revealed rather ambiguous results and suggest that this particular social identity management strategy is less straight forward than originally assumed. The present paper reports a meta-analysis conducted to address the following questions: (1) what is the overall impact of perceived permeability, stability, legitimacy and ingroup/outgroup identification on social identity? (2) what are the operationalisations of social mobility and its correlates? and (3) what kind of moderator/mediator variables can be identified? The results of the meta-analysis are presented and discussed in relation to future research.

Nostalgia from a social psychological perspective
Kitty Dumont South Africa; Lyn Lupke
From a historical point of view, the conceptualisation of nostalgia started off as medical disease (17th–19th century), evolved to a psychiatric disorder (20th century) and is now emerging as a fundamental human strength (21st century). Recent research has demonstrated that nostalgia is a common experience of individuals. It features more positive than negative events, is a self-relevant and social emotion, enhances positive self-regard and strengthens social bonds (Wildshut et al., 2006). An outstanding question, however, is whether nostalgia is possible on a group level, that is to say, as a second-hand emotion. Other emotions such as guilt, shame, happiness and pride have been shown to be experienced on behalf of in-group members. The present paper reports a descriptive study which collected both content of nostalgia on an individual level, and on a group level. The results are presented and discussed with regard to future research.

Being in intimate relationships: A comparison between romantic relationships and cross-sex friendship
Sajf Farooqi University of Delhi, India; Narender Chadha
Two people are said to be in an intimate relationship if they have mutual impact and interdependence. Satisfying relationships lead to happiness, whereas disturbing relationships lead to maladjustment. The purpose of this study is to compare two types of intimate relationships, romantic relationships and cross-sex friendship, and differentiate the affect that they have on the individual. The study examines individuals’ relationship quality and its role on their facets of self (self-esteem, self-disclosure, and self-monitoring) and emotional wellbeing. Self-report measures were administered on 60 people in a romantic relationship and 35 people who have a cross-sex friend and are not in a romantic relation-
ship. Relationship quality was measured in terms of six high and six low indicators. The people in a romantic relationship were asked to keep their romantic partner in mind, and the people in cross-sex friendship were asked to keep one of their cross-sex friends in mind, while responding to the scale used for relationship quality. For the other scales, the respondents of both the relationships were asked to give a general response. Significant differences were found between the two relationships on two indicators of relationship quality: relationship assertiveness and fear of relationship. Relationship quality was found to have a greater affect on facets of self and emotional wellbeing in romantic relationships, compared to cross-sex friendship. The data collection for cross-sex friendship is still in process, therefore, later changes in the findings may occur.

School at work or work at school? Social representations of students about technical education

Lígia Feitosa Instituto Federal de Goiás, Brazil
The present work seeks to identify the beliefs and perceptions of high school students concerning the technical education, once these students are inserted in a program that blends the regular high school education with the technical one. The framework used was based on the Social Representations Theory and the basic policies of Technical Education. The data have been collected by Free Word Association Tests and semi-structured interviews. The sample was composed of 40 high school students from the Federal Institute of Goiás, in Luziânia. This public was chosen due to the deployment time of this institution of education and the need to have access to what students were thinking about this new reality in Luziânia. The results demonstrate the need for a wider debate about the repercussions of technical education in the region and in the academic career of the students. Moreover, proposing future research about this subject is essential for building new knowledge with the already existing productions on the Technical Education category and mainly to demarcate their respective contributions to the world of work.

Identity and affirmative policies in Brazilian higher education

Norma Ferrarini Universidade Federal do Parana, Brazil; Crisfanny Soares; Miriam Pan
Affirmative policies that enable minority groups to enter Brazilian higher education have been in place since 2003. This case study analyses the transformation, in the construction process, of the identities of young people who have earned a place at the Federal University of Paraná through the racial quota program and have taken part in the Afroatitude Project conducted by the Federal University of Paraná through the racial quota program and have taken part in the Afroatitude Project. The discourse analysis of the testimonies of two students reveals how the transformation process of their identities took place. Initially, they were tied to a naturalistic conception of racial matters, either in terms of the constitution of their identity or concealment of prejudiced social attitudes, or the awareness of different concepts and scientific theories that impose a certain way of how social relations are understood. The results show that by participating in the Afroatitude Project these young people gained a new meaning of racial identity, university identity, the identity of the students who benefited from the racial quota and group identity. This transformation afforded the racial quota students greater integration with the institutional framework of the university and its culture, access to social knowledge and places, a better understanding of the multiple social determinations in the constitution of identity and the emancipation of individuals, experience of political awareness capable of mobilising forces of change, substituting the inertia of stigmatised identity with active participation as part of the construction of society.

Living on the edge: Violence and homelessness

Sonia Ferreira University of Coimbra, Portugal; Dora Redrullo
This communication focuses on the multiple facets that violence (psychological and physical) affect everyday people who experience homelessness. In this context, violence is analysed, taking into consideration its emergence and perpetuation, in different contexts and various forms, during their life trajectory (before, during and after experiencing homelessness). We intend to explore different shapes and consequences of violence on the person (e.g. physical and psychological abuse, aggressive and confrontational relationships, emotional abandonment, fear or no emotional ties with family and friends) that men and women in situations of homelessness experience. We also examine how those patterns of interaction (with different degrees of intentionality) perpetuate a strategy of "adaptation" to life on the street. To do so, we describe the increasing extraversion of reactive, conflicting and aggressive behaviours, the acceptance of violence and naturalisation of aggression in order to survive or, in the opposite extreme, the reaction of complete alienation from their situation. The conceptual matrix of Grounded Theory surviving on the streets (Maires Ferreiro, 2011) will be the conceptual support for reflection on this subject, particularly regarding the analysis of the dynamics of sociability of different groups of people who are/were homeless. For its generation the first author undertook participant observation of six Street Teams (started in December 2006; n=300 street interventions) and conducted 95 interviews with formerly homeless and professionals, having produced an original theoretical contribution with that of the out-group at three levels. Maires Ferreiro, 2011 will be the conceptual support for reflection on this subject, particularly regarding the analysis of the dynamics of sociability of different groups of people who are/were homeless. For its generation the first author undertook participant observation of six Street Teams (started in December 2006; n=300 street interventions) and conducted 95 interviews with formerly homeless and professionals, having produced an original theoretical contribution with that of the out-group at three levels, namely, "simple categorisation", "double cross-categorisation" and "tribe cross-categorisation", the effects of cross-categorisation can be investigated. The other two experiments were based on the first one. In order to explore whether positive or negative emotions of participants could influence intergroup deviation and the effects of cross-categorisation, a status factor was added in experiment 2. By adding the status factor, participants' locating of high or low status would be evoked, which helped us to explore whether higher or lower status could influence intergroup deviation and the effects of cross-categorisation in experiment 3. The research findings are as follows: (1) In general, cross-categorisation can decrease intergroup deviation, and the decrement decreases with increasing the dimension of classification. (2) In the positive or high-status situation, intergroup deviation and the effects of cross-categorisation were significant, but not in the negative or low-status situation.

Measuring of intimacy attitudes in Iran the intimacy attitude scale

Fakhteh Ghafari Payamnour University, Islamic Republic of Iran
Many theorists agree that intimacy is a multi-dimensional concept, consisting of several specific factors, and that intimacy attitude components are not the same thing. The Intimacy Attitude Scale originally developed by Edmund Amidon defined...
intimacy attitude components as: general intimacy, fear of rejection, loss of control in interpersonal intimacy and sexual physical closeness. In the present study the authors attempted to determine if the Intimacy Attitude Scale actually assesses these 3 components, and if gender and age cause differences in intimacy attitudes. 521 students completed the Intimacy Attitude Scale. The scale Cronbach alpha was 0.84 and test-retest correlation was 0.83 which shows that the Intimacy Attitude Scale – revised is a valid instrument. Also the Iranian norm for intimacy was 164. The results of factor analysis supported the 4 specific components of intimacy attitude, comprising different sub-scales. Multivariate analysis of variance results corroborated that intimacy attitudes are the same in different age groups and genders but vary regarding these 4 components.

Advancing African-centred psychology theory, epistemology, and praxis
Cheryl Grills Loyola Marymount University, United States of America

African-centred Psychology, as a concept within the academy, is still very much in its infancy. As a practice with philosophical and spiritual roots, it is centuries old. Scholarly debate is essential to its ongoing evolution. However, it must be a debate that is neither constrained to the lens of, nor concealed to, the self-ascribed authority of Western psychology. Further, this engagement must include serious discussion regarding: articulating the essential structures of knowledge in African-centred psychology that should guide training and socialisation of faculty and students; the parameters within which the tasks of research, teaching and praxis should be conducted; and establishing the legitimate modes of inquiry that should define what and how data is collected, and interpreted, and determining what constitutes evidence. Critical topics requiring greater attention will be discussed, including the essential role of community in understanding personhood, which is both bestowed and earned in African societies. We have yet to fully explore the insights from African metaphysics and epistemology for application in psychological work with, and counselling of, persons of African descent throughout the diaspora. If given due attention the implications are threefold: (1) greater attention to community building efforts in African-centred Psychology, (2) greater attention to resiliency and positive psychology, and (3) increased attention to interventions that build sense of community, social capital, and community safety nets to promote community and individual well-being.

Coping strategies and identity management of stereotype threat of rural-to-urban female migrants
Jian Guan China

The concept of stereotype threat is a situational predicament where individuals are at risk, by dint of their actions or behaviours, of confirming negative stereotypes about their groups. The general aim of our research was to investigate the effects and coping strategies of stereotype threat of rural-to-urban female migrants. The sample consisted of 124 rural-to-urban female migrants recruited using a snowballing technique. The present research consists of four co-relational studies. Study 1 began with a measure of identity fusion to explore Chinese female rural-to-urban participants’ city identity and country identity. The results indicated that female participants’ city identity was significantly lower in baseline than the rural identity. Study 2 used the measure of stereotype threat and measure of impression management to test coping strategies and identity management. It showed that, when facing the stereotype threat of city identity, the city identity of participants who had high impression management did not improve significantly, but the rural identity had a significant decline. Both of them were not significant of low impression management. In study 3, we used the measure of extreme behaviour. The results found that participants of high city identity had more city identifying behaviours than low city identity participants. Years of working in the cities as well as income influenced city identity. In study 4, a measure of role models was adopted. The results showed that the subscale improves significantly of city identities of participants who receive deserving role models, and that they had a significant decline of rural identity.

The picture of blind musicians in the fine art as a specific reflection of the society’s negative attitude
Vytautas Gudonis Sauliai University, Lithuania

With the help of fine art, we could encode the society’s attitude towards marginal groups (e.g., beggars, homeless, disabled and etc) in different eras. The attitude towards the disabled in ancient times was depicted in fine art. Looking from the realistic art perspective, historians, socialists of art, psychologists and other science representatives receive and obtain very interesting and useful information about the disabled. Through art, we could not only encode the real facts of life that painters was trying to depict in their works, but we could also obtain the historical concept of a particular era. More than 1000 reproductions of art works from the art collection "The Blind in the Fine Art" were studied. The goal of the research was to decode the society’s attitudes and stereotypes towards the blind in these art works. Meta-analysis and analytical interpretations. Theoretical research methods helped to determine the image of blind people. The examples of fine art have been studied as a social phenomena in order to determine historical realities and concepts.

Testing affective mediators of contact on endorsement of collective action taken by the outgroup
Meltem Guler Ministry of Justice, Turkey; Huseyin Cakal; Elvan Erturk; Miles Hewstone

Research on Collective Action rarely looks at the impact of the ingroup to support collective action taken by the outgroup. In this study we investigated the role of affective mediators of contact, i.e. perspective taking and trust, in predicting positive attitudes and collective action taken by the outgroup. 7039 participants solving the problem of the ingroup and outgroup identification in the case of non-human objects. In experiment 2, the ingroup and outgroup made the decision to support collective action taken by the outgroup or not to support it. The results found that participants with high city identity had more city identifying behaviour than low city identity participants. Years of working in the cities as well as income influenced city identity. In study 4, a measure of role models was adopted. The results showed that the subscale improves significantly of city identities of participants who receive deserving role models, and that they had a significant decline of rural identity.

Identification with all humanity and its predictors
Katarzyna Homer Chodchowska University, Poland

Identification with all humanity is one of the widest existing social identities existing. Individuals strongly identifying themselves with people all over the world feel close to them, care for them and perceive them as an in-group. Psychological literature gives evidence for an important role of this very broad social identification in enhancing prosocial behaviors and human rights orientation. Psychologists have also found its negative connection with social dominance orientation, ethnocentrism and right-wing authoritarianism. The author searches for the psychological background of identification with all humanity, in a current study focusing on the possibly predicting role of personality traits and empathy. Measures used in the study included the Identification With the All Humanity Scale by McFarland, The Interpersonal Reactivity Index by Davis and the NEO-Five Factor Inventory by Costa & McCrae. Eighty-five students between 19 and 50 years of age (54% females, 46% males, with places of residence from small villages to big cities) were tested. The results together with findings from previous studies on non-student samples, proved the crucial role of openness to experience and empathy (especially empathic concern and perspective taking) as characteristics which explained 41% of the variance in the strength of identification with all humanity. They can be thus perceived as a psychological basis to build strong broad social identifications, with all humanity as in-group. They are also important in the face of global problems of humanity, which may need global cooperation to be solved. These are economic crises, global warming, degradation of the environment, hunger, thirst and others.

As we see each other: Ethnic prejudice among Iranians
Fatemeh Hamzavi Islamic Republic of Iran; Fateh- meh Abed Hamzavi; Fatemeh Bagherian; Fatemeh Bagherian

Ethnic prejudice is a ubiquitous fact; however its challenge for individuals and societies’ wellbeing is much greater in multi-ethnic societies. This research makes the first attempt to provide an overview on ethnic prejudice among Iranian ethnic groups. 274 participants answered a questionnaire designed to
explore beliefs about the five major Iranian ethnicities including Baluch, Fars, Kord, Lor, and Tork. Results revealed interesting patterns of prejudicial common beliefs about each ethnicity. For example 78% of participants believed that Lors are naïve and foolish, 44% believed the same for Torks. About 20% argued that people of Baluch ethnicity are culprits, and 37% said that Kords are rigid and prejudiced. The Fars ethnicity, consisting of the majority of Iranian people, were described as benevolent by most of respondents. However, there were common beliefs regarding the Fars ethnicity as deceptive liars and arrogant people as well. The importance of these results indicate the necessity of addressing this issue and paying serious attention to this problematic phenomena in order to reduce the degree of negative attitudes among ethnic groups toward each other. The existence of negative attitudes would be a potential risk to the well-being of society.

Interpersonal values of Bangla and English medium school students
Md. Ashikul Haque Mahalapye Hospital, Botswana, Bangladesh
A comparative study was designed to investigate whether student’s interpersonal values differ as a function of medium of school, sex and family income in Bangladesh. School has an important role in influencing the development of interpersonal values. It was assumed that there might be different personal values in students in Bangla and English medium schools, due to a different mode of curriculum; environment at school; and economic background. The sample consisted of 100 students. Among them 50 students were from a Bangla medium school (25 male and 25 female) and 50 students (25 male and 25 female) were from an English medium school. They were taken from three different income levels. All the students were selected from class-X. The values in this test were measured with the Bangla version of Gordon’s “surveys of interpersonal values”. The data were analysed by 2x2x3 analysis of variance. Sex was found to be a significant variable in benevolence, conformity, leadership, support and recognition. Family income had influence on interpersonal values like benevolence, leadership and independence of these school level students. Medium of schools had no significant effect. The interaction between sex, income and medium was found as a significant variable in case of recognition.

The influence of meta-stereotype on intergroup relations of different social classes
Wen He Shanghai Normal University, China
The effects of meta-stereotypes on intergroup relations was studied in nationwide probability samples of higher social class and lower social class groups in China (N=347). The result showed: (1) For higher social classes, different manipulation of meta-stereotypes had no significant effect on perceived intergroup relations and desire for contact. For lower social classes, manipulating the salience of negative meta-stereotypes lowered outgroup attitude and perceived intergroup relations, and had no significant effect on desire for contact. (2) Outgroup attitude and perceived intergroup relations of the higher social class were significantly lower than those of the lower social class. Perceived intergroup relations had no significant difference. (3) Outgroup attitude of females was significantly higher than that of males, and perceived intergroup relations and desire for contact had no significant gender difference. (4) Mediation analyses revealed that for lower social classes desire for contact partially mediated the effects of outgroup attitude. Positive outgroup attitude improved the desire for contact, while negative outgroup attitude lowered the desire for contact.

Family processes and separation experiences in Mayan transnational mixed status families
Rachel Hershberg Boston College, United States of America
This paper presents findings from research with ten Maya K’iche’ transnational and mixed status families living between the U.S. and Guatemala. The study explored relationships within these families and how they are maintained or ruptured in contexts of prolonged separation as influenced by U.S. immigration and deportation systems. A grounded theory analysis of ethnographic data and in-depth interviews with at least one U.S.-based undocumented migrant parent, one Guatemala-based child, and one Guatemala-based or alternative caregiver from each family was developed to better understand and characterise the ways in which diverse family members perceive and narrate family relationships and separations. Findings suggest that caregiving efforts enacted by migrant parents in the U.S. vis-à-vis children in Guatemala—including persistent cross-border communication, financial support or remittances, and provision of advice or conselos-enable parents in the U.S. and children in Guatemala to maintain relationships despite prolonged separations. Findings also show that alternative caregivers and children in Guatemala form strong, nurturing attachments to one another, yet tensions arise in this relationship over time. This study purports that undocumented migrant parent(s) in the U.S., children in Guatemala, and alternative caregivers nonetheless contribute to their transnational families in unique ways. Findings also support research arguing that immigration and deportation policies violate the rights of families from the global south who migrate north to support relatives in origin countries. Implications for comprehensive immigration reform and new directions for research in psychology with transnational families are discussed.

The influence of choice on loss aversion
Mengjie Jiang Peking University, China; Lei Wang Peking University, China
Loss aversion is a kind of non-rational activity of human beings, and always affects our important decisions. It can result in serious social consequences. Numerous studies have confirmed the universality of loss aversion during the last 30 years. However, little has been found out about its causes. Some researchers pointed out that the reasons of loss aversion may be due to motivation bias. But there is not sufficient evidence supporting the explanation. To fill this gap, this paper explored the impact of choice on loss aversion. According to self-determination theory and cognitive dissonance theory, on one hand, things can be associated with themselves through choosing. On the other hand, people have the motivation of self-defense. So loss aversion can be enlarged when people have a choice. We ran two studies to test our hypothesis. Study 1 used the method of self-report questionnaire while Study 2 was a controlled experiment. The result from Study 1 showed that during the investment activities, there were more people choosing to sell the loss fund in the no-choice group than in the choice group. This result was confirmed by Study 2 that loss aversion is larger when they make choices by themselves. Results showed that choice had significant impact on loss aversion. It demonstrated that motivation may have a big impact on loss aversion. Results supported the argument that motivation bias may be a reason of loss aversion.

Attitudes toward migrant-workers and implicit motivation to control prejudice moderates the implicit attitude
Wen Jiang Central China Normal University, China; Na Ren Central China Normal University, China; Bin Zuo Central China Normal University, China; Dong- qin Fu Central China Normal University, China; Feixiang Hou
This study used explicit scene test and GO/NO-GO association task to measure attitudes to migrant workers. In Study 1, university student participants (N=161) inferred the thoughts of targets talking about their experience of becoming first time mothers. In Study 2, student participants (n=142) inferred the thoughts of other student targets discussing experiences of parental divorce, which, unlike motherhood, several participants had experienced themselves. In both studies, participants whose inferences were more consistent with stereotypes about these experiences (e.g., inferring that new mothers were tired, or that students with divorced parents had trouble getting along with step-parents) were more empathically accurate. Thus, shared schemas about particular experiences helped perceivers more accurately understand individuals’ thoughts. Furthermore, in Study 2, stereotype use helped perceivers equally, whether their own parents were divorced or not. Although past empathic accuracy research has frequently focused on finding “good perceivers” who are sensitive to reading idiosyncratic cues from targets, the current studies show that a substantial amount of empathic accuracy is achieved by relying on previously acquired knowledge.
workers in China from positive and negative stereotypes. The role of Implicit Motivation to Control Prejudice (IMCP) in moderating the implicit negative attitude was examined. Study 1 shows the result that College students proved prejudiced towards the groups by means of inhibiting the personality trait attribution on good behaviour, but have no effect on their wrong behaviour. In study 2, a Go/no-go test shows an implicit negative attitude to this group. This means there were significant differences between "group + negative stereotype traits" and "group + positive stereotype traits" words. Second, IMCP had no direct effect on GNAT effect, but the interaction of NAP and BOP did. In other words, Individuals high in NAP, and who consider themselves immune to bias (are high in BOP), might not be implicitly motivated to avoid bias, they have more implicit negative attitudes to the group. But those low in BOP would not be motivated to avoid bias if they do not think it is a bad thing, as assumed by Glaser and Knowles (2008). Third, there is a weak relationship between internalisation of the non-prejudiced scale and NAP, and explicit scale cannot predict implicit attitudes.

The effect of social categories in face perception of groups

Wen Jiang; Central China Normal University, China; Chua Zhang; Hongqiao Wang; Central China Normal University, China; Chuangang Ai; Central China Normal University, China; Bin Zuo; Central China Normal University, China

Although the cross-race effect (CRE) is a universal phenomenon in many races, both perceptual-experience and social-categorisation models have been used to explain the effect. But IOM supposed by Spero (2001) mix up the holistic processing between Experts-Novice and in-group/out-group. In study 1, we use a learning-recognition paradigm to prove that categorising people into in-group and out-group are sufficient to emerge advantage recognition, even when perceptual expertise is constant. The results show that college students in China did not show CRE, they have more face perception in race (stimulates include Chinese and Foreigners). We also use minimal groups to investigate the disappeared recognition of advantage to the in-group for a minority. In study 2, we use a two stage task including process style and process level to examine the IOM with the same race stimulus. And we found process level can improve face recognition. A composite face paradigm task has only a weak relationship with in-group and out-group processing styles. The first two experiments suggest that humans have self-protection motivation to recognise in-group members. In study 3, we add expressions of emotion to test the effect of face recognition. Results show that people have an advantage in recognising in-group members' positive faces, however to recognise out-group members' negative faces. At the end of the paper we use Evolutionary psychology and Error Management Theory to explain the face recognition of groups.

The relationship between European identity and various social-identity categories

Pelin Karakus; Ege University, Turkey; Tuğçe Erdem; Melek Göregeñli; Irem Umuroğlu

The aim of this research is to examine the relationship between European identity and various social identities in the context of social psychological determinants such as social identity process, multiculturalism and intergroup relations. A questionnaire focusing on identity and attitudinal issues pertaining to sex, ethnicity, urban-related identity, religion and Europeanness was administered to natives and ethnic minority members in Izmir. A field research was conducted with 250 adult participants. The 'visual representation of identities task' (Cinniarella & Hamilton, 2007) was adapted to Turkish. Gender identity was the most important category and was closer to the core self than all of the other identity categories. Ethnic identity was stronger and more central to ethnic minorities in Turkey than a sense of Turkish identity. This finding is line with previous studies (Göregeñli, 2010; Sandal-Önal, 2007).

Effects of situational concerns on the expression of gender stereotypes

Philippa Kerr; University of KwaZulu Natal, South Africa; Kevin Durheim; Nonhlanhla Mthiyane

Stereotype content research in social psychology typically ignores the situational, intergroup and interpersonal determinants of stereotyping, while experimental studies of stereotyping processes ignore the meaningfulness of stereotype content. Both traditions of research have neglected to study the details of how stereotypes are expressed in conversational social contexts. This paper reports a hybrid investigation, using highly structured interviews in an experimental design. It investigates the effects that variations of participant accountability and the interpersonal and intergroup context have on the content and performative features of gender stereotype expression. In the study, 240 white students and 240 black students at the University of KwaZulu Natal were interviewed by an interviewer of the same race as them. Participants were asked to give stereotypes about their own or the other gender, held either by them personally, by people of their gender, or by people in general, while the gender of the interviewer and the interviewee were manipulated. Data analysis is currently under way. We hypothesise that participants will present their own gender group – ‘men in general’ or ‘women in general’ – as more sexist than participants present themselves, as judged by the stereotypes they offer in each condition, which have been rated for communicability, favourability, warmth and competence. These studies join the growing literature which presents an image of stereotypes as resources for strategic activity, and potentially challenge the common social psychology finding that group members always exhibit an in-group bias.

Notions of identity among second generation ethnic return migrants of Oman

Nafaa Kharusi; Sultan Qaboos University, Oman

This paper explores the nature and construction of identity among second generation ethnic return migrants of Oman, a country on the south-eastern edge of the Arabian Peninsula. Applying an integrative social psychological approach in which identity is conceptualized as socially constructed, the study examines the narratives of 13 interviewees as they reveal their notions of belonging and subjective understandings of what it means to be an Arab, an Omani and a Zanjibari, the latter being the label used to refer to the migrants. Against a backdrop of socio-historical discourses, the role played by family and social networks is also investigated to reveal how this generation’s multi-layered notions of identity develop, as it defines and positions itself in interactions.

Racial integration study: A social intervention at the University of Cape Town

Caroline Kim; University of Cape Town, South Africa

Previous studies on contact theory have examined prejudiced attitudes, showing evidence that increased contact under optimal conditions decreases prejudiced attitudes. However, recent observational studies in settings that reflect optimal conditions for contact have reported a discontinuity between changes in intergroup attitudes and behavioural patterns, namely that improved attitudes do not reflect an increase in contact. Contact research in the University of Cape Town has shown persistent self-segregation, which impedes opportunities for contact in a context that promotes and supports intergroup interactions. This paper presents a social intervention implemented to create more opportunities for structured and ongoing interracial contact in a university residence setting where students live together in diverse bodies, but self-segregate. The impact of the intervention on friendship patterns, dining hall seating patterns, contact patterns, and attitudes toward outgroups and toward diversity-related issues will be discussed.

Exploring the sense of belonging of Setswana-speaking older women in Ikageng

Patricia Kolobe; North West University (Potchefstroom Campus), South Africa; Vera Roos

Older Setswana-speaking residents (60+) of Ikageng were asked to identify places of importance to them in Ikageng and the meanings they attached to the places. However, none of the residents identified any places of importance in Ikageng but repeatedly referred to their lives in Klerksdorp, the location they had been forcibly removed from in terms of the South African Group Areas Act of 1950 more than 57 years ago. The responses of these older people led to this research which aims at exploring their sense of belonging in the two locations. A qualitative research approach was followed, and participants were purposefully selected. Two sets of data were gathered and reported on with the focus on the narrations of 11 older Setswana people from the Day Care Centre for the Aged in Ikageng, a location outside Potchefstroom in the North West Province of South Africa. A narrative approach was followed for the data collection and analysis, and various qualitative research methods were used to collect the data including the Mmogolo-MethodTM, videos, focus group discussions, photographs and observational notes. Thematic analysis of the textual data, narrative-oriented inquiry and visual data established the trustworthiness of the research through crystallisation. The results of this study revealed that sense of belonging is a relational phenomenon: People have relationships with the physical environment, close interracial connectedness, as well as intergenerational cohesion. Forced removals disrupted the relational connections. The older people coped with the relational disruptions by displaying dispositional optimism and agency and by creating micro-communities.
Individual and majority action/inaction in regret
Lilavati Krishnan Indian Institute of Technology, India; Lilavati Krishnan

Studies examining whether regret is greater under action (commission) than under inaction (omission) have more commonly demonstrated greater action than inaction regret. However, there is also sufficient evidence of greater inaction regret. Investigations in this area rarely include social variables such as information about majority action/inaction. Two scenario studies involving student samples in India that investigated individual and majority action/inaction effects on regret, causal attribution, and subsequent action, are reported here. Study 1 showed a significant effect of individual action/inaction and a significant interaction between individual and majority action/inaction in the case of regret. Action regret was greater than inaction regret. However, in Study 2, the modified dependent measures hinted at the greater role of a match or mismatch between individual and majority action/inaction, rather than a clear individual or majority action or inaction effect on regret. Regret was greatest when both individual and majority acted, and least when both did not act. Subsequent action likelihood showed a weak but significant effect of the same variables. It was lower under individual action than inaction, and under majority action than inaction. Taken together the findings of the two studies point attention to the importance of social ‘norms’ of action/inaction and of implicit social comparison in the experience of regret. Possibly this social component provides a basis for external rather than internal attribution for the negative outcome.

Need satisfaction mechanism linking volunteer motivation and life satisfaction: Mediation study in volunteer’s subjective well-being
Yan Yuen Kwok Chinese University of Hong Kong, Hong Kong; Yan-Yuen Kwok; Eric Chul

A mediation model explaining volunteer’s subjective well-being was tested, and self-determination theory was deployed as the conceptual scheme. In the model, the effect of intrinsic motivation on volunteer’s life satisfaction, with need satisfaction experienced in volunteering as a mediating variable, is examined. Four hundred and forty-three participants, both with or without past volunteer experience, were recruited to complete the questionnaire. Mediation analysis suggested a path from intrinsic motivation to volunteers’ life satisfaction through need satisfaction experienced in volunteering, as identified during the volunteer experience. Neither volunteer participation per se nor extrinsic motivation was found to be related to volunteer’s life satisfaction. The roles of volunteer motivations and need satisfaction in affecting volunteer’s life satisfaction were identified in the present study, which provide insights for developing future volunteer programs.

Social groups’ adoption of both self and other-orientations increases power perceptions
I-Ching Lee National Chengchi University, Taiwan, R. O.C.

According to Pratt, Lee, Tan, and Piptian (2011), power is to meet one’s needs. Powerholders can use power for own benefits or for others (Lee-Chai & Burg, 2001). Previous researchers consider self-other orientation as a bipolar dimension, in which powerholders who use power for others would be less likely to use power for themselves (e.g., Chen, Lee-Chai, & Bargh, 1999). The current research investigated whether empirical evidence supports such an implicit assumption. Moreover, if powerholders are capable of flexibly using power for self and others, they should be well liked and respected, but at the same time less likely to have obligations than powerholders who use power for others. Thus, this research examined whether an adoption of both self- and other-orientations is related to participants’ power perceptions. According to a survey study of 105 females and 63 males in Taiwan regarding their ratings of social groups, the results suggested that self- and other-orientation should be conceptualized as two dimensions. Some groups (e.g., business executives, politicians) were perceived to be high on both self- and other-orientations. After controlling for familiarity ratings, the adoption of both self- and other-orientation was associated with power perceptions (r=.47, p=.002), but not with trust perceptions (r=.20, p=.21). Implications regarding self- and other-orientations and perceptions of power and trust were further discussed.

The influence of parenting style and self-regulation on adolescents’ flaming online
Li Lei Renmin University of China, China; Zhongming Wang

This study explored the relationships among parenting styles, self-regulation and flaming online of 710 adolescents since flaming has been a focus on the Internet. The results showed that: First, adolescents’ self-regulation had a significant direct negative effect on flaming online. Second, mothers’ negative parenting had a positive direct effect on flaming online, meanwhile its indirect effect was not significant. Third, although fathers’ negative parenting had no significant direct influences on flaming online, its indirect effect through self-regulation was significant. Both mothers’ and fathers’ positive parenting had no effect on flaming online.

Effects of pre-discussion preference characteristics on information exchange in group decision making
Hongchang Li HRSD, Zhejiang University, China; Zhongming Wang

The present research investigated the effects of pre-discussion preference characteristics on information exchange in group decision making by utilising a new experimental paradigm that eliminated the effects of information characteristics. Based on the perspective of motivated information processing, the authors predicted a positive effect of preference diversity on preference-consistent bias and tested the effects of the subgroup type, preference strength and their interaction with preference diversity. 84 undergraduate students formed 28 three-person groups and participated in a personnel selection task. Repeated measures ANOVA was used for the analysis of group level effects and confirmed the positive effect of preference diversity on preference-consistent bias. HLM analysis showed that individuals in majority subgroups had stronger bias than those in minority subgroups, while those inconsistent groups had the smallest bias. The bias were weakened by group preference diversity for majority subgroup members but were strengthened for minority subgroup members. Neither the main effect nor moderating role of preference strength on preference-consistent bias was significant, although it did decrease the exchange of preference-inconsistent information. The results showed the importance of preference characteristics at different levels, and methods to improve group decision making were suggested.

Clarifying the group boundaries: The role of intergroup threat
Tingyan Li Southwest University, China; Zhao Yufang

The present research investigated help behaviour from an intergroup perspective. We examined how intergroup threats might impact prosocial behaviour in an intergroup context. In Study 1, laboratory groups were used to compare help behavior toward the threatening out-group and the non-threatening one. In Study 2, real groups and a fictitious group were used to compare help behaviour toward the in-group, the threatening out-group, and the non-threatening one. Across two studies, when no intergroup threat was perceived, participants acted prosocially toward both the in-group and the non-threatening out-group. However, when intergroup threat was perceived, in-group members received more help than members of the threatening out-group. In addition, the non-threatening out-group received more help than the threatening out-group. Overall, the findings suggest that intergroup threat functions as a differentiation in group boundaries and a differentiation in prosocial behaviour in an intergroup help context.

The social representations of mental illness in China: A new approach to the study of the stigma of mental illness
Qiang Li Nankai University, China; Wenjun Gao Nankai University, China

It is widely acknowledged that the stigma of mental illness can impede the treatment and recovery of people with mental illness. Efforts to further understand stigma should be informed by research on components of stigma and factors related to them. One way to do this is to study the social representations of mental illness, and this new approach allows us to examine stigma in the context of its social and cultural backgrounds. However, such research is rare in China, even though the stigma is more prevalent in China than in Western societies. The present research aims to fill this lack of knowledge by exploring cognitive components of the stigma of mental illness from the social representations approach. We recruited 1028 Chinese community residents from 12 different regions of China to complete a battery of questionnaires. There were three main results: (a) Social representations of mental illness include six facets: unpredictability, unusual appearance, social withdrawal, character flaws, care requirement and communication disability, which constitute the cognitive components of stigma; (b) people varied in their endorsement of these representations in terms of gender, age and education backgrounds; and (c) traditional values can predict these representations, and this finding reflects a Chinese cultural characteristic of stigma and indicate that traditional values
might be a source of stigma. These findings elucidate the components of the stigma of mental illness in China and suggest that one way to reduce stigma is to develop targeted strategies to change negative and inaccurate social representations.

Relationship between measurement of the college students’ time management tendency and culture approach

Wen Liu, Liaoning Normal University, China; Shan-shan Zhang

The general aim of the study is to investigate the structure of time management and its relationship with value. Thus, the study includes the psychological as well as the economic perspective.

According to the time management theory, and the relevant questionnaire and scale, we put forward the theoretical structure of time management questionnaire. We randomly selected 872 college students (484 female and 388 male) from four universities in Dalian, China. Participants filled out two validated questionnaires in classroom, including the measurement of time management tendency, Individualism-Collectivism. It took about 30 minutes to complete the questionnaires. The correlations between factors were calculated with spss16.0 and the structure models were analysed with AMOS 4.0. In the analysis of structural equation modeling, the structure of questionnaire about the measurement of time management tendency was constructed. Preliminary inquiry theory structure was analyzed by exploratory factors and confirm factor. The results showed that: (1) The Time Management Questionnaire includes six factors: planning, delay time perspective, controlling, confusion tendency and resistance. (2) We also test the reliability and validity of the questionnaire, the study indicates that the homogeneity reliability, split-half reliability and test-retest reliability are all very high, and concurrent validity is obvious. (3) Vertical Individualism can forecast the planning, controlling, confusion tendency. Vertical Collectivism has significant positive effects on time perspective and stress.

Desirability or feasibility: Self-other decision making differences

Jingyi Lu, Peking University, China; Xiao-fei Xie, Peking University, China

For most decisions, people either decide for themselves or act as advisors. The current research examined how people weighted desirability and feasibility differently when deciding for themselves versus others. Based on Construal Level Theory, we propose that in the decision making processes, compared to deciding for themselves, individuals who choose for others would focus more on desirability, yet less on feasibility. Across five experiments, the predicted self-other differences emerged in preferences during decision making (Experiment 1a and 1b), information seeking before choosing (Experiment 2), and attributes recalling after decisions having been made (Experiment 3a and 3b). These findings suggest that decision behaviors are determined by decision target.

The discourse and rhetoric of marginalisation among Muslim men in the United Kingdom

Russell Luyt, University of Winchester, United Kingdom

This paper considers how the discourse of marginalisation is (re)produced, and how Muslim men’s identities are constituted, through situated interaction in the United Kingdom. It points toward the important role played by the discourse and rhetoric of marginalisation in Muslim men’s accounts of their everyday life. Six focus groups were held with men resident in Southern England. A technique of discourse analysis that emphasizes norm-referencing rhetorical devices was applied. Findings, whilst indicating some complexity and diversity in participant accounts, reflected a high degree of agreement. Such high levels of agreement are unusual. They suggest the emergent discourse of marginalisation was orientated toward a similarly monolithic, but negative, dominant societal discourse concerning Muslim men. The discursive challenge posed by participants to this societal discourse sought, by contrast, to cast these men in a positive light. Findings hold important implications for our understanding of, in particular, marginalisation and men’s radicalisation.

A qualitative inquiry into relationality between 3rd generation American Jews and non-Jewish Germans

Charla Malamed Adelphi University, United States of America

I will present a qualitative inquiry into post-Holocaust relationships between 3rd generation American Jewish and non-Jewish German descendants of families who lived during the Nazi Regime in any of the Nazi-occupied areas. An unique component of this study is that each participant, in order to be eligible, needs to have had a meaningful emotionally invested ongoing relationship with the “other” (Jews with non-Jewish Germans, and vice versa). The interviews are clinical, dynamic, and open-ended, allowing the participant to speak about whatever they have found to be most meaningful. Using material from these interviews, I will discuss the ways in which individuals navigate their familial history, cultural memory, and personal experience with the ‘other’ in the ongoing construction of ‘self’ and ‘other’ identity. I will use psychodynamic theory to locate and interpret themes in this material, making links between individual histories and relationship patterns. Finally, I will identify the mechanisms by which intimate relationships permit individuals to separate out familial experience and cultural discourse from personal experience, thereby allowing for a progression away from the post-Holocaust dialectic between the “German perpetrator” role and the “Jewish victim” role.

Why do young people remain homeless on the street? The social environment as a de-motivating element

Jakub Marek, Psychiatric Center Prague, Czech Republic; Ladislav Csemy; Marie Vagnerova

Prague is among the cities with the lowest unemployment in Central Europe. Approximately 5000 homeless people live there, of whom one quarter are young people under 26 years of age. It turns out that the biggest problem of young homeless people is the lack of willingness to change their lifestyle. To determine the incentive structure of the respondents, we drew from the analysis of a semi-structured interview, a brief test TAT and a decision form. The target group consisted of 90 homeless people attending a day low threshold centre. The article examines the data through a qualitative approach. Most respondents considered “a good job” the major motivational element, which was beyond their current abilities and possibilities. They considered their life in the street as temporary. They perceive it as a “holiday” from normal duties or as a “school”, which provides subjectively important information or experience. The cycle of clients at the day centre indicates that respondents often go off the street alone without professional help. The problem occurs when there is a relapse of their homeless lifestyle, when the respondent fails to meet the standards of society and gets back on the street. The factor of permanent change lies in firm social relationships with people who do not live on the street. The ability to find functional social relationships is missing in the respondents. This is one reason why people return back on the street. Social relations are implemented in simpler living standards than in the resident society.

Transformational leadership in higher education: Developing a measure

Lauren Mawn Bangor, United Kingdom; James Hardy; Nichola Callow; Calum Arthur

Employing the differentiated model of transformational leadership (TL) (Hardy et al., 2010), Study 1 examined student and lecturer perceptions of TL in Higher Education (HE) lecturing. 29 students and 6 lecturers participated in focus groups and semi-structured interviews examining perceptions of TL. Results indicate the differentiated model of TL can be employed to understand lecturing behaviors. However, acceptance of group goals did not emerge as a relevant behavior in HE. Furthermore, ‘sense of humor’ and ‘self-confidence’ emerged as themes previously not represented in the TL literature. Study 2 aimed to develop a relevant measure of TL in HE. Utilizing established instrument development procedures, items evolved from Study 1, meaning units were subject to content validity examinations involving TL researchers, HE experts and students. Students (N=349) responded to the questionnaire in week five of the semester. Additional measures of satisfaction, efficacy and internalization were collected at week one and week nine. Reliability, factorial validity and predictive validity were examined using alpha coefficients, confirmatory factor analysis (CFA), and regression analyses respectively. Results showed the 8-factor model demonstrated acceptable alpha coefficients (> .7), reasonable factorial validity (RMSEA=.07 and CFI=.97) and good predictive validity, positively predicting variance in student satisfaction, academic and intrinsic motivation controlling for variance predicted by these at week one in addition, the measure also positively predicted variance in student performance (i.e., grades). In conclusion, these results offer support for the application of TL to the HE context.

The effect of culture priming and concept of money when we make choices of altruistic behaviour

Xue Mengjie, Central China Normal University, China; Chu Zhang; Bin Zuo Central China Normal University, China; Guoju Wang; Shan Sun Central China Normal University, China

Social Psychology
The current study explored how the concept of money and culture priming affect our choice of altruistic behaviours. 56 undergraduate students were selected to explore how culture priming, concept of money and position influence altruistic behaviour. The present experiment used a 2 × 2 × 2 mixed design, different culture primings, concept of money, and different positions (outsider, insider). According to different situations, subjects would make their choices after reading the story of an ex-student of the University of Cape Town. The results showed that culture priming, concept of money and position all had significant main effects. The results of our study supported the assumption that a lecturer’s race influences students’ perceptions. Experimental design photographs, allegedly of African and White lecturers, were presented to undergraduate students (n=173). Students rated each lecturer on six variables representing two broad dimensions: Likeability and ability. Results showed that African and White students rated African faces as higher on the likeability dimension (more attractive, friendlier and less strict) than White faces, while no pattern emerged for Indian and Coloured participants. Yet, White, Coloured and Indian students ascribed a higher teaching ability and competence to White lecturers. White and Indian students also preferred to be taught by White lecturers. African students, on the other hand, preferred to be taught by African lecturers. They saw African and White lecturers as equally competent. They ascribed higher teaching ability to White lecturers. Students thus form opinions about lecturers based on minimal demographic information. As this is the type of information available to students when interacting with lecturers for the first time, it seems plausible that African lecturers have to work harder to be seen as equally competent to their White colleagues. It is also argued that White students might use their ratings strategically. They might rate African lecturers as more likeable in an attempt to justify describing them as less able.

Does spirituality affect the quality of family relationship
Sajjad Mohammad Islamic Republic of Iran; Fatehagh Bagheriyan; Mohammad Seyedi; Fatemeh Bagheriyan Shahid Beheshti University, Islamic Republic of Iran

The purpose of this research was to study the role of spirituality in the quality of family relationships and coping strategies, and the mediating role of family communication in relation with family spirituality and family coping strategies. In order to examine the mediating role, 375 parents of students in Kemanshah participated in the study. They were selected through a multi cluster sampling. These parents answered the Family Communication Scale (FCS), Sanctification of Marriage Scale, Sanctification of Parenting Scale, and Family Crisis Oriented Personal Evaluation Scales (F-COPES). Results of simultaneous regression analyses and one way ANOVA showed that families with a high level of spirituality used coping strategies; cognitive reframing (F=18.68, p < .001), spiritual social support (F=18.86, p < .001), and mobilizing the family to acquire help (F=5.2, p < .006) more than families with a low level of spirituality. In addition, families with a high level of spirituality used passive appraisal (F=3.12, p < .04) less than families with a low level of spirituality. Results also indicated that family communication directly and indirectly plays a role of mediation between family spirituality and family coping strategies. Families with high spirituality, through appropriate communication, can better cope with internal and external family tensions.

Language and identity in indigenous African language speaking adults who attended ex-model C schools
Boitumelo Monageng University of the Western Cape, South Africa

The central aim of this study was to explore the identity formation of black African middle class young adults in the context of their educational and language experiences in ex-model C schools. The rationale for conducting the study was motivated by a need to understand how socio-historical events, which play out in language in education policies and practices, affect the identity constructions of young black adults who have been through a school system where English was used as the language of instruction. Post-colonial approaches to identity construction were utilized, influenced by the works of Fanon and Bulhan. Three participants who formerly attended ex-model C school were interviewed. With regard to the findings of the study, three main themes were identified, namely making sense of the new school environment, identity construction and the role of language in participants’ lives. Overall, findings of the study revealed that identity constructions were not static but rather reflected the historical and social processes wherein the participants lived. The participants adapted to the language of the school and considered themselves as multilingual. Race and class as markers of difference emerged as important constructs for identity formation. The mother tongue was still used by these participants; however it was used in contexts which were deemed appropriate by participants. If African languages are presented as having some sort of utility in the economic sector, this will hopefully result in a change of attitudes amongst indigenous African language speakers towards their own languages.

An adaptation of the needs based model of reconciliation to the South African context
Ines Meyer University of Cape Town, South Africa; Lisa Ferraz; Pumlita Hako

The Needs Based Model of Reconciliation postulates that in post-conflict situations perpetrators and victims have different socio-emotional needs. Victims are argued to have a need for empowerment and perpetrators want to be accepted in society. Three studies were conducted to test this assumption in the South African context. White South Africans who were privileged under the apartheid dispensation were equated to the perpetrator group while individuals from population groups who were disadvantaged were classified as victims. Data was collected via questionnaires. Sample 1 comprised employees (n=384) and undergraduate students (n=426). As expected, white individuals had a higher need for acceptance than empowerment, but previously disadvantaged individuals had equally high needs for empowerment and acceptance. It was assumed that previously disadvantaged individuals might feel disempowered, but also unacceptable when affiliated to institutions with a predominantly white culture. Study 1 was thus replicated in a sample of mostly unemployed South Africans living in black townships (n=243). Contrary to expectations, individuals again indicated similar levels of acceptance and empowerment needs. Study 3 assessed needs of acceptance and empowerment in the workplace (n=278). In this study, white and previously disadvantaged South Africans had a higher need for empowerment than for acceptance. The results of Studies 2 and 3 thus do not support the assumption that a white institutional culture creates a high need of acceptance among previously disadvantaged South Africans. Suggestions for alternative explanations of the results of Study 1 are provided.

“You like you therefore I am no racist”: The influence of first impressions on lecturer ratings
Ines Meyer University of Cape Town, South Africa; Zeleika Kinneer

Anecdotal evidence suggests that African academic staff at historically White universities in South Africa experience greater resistance from students than White staff. This study sought to assess whether
amongst indigenous African language speakers towards their own languages.

The percent and sequence of the ambivalent moral informations: Which is the stronger factor impacting the automatic evaluations

Ren Na Central China Normal University, China; He Wenhui Central China Normal University, China; Bin Zuo Central China Normal University, China; Guoju Wang; Dongpin Fu Central China Normal University, China

Our research was on the basis of studies of Rydell, Gawronski and other researchers (2009,2010). We manipulated the proportion and the sequence of the ambivalent moral informations about the target person to explore the formation of automatic evaluation. In our experiments participants received some positive (negative) moral informations about a target person in one color (e.g. red) context, then they saw some negative (positive) moral informations about the same person in another color (e.g. blue) context. Finally participants completed some measures of automatic evaluations to the target person and a unknown person in the two familiar color (red and blue) and a new color (gray) contexts. We found that when participants encountered heterogeneous moral informations about the target person, automatic evaluations became context sensitive. That was similar with Rydell and Gawronski (2009). We also found that the phenomenon that new contexts elicited automatic evaluations that reflected the valence of first experiences with the target person wasn’t stable. When the percent of informations in the second context increased from 50% to 60%, the automatic evaluations in new context acted on the recency effect. Furthermore in some situations the experiences of participants to the target person seemed generalise to the unknown person. The explicit evaluation was investigated too. Participants were Chinese undergraduates. There were 31, 19 and 38 participants in 3 experiments.

Cultural crisscrossing: Intergroup psychology among students involved in community engaged learning

Luzelle Naudé University of the Free State, South Africa

During the last few decades most countries have been confronted with the challenge of redefining themselves in the face of social change. In South Africa, these years coincided with the transition into a post-apartheid environment and the development of a society embedded in its own unique multicultural, multiracial, and multilingual context - a transformative experience of dramatic and deep significance. Through the lenses of contemporary social psychological perspectives this presentation explains how, by using service-learning and reflection as a vehicle to facilitate change, the conditions of optimal intergroup contact can be applied. The aim in the presentation is to describe how students from various cultural groups respond to the service-learning experience and create meaning from these cross-cultural experiences. Focus groups were conducted with postgraduate Psychology students that participated in a school engagement programme. Transcribed focus group records were analysed making use of constant comparative analysis. An argument is made for how cultural immersion through service-learning transforms students through the change processes of (1) resistance to take the first step, (2) border crossing; reacting to difference, (3) becoming conscious of complexity, (4) seeing similarity, (5) intercultural comfort and competence, (6) celebrating diversity, (7) forming friendships, and (8) paying it forward. I propose in this research that, in the South African context where diverse students do not have much opportunity to share social spaces, service-learning creates living and learning opportunities that balances challenges with support and diversity, with connecting in similarity.

The production of fantasy in talk, space and embodied practice

Tamaryn Nicholson University of Kwazulu Natal, South Africa

Historically, the study of fantasy has been one of the innermost workings of the psyche, making it largely inaccessible to those unwilling to work with a psychoanalytic model of the mind. This means that an important area of study remains largely unexplored by those working within alternative paradigms. However, with recent work by theorists such as Billig (1999), Burkitt (2010a, 2010b) and Durheim (2012) on the dialogic unconscious and repression, areas previously confined to psychoanalytic-lytic study are becoming more accessible to interactionist approaches. This paper theorises the production of fantasy in talk, space and embodied practice. Fantasy is argued to be accomplished through implication rather than articulation and to be produced on the boundaries of that which is speakable or performable within a given context. This paper reports on an ethnemethodologically informed ethnographic study which took place at one South African night club over the course of several months.

Over-confidence among male and female sports gamblers: Two different dynamics

Thomas Oberlechner Webster University, Austria; Donald Baillie; Julia Pitters

Based on a survey and actual betting data from N=434 male and female spectators of the EURO 2008 soccer tournament, this research examines the presence and reasons for over-confidence among people who place bets on sports in an online betting contest. While the results show no evidence for a better-than-average effect among spectators regarding their general prediction abilities, spectators systematically over-estimated the returns they expected to generate by betting on the outcome of games. Moreover, there was a strong link between the subjective importance assigned to soccer and self-rated ability to predict the outcome of games. However, self-rated soccer expertise was only very weakly correlated to objective prediction skills and to realised betting returns. Results also show that there were gender-specific differences in how the role of chance in the outcome of games is perceived. While men perceive a negative correlation between the role of chance in the outcome of soccer games and expected returns, women perceive this correlation to be positive. Results suggest that there are two different dynamics which may lead to over-confidence among sports gamblers, and that these dynamics are gender-specific. Perceiving soccer as important, leads to a wrong sense of subjective expertise and success when betting on the outcome of games. For self-declared non-experts to whom soccer is not important, attributing the outcome of games to chance involves betting over-confidence by way of feeling lucky. These dynamics in the over-confidence of sports gamblers may also be relevant in other areas of human judgment and decision-making.

The relationship between attitudes toward homosexuality, ambivalent sexism and perception of religiosity among Turkish university students

Nur Okutan Ankara University, Turkey

The aim of this study was to examine the relationships between attitudes toward homosexuality, ambivalent sexism, ambivalence toward men and perception of religiosity among Turkish university students. Index of Homophobia, Ambivalent Sexism Inventory, Ambivalence toward Men Scale and Perception of Religiosity Scale were administered to 275 Turkish university students (137 women, 138 men). The results revealed that the group with the higher negative attitudes toward homosexuality had higher levels of perception of religiosity, ambivalent sexism, and ambivalence toward men than the group with lower negative attitudes toward homosexuality. The findings were discussed within the framework of the related literature.

Quality of life as a facilitator of social tolerance

Diana Olukalne University of Daugavpils, Latvia; Mara Vidmire

This research examines the problem of life quality, as well as its connection with social tolerance, which is a significant factor affecting society’s social tension in the current uncertain economic and the labour market situation in Latvia. Temporality of the research associated with the Latvian population’s living conditions change. Social tolerance is one of the most important personal qualities in the context of cultural interaction in the modern world. People are not prepared for sudden changes in life and, therefore, it is difficult to assess the reality of, and share the responsibility to maintain harmony in a relationship with others. Previous studies among students found a negative correlation between quality of life and tolerance, and identified them as the major health and social relations problems, which became the basis for the purpose of this study: to investigate the quality of life and social tolerance of men and women as related to social indicators of individual behaviour. The study included 150 participants from the region of Kurzeme. To investigate quality of life and social tolerance the following methods were used: Diversity Icebreaker by B.Z.Ekelund, E.Langvik, method of determination of tolerance index by U. Soldatova, O.A. Kravtsova and O.J.Huhlayeva, life quality questionnaire. Data were processed in SPSS 19.0 programme. Analysing the data of tolerance index, the results showed that in the selection, average level of social tolerance dominates. In the result of data mathematical process, and analysis, a correlation between quality of life and social tolerance indexes was found.
Between morality and pathologisation: Attitudes towards de/criminalisation of suicide in Ghana and implications for the criminal code against attempted suicide

Joseph Osafo; Fatima Peters; Hjelmeland; Birthe Knizek; Charity Akotia; Luis Duque; Nilton Montoya; Heidi Peters; Fatima Peters; Hjelmeland; Birthe Knizek; Charity Akotia

Although there are no national statistics on suicide in Ghana, the act is becoming a considerable public health problem in the country. To understand attitudes towards suicide in the country, which could inform policy and prevention strategies, interviews were conducted on psychology students, nurses, psychologists, lay persons, police, politicians and key informants to understand their attitudes towards suicide. One of the attitude areas where informants’ views on suicide were examined was the present criminal code against suicide. Analyses of interviews using interpretative phenomenological analysis, showed that generally, attitudes towards suicide in Ghana lie between morality and mental health. For instance, whilst psychologists conceived suicide as pathology, psychology students, nurses, lay persons, and the police viewed it as constituting communal and religious transgressions. Such attitudes were also found to be consistent with informants’ perceptions regarding de/criminalizing suicide. Viewed as a moral issue, the act constituted the breach of a rule and the suicidal person was seen as culpable and worthy of societal condemnation and criminalization. However, viewed as pathology, the act constituted a disease or health crisis and the suicidal person was regarded as unwell and needing care, empathy and treatment. This presentation seeks to highlight the implications of these ideologies about suicide for the existing criminal code against the act in the country.

The predictors of non-Muslims’ attitudes living in Turkey towards Muslims

Ozgun Ozkan; Ankara University, Turkey; Derya Has- to; Fatma Yasin

The aim of this study is to investigate the effect of religious and ethnic group belonging, social dominance orientation, and perceived discrimination of non-Muslims living in Turkey, on their attitudes towards Muslims. The data collection instruments were Demographic Information Form, Religious Identification Scale, Perceived Discrimination Scale, Muslim Prejudice Scale, Social Dominance Orientation Scale, and Ethnic Identification Scale. The analyses were conducted on 67 participants.

Factors associated with the reduction of intimate partner violence

Alexandra Restrepo; University of Antioquia, Colombia; Luis Duque; Nilton Montoya; Alexandra Henao

The aim of this study was to determine factors associated with the reduction of intimate partner physical violence in the Medellin, Colombia, between 2004 and 2007. Two household surveys were conducted in Medellin, Colombia (2004 N=5,781 and 2007 n=4,653). These surveys used the same instrument to measure interpersonal violence (witnessing, victimisation and perpetration of intimate partner violence). We calculated the mean annual change in physical violence, using the Straus Conflict Tactics Scale. Logistic regression was used to estimate the relationship between change in physical violence and associated factors. Between 2004-2007 there was a relative reduction of partner physical violence of 50% (17.5% vs. 8.5%). Factors associated with this change were an increase of collective efficacy (B=3.3; standard error=1.0), and reduction in the following: Past year unemployment (B=0.06; standard error=0.12), perceived neighbourhood disorder (B=1.4, standard error=0.66) and violence, distrust (B=2.0; standard error=1.1), violence legitimation and interpersonal aggression (B=1.5, standard error=0.12 ). Frustrated expectan- cies and tolerance of law breaking reduction. Changes in the social environment contributed to the reduction in physical intimate partner violence in Medellin. Promotion of public policies that de- crease social factors such as machismo attitudes and distrust, and promote collective efficacy and employment, may contribute to reduction of partner physical violence.

The role of emotional intelligence and social health in adolescents

Azamidokht Rezaei; Islamic Azad University, Isla- mic Republic of Iran

This study aims to investigate the emotional intelligence and social health in adolescents. For this purpose 150 adolescents, boys and girls, were selected and the questionnaires of emotional intelligence and social health administered on them. Data analysed through correlation and the differences of variables in both groups were also analysed. Results

When illegible handwriting builds up confidence: Disfluency as a positive cue in social judgement

Nicolas Pierre; University Paris Ouest, France; Nico- las Pierre Andre

Fluency – the subjective experience of cognitive ease – has been shown to be an influential cue in social judgements. It had been assumed that fluency is experienced by people as something good (Jacoby, 1983). But expanding on the idea that people implement personal knowledge about what fluency means depending on the context (Schwarz, 2004), positive value associated with fluency is hypothesised to be malleable. A pilot study established that people have specific beliefs and personal theories about how handwriting reflects competence. A majority of our sample (91%, N=102) believed that physicians have illegible handwriting. In the main study, students (N=95) had to look at two sets of handwriting (legible vs illegible). Half of the participants were told that the two sets of handwriting were produced by doctors, and the other half, that they were produced by students. The main task was to judge each handwriting for legibility and writer’s competence and confidence. As hypothesised, the interaction between fluency and social judgement strength was significant. Judgements were more favourable for legible (fluent) handwriting among participants who were told that the handwriting was that of students. Inversely, judgements were more favourable for illegible (dis- fluent) handwriting among participants who were told that the handwriting was that of physicians. Discussion focuses on the role of naïve theories on the value associated with fluency. The current findings demonstrate that changing the meaning of fluency changes the direction of the positive hedonic effect of fluency.

Societal perceptions towards the hearing-impaired and their psychological implications

Mashakgene Ramokgopa; University of Limpopo, South Africa; Mahlogonolo Matlala

The aim of the study is to investigate societal perception towards the hearing-impaired and their psychological implications thereof. It is hypothe- sised that people with hearing impairment tend to think that they are negatively perceived by those who can hear. The study is qualitative in nature and is conducted among ten hearing-impaired partici- pants, who are conveniently sampled. Open-ended questionnaires are used to gather information. Vid- eo recordings are also used to supplement the ques- tionnaires. The Interpretative Phenomenological Analysis (IPA) is then used to analyse gathered data. The result indicates a positive correlation between perceived societal perceptions and self-perception. The implications of the findings are that negative societal perception results in negative self- perception and negative regard towards their impair- ment. The result of the study also highlights the importance of people learning to communicate in sign language, so as to make the hearing-impaired to feel well understood. This will foster better communication between the two communities, and will eradicate communication barriers.

The construction of sexual consent/coercion amongst incarcerated adolescent males

Fatima Peters; University of Venda, South Africa; Umesh Bawa

The increased reported number of sexual violence cases in the general community, amongst adoles- cent’s is a major psychological and economic prob- lem, placing them at greater risk to multiple risk factors such as HIV and Aids and teenage preg- nancy. Institutionalised youth not only face these risk factors, the expected and taken for granted sexual violence inflicted against them, is exacerbated by the fact that the only way to protect themselves is though aggression and violence. The culture of violence and gangsterism, within secure care insti- tutions is confounded by multiple and contradictory discourses related to sexual consent. Understanding how institutionalised, adolescent males construct sexual consent and its intimate association with coercion is what this paper aimed to address. This question is approached from a qualitative method- ological framework. Thirteen adolescent males par- ticipated within a semi-structured interview. Data was analysed thematically and a social constructiv- istic theoretical framework situated the research. The research identifies that the construct of sexual consent was densely convoluted and that sexual violence was often associated with the cultures of violence and gangsterism within secure care institu- tions for adolescents.
Psychological adaptation to isolation and confinement in a multicultural group in Antarc-
taxica: A multidisciplinary approach

Elisabeth Romet, INSEP, France; Carole Tafforin; Karine Weiss

The paper presents the psychological adaptation of the first two groups of winterers in the French and Italian polar station, Concordia. This station, around 1000 km inside the Antarctic Continent, induces strong isolation and confinement for at least 9 months. Groups of 13 and 10 winterers include French and Italian volunteers who work to maintain the station and to conduct scientific experiments in astronomy, seismology, magnetism, etc. Isolation and confinement in extreme environments, leading to various individual and social phenomena. The main areas of adaptation involve mood, interpersonal relationships, somatic symptoms, and performance. The methodological approach chosen here is a combination of psychological, ethnological, and ethnographical techniques including self-assessment questionnaires, individual interviews, cognitive maps, observation of public spaces and the way in which these impact on her self-image and self-worth. Ultimately, the victim is empowered and is able to find a more appropriate way of expressing her individuality. This research presentation argues that make-over programmes, such as the one described in this vignette, appropriate psychological language and concepts in the service of fashion, in the ways in which these discourses and ways of speaking function are highlighted through reference to episodes of popular ‘make-over’ television series. In particular, the presentation focuses on the way in which the use of these discourses creates positions of power within the narratives, leading to the inevitable paradoxical conclusion that only certain socially acceptable expressions of individuality are authentic. Thus, through using a language of empowerment these psychological fashion discourses actually create the very victims they claim to rescue, in accordance with Schirmer’s (2010) formulation that “a fashion victim ... is an individual who negates his own individuality in the very act of exercising it” (p. 9).

Causal explanations for infidelity of Latvian residents of different age groups

Ivets Ruza Daugavpils University, Latvia

People in general tend to express a negative attitude towards infidelity. However infidelity is a common phenomenon, which can happen rather often in romantic relationships. The experience of being betrayed by a loved one can substantially affect the sense of self-worth, and might therefore negatively influence a person’s general psychological well-being. The causal explanations for infidelity may increase or reduce the effect of traumatic emotions for a betrayed partner and feelings of guilt for betrayer depending on how partners explain the act of infidelity to themselves. Getting older, people tend to change their attitudes towards the world and things because of their experience. It is supposed that people of different ages might have different explanations for infidelity. The current research focused on causal explanations and verbal responses concerning infidelity in romantic relationships presented by Latvian residents of different age groups (N=886). The results demonstrate significant differences in causal explanations for infidelity between the different age groups of participants. Implications of these findings and directions for future research are discussed.

The appropriation of psychological discourse in the service of fashion

Carolina Saccaggi University of Johannesburg, South Africa; Marissa Morkel University of Johannesburg, South Africa

During an episode of a popular ‘make-over’ television series the fashion victim, who has been targeted as the fashion victim, makes over the victim’s host, an impeccably dressed facilitator, and reframes the victim’s victimhood by making her into a more fashionable person. This paper focuses on the way in which the use of these discourses creates positions of power within the narratives, leading to the inevitable paradoxical conclusion that only certain socially acceptable expressions of individuality are authentic. Thus, through using a language of empowerment these psychological fashion discourses actually create the very victims they claim to rescue, in accordance with Schirmer’s (2010) formulation that “a fashion victim ... is an individual who negates his own individuality in the very act of exercising it” (p. 9).

A negative relation between shyness and self-esteem investigated with an implicit asso-
ciation test

Takafumi Sawauami The University of Tokyo/CRET, Japan; Tsutomu Fujii The University of Tokyo/CRET, Japan; Atsushi Aikawa

An increasing number of studies use an Implicit Association Test (Greenwald, McGhee, & Schwartz, 1998; IAT) as a measure of implicit personalities, attitudes, and self-concepts such as shyness, anxiety, and self-esteem. As one of its validity, the predictive validity of IATs measuring implicit shyness, anxiety, and self-esteem has been demonstrated (e.g., Asendorpf, Banse, & Mülke, 2002; Egloff & Schmukle, 2002; Greenwald & Farnham, 2000). As important as this, however, the concurrent validity has been ignored so far. Hence, we intend to show the concurrent validity of IAT for shyness. Previous research has consistently revealed a negative association between shyness and self-esteem (e.g., Cheek & Buss, 1981). Unless implicit constructs are entirely distinct from explicit counterparts, we expect that implicit shyness would be negatively correlated with implicit self-esteem. For investigation, a computerised experiment was conducted. Fifty-nine Japanese participants completed shyness IAT and self-esteem IAT twice with an interval of one week. In Structural Equation Modelling, the two parts of each psychological construct were set as latent variables in order to steer clear of attenuation. Consistent with our hypothesis, implicit shyness was negatively correlated with implicit self-esteem (r=-.72, p

Mate selection: Preference or importance?

Safoora Sepahi Shahid Beheshti University, Islamic Republic of Iran; Fatemeh Bagherian; Warren Thorngate; Fatemeh Bagherian

Most research in this area has been done through questionnaire methods. In this way, only criteria of preferences and not the criteria of importance have been investigated. For example, beauty has a higher preference rate for males than for females, but it has not been studied how important this is for males when selecting a wife. This study measures the differences and importance of criteria in mate selection. The tool was a computer program creating virtual space for mate selection. Participants were 295 people, 44 male and 151 female, with ages ranging from 18 to 35 years. Sex differences in Criteria of Preference were assessed by the Wilcoxon Test for both males and females. Sex differences in Criteria of Importance were studied by the Chi square Test. The results showed sex differences in both preference and importance; however, sex differences were not the same among males and females. For example, beauty had priority among all male participants compared to the female participants during decision making (Wilcoxon W =996.500, p < 0.001) but there was not any sex differences between them in their selected wife and husband regarding beauty. On the other hand, sexual relationship was more important for male participants than for female participants (W=9,744, p<0.01), but they didn’t choose it sooner than female participants. In conclusion, participants chose criteria of potential mates according to their preferences, but ignored some of them and paid more attention to others.

Antecedent of reactions to norm violation: Intergroup emotions or contextual factors

Roomana Siddiqui Aligarh Muslim University, India

Norms are shared realities that have considerable impact on behavior and vary from culture to culture.
Instances in which people act in ways that are congruent or incongruent with these shared realities may lead to feelings that start a chain of processes. According to the Norm Violation Theory (DeRidder & Tripathi, 1992) in an event of norm violation a process of escalation or de-escalation of negative intergroup behavior is expected. Its direction and intensity however will depend on various social and psychological factors. The present study aims to explore the role of contextual factors and felt emotions in regulating action tendencies in norm violating situations. Data was collected on 388 respondents (Hindus=221, Muslims=167). To measure action tendencies three situations of norm violation were examined and subjects were asked to rate the extent to which they experienced anger, fear or anxiety as a result of it. Three response alternatives (reconciliation, retaliation and retribution) were also provided and subjects were asked to choose the one they preferred most. The finding of the study shows that across the three situations anger was the most intensely experienced emotion followed by anxiety and fear. Further, respondents using retribution and retaliation experienced significantly more anger compared to those who preferred reconciliation. Apart from emotions it was the placement of groups in the social hierarchy along with the nature of the norm violated that determines the pathway in which emotions will motivate and regulate action tendencies.

When is bad stronger than good? A construal level perspective
Smita Singh James Cook University Singapore, Singapore; Shehnas Alam James Cook University Singapore, Singapore
The importance of bad or negative life events has been emphasised primarily all across in different domains of psychological literature (Baumeister, Bratslavsky, Finkenauer, & Vohs, 2001). In the present research, this supremacy of negative events was re-examined by adopting a novel method of Construal Level Theory (Trobe & Liberman, 2000). In addition, positive life events was also compared and contrasted with the negative life events. Participants responded to 20 positive and negative life event statements in terms of either the event taking place in a near or temporally proximal condition (yesterday) or far or temporally distal condition (one year ago) and whether these life events happened to them or others (social distances). Two hundred and fifty-six participants (110 males and 146 females, Mage=24.63, SD=6.08) were randomly assigned to a 2 (temporal distance: proximal vs. distal) x 2 (events: positive vs. negative) x 2 (social distance: self vs. others) mixed-factorial design experiment, where each participant was presented with a Life Perception Scale (LPS). The findings supported the hypotheses that greater psychological distance (temporal and social) indeed leads to decreased positivity and negativity associated in its perception. Further, perception of temporally distal events (both positive and negative) was found to have significantly lesser impact than temporally proximal events. Events (both positive and negative) perceived for another person (socially distal) showed a significant impact reduction as well; perceptions of negative or positive events for another person were indeed considered less positive or negative.

Sensory experience in the Mela: Noise and the perception of time duration
Tushar Singh Banaras Hindu University, India
The Mela is an incredibly noisy event with religious discourses, chanting, music etc. played (simultaneously) across hundreds of different sound systems. In two studies we investigated the experience of such a loud noise mixture. Such noise may be assumed to be inherently aversive (and as diminishing the pleasure of collective participation). However, perceptual experiences can be influenced by top-down influences, including cultural and social factors. We report two quasi-experimental studies in which a loud noise (a mixture of many sounds) was depicted as being recorded at either the Mela or at city (secular) locations. After listening to a 20 second sound clip, pilgrims reproduced its perceived duration. Previous work shows the perception of stimulus duration to depend on the meaningfulness of the stimuli (longer estimations when the stimulus is meaningful). In Study 1 we found longer estimations of elapsed time when the clip was attributed to a religious event. In order to investigate whether the results are due to mental processes occurring during encoding or during the time re-production task itself we conducted Study 2 in which the attribution of the noise to a source took place after the noise was played. Here we found no difference in the two conditions. This suggests the effect in Study 1 reflects processes occurring during the listening to the noise and that when the noise was attributed to a religious site it was experienced differently to when it was attributed to a secular site.

The joys of fatherhood: Teenage fathers talk about fatherhood
Nicole Smith University of the Witwatersrand, South Africa
Teenage fatherhood is an issue that needs to be considered particularly in the South African context and with regards to teenage pregnancy. The study aimed to explore what it means to be a teenage father, specifically in the disadvantaged community of Alexandra Township, Johannesburg. The study was qualitative in nature and individual interviews were conducted with five teenage fathers aged between 18 and 23 years. The data was analyzed using thematic content analysis. Key findings suggest that teenage fathers have strong feelings around how difficult it is to be a father at such a young age, the responsibility associated with financially providing for their child, and simply being present in the life of their child. This study gives teenage fathers a voice and illustrates their need for inclusion in the child rearing process and research on teenage pregnancy. The need for interventions to be put in place to help these fathers is highlighted.

Self-image maintenance and discrimination: A study of prejudice towards Chinese in Bandung Indonesia
Willis Srisayekti Padjadjaran University, Indonesia; Rasyid Bo Sanisasso; David A Setiady
Past research discovered that threatened self-esteem could increase prejudice, and that it would be followed by certain discriminatory behaviour, i.e. avoidance behaviour towards minority ethnic groups. This study was aimed at examining the effect of self-threat on discriminatory behavior towards Chinese. Applying experimental methods and studied in Bandung, Indonesia, Study 1 involved 28 female students (Sundanese, age 18-20 years; M=18.55, SD=0.8). Results showed that receiving negative feedback led to lowered self-esteem (.048; p Discussion focused on the conditions under which behavioral consequences of stereotype activation might be observed.

Gender stereotypes in high school girls threaten choice of science subjects
Mein-Woei Suen Chung Shan Medical University, Taiwan, R.O.C.; Liang-Ju Chiu; Yu-Chen Chen
The influence of gender stereotypes have been found in many conditions, such as in our working places or schools. Therefore, understanding the impact of stereotypes and deducing negative effects from stereotypes are becoming popular and important issues. In 1995, Steele and Aronson indicated that gender stereotype threat effect (STEs), explaining that stereotype threat effects would affect stereotyped individual’s performance. This study, thus, conducts a 2 (subjects: science vs. literary) x 2 (condition: control vs. threat vs. threat deduction) mixed participant design aimed at understanding how high school students who are influenced by negative gender stereotypes select science and engineering as major subjects. 339 female high school students in Taiwan participated. The subject-selected willingness was used as an independent variable. The statistical analysis reveals results as: (1) Significant interaction effects between subject and condition was found (F(2, 136)=4.056; p<.05); (2) There is a significant main effect of subjects (F(1, 136)=228.241; p<.001). The willing score to literary (M=537.27) is higher than to science (M=276.18) \( t(73) \). In science subjects, the threat deduction group had the highest inclination scores (M=321.23) than threat group (M=241.05), and then control group (M=272.41). In addition, this study also explores factors which may influence the choice of their major. More details and findings are discussed.

Followers’ characteristics and their leadership preferences
James J-M Sun Renmin University of China, China; Jian-Min Sun; Caihu Lin
Based on implicit leadership theory and similarity attraction theory, this study examines the relationship between followers’ core self-evaluations (CSE), power distance orientation and their preferences for charismatic leadership and paternalistic leadership which has three dimension namely, moral, benevolence, and authority, respectively. Descriptive statistics, correlation analysis, and hierarchical regression were conducted with data collected from 314 Chinese employees in different types of organizations. It was found that followers’ CSE correlates positively with their charismatic leadership preference and moral leadership preference. Followers’ power distance orientation correlates positively with their authoritarian leadership preference, but negatively with their moral leadership preference. A moderating effect of power distance orientation is found in the relationship between followers’ CSE and their charismatic leadership preference. Implications and limitations of the research were discussed.
Gender stereotypes of men about women: job involvement
Mahnaz Talebzadeh University of Isfahan, Islamic Republic of Iran; Aboughaseem Nour

The real development of the world requires the participation of all citizens in the process of development, but it is not possible without the complete participation of women. For better development, organisations need those employees who can play a greater role when using all their talents and experience possible when they are involved in their jobs. Some research findings indicate that men stereotypically think that women are less involved in their jobs. Therefore the purpose of this study was to investigate and answer this question: Is there any difference between men and women in job involvement? For this aim, a random sample of 125 persons were selected from employees in Isfahan Water and Wastewater Company, Iran. The research instrument was Kanungo involvement questionnaire and Demographic questionnaire. The results showed that there is no significant difference between men and women in their job involvement. It must not be ignored that these stereotypes may result in self-fulfilling prophecies, and that women, instead of being job centred, see themselves as family centred and this attitude prevents them from entering higher positions. It is suggested that social psychology researchers attempt to clarify this social issue and conduct more scientific and applied studies in this context.

Complexity of in- and out-group images
Yona Teichman Tel Aviv University, Israel

The relationship between the complexity of objects of attitude and attitude extremity or moderation was studied with adults (Blair, Johnson & Zanna, 2005; Linville, 1982; Linville & Jones 1980). Based on ample findings indicating that young children possess and express stereotypes and prejudice (Teichman, 2001; Teichman & Bar-Tal, 2005), we present two studies. One examined Jewish Israeli children, 3 – 11 years of age. Different aspects of complexity of mental images of ‘a Jew’ and ‘an Arab’ who are adversaries in the conflict known as the Middle East conflict were investigated. The second examined traits attributed by children of similar age to the same images. This study included Jewish and Arab participants. In both studies the images were assessed using HFDs (Human Figure Drawings) that were systematically scored (Teichman 2001; Teichman & Bar-Tal, 2005). The drawings were followed by questions regarding names and attributed traits. On all variables (image complexity, number of traits, type of traits, and familiarity with names) Jewish participants favored their in-group. They also attributed more positive traits to their in-group. Arab participants did not differentiate between images. Assuming that early interventions regarding stereotyping, prejudice, or racism are desirable, our findings indicate that introducing more complexity to social representations at a young age may facilitate such change.

Examing the predictive value of five drinker prototypes in explaining drinking behaviour
Britt Van Lettow Erasmus MC, Netherlands; Pepijn van Empelen; Hein de Vries; Alex Burdor

We aimed to extend the Prototype/Willfulness Model (PWM) by examining other prototypes besides the generally examined abstainer and drinker prototypes. The predictive values of favorability and similarity of five drinker prototypes (abstainer, moderate drinker, heavy drinker, tipsy, drunk) were examined in explaining intentions, willingness and drinking behavior. An online prospective study was completed among 450 Dutch adults aged 18–25. At baseline, favorability and similarity (to oneself) for each prototype were assessed, besides other Theory of Planned Behaviour and PWM concepts. Drinking behaviour was assessed at one month follow-up. Structural Equation Modelling was used. Also, pairwise parameter comparisons tested moderation by gender. Drinking behaviour (R² = .40) was predicted by heavy drinker, abstainer similarity, intention (among women) and tipsy prototype similarity (among men). Intention was related to injunctive norms, drunk prototype similarity, and (among men) attitude, descriptive norms, tipsy and heavy drinker prototype similarity, and (among women) abstainer and drunk prototype favourability. Willingness associated with perceived behavioural control, abstainer favourability, drunk similarity, and (among men) moderate drinker and drunk prototype favourability, and (among women) attitude, abstainer and heavy drinker similarity. In conclusion, prototype similarity predicted behaviour, willingness and intentions. Favourability related to willingness and intentions. Interestingly, women’s drinking seemed intentional whereas men’s drinking seemed normative. Including more prototypes such as a drunk, moderate and heavy drinker prototype could augment the PWM. The results suggest tailoring and targeting interventions and research aiming to reduce alcohol consumption through drinker prototypes according to gender.

Ethnicity, gender and self: A study of North-Eastern Indian women
Sunil Verma Vivekanand College for Women, India; Dikki Bhutia; Tushar Singh Vivekanand College for Women, India

Women in India have been seen as the virtuous holders of the society, living a life of roles and doing their duties as daughters, wives and mothers. They have been confined to the predominant triangle of children, kitchen and temple. However, the changing era has affected various aspects of traditional Indian society as well as the status of Indian women. Women in India are now expanding their horizons, taking up new challenges and are pursuing higher education. While doing so they are challenging the traditional boundaries made for them. The present paper explores the conflict experienced by women of three ethnic communities and the types of strategies used while trying to maintain a balance between their professional and traditional role demands. A total of 170 women graduate students from three different ethnic communities (Nepali, Bhutia, and Lepcha) of Sikkim were administered the source of self-esteem inventory, the primary-secondary control scale, the Depression scale, the loneliness scale and the relational self-scale. Findings of this study revealed differences in self-concept in the women of the three different communities. Findings show different conflict and psycho-social patterns for different communities. The results are discussed in light of existing literature of ethnic differences and existing theories.

Your “truth,” my pain! A psychosocio religious study of abuse in the church
Rosemare Visser University of Pretoria; South Africa; Mihaly Berkics; Tamas Nagy; Xuejun Bai

In social structures people often claim to experience “abuse” and/or unfair treatment by superiors. The church as conventional supportive structure in society is one such structure and was the chosen context for the study. Secondary to blatant intentional abuse of power, the author researched unintentional actions and behaviours as reported by participants, resulting in their experiences of abuse in their respective church systems. An interdisciplinary psychosocio-religious qualitative study from a social constructionist narrative perspective was conducted. The thematic analysis of case studies revealed that dominant discourse and other social constructions played a role in these experiences of and interactions involving abuse. Apart from stimulating greater awareness of this phenomenon, the author suggests a humble revisiting of the origins of solidly held and imposed beliefs and so-called “absolute” truths by individual and collective groups. Focused dialogue between people, cultures, groups and disciplines is encouraged in this study.

Defence and efficiency motivated in group projection: Motivational underpinnings of ethnocentric judgments
Sven Waldzus ISCTE-IUL, Portugal; Miriam Rosa
Members of social groups often tend to ethnocentrically overestimate their ingroup’s relative prototypicality in comparison with relevant outgroups due to ingroup projection, that is the generalisation of distinctive ingroup characteristics onto superordinate categories encompassing both the ingroup and the outgroup. Predictors of ingroup projection have been identified, but the underlying motivational processes are still unclear. We propose that ingroup projection in insecure intergroup relations is defence motivated, whereas in secure intergroup relations it is the outcome of efficiency motivated cognitive biases. In three experiments we manipulated the security of the intergroup situation (stable vs. unstable higher status) and information processing (heuristic vs. systematic). In line with our hypothesis we found that in secure intergroup relations ingroup projection was stronger under time pressure (Study 1, artificial groups, N=91), cognitive load (Study 2, artificial groups, N=128) or lack of thoughtfulness (Study 3, natural groups, N=144), whereas the opposite pattern was found in insecure intergroup relations. We conclude that two different motivational processes can lead to the same ethnocentric judgments. Results have implications for attempts to reduce intolerance, oppression and misunderstanding between groups of different social status, as they suggest differential strategies depending on the context of intergroup relations.

The moderating role of gender and social anxiety on the relationship among Chinese adolescents’ online communication, self-disclosure and quality of friendship Jinliang Wang | Center for Mental Health, China; Dajun Zhang; Linda Jackson

Online communication, characterized by reduced visual, auditory and contextual cues, can make users less concerned about the perceptions others have of them. Recent studies have found that online communication can promote friendship quality when users communicate with their friends. The rich-get-richer hypothesis suggests that socially competent adolescents are more likely to use online communication as another means of maintaining their existing friendships. However, it is reasonable that adolescents with social anxiety often prefer to disclose their feelings and concerns in online settings. Adolescent boys usually face more inhibitions when self-disclosing in offline settings than adolescent girls. In online settings, however, where factors that might cause uneasiness in communication are removed, adolescent boys will be more likely to discuss intimate topics. In the present study, we examined relationships among gender, social anxiety, self-disclosure, quality of real-world friendships and online communication by Chinese adolescent Internet users (n=190) with a mean age of 16.6±1.22. Results indicated that online communication and self-disclosure are not related to quality of friendship, and online communication is positively related to self-disclosure. Participants were asked to fill in scales of Online Communication, Friendship Quality, Social Anxiety, and Online Self-Disclosure. Results found that for adolescent boys and adolescents with high social anxiety, online communication can explain more variance in users’ self-disclosure, indicating that gender and social anxiety moderate the relationship between online communication and online self-disclosure.

Positive gender-related role models can protect Taiwanese women from stereotype threats

Jui-Hsing Wang | Division of Infectious Disease, Taiwan, R.O.C.; Mein-Woei Suen; Jeaw-Mei Chen

It is common to evaluate mathematics ability using a exam result. Steele and Aronson (1995) indicated “Stereotype Threat Effect, STEs”. Some studies successfully use positive gender-related role models to deduce STEs on females’ mathematics (e.g. Marx & Roman, 2002; McIntyre, Paulson, & Lord, 2003). McIntyre et. al. used articles related to successful females in different fields to manipulate, and found better performances. However, they did not test whether a manipulation with opposite-gender role model can cause STEs or not. Thus, this study uses a 3-part (Role model: male vs. female vs. control) construct between-participant experiment design, and the accuracy of 23 GRE mathematical items is DV. One-way ANOVA (N=66 female Taiwan university students) reveals interesting results: (1)A significant main effect of Role model (F(2, 63) =6.48, p<.001) shows that different gender-related role models reveal different influences; (2)By Post Hoc analysis, male role models cause the significant worst math scores (M=71.07) rather than control condition (M=81.07; p<.005), and then female model (M=77.03; p<.05). As expected, this results support that a male role model can cause STEs and a female model seems to induce threat deduction. (3)Post Hoc interestingly shows no significant different between female model and control condition (p=.153). This finding differs from the results of McIntyre et. al. and needs be discussed. More details and findings are discussed. < .001) and post hoc test shows that participants in mixed-gender situation obtain lowest scores (M=69.64), in order, rather than same-gender situations (M=74.45; p=.06), and later individual situations (M=78.43; p<.05). More details and findings are discussed. < .001) and post hoc test shows that participants in mixed-gender situation obtain lowest scores (M=69.64), in order, rather than same-gender situations (M=74.45; p=.06), and later individual situations (M=78.43; p<.05). More details and findings are discussed. < .001) and post hoc test shows that participants in mixed-gender situation obtain lowest scores (M=69.64), in order, rather than same-gender situations (M=74.45; p=.06), and later individual situations (M=78.43; p<.05). More details and findings are discussed. < .001) and post hoc test shows that participants in mixed-gender situation obtain lowest scores (M=69.64), in order, rather than same-gender situations (M=74.45; p=.06), and later individual situations (M=78.43; p<.05). More details and findings are discussed. < .001) and post hoc test shows that participants in mixed-gender situation obtain lowest scores (M=69.64), in order, rather than same-gender situations (M=74.45; p=.06), and later individual situations (M=78.43; p<.05). More details and findings are discussed.

Mixed-gender testing situations and their effect on performance in mathematics in Taiwan university students

Jui-Hsing Wang | Division of Infectious Disease, Taiwan, R.O.C.; Mein-Woei Suen; Jeaw-Mei Chen

In schools, holding a mathematics exam in a mixed-gender situation is a common way to evaluate students’ academic achievement. However, since Steele and Aronson (1995) indicated “Stereotype Threat Effects, STEs”, most of STEs studies were conducted in individual testing situations which are different to our actual school situation. Thus, we conducted a two-factor experiment design. The accuracy of 23 GRE mathematics items are manipulated in testing situations (M=78.43; p<.05). More details and findings are discussed.

Warmth and happiness: A study on physical warmth and psychological warmth

Zeng Wang | Hebrew University, China

Happiness is one of the abstract and social perception concepts. In study 1, after finishing a scrambled-sentences task, participants with a happy experience gave higher estimates of room temperature than the participants in the control group. In study 2, participants who recalled a real, past experience of happiness gave higher estimates of room temperature than participants who recalled an unhappy experience. In study 3, participants who briefly held a cup of hot coffee judgments that target person as being significantly happier than those who briefly held a cup of iced coffee. These results suggest that the priming of happiness induces an actual feeling of warmth, and warmth makes people feel much happier. These findings are consistent with the embodied view of cognition and support the notion that social perception involves physical and perceptual content.

How the social contexts modulate the relationship between physical warmth and interpersonal process

Wenqi Wei | Peking University, China

Williams and Bargh (2008) found that experiences of physical warmth increase feelings of interperson al warmth. However, the results were obtained under positive social contexts (e.g., reading positive words or donating to a friend) and uncovered only the warm (positive) side of “warmth”. We developed a two-factor model with a physical-social perspective to explain how physical experience and social context interactively determine the interpersonal process. We conducted three studies to examine our two-factor model. Study 1 found participants who experienced physical warmth under negative social context made colder interpersonal judgment than those who experienced physical coldness. Study 2 and Study 3 further showed that physical temperature and social context had signif-
ic interaction effect on interpersonal behavior. Particularly, under negative social context partici-
pants in warm group showed less interpersonal warmth (less willing to forgive other’s fault (Study 2) or listen to sales promotion (Study 3)) than those in cold group. Our findings indicate that physical warmth may increase negative feelings associated with interpersonal processes and the effect of phys-
ical warmth on interpersonal processing is social-
context dependent.

**Engendering masculinities**

Nombasa Williams University of Adelaide, Australia; Sanjay Pattanayak; Roomana Siddiqui

According to the literature on culturally and linguis-
tically diverse parenting, refugee parenting practices and styles that are normative in countries of origin may not be sanctioned in Australia. In the case of refugee parenting, beliefs, practices, and values may be decentered in pre-resettlement contexts where survival becomes the primary concern. Engendering the discourse of masculinities to reflect a relationship between child protection and the experience of refu-
gee parenting for African men in both pre-and post-
resettlement contexts will inform culturally compe-
tent practice, intervention, and community develop-
ment that is inclusive of their gender-specific needs. This article brings an expanded masculinities per-
spective to the ecology of refugee parenting for resettle African men resulting from larger research findings with focus group participants. Incorporating notions of masculinity into the child protection discourse is an attempt not only to reduce existing gender under- and misrepresentation among South Australian refugees, but also to ensure greater visi-
bility and increase the role of refugee men in the process of developing culturally relevant and appro-
priate policies, practices, and services to assist suc-
cessful resettlement transitions while strengthening family well-being. The concept of masculinities, this article argues, must be treated as integral to any approach to working with refugees, particularly in areas that penetrate and may define the quality of their life experiences, expectations, and aspirations. Masculinities matter. Exploring refugee male percep-
tions, interpretations, and the enactment of masculin-
ity may unmask the differential experiences of refu-
gee women from men and ensure their integration into child protection services practice.

**Evaluative conditioning: The role of display duration, valence intensity and contingency awareness**

Zhao Xian School of Psychology, Beijing Normal University, China; Ye Li; Li Liu; Hongling Zeng; Jian Zheng

The purpose of the present study was to investigate the effect of display duration of US, retest the effect of valence intensity, CS-US contingency awareness, and their integrated mechanism on evaluative con-
conditioning, measured by explicit evaluative rating, combined with four-picture recognition test and item-based analyses. The hypotheses were tested in a 2 (display duration) × 2 (valence intensity) × 2 (CS type) mixed design, with CS type as a within-group factor, participants were randomly assigned to four groups: US short display (120ms) -strong valence, US long display (1000ms) - strong valence, US short display -mild valence, US long display -mild valence. Results showed that evidence was obtained for EC effect on the global level, with more positive ratings of CS+ than of the CS-. For display dura-
tion, EC emerged only on long display level. For valence intensity, EC was found only on strong valence level. And only participants who were categorised as "contingency aware" showed signif-
icant EC effects. However, contingency awareness did not significantly mediate the relationship be-
 tween display duration and EC effects, nor does the relationship between valence intensity and EC effects. This pattern of results partly supported the hypotheses, and emphasised the role of attention and awareness on EC effect. EC relies on US display duration, US valence intensity and CS-US contingency awareness, which is in line with a propositional account. Results also raise doubts about the views in implicit misattribution mecha-
nism and APE models. EC is unlikely to be an associ-ative evaluation process which requires little cognitive capacity and contingency awareness. The insignif-
ificant mediation effect also indicates that a propositional account needs further modification.

**Automatic and controlled cognitive re-
sponses to intergroup threat as assessed using the process dissociation procedure**

Ling Xiang Southwest University of China, China; Zhoa Yufang

Explicit and implicit methods are typically employed to investigate the respective controlled and automatic cognitive responses to intergroup threat. However, these may not be ‘process pure’ measures of automatic or controlled responses. The present study used the process dissociation proce-
dure to investigate the relative contributions of automatic and controlled cognitive responses to intergroup threat. Following exposure to a threat/ no threat manipulation, 50 rural undergraduates completed a recognition memory task, in which they were asked to identify all or select ‘old’ (pre-
viously presented) trait words relating to an urban outgroup. The results showed that, compared to the non-threat group, when rural members perceived threat from an urban group, their automatic re-
sponse was a decrease in favoritism for this out-
group - although it was not derogative - whereas the controlled response was neither positive nor nega-
tive. These findings are inconsistent with previous research using explicit and implicit methods. This discrepancy is probably due to the participants chosen being of low-status. There is an increasing body of evidence indicating that low-status group mem-
bres sometimes indeed display positive outgroup belief. Thus, it is not enough to illustrate that the cognitive responses to threat measured via explicit and implicit methods are not ‘process pure’. How-
ever, the current study has demonstrated that com-
pared to explicit and implicit methods, the PDP can successfully distinguish between the contribution of automatic and controlled processes, and provide a clear view to further explore cognitive responses to threat.

**The contents and automatic activation of the stereotype of Chinese migrant workers**

Zhang Xiaobin Central China Normal University, China; Qiao Chi; Fangfang Wen Central China Nor-
mal University, China; Shan Sun Central China Nor-
mal University, China; Bin Zuo Central China Normal University, China

These studies explored the contents and automatic activation of the stereotype of Chinese migrant workers. In study 1, we used the methods of inter-
views (50 college students as participants), ques-
tionnaires (300 college students as participants) and content analysis, and found the dimensions of stereotypes of Chinese migrant workers. The ste-
reotype contains three dimensions: The Chinese migrant workers are aggressive, thinking behind, and they always have bad behaviours. Study 2, using the classical method of implicit association test (50 college students as participants), confirmed the stability and automatic activation of stereotypes of Chinese migrant workers. The results were dis-
cussed with reference to the Chinese social system of division between the urban and the rural.

**How perception of power affects the percep-
tion of physical reality**

Qian Yang Tsinghua University, China; Xueya Zhou; Yang Bai; Ruqiao Zheng; Bohan Ye; Kaiping Peng

This experimental study focuses on how perception of power differences affects people’s perception of physical attributes in China and the US. In line with an embodied simulation, but contrary to a meta-
phor-enhanced perspective, this work shows that when comparing the same targets with different power/status cues, the participants perceived differ-
ent physical attributes of the targets. In the first
study, participants were asked to estimate the door sign size of “Manager’s Office” and “Janitor’s Office”, while in fact half of the times both signs were exactly the same size. Results show that, both Chinese and Americans falsely consider the signs of “Manager’s Office” to be much bigger than the signs of “Janitor’s Office”. In study 2, cartoon figures of both genders were presented to participants. The pairs are exactly the same figures but wearing different clothes (suite vs. casual clothes). Although there is culture difference in considering which kind of clothes stands for high power logo, and in error judgments on the female figures’ height, we found that people from both cultures make errors in judging the male figures with power to be taller. These findings extend previous research by showing that the perception of physical reality can be influenced by people’s perception of power differences. Implications for understanding the relationship between physical reality and psychological reality as well as the scopes of cultural differences are discussed.

Hometown and present location in relation to place identity

Yi Yang Beijing Forestry University, China; Jianping Wu

Place identity is one of the most important directions in the study of “people-place”. Under the conditions of Chinese modernization, the fluidity of the population increased, causing environmental changes that result in psychological effects on individuals that have become a prominent issue, and place identity is a key point. Place identity is a part of self-identity, which increases the personal feeling of belonging to a certain group, it also has a major impact on environmental values and the communication of policies. In this study, a 13-item place identity scale (hometown and Beijing separate) with one dimension was tested on a sample of non-local students who have separately studied in Beijing for one, two and three years (n=213). The majority of respondents were female (63%), and the average age was 20.3 years. Reliability and validity were strong. The Alpha coefficient was 0.91 overall, hometown and Beijing (present location) separately was 0.94 and 0.85; through exploratory factors, the KMO was 0.93; with related test values greater than 0.70. The results show that: (1) Hometown and Beijing (present location) in place identity are independent of each other. (2) There was no significant difference across gender. (3) Place identity and time had no significant linear relationship. (4) Place identity was one dimensional.

An investigation into mobbing experience, social dominance orientation, and organisational justice perception

Fatma Yasin Ankara University, Turkey; Derya Hasta

The aim of this study was to examine the relationship between social dominance orientation and organisational justice perception with mobbing experience. The sample of this study was composed of 139 volunteer participants, 66 (47.5%) private and 73 (52.5%) were public bank employees. The data collection instruments were Mobbing Scale, Attitude Survey, Social Dominance Orientation Scale and Organizational Justice Perception Scale. The findings of this study revealed a significant relationship between social dominance orientation and social mobility behavior (r = -.24, P < .5); struggle and mobbing (r = -.29, P < .01), passive coping and mobbing (r = -.31; P < .01). Mobbing was also significantly related with distributive justice (r = -.36; P < .01), interactional justice (r = -.42; P < .01) and procedural justice (r = -.44; P < .01). Besides, it was observed that the participants with low level education had more passive attitudes towards mobbing than participants with high level education (means; 5.38 (95), 4.89 (s=1.15); F1-135= 6.39, P < .01; eta2= .06). Passive attitudes level of private bank employees was significantly higher than public bank employees (means; 5.45 (s=.84), 5.12 (1.12); F1-135= 6.39, P <.01; eta2= .04). Social dominance orientation of private bank employees was also higher than public employees (means; 50.28 (s= 12.35), 44.17 (15.65); F1-135= 6.39, P < .01; eta2= .04). The findings of this study were discussed within the context of literature.

The relationship between attitudes toward social media and social support in Japanese university students

Masataka Yoshihara Kio University, Japan; Ritsuko PhD

In this investigation we conducted a questionnaire survey administered to Japanese university students (N=169) with the aim of clarifying the relationship between attitudes toward social media and social support. The factor analysis of attitudes toward social media yielded 3 factors: self-esteem, safety and misrepresentation. Active social media users scored significantly higher on the categories of self-esteem and safety. As a result of this partial correlation analysis, social support demonstrated to be positively correlated with safety as well as negatively correlated with misrepresentation.

Emotional expression recognition: Evaluative associations or stereotype associations?

Yancong Zhang School of Psychology, China; ChuZHANG; Yan QU; Chao QI; Bin Zuo School of Psychology, China

By adopting the comparative context experimental paradigm used by Bijlstra et al. (2010) and programming with E-prime 2.0, this study explored whether social categorisation processes influence emotion recognition by evaluative associations or stereotype associations. 85 subjects were randomly assigned to comparative context conditions including a dual-valence comparative context condition in which participants categorized happy versus angry, or happy versus sad expressions and a single-valence comparative context condition in which participants identified angry versus sad expressions. Participants were asked to identify and classify the two emotional expressions. In study 1, cartoon subjects were presented to participants. The single-valence comparative context condition, subjects identified sad expressions displayed on female targets faster. (2) In the dual-valence comparative context condition, subjects identified positive emotions displayed on female targets. (3) In the dual-valence comparative context condition, subjects identified sad expressions displayed on men targets faster, whereas in the single-valence comparative context conditions, subjects identified sad expression displayed on female targets faster. (3) On the response to angry expression, there was no difference between the dual-valence and single-valence comparative context conditions. The results indicated that when the valence of emotional expressions does come into play, that is to say, the valences are different, evaluative associations influence emotion recognition. When the valence of emotional expressions is the same, recognition facilitation occurs for stereotypically associated discrete emotional expressions.

In or out of the research situation: The case of ‘equal status’ in contact theory

Buhle Zuma University of Cape Town, South Africa

With particular focus on the South African context, this paper explores the optimal contact condition of ‘equal status’, stipulated in Contact Theory (Allport, 1954). Pettigrew (1973, 1998) argues that Allport meant ‘equal status’ in the research situation and not that people should have equal status prior to coming into the research situation. This is the accepted view in Contact Theory. This view allows for suspension of real differences and inequalities between social groups while they are research participants in the laboratory, or other equivalent situations. Yet people do not live their lives in the laboratory, and therefore the overlooking of real life inequalities is a glaring theoretical limitation. It is argued that socio-economic class is a crucial base for life chances, and for living a dignified life, and is thus salient in the relations between social groups wherever they occur. Race and socio-economic status are closely linked in South Africa, and differences in status in contact situations should not be downplayed. All this raises questions about the usefulness of Contact Theory. More broadly, it also raises questions about the aims and role of social psychological theory.

Session Type: Posters

Relationship between seating behaviour and interpersonal distance in Japanese undergraduates

Kenta Abe Gakushuin University, Japan

In social interactions, interpersonal distance is an important aspect of nonverbal behaviour, and seating positions in a university classroom provides a variety of information about individual students. There have been many laboratory experiments and projection methods in recent studies. However, there were few studies on seating positions in real situations. The aim of this study was to observe and investigate Japanese undergraduates’ seating behaviour in a natural setting. Seating positions were surveyed continuously for nineteen days. On each day, the observer recorded seating behaviours in a university computer room for an hour. Three hundred and thirteen students, 131 males and 182 females, were monitored in this study as the subjects. The observed items of information are as follows: The position of the seats chosen, the order of selected seats, and occupation time for each seat. Results revealed the following. (1) Seats near the ends were most frequently chosen. (2) When the seat at both ends was occupied, the vacant seat 1 or 2 seats away was occupied next. (3) The subject who occupied the seat at both ends tended to stay for a long time. The present study suggests the existence of the optimal interpersonal distance. The
results suggested that the students who selected the seats at the ends had sufficient interpersonal distance and felt comfortable compared with students who chose other seats.

**Influence of locus of control, perceived self efficacy and alcohol intake on risky sexual decision making among undergraduates**

Olukayode Afolabi Adekunle Ajasun University, Nigeria; Joan Obuseh

This study examined the influence of locus of control, perceived self efficacy and alcohol intake on risky sexual decision making among undergraduates. One hundred and thirty (130) participants residing and schooling in Ekpoma, Edo State, Nigeria took part in the research. They consisted of 67 (51.5%) males and 63 (48.5%) females. Three hypotheses were tested. From the results, it was found that there was a significant interaction effect of locus of control and perceived self efficacy (F = 2.785, df = 120, p < 0.05). It was recommended, among other things, that individuals be taught how alcohol intake, locus of control and perceived self efficacy can affect their relationship appraisals. This will in turn affect their cognition during a sexual encounter and ultimately lead to a better sexual decision making.

**Dating violence victimisation among Japanese High school girls and late 20s women**

Miyuki Aiba University of Tsukuba, Japan

The purpose of the current study was to identify the dating violence victimisation among Japanese adolescents, and to examine differences between high school girls and late 20s women in this victimisation. 430 high school girls (15~18 years) and 407 late 20s women (25~29 years) in Japan, responded to the internet survey. They completed self-report measures of victimisation in dating relationships (physical violence, emotional violence, economic violence, social violence, and sexual assault). Results indicated that 68% reported experiencing some form of dating violence in dating relationships. Emotional violence was the most experienced, and sexual assault the most painful. Comparison of the experiences of teenagers with those in their 20s, showed that late 20s women experienced significantly more of all kinds of violence than high school girls. In contrast, the degree of afflication had no significant difference between late 20s women and high school girls. The results showed that the most painful victimisation was different from most frequently experienced victimisation. Women in their 20s experienced more violence because they had many and various romantic experiences.

**Essential beliefs about mental disorder groups: natural vs. etiulative categories**

Eva Arino-Mateo University La Laguna, Spain; Armando Rodriguez-Perez, Veronica Betancor-Rodríguez

Recent research has shown that people perceive social categories in terms of fixed and underlying realities. Belief in the fixity of features and categories, not only has been a focus of research in the tradition of the implicit theories of the person, but has also been discussed in research on psychological essentialism (Gelman, 2003). The objective of this research is to analyse the essential beliefs from various mental disorder groups and to observe if lay people essentialise more to some groups than to others, and under which dimension it is done – the natural or the etiulative essentialist dimension. In the research presented, data are analysed from four questionnaires administered to 216 people which included a list of 20 mental disorder stigmas estimated through four dimensions: Biological basis, immutability, discreteness and informativeness. The cluster method that was used is the between-group linkage and the measure is based on squared-Euclidean. The results establish a clear distinction between two types of categories: Natural and artificial. Furthermore, this essentialist categorisation relates to similar observable or superficial characteristics of these social groups with their deep features. Thus, senses of surface features generates a mental representation of the category and its components.

**Social support for parents with multiple exceptional children and multiple normal children**

Ali Akbar Arjmandnia University of Tehran, Islamic Republic of Iran; Keivan Kakabaraei; Gholam Ali Afroz

The purpose of this study was to compare the perceived social support in parents with more than one exceptional child, and parents with more than one normal child. In this ex-post facto research, the parents, n=800, (400 with exceptional children, and 400 with normal children), were selected by random and multi-stage sampling. They responded to the Multidimensional Social Support Scale (MSPSS, Zymth, 1988). Analysed data, with multivariate analysis of variance, showed that there are significant differences in three dimensions of social support (family, friends, others) between the two parent groups. Results show that parents of exceptional children had lower scores on the all dimensions: family, friends and others.

**Sarcastic intent: Funny or fearful?**

Dawn Blasco Pennsylvania State University, United States of America; Ashley Kerr; Victoria Kazmerski; Bryan Fleeson; Robert Fogle

A large body of research has examined the common situation where one thing is said in order to express another. Nonliteral language, such as metaphor, has been explored in depth, but sarcasm has been less studied. Sarcasm understanding relies on the consideration of social and cultural factors which are often ignored in models of language. Some have hypothesised that sarcasm is used to mute a criticism by infusing it with an element of humour. Others have focused on sarcasm as one aspect of relational aggression or bullying. We examined how college students perceived sarcasm. In Experiment 1, we found that hearing a word with sarcastic prosody while viewing a face created the perception of bad intent. In Experiment 2 we added contextual information and asked participants to read short texts in which a remark is made that, based on the context, is intended as either sarcastic or sincere. Participants were asked to rate how well faces with different emotions (Sad, Angry, Disgusted, Neutral, Surprised, Happy) matched the speaker’s intent. In addition, they completed measures of personality, relational aggression, and romantic relationship attachment. Gender emerged as a key factor in perception of intent, with male faces more likely to be perceived negatively in sarcastic situations. There were correlations between the tendency to use sarcasm and the Big 5 Personality factor agreeableness. These data support interactive models of non-literal language processing, in which social and cultural factors serve as early-acting constraints on interpretation.

**The model of student perceived professors epistemic authority**

 Solveiga Blumberga RISEBA, Latvia

The study analyses the social epistemology issue of transmission of knowledge in the context of social psychology, essentially focusing on authority as an attitude, and on an analysis of the structure of authority and situational structuring of authority. The aim of the study is to explore the epistemic authority of professors in institutions of higher education, as perceived by students of various study areas. The concept of epistemic authority has been used to pursue the aim (Raviv, Bar – Tal, Raviv, Abin, 1993; Kruglanski, 2005; Hepburn, 2006; Assmuth, Svennevig, 2009; Glenn, LeBaron, 2011). Exploring epistemic authority is related to exploring the degree of trust in epistemic authority (Kruglanski, et al., 2005). An epistemic authority study methodology including three interrelated surveys has been used in the study (Raviv, Bar – Tal, Raviv, Abin, 1993). Results showed that professor authority has a larger importance in student professional socialisation, cognitive and cognitive emotional aspects. Differences between the three areas of student views on professor epistemic authority were observed only in some cases. It was discovered that whether students acknowledge the professor as authority or not, affects reliance on information provided by the professor. However the overall reliance level is medium low, which proposes need to further research such situational causes.

**Risk determinants for alcoholism in Brazilian prison employees**

Juliana Campos UNESP - Universidade Estadual Paulista, Brazil; Valeria Schneider; Joao Maroco

The objective of this study was to assess the demographic and psychological factors that contribute to the risk factors for alcoholism, in 336 employees of two Brazilian prisons. The Alcohol Use Disorders Identification Test (AUDIT), the Brief-Cope, the satisfaction and social support scale (SSSS) and the Maslach Burnout Inventory - General Survey (MBI-GS) was used. A structural equation model was developed to assess the contribution of demographic, work related and psychological factors (Burnout, coping strategies and social support) to the risk for alcoholism. The instruments presented an appropriate adjustment to the sample (AUDIT: X2/df = 3.190, CFI = 0.983, GFI = 0.985, RMSEA = 0.081; Brief-Cope: X2/df = 1.631, CFI = 0.962, GFI = 0.920, RMSEA = 0.043; ESSS: X2/df = 2.899, CFI = 0.900, GFI = 0.913, RMSEA = 0.077; MBI-GS: X2/df = 2.864, CFI = 0.955, GFI = 0.915, RMSEA = 0.075). The variables included in the model explained 38% of the variance of the risk factors for alcoholism. The psychological
variables and labour had \( \beta \) close to zero. There was significant contribution of gender (\( \beta = 0.287, p = 0.004 \)), religion (\( \beta = 0.171, p = 0.027 \)), smoking (\( \beta = 0.286, p = 0.002 \)) and alcohol intake (\( \beta = 0.838, p = 0.001 \)). The risk factors for alcoholism was significantly associated with demographic variables.

Implicit social comparison through self-other substitution and its role in behaviour change

Adam Chesterman
Université de Nîmes, France

When dealing with "sensitive" objects, studies have observed a mask/unmask phenomenon of certain elements of social representations: Negative opinions are masked in the first person, but unmasked in the third person (substitution). This phenomenon either corresponds to a drop in normative pressure, or a social comparison process allowing people to positively value themselves. Studies indicate that substitution drives people to adjust their behaviour to what is socially desirable. The present study aims to compare substitution with explicit social comparison, using one normative and one non-normative object (environmental awareness and collective gardening). We expected a devaluation of others through substitution and positive self-evaluation in the case of social comparison. 69 first year students participated, and were divided into three groups: Substitution, social comparison and standard. By using two questionnaire results show that individuals seem more favourable to both objects when submitted to substitution or social comparison paradigms. We observed a devaluation of others through substitution and positive self-evaluation through social comparison, but only in the case of environmental awareness, seemingly a normative object when compared to collective gardening. Self-other substitution seems to only induce social comparison in the case of normative objects. If this is not the case, individuals have no reference point from whence to compare. These results put into question the use of self-other substitution in the field of behaviour change, in favour of explicit social comparison, and drive us to develop a technique to effectively measure object normativity.

A description of the network of relations in an intergenerational research project

Johannes W Cilliers
North-West University, South Africa; Johannes Cilliers; Vera Roos

This presentation aims to explore the perceptions of members of two generations (older and younger people) about whom they regard as part of their intergenerational network. It is conceptualised that the focus of intergenerational relations is not clearly spelled out. The theoretical framework that informs the study includes intergenerational positions such as solidarity, ambivalence and conflict. In this research 18 white Afrikaans speaking people older than 60 (5 male), and 11 white and two coloured Afrikaans speaking students (one male) from NWU, aged 20–30 years, participated. Convenience samples were used. The participants made visual presentations (the Mmogo-methodTM, Roos, 2008) to describe whom they perceive as part of their intergenerational network. After the visual presentations an informal group discussion was held to obtain more in-depth knowledge. Visual and textual data were obtained and analysed thematically. Findings revealed that, both the older and younger people, when asked how they experience their relations with the other age-group, focused on intimate family relations (grandchildren and grandparents) and not on relations in general. This may have certain implications namely that, biased conclusions in terms of relations in general may result. Furthermore, if in fact the intergenerational relations in practice are merely focused on intimate family relations, the building of positive relations with other community members in general, may be hampered. It is recommended that data like this should be interpreted with caution and, for the sake of general well-being, the building of wider collective relationships should be encouraged in western cultures.

Implicit social comparison through self-other substitution and its role in behaviour change

Adam Chesterman
Université de Nîmes, France

These results put into question the use of self-other substitution in the field of behaviour change, in favour of explicit social comparison, and drive us to develop a technique to effectively measure object normativity.
in their collective memory, the main transformations in the landscape of this city. Interviews, tests for psychological assessment, and collection of material imagery will be instrumental in the research methodology employed. The largest goals of our project are the creation of a core interdisciplinary study of the memory in the rural context of Rio de Janeiro, as well as the creation of a digital collection with images testifying of changes in urban form of Seropédica.

Youth’s representations about terrorism
Alena Falomeeva
Moscow State University, Russian Federation

In the first phase of the study (2011), we conducted a series of in-depth interviews (12 women and 10 men at the age of 18–24 years, in Moscow). This study helped to identify several ideas that young people have about terrorism and the terrorist threat, and helped to make some meaningful conclusions. (1) Young people’s ideas about terrorism are not uniform. There is a generalised image of an anonymous enemy, acting in an “unpredictable and extremely cruel” way. (2) Interpretation of ideological bases and terrorists’ demands are grouped around five vectors: a manifestation of unwarranted aggression, fighting for a fair distribution of resources (poor against the rich, East against West), religious intolerance, ethnic conflict, reaction to the actions of Western politics. (3) Responsibility for terrorist acts goes to specific terrorist organisations (their leaders), or the state, which cannot ensure the safety of citizens, and the forced harsh measures which the state carries out on the organisers of the attacks, cause new waves of violence. (4) The consequences of terrorist attacks: the psychological and physical harm, fear and negative emotions, xenophobia, the growth of aggression and discrimination, restriction of democratic freedoms, threat of new terrorist attacks, destabilisation of the economy etc. (5) Perceptions of the threat of terrorism supported by feelings of vulnerability, loss of temporal perspective, non-localised anxiety, lack of control over their lives.

Evaluation of students adaptation at CESUCA’s college: An analysis of career identification and institution satisfaction
Marcia Franco Cesuca Faculdade (INEI, Brazil); Eva-Nisa De Brum; Fernanda Hartmann

An institution that seeks quality needs to establish and implement provisions and actions that help the student to integrate satisfactorily in the context of higher education, and also assist him/her in his/her professional and personal development. This study aimed to evaluate the suitability of Psychology students of the CESUCA (Higher Education Complex Cachoeirinha - Brazil) through a longitudinal study. The instrument used was the QVA-R (academic experiences Questionnaire: Revised, Almeida & Ferreira, 1997), which allows an assessment of the experience of college students. Our analysis focused on only two dimensions: career and institutional. The sample consisted of 33 students, evaluated when attending the second and fifth semesters, in a comparative analysis. There was an increasing identification with the course, revealing that as they evolve in the course, they are more identified with Psychology, believe they have made the right choice, and that the Psychology course enables them to have a professional achievement. Although they appeared to be more critical about the institution, the students revealed that, even if they could change the institution, they would not do that. The results provide everyone involved in the process of higher education with a lot of information and offer the Core Teacher Structuring (specific group of teachers who evaluated the course curriculum) elements to promote ideas and improvements, evaluating the suitability of the course in relation to demands in the current context.

Exploring interpersonal relationships of college students
Dongqin Fu
Central China Normal University, China; Bin Zuo
Central China Normal University, China; Yan Qu
Chuanguo Al Central China Normal University, China; Guan Quan

With the improvement of living standards and the reforming of the university system, as well as the income gap in regional economic development, there are many impoverished college students who are unable to afford the tuition fees. Some problems have appeared among them due to poverty, such as inferiority, interpersonal sensitivity and so on. This paper with three 22 between-subjects designs explores the effect of poverty and inferiority on interpersonal relationship of college students, which investigate the interpersonal relationship of 100 poor college students and 200 college students. Study 1 discuss the influence of poverty on the interpersonal relationship of college students by using the interpersonal relationship rating scale. Study two makes a diagnosis and analysis of inferiority of impoverished college students through measuring inferiority psychology diagnosis. Study three probes the effect of inferiority on interpersonal relationships by having a between-subjects design. The main findings of this research were stated as follows: Poverty has an important influence on the relationships of college students; poverty is the main reason for the generation of students inferiority; inferiority play a role of mediating variables in the influence of poverty on interpersonal relationships of college students. Through these researches we investigate the interpersonal problem of poor college students, and take effective intervention methods on their psychological adjustment. The principle aim of this study is to help students solve the economic and psychological issues so that they can develop healthily.

Five personality factors and intimacy attitude
Fakhteh Ghahami
Payamnour University, Islamic Republic of Iran; Azizollah Tajik Esmaeili

Associations between the personality variables of the five-factor model and intimacy attitude variables (Inclination for intimacy, Abstinence from intimacy, Physical and sexual attractiveness and Fear of intimacy) were explored. Participants (N=200) from committed relationships were administered the NEO Personality Inventory-Revised, Intimacy Attitude Scale-Revised and a demographic questionnaire. Correlation and regression analyses revealed that neuroticism was negatively associated with intimacy attitude. The association between Extraversion and intimacy was completely mediated by possessive for females but not male. Openness, agreeableness and conscientiousness are associated positively with intimacy but with different patterns in female and male. Implications of these findings are discussed.

Tolerance and moral judgment in college students of Lima
Mirian Grimaldo
Universidad San Martín de Porre, Peru; Cesar Merino

The aim of this study is to establish the relationship between each factor of the tolerance and the moral judgment in a sample consisted of 301 college students from the first cycle of a public university, according to sex and employment status (working and not working) from Lima, using the Morally Debatable Behaviours Scale from Harding & Phillips (1986) and the Sociomoral Reflection Objective (SROM) from Gibbs et al. (1984). We found a moderate correlation between factor of dishonest behaviour towards permissiveness and morals in the group of working students. No relationships were found between the factors of permissiveness and moral men, women, or the group of students who do not work. We discuss the importance of the work activity during university life. There the students learn not only about the specific activities of their profession, but also incorporate the necessary skills to develop as citizens.

Heterosexuals’ attitudes toward gay men: Classical and modern forms to express sexual prejudice
Jacopo Grisoli
University of Florence, Italy; Cristina Stefaneli

Negative attitudes toward gay men are considered one of the most deeply held prejudices in European countries. The way to express prejudice has changed, according to research that underline social norms. Now it is considered blatant prejudice and unacceptable. We examine if attitudes toward homosexual male people consist of one or two forms. Classical and modern prejudice, where the classical is blatant and the modern is more subtle and covert, were analysed. Using a group of Italian university students, self identifying as heterosexual, we administered a questionnaire with self report scales tapping classical sexual prejudice, modern homonegativity, Social Distance, Social Dominance and Authoritarianism. As hypothesised, participant’s level of modern male homonegativity correlated positively with their level of old-fashioned prejudice, social distance, authoritarianism and social dominance. The results also supported and revealed that modern and classical forms are distinguishable. We made a further examination of the discriminant validity of the scales on the basis of the participant’s gender. These results suggest that the prejudice toward gay people can be expressed by different forms. The findings integrate the research on attitudes toward male homosexual people with the main body of attitude research, in particular with models of attitude change and expression of prejudicial beliefs. Overt and blatant measures of homosexual prejudice are probably now not suited as to modern forms that offer a more sensitive indicator of homonegativity attitude.
Trust repair process: The effect of implicit theories and attributional styles
Vue Guo-An Nankai University, China; Hua-Wei Ma; Qi Yao
Although the positive effect of trust in organisations has been widely recognised, trust is easily violated and trust violations are more and more common in organisations. Previous research on trust repair mostly focuses on trustees’ repair tactics (e.g., apology and denial) and rarely considers trustees’ traits, or taking both parties’ traits into account. The present study aims to investigate how implicit theories of trustor and attributional style of trustee influence the effectiveness of trust repair. 2 (implicit theories of trustor: entity vs. incremental) × (attributional style of trustee’s apology: internal vs. external) between-subject experimental design was adopted and a simulated scenario, involving a context in which a employee violated his employer’s trust by job-hopping and wanted to return, was used. 520 undergraduates participated in the study. The findings show that the main effect of attributional style of trustee’s apology on the effectiveness of trust repair was significant. That is, the internal attributional style of apology was more effective than the external one. Furthermore, there was no significant effect of implicit theories, but the interaction between attributional styles of apology and implicit theories of trustor was significant. For trustor with incremental theory, the effect of internal attributional style of apology on trust repair was more effective than that of external one, whereas for trustor with entity theory, the above difference was not significant. The present research can enhance our understanding of trust repair process from the perspective of interaction between individual and context.

Mobbing in the academia: Understanding and predicting psychological violence in higher education
Benicio Gutierrez-Dona Universidad Estatal a Distancia, Costa Rica; Maria de Los Angel Carrillo
This study investigates the prevalence and predictors of mobbing in the academic world. It examines the effect of sex, job position, job condition, and discrimination experiences on 24 mobbing behaviours and three patterns of mobbing strategies, namely, attacking the victim’s (a) social communication and integration, (b) personal integrity, and (c) occupational or professional capabilities. Data was gathered from a randomized sample of N=639 university academics, administrators, and officials. 24 selected items of the Leymanns Inventory of Psychological Terrorism were factor analysed to identify mobbing patterns. A set of ANOVA and multiple regressions was calculated to identify predictors. Results showed that job position and job condition explained significant differences in the experience of mobbing, whereas no significant effects emerged from analyses defining sex as a predictor. Findings also revealed that discrimination due to victims’ job achievements, aging, political beliefs and professional envy accounted for 52% of the variance in attacks to victims’ social communication and integration. Discrimination due to victims’ education and political beliefs accounted for 29% of the variance in attacks to victims’ personal integrity. Finally, discrimination due to victims’ education and religious beliefs accounted for 29% of the variance in attacks to victims’ occupational and professional capabilities. Results are discussed in the light of Heinz Leymann’s theory of mobbing, considering mobbing prevention, early management interventions and vocational rehabilitation.

Multilevel approach to combat depression among high school students: Social capital and health
Michimasa Hago Nihon University, Japan; Tadakki Tomie; Shinji Sakamoto Nihon University, Japan; Yui Sakano
This study examines the relationship between depression, cognitive behavioural factors (e.g. cognitive social capital, social skills, and behavioural activation), and social environmental factors with regard to Japanese high school students. Kawachi (2008) argues that social capital is conceptualised as the resources available to the members of social groups. In particular, cognitive social capital, which includes shared norms, values, attitudes, and beliefs, predisposes people towards mutually beneficial collective action. Cognitive social capital is believed to enhance mental health. We collected data (N=1,217) through a random sampling method in Hokkaido (northernmost of the four main islands of Japan) and analysed the data through a multilevel approach (i.e., ML-SEM). The multilevel approach is a statistical technique which involves the use of a multilevel covariance structure model. In the modelling results, factors at the individual level that were significantly related to depression were Deficient Breakfast (p<.10), Sleeping (p<.01), Extra-curricular Activities (p<.01), Behavioural Activation (p<.01), Neighbourhood Cognitive Social Capital (p<.01), and School Cognitive Social Capital (p<.01), while the factor at the local level that was marginally significantly related to depression was the lack of Amusement Stores (p<.10). Coleman (1988) argues that social capital is a resource, which can be used to introduce social structure in the rational action paradigm. The multilevel approach suggests that we need to consider behavioural cognitive factors as well as social environmental factors.

Psychological roots of generalised intolerance
Katarzyna Hamer Chodkowska University, Poland; Hanna Hamer
The authors searched for psychological roots of generalised intolerance toward different groups usually stereotyped, discriminated and toward whom people have prejudices, like elders, women, homosexuals, addicts, people with different nationality or different attitudes toward moral dilemmas and others. In a current study authors focused on possible predicting role of personality traits, empathy, self-esteem and social identifications. Measures used in the study included Interpersonal Reactivity Index by Davis and NEO-Five Factor Inventory by Costa and McCrae, Self Esteem Scale by Rosenberg, Identification With All Humanity Scale by McFarland and Generalised Intolerance Scale by H. Hamer. 85 students were tested, 19–50 years of age, with places of residence from small villages to big cities, 46% males, 54% females. The results proved a crucial role of self-esteem, openness to experience, identification with friends and empathy (especially perspective taking and personal distress) as characteristics which explained together 60% of the variance in the strength of generalised intolerance. Intolerance was also connected with reluctance to prosocial behaviours: Participating in charities and in voluntary activities. The results are discussed in the context of future studies.

An empirical research on the well-being and its influencing factors of the rural left-behind elderly
Anming He School of Education Science, China; Yajing Xie; Peng Wu; Xiaoyong Hu School of Education Science, China; Quiping Hui
In order to explore the well-being and its influencing factors, such as variables of demography, gratitude and emotional intelligence, of the rural left-behind elderly, the 153 rural elderly whose children work as temporary labourers outside, were selected to fill in questionnaires, and the methods of variance analysis, correlation analysis and regression analysis were adopted. The results indicated that the rural left-behind elderly were satisfied with their lives in the main, influences of children connection and condition of health had significant difference on well-being, those who were healthy and usually connected by their children had higher well-being, the interactions of gender with condition of health, spouse with health conditions and connection with condition of health were significant. Gratitude was significantly positively correlated with the well-being of the rural left-behind elderly. Gratitude influenced well-being of the elderly through the mediating effect of emotional intelligence.

Exploring the blood relations and friendship strategies of help
Min Hu Central China Normal University, China; Tingting Teng Central China Normal University, China; Quan Gan; Bin Zui Central China Normal University, China; Yan Qu
Chinese interpersonal communication has two basic kinds of forms: Relatives and friends. When a person is in need of help, the motivation and forms of the help that come from family and friends are different. Researchers suppose that relatives are more willing to provide a great significant help to tide over the difficulties, and do not have very great patience about the real trivial things. Friends tend to build a reciprocal communication mode they could afford, and are more willing to show helplessness for very important, especially with a large amount of money, requirements. Firstly, we provide a definition for the most representative relationship of relatives and friends. Second, this paper explores the motivation of help to different people with the form of questionnaire for 800 people in all kinds of jobs. Thirdly, the experimental design divides 200 people into four groups. The first group of people decide how much money they will provide for relatives with a certain amount of money. The second group people decide how frequency they will provide help to different people especially with a large amount of money, require-ments. More attention should be paid to the deep reason of these problems, and how to handle kinship and

Social Psychology
friendship so as better to receive more harmonious interpersonal relationships.

The role of emotional intelligence in gratitude and subjective well-being of the rural left-behind elderly: Mediator or moderator? Qiuping Hui Xinyang Normal University, China; Anming He Xinyang Normal University, China
In order to explore the relationship and mechanisms of gratitude, emotional intelligence and subjective well-being of the rural left-behind elderly, 153 rural elderly people (whose children work as temporary labourers outside) were selected to fill in the Gratitute Questionnaire-6 (QQ-6), Memorial University of Newfoundland Scale of Happiness (MUNSH), and Emotional Intelligence Scale (EIS). Statistical methods, including variance analysis, correlation analysis and hierarchical regression analyses, are applied. The results indicated that: (1) Levels of gratitude, subjective well-being and emotional intelligence of the rural left-behind elderly were relatively high. (2) Gratitude was significantly positively correlated to well-being of the rural left-behind elderly, (3) gratitude influenced subjective well-being of the elderly through the mediating effect of emotional intelligence, and (4) emotional intelligence did not act as a moderator, and could not change the intensity and direction of the relation between gratitude and subjective well-being significantly. Thus, it seemed that emotional intelligence of the rural left-behind elderly plays a mediating role between gratitude and subjective well-being.

Individual differences in construal level and decision making
Takashi Ideno Graduate School of Waseda University, Japan; Kazuhisa Takekura; Shigetaka Okubo; Yuki Tamari; Shuzo Abe
Previous research of construal level theory (CLT) (Troe & Liberman, 2003), manipulated psychological distance or CL as independent variable. This research examined the relationship between individual differences in construal level and decision making. An internet survey was administered in Japan, garnering responses from 1600 participants. Our questionnaires consisted of 6 parts. Each part contained following items: (1) construal level scales (CL-scale) which reflected high/low-level construals, (2) decision-making scales (DM-scale) based on theories and well-known phenomena which indicated anomaly of decision-making, (3) scales for measuring respondents' time perspective (ZPTI short form), (4) Behavioural Identification Form, (5) judgment task, and (6) Regret and Maximisation Scale. Three latent factors were estimated from construal level scale (16 items) by factor analysis: (1) goal-oriented, (2) state dependency, and (3) simplification. Goal-oriented factor and simplification factor was mainly reflected high-level construal items, and state dependent factor reflected low-level construal items. Then 5 latent factors were extracted from decision-making scales (26 items) (i.e. deliberative decision, consistency, satisficer, uncertainty averse, risk seeking). Correlation analysis found that medial correlation between goal oriented (CL-scale) and deliberative decision (DM-scale) (r=0.58, p<0.001), and between goal oriented (CL-scale) and consistency (DM-scale) (r=0.42, p<0.001). State dependency (CL-scale) had medial correlation with deliberative decision (DM-scale) (r=0.58, p<0.001). Our results suggested that both high and low CL have close relationships with a deliberative aspect of decision making.

Selective attention can eliminate the mere exposure effect
Akiko Kamoda Bunkyo University, Japan; Nobuo Usui; Daisuke Yoshino
The mere exposure effect defined as the increased preference for a stimulus, following its repeated exposure (Zajonc, 1968). In this study we examined whether attentional inhibition for stimuli can eliminate the mere exposure effect. In experiment 1 (n=59), photos of four items from each of five categories (scissors, mechanical pencil, glass, jewellery, and bouquet) were presented randomly at frequencies of 0, 1, 5, and 10 times. These stimuli were presented at 1000 ms separated by 250 ms intervals. In the following task, participants were presented with the two stimuli from the same category and asked to indicate which stimulus they preferred. In experiment 2 (n=53), a filler task, hitting a space key as soon as possible, only when they found photos of cats, was added to experiment 1. The results showed that repetition without the filler task increased the preference for repeatedly presented stimuli, but did not show this tendency with the filler task. Selectively paying attention to the filler stimuli could mean the inhibition of attention to the experimental stimuli. Raymond, Fenske, & Tavassoli (2003) showed a similar effect of attentional inhibition with a rating scale and suggested that attentional inhibition may serve to reduce emotional salience of these stimuli. Our studies showed that the effect of attentional inhibition could be found at a behavioural level in the selection task between two items. It is suggested that attentional inhibition for stimuli can eliminate the mere exposure effect.

How do undergraduate and graduate students act in time of disaster?
Kimino Kawasumi Gakushuin University, Japan
The aim of this study was to elucidate how people act, and what information people seek, in times of disaster. Two hundred and twenty undergraduate and graduate students living in a metropolitan area were asked to answer the questionnaire, and their replies were analysed. The questionnaire included their action right after the Great East Japan Earthquake. Because all of them had no full-time job and were in the period of spring break, this investigation revealed how people without any time constraints had behaved just after the earthquake. Immediately after the disaster, the transportation systems were not functioning, and it was difficult to get information about traffic network, the seismic size, and so forth. The students tried to gather information by various means. This study also shows their way of obtaining information for making a decision whether to go home or stay out. Results are as follows: the behaviour depends on where they were at the 3/11 earthquake, and each of difficulty and necessity to go home were positively associated with their accessing the Internet immediately after the disaster. On the other hand, the quantity of information on the spot worked negative...
Societal judgments made toward pregnant women with stigmatised illnesses
Karen Lawson University of Saskatchewan, Canada; Melanie Bayly; Emma Cey
The present study examined social judgments made toward pregnant women with stigmatised medical conditions in terms of parental fitness and deservedness of social services and financial aid using attribution-affect-action (A-A-A) theory (Weiner, 1980) as a framework. University students (N=160; 124 female) were randomly assigned to read one vignette describing a pregnant woman whose medical condition varied in terms of the level of associated stigma (HIV, obesity, skin cancer, diabetes) and locus of causality (internal, external). Across medical conditions, an external locus of causality elicited more positive judgments toward the pregnant woman with respect to deservedness of social/financial services and ratings of parental fitness. Further, across all four medical conditions combined, attributions of blame were associated with higher ratings of disgust and lower ratings of sympathy toward the pregnant woman. In turn, sympathy was associated with higher ratings of the woman’s deservedness of aid, while disgust was associated with lower ratings on this variable, thus supporting the A-A-A model. Subsequent analyses revealed, however, that personal familiarity with the medical condition moderated the findings such that participants lacking familiarity evidenced the typical pattern of relations among the variables supporting the A-A-A model, while those that had personal familiarity did not. For these participants, neither the attribution of blame nor affective responses were associated with ratings of the woman’s deservedness of social resources. The role of personal familiarity in moderating responses to individuals with stigmatised medical conditions is discussed.

You should not feel that way! Boundaries of the emotional victim effect through expectancy violation
Kim Lens INTERVICT, Netherlands; Antony Pember- ton; Janne van Doorn; Stefan Bogartz
Research has shown that an emotional victim is perceived as more credible than a victim who behaves in a controlled manner. We explored possible boundaries of this ‘Emotional Victim Effect’ and examined the mediating role of Expectancy Violation. Seventy-nine students participated in this experimental study. Participants were randomly assigned to either a high crime severity (rape) or a low crime severity (threat) condition and had to read a highly emotional Victim Impact Statement. We extend previous research in three important regards. First, we expose negative effects of delivering a highly emotional victim impact statement, and demonstrate a mediating effect of expectancy violation: Observers expect a victim of a severe crime rather than a less severe crime to deliver a highly emotional victim impact statement, and in turn, base their credibility judgments on these expectations. Second, this study showed that a ‘mismatch’ between the observers’ expectations and a victim’s emotional demeanor negatively influences the observer’s attitude towards the victim. More specifically, incongruity leads to victim derogation and less sympathy for the victim. Third, incongruity can have important implications in the criminal justice procedure, in a sense that it could lead to negative effects on the extent to which observers would think that the described consequences should be taken into account when determining the punishment of the offender. In sum, we conclude that also victims who deliver a highly emotional Victim Impact Statement run a risk of secondary victimization by their environment.

Psychological adjustment of Vietnamese immigrants in South Florida, USA
John Lewis Nova Southeastern University, United States of America; Thuong Truong
This study examines the level of acculturation and the concomitant factors within the Vietnamese immigrant population in South Florida using the Nova Acculturation Scale, Vietnamese Revised (NAS-VR). Previous national data have shown that Vietnam is the fourth largest growing ethnic group in the U.S., but the literature on the level of acculturation or well-being of these Vietnamese immigrants, especially in Southeastern Florida, is limited. In phase I of the study, researchers translated the Nova Acculturation Scale into Vietnamese. In phase II of the study, researchers recruited participants and administered the Vietnamese version of the NAS-VR at various cultural events and places. Phase III of the study will consist of analysing the data to determine the actual level of acculturation and integration of this group in the American society. It is anticipated that the level of acculturation is related to age, length of time in the United States, SES, and gender. Furthermore, the data from this study will be utilized to determine the Vietnamese immigrant’s cultural identity: Do the participants identify with the mainstream US culture, Vietnamese culture (monocultural identity), or a blend of both cultures (bicultural identity)? Comparisons of the Vietnamese American immigrants’ level of acculturation to other ethnic groups and to other Vietnamese groups in the U.S will also be examined.

Interpersonal perception and relationship quality in university dormitory
Yuhui Li Renmin University of China, China; Fei Huang Renmin University of China, China
Twenty freshmen dormitories (18 6-person and 2 5-person dormitories) of a university participated in a round-robin design of interpersonal traits perception and its connection with relationship quality in their rooms. Both circumplex and traditional scales of interpersonal dimensions and both rating and
responses can explain extra variance in mathematical performance beyond explicit measures. Therefore, this study highlights the importance of adding AMP, a valuable way to measure automatic affective responses, to increase the predictive validity of performance.

Subjective well-being and locus of control: Moderating effect of personal belief in a just world
Ying Ma Peking University, China; Luning Ren; Lei Wang Peking University, China

Previous studies indicate that locus of control associates with subjective well-being (SWB), but the findings about this relationship are contradictory. Most research demonstrated that internal control related to SWB positively, while other research indicated adverse result. The present research aimed to clarify the mixed findings. We hypothesise that (1) the locus of control has significant correlation with SWB, (2) Personal Belief in a Just World (PBJW) moderates the effect of locus of control on SWB. PBJW is identified as the belief that the world is more just for me than generally. A total of 593 citizens from China were tested by questionnaire assessing SWB, PBJW, and locus of control. Multiple regression analyses revealed that individuals with internal control reported higher SWB. PBJW served as a moderator between locus of control and SWB: When citizens had higher scores in PBJW, the positive relation between internal control and SWB appeared more significant. Implications for theory, research, and practice are discussed.

A basic research on infidelity amongst contemporary adolescence in Japan
Koshi Makino JPA, Japan

In this study I conducted a questionnaire survey administered to Japanese university students (N=400) with the aim of understanding their experience of romantic love and infidelity. Their average age of participants was 19.09 years old. 52 students experienced infidelity out of the 400 participants. Results of the survey indicated as follows: (1) The experience rating of infidelity was 13.0 of the whole, and 17.4 of those having experienced romantic love. There was no difference based on sex. (2) Regarding infidelity, experienced people were reported to have had sexual relations with the others of the same age. (3) The main reason for infidelity is “sexual desire” in men, “attractiveness of the man” in women. The most frequent number of love affairs was 1 or 2 times. (4) The main reason of the end of infidelity was “feelings of guilt for the lover” in women.

The drawing power of crowds of different sizes and genders
Anum Malik Forman Christian College, Pakistan

The drawing power of crowds of different sizes and genders is a field experiment in social psychology that plans to investigate conformity in crowds. Inspired by the experiment conducted by Milgram, Berkowitz and Bickman (1969), the experimenter, Anum M. Malik, will use confederate crowds of different sizes and varying genders to gauge whether or not unaware individuals passing by a crowd have conformed or not. The stimulus (confederate) crowd will be exposed to an available population that is the individuals walking by in a busy marketplace (Liberty Market, Lahore, Pakistan). The crowd shall gaze upon a plain flag placed at the top of a building and the response of the bystanders will be recorded. There are three distinct hypotheses: the first is that the larger the stimulus crowd, the more likely the bystanders will adopt the gazing behaviour exhibited by the confederates. This gazing behaviour will be of two kinds: stopping and gazing up at the building or walking and adopting the gazing behaviour, both indicative of conformity. Bystanders may continue to walk on and ignore the situation, thereby not conforming. The second hypothesis states that the gender of the participants will affect the level of conformity and the third hypothesis states that the gender of the confederates will affect the level of conformity. After running 30 trials, trained judges will tabulate data using a set criterion. Statistical tests such as the ANOVA (linear contrast) and independent chi-square test will be run on the collected data and cautionary interpretations made.

Knowledge and attitudes in relation to HIV-AIDS in secondary schools: A comparatives study
Benvindo Maloa Mozambique; Marcos Pereira

The study’s aim is to analyse the knowledge and attitudes of students and teachers in Maputo and Niassa Provinces towards HIV-AIDS, at secondary schools where the Biz Generation program is being implemented as well as others schools where this program is not yet being implemented. In order to collect data, three instruments were used, namely, the social demographic questionnaire, Test of Scientific Knowledge of Aids (TCC AIDS) and Scale of Attitudes towards AIDS (EFA AIDS), 391 students and 66 teachers participated. The students from Maputo had more positive attitudes in all aspects on the EFA AIDS compared to the students from Niassa, although these students have obtained high levels of knowledge in the dimension of infection and treatment on the TCC AIDS. The students from schools where the program is being implemented had more positive attitudes than the students whose schools are not implementing the program. The students in whose schools the program is not being implemented achieved higher scores in the TCC AIDS than those in schools that are implementing the program in the infection and treatment dimensions. At the time present study was conducted no significant statistic differences were found on the TCC AIDS as well on the EFA AIDS on students and teachers in Maputo and Niassa, and neither between the ones that are currently implementing and those not implementing the program.

The causes of homelessness among young people in Prague
Jakub Marek Psychiatric Center Prague, Czech Republic; Marie Vagnerova; Ladislav Csemy

There are approximately 5000 homeless people living in Prague. One quarter of them are young people under 26 years. In order to determine the motivational structure we performed content analyses of in-depth interviews with young homeless people, analyses of answers to TAT pictures and evaluations of
Indian alphabetisation workshops: Exercising the otherness
Joao B. Martins Universidade Estadual de Londrina, Brazil; Grazielle Silva
This study aims to report the process of learning after observing the Indian school routine in the North of Paraná, Brazil, from a social, historical, cultural view, using the human development theory. In 2006, the Parana Estate Secretary for Education initiated a course for elementary school teachers (normal bilingual kaingang modality, under the auspices of Fundação Araucária - Paraná - Brazil, in an effort to enable new approaches to be developed, considering the importance of the learning process regarding the Indian people's values, along with the regular universal curriculum. The schools situated in Indian reservations, began to teach the Indian language concurrently with the Portuguese language. However, the research conducted at these schools showed that the results are not always positive, because the children find difficulty in learning both languages at the same time. In an effort to overcome this situation, a project was implemented to target the Indian daily routine and the process of alphabetisation inspired by the Vygotskian theories of social, historical and cultural development via workshops, where the alphabetisation experience and dynamics took place through teacher-oriented games. Thus, an intercultural education experience and dynamics took place through development via workshops, where the alphabetisation learning both languages at the same time. In an event, the impact of the event on the researchers and the impact of the researchers on the event. The aim of this research was to explore the experiences of the researchers participating as staff members in a particular group relations event, SAOT. Qualitative research using the hermeneutic paradigm was done. The data collected by the researchers during 2010 and 2011 was analysed through thematic analysis. Thematic analysis resulted in themes, for which working hypotheses were formulated, and integrated into the research hypothesis. The themes, working hypotheses and research hypotheses about the conscious and unconscious role of the researcher in a particular group relations event and the impact of the research component in a group relations event on the researchers, consultancy staff, the executive management and participants of the event will be presented.

Sarcasm in relationships: Hurtful or humorous?
Joslyn Mesing Pennsylvania State University, United States of America; Danielle Williams; Dawn Blasko
Sarcasm is an indirect form of speech used to convey a criticism. However, sarcasm is very ambiguous and therefore leaves the decoder of the conversation responsible for interpreting the speaker's intent. It has been found by previous research that several forms of sarcasm are used in communication and they are highly situational (Fiske & Glucksberg, 1989). The current study investigated the role of the speaker and listener's relationship status on the perception of sarcasm. Participants consisted of 31 male and 35 female undergraduate college students from the United States. Participants were asked to read scenarios that involved a conversation between two people who were in one of the three relationships: Romantic relationship, friendship relationship or stranger relationship. Each scenario ended with a comment that could be understood sarcastically or literally, e.g., "You are a great driver." Reading times were recorded for the scenario and the final comment. Participants were then asked to rate the scenarios on their degree of humour, sarcasm, insult, anger, and sadness on a scale of 1 (low) to 7 (high). Reading times showed that sarcastic comments took longer to process than literal comments. This effect was strongest in the stranger condition. The sarcastic scenarios in comparison to the literal scenarios were rated as more insulting and more humorous. This was true for all three relationship types.

Social support in spouses of alcohol abusers in an indigenous community: Qualitative analysis
Graciela Morales-Trujillo UNAM, Mexico; Guillermina Natera; Graciela Morales
The importance of social support and the relationship that it has with the health and wellbeing of people, has previously been demonstrated. It is therefore important to study vulnerable populations who are under chronic stress, such as living with an alcohol-abuser. In Mexico this perspective has not been delved into within the indigenous population. The objective of this study was to identify the social support that indigenous women have to combat stress, as a result of a husband who is an alcohol abuser, and to identify their main sources of support. We conducted a qualitative study based on grounded theory. The data were obtained through in-depth interviews, using the constant comparative method, and the number of interviews was determined by theoretical saturation. The greatest concern is the lack of economic resources, which is exacerbated by the husband's alcohol consumption, and the violence that they and their children experience. Other matters were infidelity and their husbands' jealousy, and the cultural context. It was observed that these women have little social support, and the use of social networks is minimal. It would therefore be important to develop interventions that help to strengthen their social networks and promote the use of those already in place, in addition to establishing standing programmes that focus on the mental health of this population.

Under the ethno-psychology approach, this cross-sectional study aims to distinguish how people perceive violence and the city in which they live, and whether this differs according to gender and educational level. This study used a sample of 450 women and 450 men, all of them students at public schools in Juarez, Mexico, ranging from 5th grade up to freshman year in college. The semantic differential rating scale was used to measure the connotative meaning of the terms “violence” and “my city.” Furthermore, a questionnaire was employed to measure the level of agreeableness when it comes to violence towards children, personal violence and military violence. Through the ANOVA test, it was possible to find a positive correlation between the meaning of the terms and the educational level. When evaluating the gender differences, there was a positive correlation between gender and the three modalities of violence, perception, evaluation and power and dynamics of the connotative meaning of the term ‘violence’ and the factor dynamics for the connotative meaning of the term ‘violence’ and for the factor dynamics for the connotative meaning of the term ‘my city.’ The only statistically significant interaction (gender/level of education) was found when examining the factor power of the meaning of the term ‘violence.’ It is intended that the findings of this study will help the decision-making process when it comes to acting upon, and preventing, violent behaviour that generates negative consequences in societal coexistence, by starting with a better understanding of the perceptual processes of a population.

Perceptions of violence in Juarez City: Psycho-socio-cultural meaning
Alicia Moreno-Cedillos University Aut. de Ciudad Juarez, Mexico
Alicia Moreno-Cedillos
Under the ethno-psychology approach, this cross-sectional study aims to distinguish how people perceive violence and the city in which they live, and whether this differs according to gender and educational level. This study used a sample of 450 women and 450 men, all of them students at public schools in Juarez, Mexico, ranging from 5th grade up to freshman year in college. The semantic differential rating scale was used to measure the connotative meaning of the terms ‘violence’ and ‘my city.’ Furthermore, a questionnaire was employed to measure the level of agreeableness when it comes to violence towards children, personal violence and military violence. Through the ANOVA test, it was possible to find a positive correlation between the meaning of the terms and the educational level. When evaluating the gender differences, there was a positive correlation between gender and the three modalities of violence, perception, evaluation and power and dynamics of the connotative meaning of the term ‘violence’ and the factor dynamics for the connotative meaning of the term ‘violence’ and the factor dynamics for the connotative meaning of the term ‘my city.’ The only statistically significant interaction (gender/level of education) was found when examining the factor power of the meaning of the term ‘violence.’ It is intended that the findings of this study will help the decision-making process when it comes to acting upon, and preventing, violent behaviour that generates negative consequences in societal coexistence, by starting with a better understanding of the perceptual processes of a population.

Deep roles: Are they real? A model of positive and negative interpersonal fantasies
Paul Moxnes AFF at NHH, Norway
In this paper I offer a model of seven bi-polar pairs of implicit organisational roles (deep roles) depicted...
as characters in European fairy tales: King vs Devil, Queen vs Witch, Crown Prince vs Black Sheep, Princess vs Whore, Wise man vs False Prophet, Slave vs Unfaithful Servant, and Hero vs Clown/Buffoon. The roles are framed on the four roles of the essential family (father, mother, son, and daughter) and its three good helpers (spiritual helper, material helper and epic helper). Fairy tale roles are not the customary language most psychologists favour. Nevertheless, this paper will demonstrate that characters from fairy tales are powerful archetypes for attributions—even projective identifications—laid upon individuals by their fellow group members. On the basis of 7234 individual deep role fantasies registered in 25 executive classes in a Norwegian business school, the deep role model of seven pairs of implicit organisational roles was confirmed. It seems reasonable to conclude that people navigate group space by constructing and consulting fairy tale role stereotypes.

Negotiating manhood among coloured men in the Western Cape
Jacqueline Mthembu University of Cape Town, South Africa; Floretta Boonzaier

It is increasingly recognised that the enactment of manhood endangers men and those around them. Participants of this study were men who reside in two low-income Western Cape communities. The purpose of this study was two-fold: firstly, to determine the relationship between conformity to traditional masculinity, gender role stress, and risk-taking behaviour among men; and, secondly, in a focus group setting, men were asked to define and explore the subjective meaning of masculinity. The study employed both quantitative and qualitative methods. Three hundred male participants completed questionnaires consisting of demographic and risk evaluation questions and three measures of male attitudes, namely the Male Attitude Norms Inventory-III (MANI-III; R24), the Masculine Gender Role Stress (MGRS) scale and the Maudsley Violence Questionnaire (MVQ). Eight focus group discussions elicited deeper meanings of masculinity. Quantitative research findings consist of the associations between conformity to traditional masculinity, gender role stress, and risk-taking behaviour. Also, qualitative discourses explored “…how socially produced ideas…” about manhood “…were created in the first place and how they are maintained and held in place over time” (Phillips and Hardy, 2002, p. 6). This study aimed to elucidate the underlying complexities of manhood that might reveal the vulnerabilities of men, and to offer some recommendations to programmes aimed at reducing health-compromising outcomes for both males and females.

Secure and disorganized attachment in the relational interactions in shelter for abandoned children in Kinshasa
Mbiyi Muadi Université catholique de Louvain, Belgium

The abandonment of children in Kinshasa and some of its psychological effects, such as attachment strategies and cognitive impairments are examined in this study. The aim of the study is to provide a suitable care needs device for not only physical, but also psychological needs of abandoned children. A sample of 50 abandoned children aged from 3 to 7 years, collected in an institutional setting in Kinshasa, DRC, compared to 50 children aged from 3 to 7 years living in families, all examined with ASCT (Attachment Story Completion Task), Raven Matrices (cognition) and a drawing of the family. The Disturbances of Attachment Interview (DAI) and Semi-structured interviews of parents and caregivers were realised. In subjects living in institutions, disorganized and secure attachment strategies are the most frequently observed with respectively 38% and 36%, followed by insecurity 22% and a special category “unclassified”, 4%. For the control group, attachment strategies are as follows: 60% secure attachment, 22% insecure attachment, and 18% disorganized attachment. The Raven Matrices showed a higher score than the average for all tested patients in the control group. In a population of abandoned children living in residential institutions in Kinshasa, caregiver-child interactions do not always give the possibility to develop a secure attachment.

Fukinshin as scapegoat phenomenon about the Japan earthquake after 3 months
Koshi Murakami Kobe Yamate University, Japan

When natural disasters or major accidents occur, people tend to react with negative feelings and assign blame to a particular person or organisation as a scapegoat. This tendency to expand the focus of criticism for epidemics and railway accidents has been reflected in newspaper analyses of disasters. The term “Fukinshin” (not proper), an everyday term used for inappropriate behaviour, has been used with increasing frequency since the earthquake in Eastern Japan. This study examined the growing number of references to Fukinshin in personal blogs. A keyword search found 30,025 blogs written in Japanese during the 3 months after the earthquake (3/11 to 6/10). The results indicated that this term was used in a large number of blogs, compared to the number of blogs in the same period. We used a sample of 3,004 blogs and created a database about behaviour identified as Fukinshin by bloggers. The results of this analysis showed that 9.4% of the blogs assigned blame for the behaviour of others directly, and accounted for 17.1%, combined with criticising this trend of assigning blame. These results differ from the above studies at expansion level.

Longitudinal study on influence of cognitive and affective empathy on aggressive behaviour in Japanese elementary school pupils
Tatsuya Murakami University of Tsukuba, Japan; Takuma Nishimura; Toyoko Sakurai; Shigeo Sakurai

Influence of empathy on aggressive behaviour among Japanese elementary school pupils was investigated in a longitudinal study. The participants were 547 fourth to sixth grade elementary school children in Japan. At time 1, they responded to the Cognitive and Affective Empathy Scale for Children, the cognitive components of which are constructed of two subcales: Perspective-Taking (PT) and Sensitivity to other’s emotions (Sens), whereas the affective components are constructed of four subcales: Positively Parallel Outcome (PPO), Positively Reactive Outcome (PRO), Negatively Parallel Outcome (NPO), and Negatively Reactive Outcome (NRO). Six months later, at time 2, participants responded to the Aggressive Behaviour Scale that consists of three subscales: physical, verbal, and relational aggressive behaviours. We conducted path analysis (using the Generalised Least Squares method) after controlling for the effect of sex. Results indicated that PT (β=.30) and PRO (β=-.13) were negatively associated with physical aggressive behaviours, whereas Sens (β=.24) was positively associated. PT (β=−.21) and OR (β=−.14) were negatively associated with verbal aggressive behaviours, whereas Sens (β=18) was positively associated. PT (β=-.21), PRO (β=−.12) and NPO (β=−.13) were negatively associated with relational aggressive behaviours, whereas Sens (β=.20) was also positively associated. These results validate and expand prior research. There was some evidence of the positive and negative influence of empathy on aggressive behaviours.

The effect of self-handicapping strategies on self-control: Does self-handicapping help to control state-anxiety?
Marumoto Nao Kansai University, Japan

The purpose of the present study was to examine the effect of self-handicapping (SH) strategies in controlling the state-anxiety and sympathetic nerve system activity as measured by the HF/LF ratio of heart rate. Participants were 46 college students (21 males and 25 females). The main experimental design was adopted from Harris & Snyder (1986). The SH scale and self-esteem scale were administered prior to the experimental session. In the experiment participants were asked to work on a task, explained by the experimenter to be a social intelligence test. Participants were provided some free time to practice before the test. A decreased amount of practice time was used as a measure of SH strategy. The results indicated no effects of self-handicapping on state-anxiety and sympathetic nerve system activity.

Reflexive modalities in different social contexts
Lyubov Nasyonova Institute of Psychology, Ukraine

The main goal of our study was to research particularities of different modalities (i.e. focus on one or another object) of reflexion and group reflexion representation in different social contexts in a natural environment. We’ve modified questions of the reflexive interview (by Naydonova M.) to receive information on reflexion and reflexion representation of reflexive environments in the natural environment by adults and young adults’ self-reports (N=123). We’ve focused on the frequency of realisation of four reflexion modalities (knowledge, experience, attitude, feelings) in different social contexts. ‘Friends’, ‘parents’, ‘other people’, ‘inner dialog’ have been specified as context environments. Scoring of each question was made according to a five-point Likert scale. Results: Age-specific (frequency of reflexion is higher for adults than for young adults - 3.2 and 2.9 points), gender (men and women types are different by modalities and environments) and context particularities of different modalities of reflexion were found. Individual reflexion takes place more often than a group reflexion (3.6 and 2.8 points). Individual particularities of reflexive modalities’ representation have been studied. Five types have been distinguished: medium, medium-
Effect of cognitive and affective empathy training on pro-social and aggressive behaviour in Japanese university students
Takuma Nishimura University of Tsukuba, Japan; Shigeo Sakurai; Toyoko Sakurai; Tatsuya Murakami
Psychological research has suggested that empathy is an important factor in promoting pro-social and reducing aggressive behaviour. In this study, we examined the effectiveness of empathy training based on anger management programmes using a pre-post-test design. Forty Japanese university students were divided into an intervention (N=17) and control group (N=23). The intervention group participated in a three-hour training session held at two times. The training comprised three sessions: cognitive empathy (e.g. to understand something from the other’s point of view), negative empathy (e.g. sharing of other’s negative emotions) and positive empathy parts (e.g. sharing of other’s positive emotions). Participants also responded to questionnaire surveys measuring empathy, pro-social behaviour, and aggressive behaviour in three times (pre-test, post-test, and follow-up). The time between post- and follow-up test was four weeks. The results showed significant intervention effects for all parts of empathy on the post- and follow-up tests and for aggressive behaviour on the follow-up test. However, no intervention effects were found for prosocial behaviour. Partial correlation analysis was conducted to investigate the empathic component that contributes to the containment of aggressive behaviour. We found that the control of aggressive behaviour is associated with variation only in positive empathy. These results suggest that this programme would help increase empathy and decrease aggressive behaviour. We also found that positive empathy is the most effective empathic component in suppressing aggressive behaviour.

Influence of causal factors on youth attitudes toward patriotism
Supida Nontamat Mahasarakham University, Thailand
The purposes of this research were (1) to develop and examine the validity of causal model influenced on the youth’s attitudes toward patriotism in the Northern and Southern regions and (2) to study Thai values, self-esteem, democratic carefulness, and media’s influences, which were affected in the youth’s attitudes. The three-stage stratified random sampling of 1500 undergraduate student from the university in the North-eastern area for the second semester 2010 academic year were selected to be the samples. The statistics for data analysis was Path analysis for Structural Equation Modelling (SEM) with latent variables. The research findings were 1) the causal model to effected attitudes toward patriotism of the youths in the North-eastern region was confirmed by empirical data regarding X2=131.277, df=110, X2/df=1.193, P=0.081, CFI=0.999, GFI=0.990, AGFI=0.986, RMSEA=0.008. 2) The directed factor to affected attitudes toward patriotism was Thai values. Both directed and indirect factors’ effect on attitudes toward patriotism were self-esteem and democratic carefulness, and the factor effected indirect on attitudes toward patriotism was media’s influences. All variables of the model could explain the 69.797 percent variance of attitudes toward patriotism.

Demographic postulates in the effects of child labour on the academic performance of secondary school students
Eunice Ohidah Kaduna Polytechnic, Kaduna, Nigeria; Victor Shammah
This study examines demographic postulates in the effects of child labour on the academic performance of secondary school students. The population is all secondary school students in the Federal Capital Territory. The sample used consisted of 6000 randomly selected students drawn from 12 secondary schools in the Federal Capital Territory. Data were collected using the designed questionnaire and respondents’ school continuous assessment/examination records. The data were analysed using percentages. Findings revealed that, respondents demographic variables influenced the effects of child labour on their academic performances. It was therefore concluded that child labour affects the emotional and psychological well-being of the students which in-turn affects their behaviours. Consequently too, the behaviour also affects their cognitive capabilities. This is evident by their overall low-academic performances, class-levels repetitions and below-average learning abilities in general. This, among other reasons, spoiled the idea of the Universal Basic Education and breed illiteracy in Nigeria even at this stage of human civilisation. Thus, the educational significance of these findings includes: The provision of insight on the nature of child labour in Nigeria thereby making it possible for educational advocacy, especially for the protection of children at risk, and the deterrents of perpetrators; information to government and human service organisations attending to child labour problems to enable them devise appropriate intervention strategies and to equip parents with information that will lead them to understand the negative effects of child labour on the development and future educational pursuits of their children.

Evidence of low life satisfaction among undergraduates in South-West Nigeria
Samuel Oladipo Tai Solarin University of Educo, Nigeria; Peter Olugbemi
The paper examined life satisfaction among 1429 undergraduates from South-Western Nigeria. An ex post facto survey design was adopted and a convenience sampling method was used. The sample comprised 475 (33.2%) males and 953 (66.8%) females, ages ranging between 16 to 27 years (M=28.47, SD=8.76). A validated scale was used for data collection, and the two hypotheses stated were confirmed, after testing with appropriate statistics. A total of 837 undergraduates (58.57%) had scores less than the mid point of 20; their mean was 14.03 (SD=2.42), 88 (6.2%) scored exactly 20, while 504 (35.33%) scored higher than 20; their mean was 22.84 (SD=4.74). Further analysis revealed that 308 (21.5%) of the male respondents have low satisfaction with life (Mean =13.79, SD=2.42), 837 (58.5%) of the female respondents have low satisfaction with life (Mean =14.03; SD=2.40). 167 (11.6%) of male respondents have high satisfaction with life (Mean=22.66, SD=4.57); 425 (29.7%) of female respondents have high satisfaction with life (Mean=22.84, SD=4.74). The conclusion reached was that undergraduates have a low level of life satisfaction. There is no significant difference between males and females regarding life satisfaction. There is need for further research to explore the factors that account for low life satisfaction among this sample.

Analysis of Rhodes University students’ experiences of Facebook: Relationships and social capital
Jessica Oosthuizen Rhodes University, South Africa
An Interpretative Phenomenological Analysis of interview transcripts from users of the popular online social networking site, Facebook, examines the relationship between Facebook usage and the production and maintenance of social capital. Bridging, bonding, and maintained. In-depth exploratory interviews conducted with five Rhodes University students, who use Facebook, provided the study data. The themes that emerged from the data were: staying close to those who matter, keeping relationships alive, Facebook "friends" with benefits, staying informed, and Facebook as a (fun) distraction along with a number of sub themes. It has been suggested that Facebook plays a huge part in the lives of Rhodes University students and aids them in the formation and maintenance of social capital. Facebook was found to be used frequently by all the students involved in the study and benefitted them all in more ways than one.

The role of relevant recent autobiographical event emotional valency in implicit measures of ethnic attitudes
Irina Pliotka Baltic Psychology and Management University Colle, Latvia; Laura Simane; Dmitry Igninin; Nina Blumenau
The aim of the study was to test the hypothesis of recent episodic information influence that is related to ethnic attitude, on response latency in unconscious affective priming tasks (UAPT). Such influence could be connected with ambiguous change of response latency in different Stimulus Onset Asynchrony (SOA) intervals, when the attitudes are measured with implicit methods. Ethnic attitudes of 200 participants from two ethnic groups were measured with UAPT. The self-report method was used to measure explicit attitudes and recent autobiographical event emotional valency with attitude value conformity determination. Of the participants, 54% were selected with polar emotional valency of recent autobiographical episodes, to which reaction times on positive, negative and neutral aim stimuli, as well as reaction time shifts were explored. Subsequently, implicit ethnic attitudes in different SOA
intervals were determined. It was found that episodic information and its interaction with different factors influence reaction times as well as their shifts that correspond with the hypothesis. The results indicated a relevant episodic information effect that had not been previously considered when using implicit attitude measures. The results allow the development of a new attitude representation model in terms of semantic and episodic component interaction.

Comparison of self-handicapping and self-esteem among champion athletes and nonchampion

Hossein Rezabaksh Islamic Azad University-Karaj B, Islamic Republic of Iraq; Leila Sabeghi; Shahla Hojat; Esmat Danesh

Abstract The purpose of this study was to compare and determine the measures of self-handicapping and self-esteem among champion athletes and nonchampion athletes in Karaj City. The research method was causal-comparative (ex post facto) one. The sample was chosen on the basis of the stratified random sampling procedure, while considering educational level (undergraduate-graduate), gender, championship status as different quotas. The sample size was 115 students, which was calculated on the estimation of sample size formula. There were two research instruments for gathering the data. The first one was self-handicapping scale (SHS) developed by Jones & Rhodewalt (1982), while the second one was self-esteem scale (SES), (Rosenberg, 1965). The statistical methods used in the research were: one variable two-way ANOVA, correlation coefficient, one variable regression analysis. The results indicated that there was a negative correlation between self-handicapping and self-esteem among athletes (r = -.276, p<.01). Self-handicapping can predict self-esteem and vice versa (r = .276, p<.01). The correlation between self-handicapping and self-esteem among nonchampion athletes were stronger than champion ones. There was no significant difference in self-handicapping among girl and boy champion and nonchampion athlete students. In conclusion, the results suggest that coaches, sport psychologists and other interventionists should endeavor to promote but self-esteem inorder to diminish low use of self-handicapping strategies among champion athletes in sport domain.

Social identity, relative deprivation and intergroup contact: A holistic theoretical framework investigating xenophobic attitudes

Guillermina Ritacco HSRC, South Africa

While the history of South Africa (SA) is rippled with segregation, the post-Apartheid promise of a ‘better life for all’, and the great civil strife in its neighbouring countries, has meant a flow of African immigrants into SA seeking a ‘better life’. The movement of foreigners into SA has been met with great unrest and large scale violence which has raised concerns around human rights and stimulated much research around xenophobic attitudes. While this research has been important, it is argued that much could be gained from a social psychological, theoretically based study of xenophobia. This study seeks to investigate the role of social identity, relative deprivation and intergroup contact in explaining variances in xenophobic attitudes. It is hypothesised that strong social identity, high levels of relative deprivation and low levels of intergroup contact will be most highly correlate with more xenophobic attitudes. The study will collect data from 600 participants in the Western Cape, stratified by age, race and income. The study will assess (1) xenophobia, using a measure of Fear-Based Xenophobia, (2) social identity with a scale of Ethnic Identification, (3) intergroup contact with a scale of Nature of Communication and a scale of quantity and quality of contact and (4) relative deprivation with the Scale of Relative Deprivation-Gratification. This study will add much needed theoretical depth needed to the SA literature on xenophobia and will be useful in informing future policies related to immigration as well as future intervention-based initiatives aimed at reducing intergroup hostilities like xenophobia.

Psychosocial perspectives of adolescents on trial for robbery and crimes involving drugs

Jose G. Salazar Estrada Universidad de Guadalara, Mexico; Monica Almeida-Lopez; Norma Figueroa-V; Norma Ruvalcaba

The aim of this study is to identify the life conditions of adolescent subjects accused of having committed robbery and drug-related crime, from a psychosocial perspective. A tally of 122 dossiers were studied, from which 50% were male and female adolescents accused of drug-related crime, and the other 50%, for robbery. Seventy percent of males and 68.2% of females had consumed a type of drugs, 66% of the total of the sample showed little tolerance to frustration, 60% had an inadequate handling of affectivity, with a significant difference when studied for every type of crime. Among the differences identified, psychological conditions, such as personality, are more associated to juvenile delinquency.

Reflections on youth social inclusion in the city and community where they live

Leila Salles Departamento de Educação, Brazil; Deborah Fonseca; Joyce Mary Silva

This paper aims to discuss the social inclusion between poor youth groups, residents in the urban periphery, and their communities and city. Focus groups were conducted with young people who differed on the violence they had experienced. Their statements about the city, the places they go to, their community and the relationship with other young people were analyzed. Data analysis sought to identify the common themes, emphases and patterns presented in the speeches of the interviewees. The analysis of these narratives indicated that the youth relationship with the city and other groups of young people is often conflicting. The city is often seen from afar as there are few places that young people frequent. The differences between groups were pronounced. Young people tend to maintain relationships with those who they believe to be like them, excluding others even though this exclusion will lead them to describe themselves as lonely or give privilege to virtual relationships. The interactions are guided by similar lifestyles, including the places they go to and the life projects they build. The exclusion is instituted by the exacerbation of specific interests. Each of these ways of social integration indicates a way of exposing themselves, establishing relationships, making choices and setting differences.

Effects of partners’ group membership on the dynamics of trust in a trust game

Katarzyna Samson University of Warsaw, Poland; Andrzej Nowok; Anna Banaszkiewicz; Magdalena Roszczynska-Kurasinska; Michal Ziembowicz; Marita Kaczynska

Emergence of new forms of social and economic relationships, made possible through the development of information and communication technologies, attracts increasing attention to the concept of trust in strangers. When deciding whether to trust a stranger or not, people use cues for trustworthiness associated with the stranger, such as their group membership. Previous research in this area yields contradictory results – some confirm the hypothesis of greater trust for the in-group than for the out-group, while others reject it. To try to solve this contradiction, in the current study we examined the effects of partners’ group membership on the dynamics of trust in an iterated trust game (Berg et al., 1995). The participants (N=60, students) played 12 rounds of a trust game with a computer. In one condition they were told they were playing with an in-group member, in the other – with a stereotyped out-group member. Results show that the participants’ overall levels of trust are higher in the in-group partner condition, but in their opening moves this pattern of results is reversed. Sequence charts of aggregated behaviours reveal very different patterns of trust dynamics in the two conditions. These results suggest that in general people do trust in-group members more than out-group members, but when interacting with out-group members, awareness of a negative cultural stereotype incongruent with personal beliefs may lead to an intentional stereotype inhibition, which results in unnaturally uniform patterns of trust dynamics.

Motivated autobiographical recall among young vs aged individuals

Rasylid Bo Sanitioso Universidade de Sampaio onete París Descartes, France; Pascale Piolino

People are motivated to see themselves positively. To this end, they see themselves as characterised by traits they believe lead to desirable outcomes (e.g., success). Studies have shown that people attempt to justify (or to come to) self-perception as characterised by a desired trait via selective recall of past behaviours indicating the possession of the trait. Thus, when led to believe that extraversion leads to success, people recall relatively more past behaviours related to extraversion. In contrast, when led to believe that introversion leads to success, they recall relatively more past behaviors related to introversion. Thus, recall of autobiographical memories play a crucial part in maintaining a positive self-perception. The present study examines the impact of age and the associated loss of access to autobiographical memories with normal aging, on the ability to maintain a positive self. Based on existing literature, we expected aged individuals to show less biased recall (favouring recall of past behaviours consistent with the desired trait) than
young individuals. In the study, young and aged participants were first led to believe that extraver-
sion or introversion leads to a long life (an outcome pretested as desirable to young and old). Next, they
freely recalled past behaviours related to extraversion
and to introversion. Contrary to expectations, aged participants recalled past behaviours related to
desired trait, as well as their younger counterparts. This
suggests that motivation, a factor that has not
been studied related to aging and recall, could increase the ability of aged individuals in recalling
autobiographical memories.

Incivilities, fear of crime and concern of crime: How broken window theory work in
two different Italian contexts
Luca Scacchi Università della Valle d’Aosta, Italy;
Mariagrazia Monaci
The aim of this study was to examine the influence of incivilities on sense of insecurity in Italy. The "broken window" thesis claims that by reducing signs of disorder, police can make lasting reductions in crime (Wilson & Kelling, 1982). Other studies argue that this changes do not lead to decreased crime rates (Taylor, 2001). However, all these stud-
ies, as well as several others, link disorder to inse-
curity: People who perceive incivilities more are more fearful (Santinello et al., 1997). Moreover, past
works have stressed the multidimensional constructs underlying psychological reactions to crime: per-
sonal fear, social concern, and perceived risk have different predictors (Van der Wuff, 1986; Amerio &
Roccatto, 2005). The present study examined the correlat-
es of distinct dimensions of insecurity in a sample of 240 university students in two different contexts (120 in a mountain region not perceived as
insecurity and 120 in a metropolitan city in Northern
Italy). A self-report questionnaire was devised whose
main variables were: Personal wellbeing (Masse et al., 1998), social support (Zimet et al., 1988), sub-
tle and blatant prejudice (Pettigrew, 1995), perception of social and physical incivilities, perception
of territorial markers, and place identity (Bonaiuto, 2004). The first analyses confirm distinct
constructs underlying insecurity. Main results reveal
significant relationships between fear and social (but
not physical) incivilities, gender, depression and
negative place identity, whereas concern is linked
to blatant prejudice, social support and territorial
markers. Further analyses comparing the two differ-
ent social contexts will be presented.

Evaluation of peace intervention program among Middle Eastern teenagers
Juliana Schroeder University of Chicago, United
States of America; Jane Risen
We studied the effectiveness of a peace intervention program, Seeds of Peace, which gives teenagers from regions of political conflict a chance to meet and interact with the "other side" for three weeks in the United States. Two-hundred eighty-five campers from the Middle East participated in 2010 and 2011, representing the nationalities of Arab Israeli, Egyp-
tian, Jewish Israeli, Jordanian, and Palestinian. Cam-
pers show significant psychological changes from pre-
to post-camp. Specifically, campers feel more positively towards, trusting of, close with, and sim-
ilar to the other side. They humanise the other side
more, are more willing to compromise with the other
side, and more strongly endorse the possibility of peace. In addition, they consider people from the
other side more warm and competent after camp than
before. The attitude changes are specific to the
groups with which participants have contact at camp. Although campers report that they understand the
other side more after camp, our results suggest that
they continue to rely on pre-existing theories for the
other side. For example, Palestinians believe that "complete control of Jerusalem" is one of the most
important issues for Jewish Israelis, and miss one of
the actual issues reported to be most important to
Israelis, which is "recognition of my country's right
to exist". Follow-ups are currently being conducted
to determine whether the initial effectiveness of the
program is maintained after the campers return home.

The investigation of the cause of Japanese communication behaviour: The cultural-self
perspective
Kimhiro Shiomura Ferriss University, Japan; Risa
Funakoshi
The aim of the present research is to investigate the
predictive relations between Japanese Communication
Behaviour and Cultural-Self Construal. The data of 128 Japanese female university students were
submitted to the analysis. The analysis model is as
follows: "Independent Self-Construal" and "Interde-
pendent Self-Construal" the 2 dimensions of Cultur-
al-Self Construal, were set as exogenous variables, and "Expression of Self-Effacement", "Perceptive
Ability", and "Self-Restraint", were set as endoge-
nous variables. The path analysis was conducted by
AMOS software. The results of the analysis for all respondents showed that higher independent self-
construal was related to lower self-effacement, and that higher interdependent self-construal was related
to higher self-effacement, higher perceptive ability,
and higher self-restraint. Using the median split on
the results of the relatively high self-esteem respondents (n=64) showed that, unlike the results mentioned above, higher
independent self-construal was related to lower self-effacement, and that higher interdependent self-construal was related only to higher self-effacement. On
the other hand, the results of the relatively low self-esteem respondents (n=64) showed the same rela-
tions as in all the respondents. These differences were discussed and should be empirically explored in
further research.

The relationship between assumed-compe-
tence and cultural-self related concepts
Kimhiro Shiomura Ferriss University, Japan; Mariko
Suzuki; Risa Funakoshi
The present research investigated the relationship be-
tween Assumed-competence and cultural-self related
concepts. Assumed-competence is a "not real" com-
petence, and it is caused by undervaluing others re-
gardless of his/her own real capability (Hayamizu et
al., 2004). This research explored predictive factors in
cultural-self related concepts toward assumed-compe-
tence. Participants are 146 female university students who are studying in Japanese women's university.
Dependent variable is an Assumed-competence, and
independent variables are five cultural-self related
concepts; Interdependent Self-Construal, Independent
Self-Construal, Self-Esteem, Perceptive Ability,
and Self-Restraint. In addition to these variables, we
adopted "Relational Mobility in Society (RMS)" (Yuki
ets al., 2007) in order to examine the relevance of
each individual's cognition of the RMS to the relationship mentioned above. The results of regression analysis
for 146 participants showed that high Independent
Self, high Interdependent Self, low Perceptive Ability,
and high Self-Restraint (marginally) significantly re-
lated to high Assumed-Competence. Moreover, based
on a median-split on RMS score, the same regression
analyses were conducted on both divided groups.
The results of the participants (n=70) who have relatively high scores and those (n=76) who have relatively low
scores of the RMS showed rather different relationship
for each group. Those results described above indicat-
ed interesting findings. The first one is the inter-
vening role of RMS. The second one is that both
Independent Self-Construal and Interdependent Self-
construal indicated same positive relation to the As-
sumed-Competence.

The exploration of predictive factors for a
subjective adjustment to a higher education-
al institute
Kimhiro Shiomura Ferriss University, Japan; Mana-
mi Tomioka
The purpose of the present research is to examine the
predictive factors for a subjective adjustment toward a university (college). In the hypothesis model, the
predictive variables were four personality traits, and
three sub-dimensions of friendship in modern adoles-
cents. The criterion variables were sub-dimensions of
subjective adjustment toward the university. The par-
ticipants were 134 females studying in a women's
university located in the metropolitan area of Japan.
The data were submitted to the Structural Equation
Model (using Amos). A subjective adjustment to-
ward the university consists of 4 sub-dimensions:
"sense of comfort", "feeling of acceptance and trust",
"existence of task and purpose", and "absence of
feelings of rejection". The findings of the path anal-
ysis showed that significant predictive factors are
different, depending on respective sub-dimension of
the adjustment. The distinguishing findings are as
follows: while low "avoiding intimate relationship"
predicted a high score in sub-dimensions of a sub-
jective adjustment, high "gathering in crowds" pre-
dicted a high score in sub-dimensions of a subjective
adjustment. The importance for educational approach
based on the findings shown above was discussed.
Especially, in these modern days, some large portions
of the students in higher educational institutes do not
value academic achievement. It is important to seek
respective predictive factors of students' subjective
adjustment in each type of educational institute.

Meta-analysis of associate factors of attribu-
tional styles in Iran (2004–2011)
Mahnaz Shirani University Isfahan, Islamic Republic
of Iran; Amir Ghamarani; Azime Fatemi
Attributional styles related with some important vari-
ables such as thinking styles (Jen, 2010), optimism
(Gordon, 2007), depression (Calvete, 2008), mental
Prashthay (Rotenberg, 2011), confidence (Ciarrochi,
2007), hope (Ciarrochi, 2007), and academic achieve-
mint (Rezae, 2010; Hall, 2007), self-esteem
(Hirschy, 2005; Mousavi, 2004), mental health
(Shark, 2007), and life satisfaction (Ahadi, 2009)
have been researched. In this regard, the goal of this study was a meta-analysis of research about associ-ate factors of attributional styles in Iran. 19 studies that were eligible for meta-analysis were analyzed. The research instrument was a checklist of meta-analysis. This study is based on 4017 participants. Results indicated that the effect size of associate factors of attributional styles was 0.7(p ≤ .001). Taken together, the effect size of associate factors of attributional styles according to Cohen’s was high.

Meta-analysis of effectiveness of psychological interventions on reduction of aggression in Iran
Seyyed Siadatian, University of Isfahan, Islamic Republic of Iran; Amir Gharamani; Ahmad Abedi; Abdolhossein Shamsi Ezhiyeh

In recent years, experts in the field of aggression were followed to assess and compare the validity and ef-fectiveness of psychological interventions. In this re-gard, meta-analysis or integrating results from differ-ent researches determine the effect size of psychological intervention. The goal of this study is meta-analysis of research about effectiveness of psy-chological interventions on reduction of aggression in Iran. This study determined the impact of psychological interventions on reduction of aggression. For this purpose among 40 studies, 29 studies which were methodologically accepted had meta-analysis per-formed on them. The research instrument was meta-analysis checklist. This study included 1150 subjects and 29 effect sizes. The results of meta-analysis indi-cated that the rate of impact of psychological inter-ventions on the reduction of aggression was 0.51 (p=0.00001). This effect size according to the Cohen table is rather high. Conclusion: psychological inter-ventions on reduction of aggression have high impact.

Contextual factors influencing responses to violations
Purnima Singh, IIT Delhi, India; R.C. Tripathi; Namita Pandey; Saurabh Maheshwari

The present study examines how the context of violation/harm, whether violation is economic, so-cial and moral, the victim-offender relationship and retributive-non-retributive responses of the victim, influence the attribution of violation by the victim, the future interaction and relationship with the of-fender. 160 respondents, both males and females belonging to three age groups, adolescents, adults and senior citizens, responded to a series of questions after reading vignettes depicting three kinds of viola-tions, moral, social and economic. Results showed that the age and gender of the respondent significant-ly influenced perceptions. Moral violations were attributed more to intentionality, disposition and the offender taking advantage of the situation. Retribu-tive responses of the victim were found to affect future interaction and offenders’ behavior.

Belief in standardised test bias may be nec-essary for stereotype threat negative impact on minority performance
Lloyd Sloan, Howard University, United States of America; Grady Wilburn; Daniel Martin

Sloan, 2000; 2009; Marx, 2006), but does with White test-givers, suggesting elaboration of Steele and Aronson’s (1995) theory. Other research sugg-ests that perceived unfair tests or biased live out-group evaluation may cause this arousal of Stereotype Threat in minority settings where it’s usually absent. Would enduring perceptions of standardised test bias therefore moderate the White experiment-er-produced intellectual performance decrements? 174 African-American university students comple-ted measures of perceived standardised test unfair-ness and validity and took challenging verbal (SAT) tests described as individually Diagnostic or Non-diagnostic by White or Black test-givers. The results showed that White test-giver/experimenter produced Stereotype Threat performance decre-ments while African American experimenters didn’t. Participant perceptions that SAT type standardised tests are inherently biased or unfair moder-ated this diagnosticity effect for White experimen-ters (but not for Black experimenters). Participants perceiving SAT-type tests as biased showed strong White test-giver/experimenter related Stereotype Threat performance decrements. In contrast, those perceiving tests as unbiased showed no Stereotype Threat effects whatever. These findings suggest that perceptions of bias in standardised testing-evalu-ation, appear to critically moderate the impact of White test-givers’ diagnostic testing. When the test itself is perceived to be unbiased, however, the White tester produced Stereotype Threat effect dis-appears. Reducing the perception of standardised tests’ unfairness therefore perhaps could diminish important stereotype threat produced performance failures.

The interactive influences of country-of-ori-gin images, subjective product knowledge, and actual quality of products on purchase intention
Mein-Woei Suen, Chung Shan Medical University, Taiwan, R.O.C.; Rou-An Chen; Yi-Ju Lee

Pereira, Hsu, and Kundu (2005) suggested that country-of-origin image includes three aspects: General country attributes, general product attrib-utes, and specific product attributes. Brucks (1985) demonstrated that there are three domains on measuring product knowledge: Subjective knowledge, object knowledge and experience knowledge. In addition, Chen, Chen, Lai, Ko, Wu, Hsu, Hsieh, Lee, and Suen (2011) have pre-liminary proved their hypothesis with Taiwan sam-ples. Thus, this study aims to extend a research on subjective knowledge and purchase intention in order to explore further relationships between them. This study followed above Chen et al. (2011) to conduct a 2 (country-of-origin image: high vs. low), 2 (subjective product knowledge: high vs. low), and 2 (actual quality of products: high vs. low) factorial design (N=129), and used general country attributes as a variable of country-of-origin image and sub-jective knowledge as a variable of product knowl-edge. The interesting results show that: The coun-try-of-origin image, subjective knowledge and actual quality of products respectively have a posi-tive relationship with the perceived quality of pro-ducts. Moreover, it shows that the country-of-origin image, perceived quality of products, and actual quality of products respectively have positive rela-tionships with purchase intention. This study, in addition, found that the subjective knowledge influ-ence the effect of country-of-origin image on the perceived quality of products. Thus, above findings can provide a basis for purchasing intention of consumers and a direction of designing advertise-ments for enterprises. More findings are presented and discussed in this paper.

Transgenerational comparison of perceived level of happiness in Chinese families
Xiaojie Sun, Dongbei University of Finance & Economics, China; Yanjun Xie; Kai Wu

This study was designed to investigate the differ-ence in the perceived level of happiness among three generations in Chinese families including children, parents, and grandparents. The Oxford Happi-ness Questionnaire was distributed among 255 people in 85 families. These included three genera-tions in Chinese families, generally in early 20s, 40-50s and 60-70s. Specifically 85 college stu-dents, who represented the youngest of the age groups, were required to distribute the questionnaires to one of their parents and one of their grandparents. The subjects from each of the gen-erations were asked to answer the questionnaire. The investigation of the differences in perceived level of happiness was achieved through the one-way ANOVA analysis. It was found that the 20s age group’s level of happiness was significantly higher than the other groups. While the happiness level between the 40-50s and 60-70s groups did not have a significant difference. The lower levels of happiness in the two older age groups may have something to do with the social and political changes that people in these ages have experienced during their lifetime.

Feeling sleepy and meaningless: The effects of social exclusion when sleepy deprived
Tina Sundelin, Stockholm University, Sweden; John Axlesson; Andreas Olsson; Mats Lekander

Social exclusion can cause depression, anxiety, and feelings of meaninglessness. These affective states are often comorbid with sleep disorders. Sleep restriction negatively affects general mood, optim-ism, and irritability. We hypothesised that being partially sleep deprived would increase the affective response to exclusion. 46 individuals (22 males) with a sleep need of 7–8.5 hours were randomly divided into a sleep restriction group (4h/night for 2 nights) and a control group. Parti-cipants then played Cyberball, a computerised ball tossing game, ostensibly with two other people over a network. The game consisted of two ses-sions, one where the participant was included and one where the other two “players” excluded the participant by not tossing the ball to them. A questionnaire was completed after both sessions assessing participants’ feelings of belonging, mean-ing, control, and self-esteem. The results showed that social exclusion leads to decreased feelings of meaningfulness, belonging, control, and self-es-teem in both groups (p<0.05). Compared with controls, sleep-restricted individuals were more negatively affected by exclusion in terms of mean-ingfulness (p=0.001). The sleep-restricted and the control group did not differ in feelings of belong-ing, control, or self-esteem. We show that after two nights of restricted sleep, the negative effects of
being socially excluded are amplified with regard to feeling meaningless, not to belonging, control, or self-esteem. The relation between sleep loss and feelings of meaninglessness may be of relevance for the link between disturbed sleep and aspects of depression.

The psychological challenges of parenting faced by orphaned children heading families in Nkaneng, Northwest Province

James Takaloni University of Venda, South Africa; Lesly Monganye

Orphans living in child-headed households within underprivileged communities are amongst the most vulnerable children other than those with parents. Due to HIV/AIDS a large number of HIV/AIDS orphans have rapidly increased. Death caused by HIV/AIDS left many of these children in great distress and poverty. The stigma and discrimination related to HIV/AIDS resulted in them being isolated. The study revealed that these children face problems such as educational sacrifice, lack of informal and access to social welfare services and disruption of normal life of childhood and adolescence. The study also discovered that most of these children felt ill-equipped to provide proper parental guidance and discipline to their siblings since they are themselves still children, young who need parental attention, guidance, love, social security and care. Researchers made use of a qualitative research approach, employing qualitative research design and purposive sampling method was utilised. Data were gathered through face-to-face semi structured interviews from sixteen (16) child-heads of households. All participants were heads of households aged between 13 and 19 years and were residents of Nkaneng informal settlement. The results of the study led to the formulation of the recommendations which are hoped to heighten awareness and stimulate interest among role players to assist these vulnerable children.

Dimensions of a "good society" using projective cognitive map techniques

Junko Takeuchi Waseda University, Japan; Masa-toshi Imaseki; Takashi Ideno; Kazuhisa Takemura

To consider the well-being and construction of society, measurement of the psychological composition of a "good society" should be an important issue. The purpose of this study was to investigate the psychological dimensions of a "good society" using new methods to measure the implicit psychological dimensions of perceived objects. In this study, two proposed methods were used: (1) Cork-board image mapping: participants (12 university students) were asked to write multiple things which compose a "good society" on cards one by one. Participants were also asked to put the cards freely in a circle of 60 centimeter in diameter on a cork-board. (2) Modified Personal Attitude Construct (M-PAC) Analysis based on PAC analysis (Naito, 2002) things which were mentioned by each participant as constituent of a "good society" were analysed based on the evaluated value of similarity. The experimenter showed the participants the result of cluster analysis and multidimensional scaling (MDS) for image mapping data and then asked participants to interpret the contents of each cluster. Referring to the protocol data of the participants, we interpreted the axes of MDS space. Individual analysis indicated that there were many individual differences for the contents and the structure of a good society, but that there were common properties of a good society such as security and happiness. Interpretations of axes of the cork-board and MDS were analyzed and the result suggested that there were main axes for judging "good society": "importance", "time", "systematic/non-systematic", and "individual/social."

Effects of empathy and cognitive biases on three types of aggression in Japanese students

Kawabata Takeyasu Shokei Gakuen University, Japan

We hypothesised that aggression will be inhibited by empathic concern, while it will be enhanced by personal distress and cognitive biases because they intensify egocentric concerns and impair empathic concern. 216 Japanese students responded to Davis’s Interpersonal Reactivity Index (IRI) including empathic concern and personal distress subscales, Cognitive Bias Scale (Okayasu, 2009) and Japanese Proactive and Reactive Aggression Scale (Isobe & Hishinuma,2007). Factor analysis of cognitive bias yielded the interpersonal sensitivity and self-deprecation dimensions and that of aggression extracted three dimensions of physical, verbal, and relational aggression. Because of gender differences in interpersonal sensitivity and aggression, we conducted SEM separately in each gender in order to test the hypothesis. The results of males showed that empathic concern did not affect aggression but two dimensions of cognitive bias indirectly increased relational aggression by increasing personal distress; and self-deprecation also increased physical aggression, but interpersonal sensitivity decreased it. Those of females showed that empathic concern decreased physical aggression but increased verbal aggression; personal distress indirectly influenced aggression by decreasing empathic concern; and cognitive biases also had indirect effects on aggression, that is, interpersonal sensitivity increased personal distress and self-deprecation increased empathic concern. Generally, the hypothesis was only partially supported by the results, which suggested more complicated relationships between the internal variables and aggression.

Classification of role relations in college students’ egocentric social support network

Wenqiang Tang South China Normal University, China; Min-Qiang Zhang; Nan-Nan Zhang; Shao-Qi Ma

Social support is fundamental for social integration and the emotional well-being of undergraduates. An egocentric social support network shows the relationships between the social support and support sources of individuals. In general, different support types may have different sources of support, the same source may also provide different support, but in a society, a particular source of support may provide a specific type of support. We plan to make a survey on about 400 college students in Guangzhou City by using a practical egocentric social network questionnaire. Log-linear latent class analysis is used to construct a typology of egocentric support networks showing the types of support respondents can expect from others with a specific role. Based on the existing research, the social support of college students can be divided into emotional support, talk support, sick support, recreational support, comfort support and financial support. For all six support items, respondents were asked to indicate from which role relation they could expect to receive that kind of support. Important role relations that are potential sources of support include: roommates, immediate kin, extended kin, friends, colleagues and neighbours.

The effects of interpersonal relationships on triggered displaced aggression

Syota Tanno Hiroshima University, Japan

Three studies examined the effects of interpersonal relationships on triggered displaced aggression (TDA). Study 1 developed a vignette method of TDA paradigm (Pedersen, Gonzales, & Miller, 2000) because of ethical concerns of conducting aggression research in Japan. The status of the provocateur was higher status and the status of the target was same status to the participants. Results conceptually replicated TDA effect as follows, (a) provocation was followed by a subsequent triggering behaviour by the target, it resulted in the most aggression, and (b) when initially provoked but then not triggered, participants displayed the least aggression. Moreover, the aggression rating in vignette was positively correlated with trait displaced aggression. Study 2 examined effect of the status of the provocateur and target on triggered displaced aggression. Results showed that low-status target is more likely to be the target of displaced aggression. This suggests that there is a possibility that displaced aggression may be directed toward socially weak persons. Study 3 examined the effect of the positivity of the relationship between aggressor and target on triggered displaced aggression. Results indicated that the positivity of the relationship between the aggressor and target acted as an aggression buffer. Although a person who is low-status is more likely to be the target of displaced aggression, it might be possible not to be the target by being nice to the aggressor. These results provide the first evidence that interpersonal relationships moderate TDA. Implications for instances of real world aggression are discussed.

Private and public collective self-esteem among students at a South African higher learning institution

Angela Thomas University of Pretoria, South Africa

This study explored the correlation between public and private collective self-esteem among 81 Black and 55 White undergraduate students, respectively, from a South African university. Two subscales of the collective self-esteem scale were used to measure private and public collective self-esteem. The former refers to an individual’s perceptions of how members of the out-groups evaluate his or her group, while the latter is an individual’s appraisal of the value of his or her group. These variables were measured in relation to respondents’ ethnicity. In this study, individuals within a larger, racially homogeneous group are further differentiated according to their native languages to form an ethnic group. A statistically significant correlation was found between public and private collective self-esteem among White respondents (r=0.405; p 0.05). Black students are a minority in the study’s context and, presumably, prone to prejudice (real or perceived). These experiences could undermine their public collective self-esteem but lead to strong
identification with the in-group in defiance and, consequently, enhance private collective self-esteem. White South Africans’ economic power and privileged social standing since the Apartheid era may account for the correlation found between public and private collective self-esteem among White respondents. It is recommended that future studies investigate the actual role of real or perceived prejudice in levels of private and public collective self-esteem and the relationship between these.

Use of non-monetary incentives as a motivational tool in sports
Tsheapeng Tshebe Michigan State University, United States of America; Dele Akpata; Brandon Irwin
The present investigation examined the extent to which Batswana athletes (athletes of Botswana) are motivated by social and tangible non-monetary incentives. Junior (ages 13–18) and elite (19 and above) athletes (190 males and 180 females) from various local clubs in Botswana responded to a questionnaire assessing their perceptions of and the extent to which they were motivated by tangible (e.g., cars, scholarships) and social (e.g., media coverage, praise from leaders, such as the Minister of Sports) non-monetary incentives. Results from the study showed that Batswana athletes placed significant value (p < .001) on both tangible and social non-monetary incentives regardless of gender and age. Also, results indicated that the level of importance placed on both tangible and social non-monetary incentives varied by sport. Boxing reported the least value (M = 1.85) on the importance of social non-monetary incentives while volleyball reported the highest value (M = 2.80). On tangible non-monetary incentives, netball reported the least value (M = 2.33) on tangible non-monetary incentives while basketball reported the highest mean (M = 3.21). These results suggest that non-monetary incentives may be a useful supplement to monetary incentives in motivating athletes to win medals in national sports organisations, particularly in Africa where economies are struggling. Results are discussed within self-determination and achievement goal theoretical frameworks.

Social and internal maladjustment caused by the perception of norms: The process of sacrificial selection in competitive situation
Yoriko Uehara Osaka University, Japan
In this study, we examined an actor’s maladjustment caused by his/her excessive normative consciousness. We earlier hypothesised that whereas ought norms, which are generally more compelling, prevent people from causing harm to others, ideal norms, which are less compelling, promote altruism. Further, we identified excessiveness as a mis-understanding of socially ideal norms as ought norms. However, although cost-benefit-related norms are prevalent, the degree to which they are considered appropriate, varies with communities. In the present study, we manipulated the rate of within-group conformance to examine its effect on identifying appropriate conformance. Participants read a scenario about a prisoner’s dilemma game played by dyads. If both players in a dyad selected cooperation or non-cooperation, both gained or lost points respectively. If either one selected non-cooperation, the non-cooperator gained points while the cooperator lost points. The participants were then asked to read about previous selections of group members, where the rate of conformance was 75%, 50%, or 25%. The participants completed a survey on their perception of cooperation. Participants who perceived cooperation as an ought in the 25%-conformance condition, and as not harming others in the 50% condition, conformed to cooperative norms even if the risks were high. In the 75% condition in which cooperation was most selected, their perception did not correspond to the selection. Interestingly, in the 25% condition, the selection of cooperation did not elicit pride, but it did so in the 50% condition. Therefore, we conclude that excessive-ness leads to further maladjustment.

Homeless people in Madrid (Spain)
Jose Juan Vazquez Universidad de Alcala, Spain; Sonia Panadero; Rosa Martin; Carolina Marin; Alejandro Iborra
Nearly a quarter of the Spanish population (19.9%) lives under the poverty threshold. Homeless people, due to their scarce social resources, are situated in the lowest position in terms of social exclusion. The objective of this study is to analyse the influence of certain variables, such as stressful life events (experiences that play a key role in one’s life and that frequently cause significant changes for the person involved (Vazquez, Munoz & Panadero, 2005)) in a homeless situation. In the last years, much research has focused on the relationship between these vital events and homelessness, and, as documented by previous studies, are a key variable to explain the origin, and maintenance of, a homeless social situation. This study was performed with a quantitative methodology, structured interviews conducted with members belonging to the three samples (a representative sample of homeless people living in Madrid city in Spain) (188 participants: men: 83%; women: 17%), an equivalent sample of high risk people and an equivalent sample of low risk people. The main characteristics of the sample and the results on stressful life events, and their influence on the processes of social exclusion-inclusion will be presented.

Perceived causes of poverty in developing countries among Spanish-speaking population
Jose Juan Vazquez Universidad de Alcala, Spain; Sonia Panadero; Jose Vazquez
In Latin America, poverty affects significant portions of the population, as vast social inequalities constitute one of the main impediments to development in the region. In this context, knowledge of attributions about the causes of poverty in less-developed countries becomes an important step towards the design of appropriate policies to counteract this impediment, as well as an important tool to guide strategies intended to modify the attribu-
tions. The present study analyses the attributions about the causes of poverty in less-developed countries made by Spanish-speaking university students originating from four countries with various levels of economic and social development: Nicaragua, El Salvador (less developed), Chile (moderately developed), and Spain (developed). Through a self-administered questionnaire, we polled over one thousand students from varying economic classes with regard to their opinions on the causal influence of various circumstances on the emergence and persistence of poverty in less-developed countries. The results show that the more than one thousand interviewed students could be divided into five, large groups which, depending on variables such as sociodemographic standing, political ideology, social class, religion or income, attribute the emergence and persistence of poverty in lesser-developed states to different factors: economic, political, or cultural factors external to the states themselves; factors relating to fatalism, natural influences, corruption and incompetence of the government; or factors related to customs, or dispositional traits of the inhabitants of the lesser-developed countries.

The relationship between account-giving and moral judgment for corporate wrongdoing

Jinmin Wang
Chiba Institute of Science, Japan

This study was designed to investigate the explaining-condoning effect in corporate wrongdoing situations. Japanese college student participants (N=102) read a short story describing a food fraud (unethical, illegal behavior of a large company) was detected by the authorities. The participants were asked to write explicit reasons for the wrong doing, and at no-explaining condition, some common names of goods. The results showed that (1) participants evaluated the "badness" of the wrongdoing itself, and the involved company "worse" at the conditions of more severe damage, or more company responsibility for the wrongdoing. Types of both accounts, and corporate transgressions, were discussed as possible reasons for the lack of explaining-condoning effect.

Perspective-taking and perception of intergroup conflicts

Zhao Xian
School of Psychology, Beijing Normal University, China; Xian Zhaq; Li Liu; Xiaoxiao Zhang; Jiaoxin Xin

Social psychologists have fruitfully investigated how to improve intergroup relations. However, less attention was paid to people's perception of intergroup conflicts. Numbers of researches showed that perspective-taking could decrease intergroup bias and outgroup prejudice. Current findings could not figure out whether perspective-taking could effectively alleviate the negative influence of intergroup conflict. We hypothesised that perspective-taking may reduce threat feelings arising from specific outgroup members in conflicts, and arouse threatened feelings arising from specific ingroup members in conflicts. Threats from specific outgroup members in conflicts may generalise to the whole outgroup, but threats from ingroup members in conflicts could not generalise to the whole ingroup. Three experiments were designed to test two hypotheses. The conflicts in first two experiments were artificial Han-Tibetans student conflicts. In experiment 3, we developed another artificial conflict with Tajfel's (1970) minimal paradigm. All these three experiments were single factor between-group design. Participants in the perspective-taking group were asked to redescribe the conflicts and write it down from the view of outgroup members in conflicts. Consistent with our hypothesis, in experiment 1, perspective-taking significantly reduced intergroup anxiety towards specific outgroup members in the conflicts and the whole outgroup, and aroused anxiety of specific ingroup members in the conflicts, but not the whole ingroup. Similar results were found in implicit threat priming tasks, explicit attitude measure and traits evaluation. Perspective-taking was a valuable tool to cool the tension between intergroup after intergroup conflicts.

Can female PhDs be high-level talents? Exploratory study of career possible selves of female PhDs

Wei Xiao
Tongji University, China; Bo Zhang; Hong Xu; Jin Liu

The contradiction between social values of female high-level talents and the phenomenon of "vacancy in high-level" has been generally confirmed. As female PhDs are reserve forces of female high-level talents, research on the career psychology of female PhDs and how they make career planning is especially important. Twenty-eight female PhDs from diverse hometowns, colleges, research fields and marital and child-rearing status participated in interviews focused on their hopes and the expected selves that they want to express and achieve. Participants suggested that career possible selves of female PhDs show significant differences in clarity, availability, balance and flexibility. Compositions of self identity and social identity, self construction and influence from others play roles of construction/direction and reconstruction/modification in the formation of their career possible selves so as to lay the theoretical foundation for the significant differences in the above external behaviour characteristics. This is a rare, female-PhDs-only study that examines the career psychology at the starting point of career decision of female high-level talents. Conclusions provide action plans for training and developing career self-awareness of the reserve forces of female high-level talents.

Impact of OTAKU phenomenon on undergraduates' living attitude and state

Min Yang Chia

OTAKU is a loanword from the Japanese language referred to people with obsessive interests, particularly animated cartoons, comics, or video games. However, it can relate to a fan of any particular theme, topic, hobby or any form of entertainment. In China, OTAKU is commonly called "Home Geek". More than 1000 questionnaires have been done among undergraduates from different majors in 15 universities. From the research, we know that OTAKU is very popular among undergraduates and addiction to computer is the main characteristic. Undergraduates hold diversified visions on OTAKU and half of them suggested certain changes on its negative effects. Nowadays, with the development and popularity of computer science and technology, Chinese undergraduates are proficient in using computers, which provided a cornerstone for them to be a "Home Geek". From the angle of social psychological development, most undergraduates belong to "born-in-1990s generation", usually they are the only child in their families, they grow up as a "spoiled generation", dare not to face the world and prefer to be addicted in a virtual social space, which help them to be a "Home Geek". Meanwhile, undergraduates have obtained much modern knowledge and are open to accepting new things, would like to show their creativity and innovation of a new phenomenon. In the process of socialisation they choose to stay at home, log onto the internet, and express themselves in their own style.

Effect of implicit attitude on automation use

Jiaoyan Yang
Institute of Psychology, China; Sun Xiangrong; Yang Jiaoyan; Wu Mingheng; Du Feng

Recent results in attitude suggested that both explicit and implicit attitude which was measured through an indirect way could predict human behaviour. However, explicit attitude was dominant in the prediction of deliberate and thoughtful behaviour, while implicit attitude was more predictive in spontaneous and automatic behaviour. In the present study we investigated participants' implicit attitude toward automation and its predictive effect on automation use. The results showed that the implicit attitude for automation was negative while it was positive for a human expert. Implicit attitude could be predicted by automation use. But the predictive effect of implicit attitude was moderated by automation reliability and judging time. Specifically, when the reliability of automation (which was 75%) approached that of participants (M=67.9%), implicit attitude predicted automation use worked very well. However, when the reliability of automation (which was 90%) and participants differed greatly from each other, implicit attitude had a smaller effect on automation use. Moreover, when the decision time was limited, the predictive effect of implicit attitude was significant, but it was not the case when time was abundant.

Antecedents and consequences of group emotions: Empirical evidence from China

Keshun Zhang
University of Konstanz, Germany; Jason Ringo; Ping Fang; Thomas Goetz

Group emotions are important as they influence action tendencies and behaviors (Smith, 2007). In China, negative group events are becoming more common (e.g. the killing of several kindergarten children, triggered a series of similar crimes, arousing anger and fear across China), however, few studies have studied group emotions. Thus, the current study explored their expression in Chinese society. Two studies were conducted assessing potential antecedents, firstly, group category and social sharing of emotion, secondly, to explore their influence on action tendencies. We hypothesised that group category and social sharing of emotion, impact on the strength of emotional reaction (H1) and that group emotions regulate group action tendencies (H2). In study 1, the group category (in and out-group) was experimentally manipulated in 144 Chinese high school students, by providing them with fake news to arouse their group emotions (happiness or anger),

Social Psychology
and action tendencies were measured. Study 2 (111 Chinese high school students) investigated the effects of social sharing of emotions on group emotions and action tendencies. Consistent with our hypotheses, in-group members generated stronger group anger and less happiness than out-group members. Furthermore, group anger intensity was maintained after emotion sharing, while, not sharing, led to the dissipation of emotion. Finally, group anger positively predicted action tendencies (spread news, protest) while group happiness positively predicted support tendency. Therefore, we concluded that negative group emotions and the generating of negative events, could be prevented, by obtaining prior knowledge about the individuals’ group categories, as well as the approaches utilized when sharing emotions.

A cross-cultural study of crime judgement

Yanyan Zhang Jilin University, China

The current research addressed three possible mechanisms through which culture shapes individuals’ crime judgements: beliefs about punishment functions, endorsement of moral foundations, and cognitive styles. In Study 1, bi-cultural Asian-American (N=213) and European-American (N=118) college students underwent cultural priming, performed computer-based cognitive tasks, read legal violation scenarios and completed various surveys and questionnaires. Study 2 directly compared American college students (N=331) from Study 1 to Chinese (N=295) college students in China. Results revealed both cross-cultural similarities and differences in crime judgements. On the one hand, there was no cultural difference in crime judgements related to the deterrence function of punishment, and those related to the modern moral foundations (i.e. harm and fairness) across cultural groups. On the other hand, culture influenced individuals’ crime judgements related to the retribution function of punishment, and those related to the traditional moral foundations (i.e. in-group, authority). On the other hand, culture influenced individuals’ crime judgements related to the “in-group” moral foundation. As hypothesised, Chinese held stronger negative attitudes toward the criminal if the victim was an in-group member. American people, however, reacted more negatively if the victim was a stranger. Finally, culture also influenced individuals’ crime judgements related to the “authority” moral foundation. Supporting my hypothesis, Chinese held stronger negative attitudes toward the criminal if the victim was an authority figure. Americans, however, reacted more negatively if the victim was a person sharing a similar social status.

Explanatory models of regionalist social participation in Chile: Between identity and rationality

Claudia Zuniga-Rivas Universidad de Chile, Chile; Rodrigo Asun

The social sciences have historically sought to explain popular participation in social movements that challenge the established order. The theories range from those ascribing social movements to irrational collective behaviour in societies undergoing accelerated processes of transformation, to models explaining popular involvement as driven by the rational calculation of costs and benefits. Despite this diversity, two large categories of models currently monopolise the attention of researchers: (1) theories related to social identity, which sustain that existing conditions cause people to question the situation of the group they identify with and explain it based on power relations with an exogroup. The endogroup then creates an active identity that challenges the power structure and seeks a solution: (2) modern theories centered on rational calculation, which affirm that involvement in collective conduct is contingent on people’s valuation of the social movement’s objective, perceived chances of success, the approval from their social milieu, and calculated benefits and costs of participation. This investigation tests both models’ predictive capacity concerning readiness to participate in regionalist movements in Chile. A representative sample (1,200 cases) in four regions was surveyed, and the data analysed using multiple regression and structural equation models. Findings are that readiness to mobilise is linked to perceptions of the objective’s importance, the mobilisation’s legitimacy, probabilities of success, significant others’ opinions and participation, prior participation experiences, and associated costs and benefits. Results are discussed according to Tajfel’s social identity theory and Klandermans’ model of individual participation in collective behaviour.

Causal attributions and meta-stereotypes among homeless people in Madrid (Spain)

Claudia Zuniga-Rivas Universidad de Chile, Chile; Jose Vazquez; Sonia Panadero

One-fifth of Spain’s population lives below the poverty line. Because of their social precariousness, homeless configure the lowest rung of society, the group most vulnerable to social exclusion. The proposed work analyses the causal attributions of homelessness and the meta-stereotypes maintained by Madrid’s homeless. Both cognitive processes (causal attributions and meta-stereotypes) are analysed according to various modulating factors, such as the utilisation of resources of assistance, age, place of origin, duration of homelessness, number and characteristics of stressful vital events suffered, etc. As reflected in the scientific literature, attributive processes as well as meta-stereotypes can exert certain effects on the inclusion/exclusion processes of the homeless. We worked with a representative sample of homeless in Madrid, interviewing them on the streets and in housing resources. The final sample comprised 188 homeless, 84% male and 16% female. A hetero-applied structured interview was applied, enabling us to avoid possible problems due to reading or comprehension difficulties of interviewees. Results show that, in relation to causal attributions, the construct has a multidimensional structure consisting of two factors: Attributions that hold the homeless responsible for their situation, and attributions that assign responsibility for the situation of the homeless to external factors. Regarding the meta-stereotypes, three possible categories are observed: The first would reflect a negative image of the homeless; the second, a positive image; and the third, a victimised image. The realisation of certain causal attributions and the use of various meta-stereotypes by the homeless are related to different variables.

Social Psychology
research results on some debated or under-researched aspects of competition, including the following: (1) The relationship between interpersonal competition and cooperation: Is it possible to compete cooperatively? (2) The cross-cultural aspects of competition: Is the concept of competition the same across cultures? Is there a collectivistic and an individualistic version of competition? (3) The developmental aspects of competition: What kind of representation 8- to 9-year-olds have about competition and winning and losing? How adolescents and young adults cope with winning and losing: Are there more and less adaptive versions? Do old people compete and in what way? (4) How morality/fairness of the competitive process shapes coping with winning and losing? (5) Is it possible to be highly competitive and be mastery motivated and task oriented at the same time? Are all types of competitions extrinsic motivations? (6) Do perceptions of the role of competition in social and economic life differ among young people brought up in different societies in terms of their political history, economic development and culture? The talk ultimately aims to demonstrate that competition is a significant dynamic force of individuals, groups and societies, but its constructive or destructive nature is dependent on individual, situational, cultural and societal factors.

Intergroup forgiveness and reparation: The role of identity and intergroup emotions
Roberto Gonzales Chile

Over the past 50 years, social psychology has prioritised the study of intergroup prejudice and conflict. By contrast, our understanding about how to actively promote positive outcomes within intergroup relations is less well developed. Studying the psychological processes of such positive outcomes is important because it could provide new insights for developing theoretical perspectives and planning real life interventions aimed at improving intergroup relations rather than simply reducing prejudice and conflict between groups. This presentation contributes to this goal by presenting and discussing new theoretical frameworks and empirical evidence examining the role of social identities and intergroup emotions in predicting intergroup forgiveness reparation in the Chilean context which is still dealing with the legacy of the political violence they experienced from the late 1960’s through the end of dictatorship in 1990. Specifically, it examines how important is to consider group identities (party identity) and superordinate (national identities) to predict several intergroup emotions associated with the wrongdoing (anger, guilt, shame, outgroup trust, and empathy), which in turn are expected to differentially predict forgiveness and reparation, the two major manifestations of the Chilean political reconciliation processes initiated after the recovery of democracy in 1990. Beyond the conceptual differences between forgiveness and reparation, this study analyses the differential relationships they have with these identity as well as emotional factors involved in the reconciliation process. Respondents were university students who identified with one of the two major political groups originally involved in the conflict (N right-wing=225 and N left-wing=264). All of them were politically socialized in democracy. Overall, the results confirmed the value of the predicted multivariate model and shows that the right-wing group differed from the left-wing group in many respects regarding the cognitive, emotional and identity factors associated with reparation and forgiveness. In addition, it was supported the meditational role that intergroup emotions play in mediating the relationship between social identities and intergroup forgiveness and reparation. This pattern of relationships was in turn moderated by the role those groups played in the conflict, supporting the central idea of considering social identities when understanding these processes. Theoretical as well as practical implications are addressed.

Social identities and intergroup relations: Models and applications in Iraq and Lebanon
Charles Harb American University of Beirut, Lebanon

When the state’s central power shrinks, collectives and groups step in to protect their constituents, and ensure the survival and prosperity of their respective members. This axiom applies to countries that have witnessed the dissolution of the state (e.g. Iraq, Palestine, etc.), an abrupt change of regime (e.g. Arab revolts 2011), or in countries with heterogeneous and fragmented societies (e.g. Lebanon). We elaborate on the Self-Categorisation Theory (SCT) to explain emerging intergroup conflict and propose a dynamic hierarchical system of identification that moderates socio-political violence. This moderating role of identities is tested in a representative sample of Iraqis (N=2724) and Lebanese nationals (N=1500 and N=1200), and is further tested in a controlled experimental setting (N=220). The implications of the model for (1) reducing intergroup conflict, (2) understanding political violence and (3) predicting social outcomes are discussed.

Social motivation, social interaction and motivated social cognition
Eva Jonas University of Salzburg, Austria

When people refuse to cooperate, distort or ignore information, and close off against well-mean improvement suggestions, the underlying reason is often that they feel threatened. The causes can be existential threats, restrictions to personal freedom, loss of control, experiences or observations of unfairness or the infringement of norms. These threats lead to the motivation to eliminate the threat - this governs our behaviour, and our cognitions. Psychological processes help explain why people often find it difficult to open themselves up to ideas and suggestions for change. When these ideas threaten the self or the in-group and related convictions, this leads to the discounting of new ideas and the corresponding interaction partner. The motivation to defend important convictions, to protect the self from attacks or to make a good impression on others affects processes regarding information seeking, the exchange of information and interaction. I present a model of social interaction and motivated social cognition in which different motivational theories are combined - such as terror management theory, dissonance and reactance theory, rational choice and fairness theories - to better understand processes in social interactions. Empirical studies exemplify how different parts of the model can be supported.

Creating tomorrow’s future: Psychologists working for the human rights of vulnerable children
Fred Bemak George Mason University, University of States of America

The next generation, the children, are the hope for our global future. Yet all over the world, many of these children are vulnerable, unsafe, and lack the opportunity for a positive and healthy personal, social, and productive future. Streetchildren, orphaned children, children affected by HIV/AIDS, school dropouts, trafficked children, migrant children, drug addicted children, and impoverished children all fall into this category, facing a life filled with uncertainty and a day-to-day existence. This presentation will illuminate the situation of vulnerable children and discuss the psychologist’s critical role in providing support.
healing, and interventions for this growing worldwide population. Culturally responsive psychological interventions will be discussed within a human rights and social justice framework which redefines psychology to address the needs of vulnerable children.

**Human rights issues with immigrants and refugees: The role of psychologists in advocacy and social justice.**

*Rita Chi-Ying Chung; George Mason University, United States of America*

The number of migrants in the world continues to grow and now constitutes over 3% of the world's population or an estimated 214 million people. Immigrants and refugees oftentimes face difficult issues of rapid social, familial, cultural, economic, and political changes. Given on-going wars, conflicts, natural disasters, famine, drought, poverty, climate and environmental changes, diseases and human trafficking, millions of refugees and immigrants are forced from their homes, villages, communities, and countries. The world's migrants have been found to have higher rates of depression, anxiety, and post-traumatic stress than the general public. Compounding their psychological social adjustment and adaptation, they are also confronted with racism, discrimination, and intolerance by members of the host country. Migrants are often viewed as foreigners whose values, beliefs, and worldview conflict with their host countries. Psychologists play a pivotal role in addressing this growing global issue of migration. Given migrants' multiple psychosocial and sociopolitical adjustment and adaptation issues, it is critical that psychologists provide culturally responsive interventions that challenge the negative societal views prevalent in many resettlement countries. This involves addressing psychological well being while simultaneously attending to human rights violations and social justice challenges faced by migrants. This presentation will discuss a culturally responsive model of psychological intervention for refugees and immigrants that addresses social justice and human rights and incorporates psychological advocacy to promote positive mental health and successful adjustment for migrants.

**De-silencing Muslim immigrants: An integration of psychological science and practice**

*Ayse Ciftci United States of America*

Religion, a dimension of cultural diversity, is one of the most critical variables in the immigrant experience. Among many immigrant groups, religion becomes more salient after migration because it affects the nature and kinds of identity embraced by immigrants. Muslim immigrants are one of the fastest growing minorities in the United States and they are expected to become the second largest religious group by 2020. Currently, there are an estimated 7 million Muslims living in the United States. Seventy-eight percent of these Muslims are born outside of it. Since 9/11 and the wars in the Middle East, there is a significant increase of the prejudice and discrimination experienced by Muslims resulting in an increasing number of civil rights cases and mental health problems. Religion can also function as a generic mental model that influences psychological well being. It is clear that religion permeates through an individuals social and culture modalities as well as the individuals psyche thus, it is imperative that psychologists fully understand how to incorporate religion more when working with Muslim immigrants. In doing so, psychologists need to understand Muslims beliefs and stigma about mental health. In this presentation, I aim to present Muslim immigrants stories from qualitative and quantitative studies as well as discuss clinical strategies to work with this population.

**Human rights advocacy: Linking psychology with global imperatives**

*Neal Rubin United States of America*

In 1948 the Universal Declaration of Human Rights (UDHR) was the first solemn compact setting forth a global human rights agenda. Together with the Charter of the United Nations, a foundation was established for the world community to secure the dignity and security of all persons. However, in the shadow of the Holocaust and human experimentation, along with the emerging Cold war and the threat of nuclear annihilation, the role of science in forwarding the aims of this international organisation was largely absent. While this omission can be understood in the post-world war two context, the question of the relationship between scientific endeavors, academic pursuits and social justice imperatives remains to be articulated. The purpose of the proposed presentation will be to explore the role of psychological science and education in promoting a 21st century human rights agenda. How can psychologists link emerging knowledge in our field with formulating responses to humanity's struggles today? What is the relevance of our emerging evidence base for conceptualising models to address pressing health and mental health imperatives before our world community? This presentation will focus on the promise of psychology and psychologists to advocate for and to substantially inform today's challenges to human aspirations for a more just and secure world.

**Propounding a new cultural paradigm for psychological analysis of social media**

*Ali G. Afroz PCI Iran, Islamic Republic of Iran; Seyed Mohsen Fatemi; Mohammad Khodayari*

This paper focuses on cultural differences in processing information on media analysis and their implications. The study has a special focus on Iranian media and their psychological impacts. The paper argues that an Islamic perspective on media and media management calls for a radical transformation of consciousness where the etiological, ontological and epistemological reference points go beyond the perfunctory and superficial layers of materialism and consumerism. The psychological implications of such a shift would have a salient impact on the renaissance of the self, the revitalisation of society and the intellectual, emotional, affective and cultural development of people. Whereas the hegemony of the current mediated technological messages within the western paradigm would concentrate on economic and material development, and the indices and templates are designed according to the growth of material assets, resources and profits, an Islamic-oriented media would offer a concentration on the quintessential needs of human beings by virtue of a transcendentental perspective on human beings. Contrary to the pervasive utilitarian media which are devoid of any indication to the strong spiritual needs of human beings, an Islamic-oriented media would propound a solid and rich status for the spiritual development of human beings. This is tied to the presence of a monotheistic worldview (Towheed) and its implications where human beings are liberated from the hooties and manacles of hubris, arrogance, selfishness and corruption. A monotheistic-driven media would augur the possibility of elevation and ascension beyond the materialist paradigms thus producing programmes that pay attention to consumption of communities in view of novel horizons of religiousness, spirituality and sublimity.

**Integrating citizens into a community that engages in climate change mitigation behaviours**

*Mica Estrada California State University, Sacramento, United States of America; Alyssa Messina; P. Wesley Schultz*

Worldwide, millions of dollars are being spent annually to increase citizen knowledge about the science of climate change. Yet, scientific knowledge is not consistently related to engagement in behaviours that mitigate climate change. This study shifts the traditional focus on science education to a study of how citizens integrate into a thought community concerned about climate change. We suggest that widespread shifts in behaviour rest upon integrating citizens into a community that engages in normative climate change mitigation behaviours. Drawing upon previous work on the Tripartite Integration Model of Social Influence (TMSI) (Estrada et al., 2011), we hypothesised that knowledge that promotes efficacy, identity and values would be most related to engagement in behaviours consistent with a concern community. One thousand citizens were sampled in a San Diego public opinion poll to test the hypotheses. Results show that while science knowledge is significantly related to conservation and environmentally friendly transportation behaviours, these relationships are significantly mediated by efficacy (belief that one can engage in mitigation and adaptive behaviours), identification with a community of concerned citizens, and internalisation of concerned citizen community values. These findings support the hypothesis that knowledge that increases efficacy, identity and values is more important than knowledge that conveys scientific facts alone when encouraging citizens to engage in normative mitigation behaviours.

**Symposium title: Psychological contributions to mitigating climate change**

*Convenor: Linda Steg*

**Revisiting the role of culture in cultural psychology**

*Sayedmohsen Fatemi Harvard University, Canada; Ghollam Ali Afroz; Seyed Mohsen Fatemi; Mohammad Khodayari*

This paper argues that culture is inextricably tied to understanding psychological phenomena. By virtue of an in-depth analysis of the role of culture in facilitating or impeding social cognition, the pre-
Rethinking South African men and masculinities in the flows of liquid culture
Kopano Ratele
University of South Africa/MRC, South Africa

The majority of studies on men and masculinities have gotten entrapped in thinking about South African men’s practices through the Manichean frames of immutable power/powerlessness, dominator/dominated, violence/non-violence and risk/safety. The influential concepts, methodologies and theories used to understand men and masculinities have become an impediment, and in failing to grasp the flows of liquid power in a changing society, unwittingly reinforce a subtly racist image of black men. On the whole, studies appear unable to help us to understand how, in a transitioning, unsettled society, practices are maintained, challenged, rethought, shift, evolve, and/or fail to change. This symposium, whose rationale is to contribute towards taking us beyond the prevalent impoverished models used to approach South African men and masculinity, is intended to provide a space for researchers, teachers, clinicians, counselors, practitioners and activists with an interest in the critical and positive psychology of men and masculinities to share their work and insights. The symposium is designed to inform, challenge, promote, debate and influence the current direction and future of research, education, advocacy, and development practice related to men and masculinities in South Africa and beyond.

What we still need: Politicising personal pain in learning to care
Kopano Ratele
University of South Africa/MRC, South Africa

How do we as men who are under greater pressure of local and global forces to change, as men who are often but uncritically referred to as upholding traditional masculinity, author a more capacious form of masculinity? Above all, I will argue that we must learn to speak of what we need(ed). Only through speaking about what we needed in our past can we overcome the pain and insecurities of the past and overvaluation of appearances, but also learn to wash more dishes, change more diapers, and care for others and ourselves. Going back to where one came from intellectually, emotionally and maybe even physically leads to more awareness about those pains of childhood that very likely persist into adulthood and towards a more secure and fulfilling masculinity. Returning to reflect on the sources that went into making one into the kind of man one became can, I hope to show, make a person understand masculinity generally and his own gender behaviour better. I will argue that experiencing poverty or witnessing inequality, especially in early life, informs how we learn about what is important and what is not in our lives, culture, and society; that is, how we learn to care or not care, what to care for and what not. In the end, teaching ourselves and others to care is even more important in the face of poverty, inequality and times of rapid change.

Symposium title: Using sport to teach HIV/AIDS intervention life skills
Convenor: Glyn Roberts

Using sport to promote HIV/AIDS education for at risk youths: An intervention using peer coaches in football
Glyn Roberts
Norwegian University of Sport, Norway; Cyprian Maro
Norwegian University of Sport, Norway; Marit Sørensen

The purpose of this study was to investigate the effectiveness of an ongoing AIDS education intervention programme (EMIMA) using peers in a sport context. A quasi field experimental study was employed in which at-risk children in Dar es Salaam in Tanzania (n=764) were recruited (average age=13.6 years) and were randomly grouped into a treatment group and two control groups. The treatment group was peer coaches conducting the AIDS education to the children within sport. The two control groups were: In school children, who received traditional AIDS education; and out-of-school children who received no education at all. The intervention lasted for 8 weeks. The results indicated that the intervention using peers in sport were more effective in transmitting HIV prevention knowledge, cognitions and perceived behaviours than the control groups. Contrary to expectation, the school based HIV education was no more effective than the informal education obtained by the out-of-school children. The use of peer coaches within the EMIMA programme was reliably the most effective means for HIV/AIDS education for these at-risk children.

Developing a men's health centre in the Eastern Cape province: Ulwaluco as a vehicle in the development of positive masculinity
Mthetho Tshemese
Nelson Mandela Academic Hospital, South Africa; Nthuthuzelo Lusawana

Every winter and summer holiday, thousands of young boys in the Eastern Cape attend "ulwaluco" (traditional initiation). According to the latest, unofficial report, by the Eastern Cape House of Traditional Leaders, there were just under 10 000 initiates who went through Ulwaluco during the 2011 winter season. About 9 900 of these young men were successfully initiated into manhood, with about 50 dying and the other 50 hospitalised. Ulwaluco thus punctuates the development of masculinity of many of these young Xhosa boys in a significant way, since after successfully undergoing the initiation they can become "amakhwenkwe," accorded a new social status and title which signifies a desirable "ubodada" (manhood). For amaXhosa males there is no greater honour for a boy than shedding the undesirable status of being a boy. Due to the risk of death or injury, there have been calls to abolish the ritual, while some have argued for the adaptation of the ritual to be "mordenised" so as to improve safety and to reduce injuries. The problems facing traditional initiation have made us ignore the possibilities and opportunities of this ritual being used as a springboard for dialogue, for the creation of healthier, responsive and positive masculinity in the Eastern Cape Province. The current National Strategic Plan (2012-2016) includes medical male circumcision as part of HIV-prevention package. This presentation will attempt to demonstrate how developing a Men’s Health Centre in the Eastern Cape Province could help in contributing to the development of positive masculinities using traditional ulwaluco as a vehicle.

Symposium title: Mobilising spiritual capacities and religious assets to promote positive masculinity
Nailema Taliep
MRC-UNISA, South Africa; Tony Naidoo; Sandy Lazarus

The incidence and prevalence of male interpersonal violence becomns the need for innovative and effective strategies to address this unbridled scourge. The promotion of positive masculinities as opposed to focusing on male deficits has been identified as a strengths-based intervention approach. Using a spiritual capacities and religious assets approach is one possible, relatively unexplored avenue that can be mobilised to promote positive masculinity. This paper explores how spiritual capacities and religious assets can be leveraged to promote positive masculinity. This paper is part of a current ongoing international study on Spiritual Capacities and Religious Assets to Transform Community Health by mobilising Males for Peace and Safety (SCRATCHMAPS), carried out under the auspices of the Safety and Peace Promotion Research Unit (SAPPRU, MRC/Unisa) and the International Religious Health Assets Programme (Public Health at UCT, and LeBonheur Healthcare in Memphis).

Gender issues in an intervention using peer coaches in sport
Glyn Roberts
Norwegian University of Sport, Norway; Cyprian Maro
Norwegian University of Sport, Norway

Young women in Sub-Saharan Africa seem to be dramatically more likely to be infected with HIV than young men (Glyn, Carael, Auvert, Kabindo, Chege. Musonda, et.a., 2001; Gregson & Garnett, 2000; Macphail, Williams & Campbell, 2002; UNAIDS, 2004; UNICEF, 2004). The higher vulnerability of females is not a question of biological differences
between the sexes, but is due to differences in gender roles in many ways. The purpose of the present study was therefore to examine the gender differences in HIV-related cognitive and behaviour intention variables of at-risk children in Tanzania and investigate whether involvement in interventions influenced male and female youths differently. Systematic gender differences occurred both at pretest and after the intervention. However, both genders benefitted from the intervention, but boys increased their scores more on some variables, especially those related to condom use. The intervention through EMIMA in particular empowered males more than females with the condom-related questions. The gender role expectations extant in the society clearly have a powerful and debilitating effect on condom use and ideas about behaviour in sexual relationships for women. To change gender norms is difficult, but it may require more systematic gender-focused interventions than in this project. Both other types of activity and using more gender sensitive measurements should be considered.

Combating HIV/AIDS in sub-Saharan Africa: Introducing mastery motivational strategies into a community based life-skills intervention through sport
Glyn Roberts Norwegian University of Sport, Norway; Cyprian Maro Norwegian University of Sport, Norway; Marit Sørensen

The research project investigated whether mastery motivational strategies could enhance the effectiveness of life-skills interventions for HIV education through sport. A quasi field experimental study was conducted in Tanzania with at-risk children (N=564) randomly grouped into two intervention groups and one control group. The intervention groups received AIDS education using trained peer coaches in football, with one group trained in using mastery strategies within the life-skills programme. Children in the intervention groups all reported significantly greater HIV knowledge and positive attitudes and safe-sex behavioural intentions. The mastery motivational strategies reliably enhanced risk reduction for some of the variables. Canonical correlation analysis revealed meaningful relationships of mastery strategies with the variables. The life-skills intervention through sport for HIV risk reduction was effective, and mastery motivational strategies enhanced that effectiveness.

Social class and prejudice: The role of ideologies supporting social hierarchies and aggression against "deviants"
Hector Carvacho Universität Bielefeld, Germany; Andreas Zick

The prevalence of prejudice among people of lower social classes has been widely documented and debated. Social class membership is accompanied by ideological configurations, which are tied to racist sentiments. Right-Wing Authoritarianism (RWA) and Social Dominance Orientation (SDO) are used as measures of ideological attitudes. RWA is conceptualised as a tendency to support aggression of strong authorities against deviants. SDO is the tendency to support the current social hierarchies. We expected them to mediate the negative relationship between social class belonging (indicated by income, educational level and job status, when available) and prejudices toward various groups, showing indirect effects in opposite directions. RWA is closer to working-class membership. Hence, higher income should lead to decreased prejudice, mediated by RWA. Conversely, SDO is more prevalent in high status groups, and is expected to explain increased prejudice among people with higher income. Study 1 tested these mediation hypotheses in a single model using SEM, including prejudice toward 8 target groups in a representative German sample. Study 2 replicated the model in representative samples from 8 European countries. Study 3 tested the mediation hypotheses longitudinally in a general population panel in Germany. Results revealed that RWA and SDO were negatively predicted by income, and independently mediated its relationship with all prejudices. RWA was the stronger mediator in most of the groups. Results are discussed in terms of ideological consistency, socialisation, and the role of aggression in the maintenance of social hierarchies.

Female violence: Attitudes toward women who kill their children
Afroditi Pina University of Kent, United Kingdom

The attitudes of mental health professionals toward individuals with mental health problems have been the topic of much debate. Carrying the "mentally ill mother" who has killed her child could provoke further negativity because that mother not only has a mental illness, but that illness has also resulted in her killing her child. Research suggests that education can result in an improvement in attitudes. The current study investigates the effect of education level on attitudes toward women who kill their children. It was hypothesised that participants would hold negative attitudes toward women who kill their children and that higher educational level (postgraduate vs. undergraduate) would improve those attitudes. A student sample was asked to complete a questionnaire that aimed to measure their attitudes toward four different cases of female homicide. The results suggest that attitudes toward women who kill their children are not more negative than attitudes toward other women who kill, whereas attitudes toward female homicide were negative. Education did affect attitudes as hypothesised. Therefore, the psychiatric care received by these women may be affected by negative attitudes and impact negatively on their recovery. It is argued that an educational program focusing on women who kill their children could be developed to improve the psychiatric care received and in turn improve the women's recovery.
Cynicism and social comparison orientation: A test of their association and consequences
Ben Chun Pan Lam Iowa State University, Hong Kong; Nicolson Siu; Wesley Wu; Sylvia Chen
Cynicism is a general belief/worldview in the negativity of human nature and interpersonal roughness. Recent research has attempted to explore the psychological mechanisms that undermine cynical individuals’ negative responses towards the world, and their psychological maladjustment. In this research, we examined social comparison orientation, a tendency to evaluate oneself in comparison to others, among cynical individuals. Results from two studies involving both high school and college students revealed that cynical individuals are more likely to compare their abilities with others (rather than opinions), engage in upward comparison to better others (rather than downward comparison), and criticise themselves in comparison with others. These socially comparative and self-critical tendencies then predicted negative psychological outcomes, e.g., dissatisfaction with life. We will discuss how the current findings can enlighten research on the cynicism, and self-process linkage.

The second edition of social axioms survey: A study in eleven countries
Kwok Leung Hong Kong
Based on a deductive, culturally decreed approach, new items were generated to improve the reliability of the original Social Axioms Survey. In Study 1, results from 11 countries supported the original five-factor structure and demonstrated higher reliability for the axiom dimensions as measured by the new Social Axioms Survey (SAS II). Meaningful associations between axiom and Big Five personality dimensions were found. Temporal change of social axioms at the culture-level was found to be quite small. In Study 2, additional new items were generated for social complexity and fate and control and then assessed in Hong Kong and the USA. Reliability was improved further for both dimensions. Two sub-factors of fate control were identified: Fate determinism and fate alterability. Fate determinism, but not fate alterability, was related positively to neuroticism. Other relationships between the axiom dimensions and the Big-Five personality factors were similar to those reported in Study 1. The short forms of the axiom dimensions were generally reliable and correlated highly with the long forms. This research provides a strong foundation for applying the construct of social axioms around the world.

The difference of social axioms found between people of Han and Zang nationality
Jianxin Zhang China; Shuang Chen; Li Ma
The present study is aimed at comparing the relations of nationality, religious faith and social axioms between Han people and Zang minority people. Participants were 196 people with an age range from 19 to 39, being recruited from Tibet and Shaanxi in China. Among the participants there are 50 people of Han nationality, and 127 people of Zang nationality. The old version of General Beliefs Scale was used to measure the social axioms, which included five dimensions: Reward for Application (α=0.90 in the present study), Religiosity (α=0.85), Social Complexity (α=0.84), Social Cynicism (α=0.88) and Fate control (α=0.81). The results showed that compared with the Han nationality, the Zang nationality held a stronger belief in religiosity [F (1,168)=4.63, p=0.03]. In addition, the females got higher scores than the males in Social Complexity [F (1, 146)=4.31, p=0.04].
The role of self-awareness in cooperation among Polish university students

Natasza Kossakowska-Berezewska University of Gdańsk, Poland; Krystyna Adamska; Małgorzata Lipowska

Cooperation is the solution for social dilemmas and processes of community coexistence and the prejudices they face. The interview was ordered to ensure that the participants offered information as they perceived it. The interviews were transcribed and analysed by the programme Nvivo. As a second phase, the study conducted four focus groups with Dominican and Puerto Rican residents in the metropolitan area, two for young people (under 21 years of age) and two adult. For the discussion of the focus groups a guide of questions was designed about the following topics: (1) Social coexistence, (2) intercultural relations, (3) conflicts, (4) adjustment processes in the host society, (5) discrimination, prejudice and xenophobia. The findings are presented and proposes future studies that can contribute to a better understanding of intercultural relations and conflicts that occur in the process of coexistence.

Changes on the social psychology in Latin America: The relation between local productions and world problems

Aluisio Lima Universidade Federal do Ceará, Brazil

In this presentation, we intend to discuss the uniqueness of Social Psychology in Latin America (especially the Brazilian Social Psychology) which, unlike the rest of the world, has a lot of controversy and opposing views on global production. For this purpose, we intend to present the impact of the crisis of relevance of Social Psychology in Latin America between 1930 and 1960, highlighting the critique about predominantly experimental model. In addition, we present an overview of the main local theories and methodologies currently developed and their relation to global issues. This discussion will allow us to explore models of science and paradigms that guide the different perspectives of Social Psychology and the challenges they face in their development.

The development of social psychology in Brazil: A case study in the necessity of a global perspective for the growth of psychological research

Karl Scheibe Wesleyan University, United States of America

In 1968, the discipline of social psychology was virtually non-existent in Brazil. Today the field is highly popular and thriving. The Brazilian Association of Social Psychology (ABRAPSO) was founded in 1980. It now sponsors biennial meetings attended by thousands of psychologists. While a number of Brazilians from the fields of anthropology, medicine, psychology and sociology were instrumental in fostering the development of social psychology, international influences have been conspicuous and important from the start - particularly from France and the United States. This paper will be a brief historical account of the development of social psychology in Brazil since 1968 with emphasis on both domestic and international influences.

Multiple goal management starts with attention: Automatic attention serves goal shielding

Julia Vogt Ghent University, Belgium; Jan De Houwer; Ayelet Fishbach

In a world overloaded by stimuli, it is important that attention is deployed to events that are relevant to the individual’s goals. However, when multiple goals are active, it would be dysfunctional if attention would be guided by all goals an individual pursues. Therefore, in order to shield the prioritised goal, attention should be allocated to events relevant to the focal goal and away from events relevant to competing goals. Three studies will be presented that tested this hypothesis for the automatic deployment of attention. The first study showed that automatic attention registers differences in value and success expectancy of competing goals meaning that more attention is deployed to stimuli relevant to a goal with a higher value or a higher success expectancy. This suggests that the attentional system prioritises the goal with the highest commitment. The second study demonstrates that events relevant to the focal goal of an individual are prioritised over emotional events referring to the survival motive (i.e., threatening stimuli). Hence,
surprisingly, the focal goal appears to be more powerful in guiding attention than evolutionary evolved motives. Finally, we investigated the automatic allocation of attention in self-control conflicts such as having to resist tasty but unhealthy food. Our findings reveal that attention is allocated to events relevant to the higher order goal (e.g., healthy food) and away from temptations (e.g., unhealthy food) but only when the conflict becomes salient. In sum, these studies highlight the role of automatic attention in self-regulation and goal shielding.

Symposium title: New findings in human values theory
Convenor: Jan Ciecich

Social change and human basic values: A nineteen-year follow-up study in Finland
Martti Puohiniemi United States of America

This presentation examines value change in Finland from 1991 to 2010, and the ways that social events and value changes are related. During this time period, Finnish society underwent all of the presumed causes of value change -economic and political turbulences, technological innovations and demographic changes. The presentation is based on two sets of data: (1) Eight representative national samples of A3-study in Finland (1991–2005; N=9839); (2) Five representative national samples of the European Social Survey (2002 – 2010; sample size in Finland N=8671). In both surveys values are measured by using Schwartz’s value inventories which measure the same ten basic values. In the former they are measured by using SVS and in the latter by using ESS21. In ESS-data the Finnish results will be compared to the European totals. Although the data sets are partially overlapping, it is not possible to compare value means directly because the instruments differ. In spite of this difference the directions of the possible changes should, however, be similar in main demographic groups. In addition to the importance of values, two different modes of value change i.e. value-redistribution and value-rescaling will be measured. Examples of the ways that various age groups react to the environmental issues and economic turbulences will be given. I will discuss the findings from the perspective of general social change in Finland and how different demographic groups react to the changes.

Symposium title: Psychosocial interventions for the OVC in sub-Saharan Africa
Convenor: Peter Baguma

Psychosocial interventions for the OVC in sub-Saharan Africa
Peter Baguma Makerere University, Uganda

Leickness et al. present emotional well-being among orphaned and vulnerable children (OVC) in two communities in South Africa with one of the highest rates of OVC in the world. However, very little is known about their emotional well-being. Data from 2234 children aged 6-18 years was gathered in a survey and analysed using percentages. Results indicated that children had poor emotions including being unhappy at times, difficulty making friends, and had scary dreams, being afraid of new situations, sometimes refused eating, and also often and/or sometimes had trouble sleeping. The importance of providing professional lay psychological counselling and support to OVC especially to children orphaned by HIV/AIDS from early on starting when the parents or guardians are seriously ill from HIV/AIDS-related illnesses in order to prepare the children for their parents/guardians’ death were suggested. Baguma et al present an assessment of Psychosocial Support Programmes for OVC in Uganda. These programmes had been running for five years unevaluated so making it difficult to improve them. A nationwide, qualitative cross-sectional study was conducted. The sample consisted of 27 purposively selected organisations, 75 FGDs were conducted with positively selected in or out of school children aged 13–17 years (separated by gender); caregivers of OVC; and community members and 41 key informant interviews were held with programme staff. Data was analysed qualitatively. Findings indicated that a range of psychosocial programmes targeted at the individual, household and community levels and had impact at these levels. Impact was affected by a numbers of factors including key barriers. Recommendations at the national and at programme levels to improve impact are provided in the text. Mambwe Kasse-Hara discusses the rationale for strengthening interventions targeting guardians and caregivers of OVC in low income communities. She notes that in Africa, orphans tend to be cared for by surviving relatives; mostly grandparents, aunts and uncles. These end up being stressed like the orphans themselves and need interventions themselves. Recommendations are presented. Some 309 orphans participated in the study under a cross-sectional survey where data were analysed quantitatively. Compassion Fatigue (CF) Burnout (BO), and Compassion Satisfaction of caregivers were assessed. Significant correlations were found between these variables. Psychosocial interventions are suggested for the orphans as well as the caregivers.

Dying to help, helping till they die? Who helps the helper?
Solomon Mumah Kenyatta University, Kenya

Recent advances in psychological research suggests that family, friends and professionals are susceptible to developing traumatic stress symptoms from being empathetically engaged with victims of traumatic events. The phenomenon of learning about another’s traumatic ordeal, and in the process, experiencing traumatic stress is called Secondary Traumatic Stress (STS), and the condition of young people orphaned by AIDS is suspect to this. Many are dispossessed of their parents’ property and must contend not only with the normal stress, dissatisfaction or work, but also with the emotional and personal feelings for their parent(s) and suffering sibling(s). This study assessed prevalence and extent of severity of STS among AIDS orphans, thereby identifying factors that predispose them to STS. Some 309 orphans from Ranchuowo District in Kenya participated in the study. The single cross-sectional survey adopted the questionnaire as the main tool for primary data collection. These were analysed quantitatively. Based on results, orphans exhibited at least 17 of the 30 symptomatology of STS investigated at a level that is comparable to people who would seek treatment for those symptoms. On the overall, more males (57.7%) than females (42.3%) exhibited these symptoms. Regarding the relationship between STS symptoms and the development of STS, the study established that Compassion Fatigue (CF) was more strongly correlated to STS (correlation=0.875; p<0.001) than Compassion Satisfaction (CS) (correlation=0.148; p<0.05). Further relationships were established between STS and sex of the respondents (F=4.947; p=0.027), level of formal education attained (F=3.013; p=0.034), number of years of paternal orphanhood (F=4.812; p=0.003), number of hours per day spent in care giving (F=9.827; p=0.000), persons to whom such care was rendered (F=9.202; p=0.000) and the involvement with household chores (F=3.348; p=0.021). The major predictors of STS were established, thus: sex (t=-2.083; p=0.045), level of formal education attained (t=-2.191; p=0.051) and number of years of paternal orphanhood (t=-2.199; p=0.035) and maternal (t=2.702; p=0.011) orphanhood. It is thus regrettably clear that out of compassion for their suffering loved ones, orphans have become victims of STS - the stress resulting from helping or wanting to help a traumatised or suffering person, and are at the verge of Secondary Traumatic Stress Disorder (STSD) - the pathological response of being exposed to another’s trauma. Who helps these helpless, yet vulnerable young helpers?

Emotional well-being among orphaned and vulnerable children in South African communities
Leickness Simbayi Human Sciences Research Council, South Africa; Geoffrey Setswe South Africa

South Africa has one of the highest rates of OVC in the world. However, very little is known about their emotional well-being. An interview-based survey was conducted among randomly selected 1409 children (47% males and 53% females) aged 6-14 years and 825 children (45% males and 55% females) aged 15-18 years from stratified random samples of 1000 vulnerable households in the Kopanong Municipality of the Xariep District in the Free State Province and the Kanana Township which forms part of the southern part of Klerksdorp-Orkney-Stillfontein- Hartbeesfontein (KOSH) Municipality in the North West Province using two age-appropriate versions of the same questionnaire. This, among other things, also measured emotional well-being. Among children aged 6-14 years, it was found that nearly one third (30%) of them were orphans 24% paternal, 17% maternal, and 3% double ones. In addition, nearly one fifth (17%) of them did not know about the whereabouts of their fathers while 2% did not know about the whereabouts of their mothers. A few children (1.3%) reported that they were heads of households. The overwhelming majority (92%) of the children reported that they belonged to a faith group, with religion reported to be very important universally (98%). Among children aged 15-18 years, it was found that over a third were orphans. Over one quarter of (25%) did not know if their fathers were dead or alive, again with Kopanong...
Municipality having more than double the rate found in Kanana Township. Twice as many children (3.4%) compared to those aged 6-14 years reported that they were heads of households. The level of religiosity was identical to that found among the OVC aged 6-14 years. Among the children aged 6-14 years, an overwhelming majority (91%) of all of them indicated that they were happy. However, a quarter of orphans (25%) reported being still bothered by their parent’s or guardian’s death. A majority of orphans also indicated that they were unhappy at times (61%), had difficulty making friends (73%), and had scary dreams (57%) while large minorities indicated that they were afraid of new situations (40%), sometimes refused eating (30%) and also often and sometimes had trouble sleeping (25%). Among those older enough to envision the future, a large minority (39%) indicated that they were hopeful especially regarding the prospects of getting both a good education and profession. It was interesting to also note that a large majority of the orphans (80%) did indicate that they did obtain a lot of emotional support especially from the community (57%) and their friends. When taken together, these findings suggest the importance of providing professional or lay psychological counselling and support to OVC especially to children orphaned by HIV/AIDS from early on starting when the parents or guardians are seriously ill from HIV/AIDS-related illnesses.

Symposium title: Situational benefits of social support: A comprehensive review
Convenor: Cecilia Cheng

The relationship of social support with psychological well-being and physical health
Sally Chan The University of Hong Kong, Hong Kong
There is a general perception that the availability of social support correlates with better adjustment to life stressors, however, it is not known if social support is associated with our psychological and physical well-being in the same manner. With limited reviews of social support, this meta-analytic study attempts to scrutinize the relation of functional social support (FSS) with psychological well-being (PWB) and physical health (PH). The meta-analytic results establish significant Fisher’s z effect size between perceived social support and life satisfaction, negative affects, and perceived health. However, received social support correlates only with perceived health. In addition, perceived and received support moderate the relationship of FSS with PWB and PH. Perceived support has stronger associations with PWB than received support while received support has stronger association with PH than perceived support. The findings suggest that both perceived and received support are important for our health, but in different areas. A research agenda is suggested to further examine the relationship of social support and health, both psychologically and physically.

Situational differences in seeking online social support: A cross-cultural comparison
Cecilia Cheng University of Hong Kong, China
During stressful situations, individuals often turn to others for support. However, it has been shown that there are cultural differences in how individuals procure social support. Growing ever in popularity, do social networking sites provide social support? If so, is it contingent upon culture? One study was conducted comparing results between a sample of Caucasians from an American university and a sample of Chinese from a Hong Kong university. It was hypothesised that Facebook could buffer the negative effects of stress by providing people with a reminder of their social support networks for European Americans but not for Chinese. A priming study was conducted using a 2 (culture: European-American vs. Hong Kong Chinese) x 2 (Facebook: exposure vs. non-exposure) design; participants wrote about a stressful experience and then were told to find information about their close friends on Facebook (priming them to activate their potential support networks) in the experimental condition to see if being on the social networking site would elicit psychological benefits (social support) versus those who viewed a less social networking site (Wikipedia). Results showed that European Americans intended to seek out others for social support more to cope with their stressful situation in the Wikipedia condition than the Facebook condition, suggesting that perhaps Facebook provides social support that reduces the need to actively seek social support from others. However this was not the case for Hong Kong Chinese, suggesting that Facebook might not provide social support in the way that it does for European Americans.

Social support: Moderated-mediation job demands-resources model
Jasmine Hin-Man Chio The University of Hong Kong, Macao
The present study proposed a revised Job Demands-Resources (JD-R) model in examining the interaction of job demands and social support in affecting job satisfaction among employees. We went beyond the original JD-R model by proposing that not only may job characteristics take the role of influencing employees’ job satisfaction, but a joint effect of job and family aspects should be taken into consideration. Three types of social support, namely: (i) co-worker support, (ii) family support, and (iii) peer support were included as resources to buffer against the negative impact of job demands on job satisfaction. In addition, work-family conflict is proposed to be a mediator between the relationship of job demands and job satisfaction. In the study, 145 Chinese employees were recruited to complete a self-administered questionnaire measuring job demands, work-family conflict, job satisfaction, co-worker support, family support, and social support. Results from regression and moderated-mediation analysis provided support for the revised model. It revealed that the negative association between job demands and job satisfaction was mediated by work-family conflict, and work-family conflict mediated the relationship between job demands and job satisfaction when co-worker support and family support was high but not when they were low. This moderated-mediation JD-R model suggested that the impact of demands-resources relationship on psychological satisfaction is more sophisticated than it was originally theorised.

Symposium title: Social categories and asymmetries in interactional contexts
Convenor: Kevin Whitehead

The construction of marriage through interactional and discursive practices
Angelika Ronge United States of America
Marriage is a social arrangement through which people’s private and public lives can be organised, and is an institution that is embedded in many cultures, if not all (Karasu, 2007). Although it has been acknowledged that interaction is a crucial part of how marriage is constructed (Amato, 2004; Karasu, 2007), to my knowledge there have been no studies focussing on the construction of marriage in interactional contexts. The aim of this study was thus to explore possible ways in which married couples and couples in long-term committed relationships “do being married” – how marriage can be interactionally constructed and negotiated. The data for the study consisted of semi-structured video-recorded interviews with six married couples and one couple that had been living together for more than 16 years. Using a discourse analytic framework and drawing on insights from conversation analysis, I examined how the participants managed their talk about marriage in the interview context. The analysis consisted of an in-depth identification, description and discussion of interactional practices used by the participants, and taken-for-granted-knowledge drawn upon during the interviews to construct marriage. In particu-
Challenges of social psychologists and social psychological research: The case of Ghana
Kitty Dumont

Social psychology has since the time of Triplett grown in nature and scope to cover a wide range of issues. Similarly, the number of social psychologists has also increased across the globe. According to Lahey (2010), social psychologists constitute about 6% of all psychologists. Although the total number of social psychologists in Africa is not readily available, it is conservatively estimated to be less than 10% of the world population of social psychologists and that their contributions in terms of publications is even less. Being a predominantly developing continent, social psychological issues abound in Africa but social researchers and social psychologists within the continent are confronted with a number of challenges which has adversely affected their ability to adequately delve into existing and emerging social issues peculiar to their setting. This situation has significantly affected the rapid development of the field in Africa. This study explores some of the challenges faced by social psychologists in Ghana and the way forward.

Culture, body image, and eating disorders among black South African female students
Kitty Dumont

Research studies in Western countries suggest that body dissatisfaction is an increasing problem during adolescence and young adulthood. It is believed that socio-cultural pressures, such as exposure to idealised media images, have largely contributed to the development of body image dissatisfaction among many young people in Western countries. The data indicates that females show greater body dissatisfaction than males. In addition, the increasing incidence of eating disorders, particularly among young women, has been attributed to negative body image. While eating disorders in South Africa have largely been associated with the white population, there are suggestions that with increasing influence of Western media and values, black South Africans may be falling prey to media-portrayed images of body attractiveness. This paper presents findings of a study focusing on body image and eating behaviour of a sample of black female South African students. The role of socio-cultural influences in body image and eating behaviour is discussed.

Symposium: Overview
Kitty Dumont

This symposium aims to provide a platform for social psychologists to report and discuss social psychological research on African issues. It further aims to bring African social psychologists together in order to discuss possible strategies for developing a continent-wide organisation for championing and disseminating social psychological research. Social psychological research on African issues has a rich and long history, but is not nearly as visible to the international community as research emanating from other parts of the world. More than one in every eight people live on the continent of Africa - roughly the same as the USA and Europe combined - and the continent has great cultural and linguistic diversity. It is therefore indisputable that Africa is a unique and important context for Social Psychological research, practice and application. It is also the case that many of the challenges that African states and groups are grappling with are amenable to the application of existing social psychological knowledge. However, and for a host of reasons, most African social psychologists have tended to establish research collaborations outside of Africa, rather than within the continent. This symposium proposes to bring a group of African social psychologists together, in Africa, with the intention of showcasing their work, but also to discuss the prospects for an African Society of Social Psychology.

Inter-racial mixing among South African students: Insights from planned behaviour theory
Gillian Finchiscue University of the Witwatersrand, South Africa

A number of researchers have noted the low level of inter-racial contact at South African universities. This paper will report two projects that have used the Theory of Planned Behaviour (Ajzen, 1991) to explore the intention of students to interact with other-race students. In the first project, a standard Theory of Planned Behaviour (TpB) questionnaire was administered to 226 students. This project found that the TpB factors, attitudes, perceived control and subjective norms were all significant variables in explaining intention to mix inter-racially. The second project built on this finding, and sought to establish whether the variable constituting barriers to mixing, which have been considered in other South African studies, interface with the standard TpB variables. In this project, 302 students completed an extended questionnaire measuring all these factors. The results again found that all three TpB factors significantly explained intention to mix with other race students. In addition, most of the ‘barrier to mixing’ variables were found to be related to the TpB factors. The implications of these findings for understanding the lack of inter-racial mixing will be discussed.

Social psychology of poverty alleviation
John C Munene Makerere University Business School, Uganda

On average Africa, especially black Africa, has consistently remained behind in growth and development. Academicians from various disciplines have joined policy makers and practitioners to find a solution to the rampant poverty. The exception to this effort is psychology. This presentation tries to create a passage into the debate by utilising Vygotsky’s theory of development and show how development according to Vygotsky is based on one’s network referred to as the zone of proximal development. Following Vygotsky (1978) an individual learns to master his/her environment by interacting with others. She/he learns new ways of living more effectively than before and "customises" the new learning. With time and with new challenges this repertoire or parts of it become(s) obsolete. It is further assumed that the individual then must seek resources from outside of him/herself or generally from his/her cultural environment. It is from this cultural environment that the individual attains higher mental functioning that allows him/her to solve the new problems. The present paper will present case studies that follow this model and demonstrate the relevance of social psychological factors in development and/or moving from poverty to economic well-being.

Mapping patterns of collaboration between African and international authors in psychology
Michael Quayle UKZN, South Africa; Megan Greer

Symposium title: The relevance of applied psychoanalysis in community settings in South Africa
Convenor: Leonora Engelbrecht

Psychoanalysis and primary health care
Astrid Berg United States of America

Traditional psychoanalysis and primary health care appear to occupy opposite ends of the therapeutic spectrum: from the private consulting room to a public space where office allocation may change from week to week; from scheduled appointments taking place within a pre-arranged time-frame to unpredictable and unplanned attendances; language barriers are such that the work needs to take place with a third adult person, an interpreter, in the room. The conditions for the analytic attitude in terms of ‘the frame’ are not there in the outer environment. Despite these differences it is possible to work psychotherapeutically within a primary health care context. 17 years of experience in a Parent-Infant Mental Health Service in a ‘township’ near Cape Town has shown that it is used and appreciated precisely because of the basic analytic attitude that prevails. Containment, confidentiality, and open space allowing for the unfolding and reflection of feelings, thoughts and actions, and attention to the individual mother-infant dyad are the ‘active ingredients’ of the work. The close collaboration with the interpreter adds a third dimension to the therapeutic space. Psychoanalysis can be applied to settings other than the traditional consulting room. As we are attempting to reach a rapprochement with other disciplines such as the neurosciences, so we should equally acknowledge the need for psychoanalysis to step out of its traditional confines and...
become the progressive social force its forebears had intended it to be.

**Symposium title:** The shared spaces: Exploring the boundaries, barriers and bridges in the contemporary world: Some Indian perspectives

**Convenor:** Purnima Singh

**Theoretical perspectives on plurality and shared spaces**

_Girishwar Misra University of Delhi, India_

The need for effective functioning at individual level necessitates formation of groups. However, once groups are formed the imperatives of group life make intergroup distinctiveness and differentiation a natural corollary. With this emerge power and status differences and if unattended they may lead to intergroup conflict and competition. The eco-cultural factors specific to respective groups offer diverse strategies to figure out a desired and balanced kind of intergroup relationship. The collectivities often function as constellations and are required to pursue the agenda of the broader societal goals. Within a complex web of multilevel functioning the processes of communication and negotiation become significant. This presentation critically examines the social psychological theories and indigenous perspectives on groups and intergroup relations to make specific predictions about the processes of social boundary formation and factors that regulate these processes. The paper also attends to the complexities emerging due to multiple group membership and concludes by identifying potential ways in which identities may be constructed in a synergistic mode.

**In search of social identities: Methodology and reality**

_Roomana Siddiqui Aligarh Muslim University, India_

Social identity is an issue of multidisciplinary interest resulting in diverse foci of deliberation at empirical as well theoretical levels. Psychologists have mainly focused on the individual and subjective level while economists, sociologists, and political scientist, etc. have tried to examine it at the macro level. The quantitatively oriented researchers essentialize identity as a fixed, coherent, and stable entity. Identity may appear bounded, as it inextricably gets linked to an identifiable group, but as groups coexist and interact with each other they get opportunity for shared spaces. Explorations of common grounds and intersubjectivity call exploring the relationship between personal experience, public meaning and different social contexts. The access to contextualized experiences of contact and participation with different groups need grounded theoretical and ethnographic approach. Taking examples from India contexts of diversity and cohesiveness multi-centric and multi-method approach is elaborated.

**Introduction to the symposium**

_Purnima Singh IIT Delhi, India; Girishwar Misra; Roomana Siddiqui_

With fast-paced social and economic developments taking place around the globe the episodes of prejudice, tension, conflict, violence, and terrorism too are increasing. Such happenings seriously disrupt the peace and harmony in the social arena and disturb the social equilibria, and derail movement toward the goals of human development. As a result the need to maintain social harmony is gaining priority on the agenda in development related discourses at national and international levels. Experience tells that the real and potential absence of harmony has been unproductive, disruptive and has substantially thwarted the goals of social and economic development and well-being. Psychology has shown more interest in understanding the sources of conflict and managing the conflict than understanding peace and harmony as a part of social behavior. This gap needs to be addressed and necessitates exploration into the ways of bringing in and ensuring peace and maintaining harmony. Against this backdrop this symposium intends to explore the notion of shared spaces through which people come together, feel the closeness and jointly engage in acts of reciprocity, cooperation, and mutual celebration. It is argued that the shared spaces are possible because of the permeable social boundaries. Such boundaries are necessary for maintaining life, identity and communication but oftentimes they become barriers. When boundaries become barriers the scope and range of shared spaces shrinks. Contrarily, when the boundaries work as bridges they rejuvenate relationships enhance mutuality and potentiate collaboration and productivity. Thus the question is to understand how the boundaries can be created so that they work as bridges and facilitate the opportunities of shared spaces. Keeping this in view the symposium participants would address the emerging concerns and perspectives to foster psychological scholarship in the backdrop of some recent research in the area of social integration, peace, and harmony.

**Understanding the shared spaces: Complexities and challenges**

_Purnima Singh IIT Delhi, India_

This presentation undertakes a psychological analysis of social diversity in contemporary societies in general and in the Indian society in particular at micro, meso, and macro levels. It documents and analyzes the socio-cultural practices and strategies used for constructing the shared spaces and deploying them to achieve the goals for collaboration with minimal compromises with their disparate identities. The threats to shared spaces challenge the integrative and cohesive processes. The plurality in the Indian cultural context is analyzed and the potentials for threats to shared spaces are examined. Results of a study conducted on 200 Hindu and Muslim respondents differing in caste background showed that main effect of caste and religion did not have effect on religious prejudice but the interaction effect of caste and religion did have a significant effect. Further analysis of secondary data showed that when legitimate choices are denied and a regimented compartmentalization imposed, then the boundaries become rigid, opaque and impervious. It is this rigidity or mutual exclusiveness that nurtures an ethnocentric mindset and attendant behaviors. The implications of this situation for theory and social policy are indicated.

**Making and unmaking of shared spaces: Some illustrations from the indian context**

_Purnima Singh IIT Delhi, India; Girishwar Misra_

For a plural society like India, coexistence of all groups/communities is of considerable significance. To this end registering and encouraging the voices of harmony, co-existence and syncretic values and ways of thinking demand attention. This is illustrated with experiences from the Indian context. Illustrations in the form of cases are presented from the Indian context that indicate a complex and dynamic scenario where deep connections and links are maintained . These cases indicate that cultural identity is not defined as ‘belongingness’ or being owned by a group but rather as formation of new realities. A series of studies conducted on Sikhs a minority group in India will be discussed. Implications of the findings for social policy are indicated.
Research Area: Teaching and Education in Psychology

Session Type: Papers

Local and regional issues in the training of Grenadian psychologists
Justina Aire
St. George’s University, Grenada

Like many developing countries, Grenada faces many challenges that impact individuals, families, communities and the nation as a whole. These challenges manifest at the macro-level, including poverty; to the micro-level, such as substance abuse. Compounding matters is the scarcity of applied psychologists to meet the individual, community, and national needs of Grenada. In response to these pressing needs, the Grenadian Ministry of Education and World Bank supported a pilot program at St. George’s University from 2008-2010 to train a cadre of guidance counselors (GUCO) already working as teachers to assume this new and important role. Due to the success of the program, the present task is to transform the GUCO pilot into a formal training program in applied psychology. The purpose of such a program would be to produce competent applied psychologists to serve Grenada and, very likely, other neighboring Caribbean island countries. The challenges of such a program are at least twofold: (1) creating a program that provides opportunities to acquire the basic knowledge and skills to work effectively in diverse settings, including communities, hospitals, private and government organizations, and schools; and (2) creating a curriculum that balances traditional and tested coursework with indigenous perspectives and methods such that graduates can offer contextually appropriate services that are both welcomed and effective. In this paper, we detail the conditions in Grenada that call for systematic applied training in a Caribbean psychology and strategies for its realization given limited resources.

Teaching psychological assessment using problem-based learning
Itziar Alonso-Arbiol
University of the Basque Country, Spain; Miriam Gallarán; Kepa Diez; Leire Aperribai; Mikel Haranburr

Problem-Based Learning (PBL) has been successfully applied to several teaching contexts (i.e., secondary schools, second-language learning) as an alternative methodology to traditional classroom learning. Its implementation in higher education is taking place slower because teaching at this level is mainly understood as lecture-based. For specialists in psychology, solving problems effectively becomes more important than just getting a collection of facts or theoretical knowledge. We present an experience of PBL in a course on Psychological Assessment, taught in the third semester for the first degree in psychology. Eight students were given a specific problem to solve at the end of the semester. Actual consultations within the clinical and educational domains were presented to students and they were instructed to choose one and to plan and carry out an assessment process along the semester. The final steps involved having an interview with the clients, who were actually actors (psychologists expert in the fields), and the elaboration of a report for them. Interviews were recorded and later discussed in a group session with all students taking part in the pilot experience and the expert psychologists. Qualitative interviews were conducted with the students to assess the difficulties found along the process and employed solutions by them. The biggest difficulty mentioned was lack of time due to overlap with other subjects in the semester. The main positive aspects were the motivating feature of the activity as well as the feedback provided by the instructors. Other institutional problems and ways to overcome them will be discussed.

Parent and guardian support of Korean migrant learners’ primary schooling experience
Merise Du Toit
South Africa; Ronelle Carolissen

The current study aimed to explore the support given by parents/guardians of Korean migrant learners with regard to the learners’ primary schooling experiences. The single case study was qualitative and explorative in nature. Nine semi-structured interviews and one focus group were used. The data was thematically analysed within an ecological framework. The results suggest that cultural capital and global positional competition play an important role in Korean migrant learners’ primary schooling experiences. Although these parents/guardians bring the learners to South Africa to move away from the very formal education system of Korea, it seems as if they are still reinscribing familiar patterns of living. Four main support systems were identified, namely emotional, physical, financial (Wills et al., 1996) and spiritual. This support influences learners’ schooling experiences. Parents/guardians felt that Korean migrant learners have both positive and negative schooling experiences. The following recommendations were proposed: introduction to schooling should focus on parental/guardian understanding of procedures, systems and expectations; improvement in communication between teachers and parents/guardians are also needed to facilitate better means of assisting Korean migrant learners in their homework and related academic and social issues; educational programs that bring families together to help parents/guardians develop knowledge and skills in providing a more supportive and attentive presence in their children’s lives in the hope of increasing Korean migrant learners’ adjustment to the new school environment and prevent problem situations.

Out of the playpen: Teaching psychological research consultation in the real world
Angelo Fynn
UNISA, South Africa; Angelo Fynn; Eduard Fourie; Sydney Butler

A common criticism of studying in the field of psychology is a lack of practical application post graduation. The Masters in research consultation programme addresses this by combining the principles of work integrated learning, basic business skill development and rigorous training in the principles and application of research process within the consultation model. Research, especially research consultation, is once again moving to the fore in the social sciences. The complex and widespread social issues faced by the South African social structure requires access to relevant, empirically sound psychological knowledge. Access to this knowledge could have the dual benefit of demonstrating the relevance of psychology to society and creating further employment opportunity for psychology graduates. The outcomes of this programme include fostering a sense of curiosity about the world and the social processes that underlie it; producing graduates who are culturally sensitive; graduates who are ready to enter the work context emotionally and intellectually prepared from day one and enthroning an understanding of the meta-frame-work of research to ensure an optimum amount of versatility. We achieve these outcomes through a rigorous on-campus programme involving multiple role players in various fields with twenty weeks of practical placements in organisations actively involved in their respective industries. In this presentation we will expound on the details of the curriculum and demonstrate how our programme is a unique for teaching psychological research in the 21st century.

Putting theory into practice: Work-integrated learning in the undergraduate psychology curriculum
Judith Homwood
Macquarie University, Australia; Theresa Winchester-Seeto; Wayne Warburton; Judy Hutchison

Psychology education follows the scientist-practitioner model, where professional practice training occurs in postgraduate coursework programs. Capstone units are relatively unusual in undergraduate programs outside the USA. This paper describes a capstone unit undertaken by psychology major students at an Australian university that are in the final year of undergraduate study and may be preparing to find employment with a psychology degree rather than entering professional training programs. The unit involves a practical placement component. The University organises the placement opportunity, or in certain circumstances the student may elect to find a placement setting of particular interest. This paper will describe the distinctive features of learning outcomes and assessment tasks of this unit. To successfully complete the unit, students are required to focus on their undergraduate learning to date and how to apply it to the workplace, i.e. the students must demonstrate their learning from their practical placement, including its application to professional and ethical practice. This focus on ‘learning by doing’ creates a different learning experience for students and requires students to show initiative, professionalism and a high level of self-regulation, all of which are key attributes of the psychologically literate graduate.

Teaching psychology in medicine and business
Shulamith Kretizer
Tel-Aviv University, Israel; Michael Kretzer

The purpose was to examine the relative utility of teaching psychology in other disciplines by applying cognitive teaching styles accepted in the other disciplines. The other disciplines were medicine and business. The course was general psychology, one semester. The teaching styles characteristic for medicine and business were considered as case studies or model presentations, respectively. The students in medicine were taught by using case presentations or regular psychology teaching. The
students in business were taught by using models or regular psychology teaching. Comparison of test results at the end of the course showed the superiority of teaching medicine students by case studies and business students by models, as compared with regular teaching. The importance of applying in each discipline the teaching and cognitive styles characteristic for the discipline is emphasised.

Structuring the capstone experience in psychology

Richard Miller University of Nebraska at Kearney, United States of America

In academia, a capstone usually refers to a course or project that synthesises the knowledge learned during a student’s academic career. The goals of nearly all capstone experiences are to have students develop the skills that go beyond the ability to simply summarise and evaluate the information they have learned. In this talk, I briefly outline the learning objectives that are generally associated with the capstone experience including (a) critical thinking, (b) scientific writing, (c) information literacy, (d) research methods and data analysis skills, (e) interpersonal skills and an appreciation of diversity, (f) frameworks for knowledge, (g) history as a context, and (h) ethics and values (Dunn & McCarthy, 2010). Next, I describe a number of different approaches to the capstone experience in psychology including (a) history and systems courses, (b) honors or independent studies/thesis requirements, (c) service learning: internships / practicum / fieldwork, (d) senior seminars or integrative experiences, (e) courses that extend the core, (f) issue-oriented iapstone iourses, (f) psychology as portrayed in the media, (h) advanced laboratory/research Options, and (i) serving as a teaching assistant/tutor. Finally, I will relate the capstone experience to assessment and address the important learning outcomes to be addressed for assessment purposes including the ability to (a) write in a clear, organized and effective manner, (b) speak effectively and intelligently, (c) work well in groups or teams, (d) make well-reasoned decisions, (e) use information resources effectively, (f) critically evaluate information, (g) understand the theories and perspectives of the discipline, and (h) use research skills (Murphy, 2008).

Promoting success in psychology and beyond: The first year learning initiative

Michelle Miller Northern Arizona University, United States of America; Blaise Scarnati

In the United States, introductory psychology is one of the most popular course selections for first-year college students. Yet like other foundational college courses, this course often suffers from high rates of student non-participation and lack of productive effort are major factors underlying low student success. This may be part of a larger problem with student engagement such as that noted by authors Arum and Roksa in their recent book Academically Adrift. To address this issue, we created the First Year Learning Initiative (FYLI), a unique program for designing and delivering foundational courses primarily serving first-year students. FYLI emphasises student effort and accountability, multi-section coordination and best pedagogical practices, with three specific groups of objectives that all FYLI courses must meet: Socialising students for excellence, course design, and alignment. To earn FYLI certification, course coordinators participate in a series of development meetings aimed at redesigning the course to meet FYLI objectives. FYLI has a remarkable degree of appeal to faculty, as evidenced by voluntary participation by over thirty-five teams in less than one year’s time. We believe that the FYLI program could be adapted to the needs of other institutions seeking ways to promote pedagogical best practices and student success in introductory courses.

Perceptions of psychologists regarding the use of religion and spirituality in therapy

Samantha Naicker Nelson Mandela Metropolitan University, South Africa; Ottilia Brown Nelson Mandela Metropolitan University, South Africa; Diane Ellkain

In the past the use of religion and spirituality were seen as taboo in therapy. Now there is evidence of an integration between psychology and religion and spirituality. Recently, studies have proved the success of using religion and spirituality to cope with psychological disorders, prevent unhealthy behaviours and promote resilience. Despite this, little research has tapped psychologists’ perceptions of this matter. This study aimed to explore the perceptions of psychologists in the Nelson Mandela Metropolitan Municipality regarding the use of religion and spirituality in therapy. Purposive sampling was employed to obtain a sample, and focus groups were used to collect data. The sample consisted of 15 registered psychologists. The data was analysed using Tesch’s model of qualitative content analysis. Thirty two themes and forty four subthemes emerged from this process. The participants emphasised that religion and spirituality are coping mechanisms for both clients and psychologists. Most of the participants indicated that they were willing to discuss religion and spirituality with their clients if they brought it up. The participants highlighted factors that made it possible for them to engage with their clients on religious and spiritual levels, and factors that made it difficult for them to do so. An important factor was the lack of training for psychologists on religious and spiritual issues in psychology. Based on the results, this study may influence professional training in psychology.

Do we need clinical psychology in medicine?

Considerations for a Singapore

Nenna Ndukwe James Cook University, Singapore

It is well recognized that chronic medical conditions can have a significant impact on an individual’s emotional wellbeing. In particular, medical conditions can generate psychological issues such as anxiety and depression, which in turn could precipitate poor coping, poor adjustment and non-adherence to treatment. In addition, concerns around prognosis and diagnosis are often central to the psychological problems associated with chronic illness. Thus, there has been considerable interest in the services of clinical psychologists within medical settings globally. However, few studies have explored the value of clinical psychology in Asian medical settings. This presentation reviews the existing literature and discusses the value of clinical psychology in medical settings in Singapore, where the profession is still being established. The objective was to illustrate how psychological input can improve symptom management, quality of life, and adherence to treatment in medical settings in Singapore. It was concluded that there is a valuable role for clinical psychologists in Singaporean medical settings. Psychological management can improve symptom management, quality of life, adherence to treatment and self-efficacy.

Psychology students’ satisfaction by the level of education worldwide

Anna Sagana Maastricht University, Greece

Over the more recent years, we witness a trend on revising the standards for performing the profession of psychologist (ex EuroPsy). Those revisions have sub-sequentially led to changes on the curriculum of psychology students. But how do students perceive those changes? Do they feel that they get all that is required to enter the professional world? If yes, what is the price to be paid? The aim of the symposium is to summarise the latest advances over psychologists’ education worldwide and assess their impact on students. The discussion will be facilitated by a follow-up study, to the one presented during the 27th International Congress of Applied Psychology (Potocnik, 2010), on students’ satisfaction. The goal is to extract and combine the positive aspects, while taking into consideration the wants of students and with it the need for a high standard of professional practice.

A comparison between the indicators for evaluating teachers in China and Japan

Hechuan Sun Shenyang Normal University, China

This research was a part of a large national project on teacher effectiveness and quality in mainland China. The whole project started in 2007 and lasted until 2011. To assess teacher’s effectiveness and quality, evaluation systems with scientific indicators were needed. It was necessary to have a close look at the teacher evaluation indicators in other countries so as to improve the indicators for teacher evaluation and quality in China. To this end, this study tried to find useful and scientific indicators for evaluating teacher effectiveness and quality from seven advanced countries. Japan was one of them. This paper is based on the final report of the project. It introduced the aim and the background of this study. In the literature review part, the key conceptions were defined and the theories of educational assessment, teacher evaluation, teacher effectiveness and efficacy were reviewed. The third part introduced the research methodology of this study. Both qualitative (to build up the research framework and to form the questionnaires for empirical part) and quantitative (to investigate whether the Japanese teacher evaluation indicators can be used in China or not) research methods were used, including thematic interviews, distributing questionnaires to over 1220 school administrators and teachers all over Liaoning Province, in addition, SPSS 11.5, EXCEL and factor analysis were used to analyse the collected data and the feedback. Finally, what China and Japan can learn from each other in
indicator systems for evaluating teacher effectiveness and quality was presented.

Teaching a critical history of psychology in the Majority World: A global psychology imperative
Ava Thompson College of The Bahamas, Bahamas
The increased availability of resources on the international history of psychology suggests a growing appreciation of the role of contextual factors on the development of psychology. Recent attention to teaching an international history of psychology, and concomitant requests for psychologists from the Majority World to write their respective histories of psychology, in order to contribute to this process (Pickren, 2011; Pickren & Rutherford, 2012) is also encouraging. Together, these developments are important responses to Danziger’s (1994) call for the growth and use of critical historiography to expand psychology’s history beyond its purely pedagogic role. This presentation advocates for the use of a critical history of psychology teaching model that can contribute substantively to the development of psychology in the Majority World nations. Key components of a critical history of a psychology teaching model, one that is embedded throughout the curriculum, include the social construction of historical narratives, a historiography of psychology’s evolving universality-diversity framework, and a meta-disciplinary focus on factors that affect the development of psychology. Advancing an appropriate framework for assessing the state of the discipline in varied contexts and promoting multidirectional exchange, integration and application of psychological content and methodologies are among the potential benefits that are briefly highlighted. The presentation concludes with a discussion on the relevance for a global psychology to serve humanity.

Graduate military clinical psychology education
Joseph Troiani Adler School Professional Psychology, United States of America
The Adler School of Professional Psychology continues the work of Alfred Adler by educating clinical psychologists to be socially responsible practitioners, who do so by engaging communities, advancing social justice, and by working with marginalized populations. One such marginalised group is military personnel and veterans. One of the developing clinical specialisations is military clinical psychology. With the current conflicts the United States is involved in running at ten years of engagement, there are over 1.4 million troops returning to civilian life facing challenges such as re-integration into society, preparing for an additional deployment, or recovering from traumatic brain injury (TBI) and posttraumatic stress disorders (PTSD). The only specialisation for military psychology exists within the U.S. Government. There are not any Psy.D. programs with a Military Clinical Psychology Specialisation until now. The Adler school’s New Program Initiatives Committee in collaboration with administration and the founder of the track has established the clinical specialisation of Military Clinical Psychology, within the Psy. D. Program. The track educates students in the providing of clinical psychology services to military personnel, retirees, and their families in the Department of Defense medical system, veterans being served in the Veterans Administration System, and organisations providing services to veterans and their families. The intention is to focus on an integrated overview of the scientific research literature in order to provide a comprehensive understanding of the psychological needs of the military, veterans, and their families.

Promoting student-centred learning: Third year psychology students’ experiences of active learning
Jason van Niekerk South Africa; Anthea Lesch; Errolyn Long; Jamil Khan
In South African higher education, the challenge to educate professionals who are able to act as transformative agents and contribute to societal transformation, is a key imperative (Walker, McLean, Vaughan & Dixon, 2007). Active learning is one approach that has potential for promoting this goal. Active learning is a form of learning that requires students to engage with, and apply, information. Active learning thus requires students to think critically about what they learn. Critical thinking promotes deep learning, such that students are able to use information and apply it across different contexts. In South African higher education institutions, the traditional model of transfer of knowledge from lecturer to student is still largely practiced. Though teaching and learning policies promote a departure away from this mode towards more student-centred approaches, contextual challenges hamper the practice of active forms of learning in university classrooms. It is against this backdrop that the pilot study reported on, in this presentation, was conducted. Third year psychology students at a South African university participated in an active learning curriculum in a module on health and behaviour. Data was collected using focus group discussions and open-ended questions on student feedback questionnaires, to address the question: How do third year psychology students experience their participation in an active learning curriculum? Data was analysed using thematic analysis. The results of the study highlight the fact that, although students found active learning challenging, they consider it to be an effective teaching method which aids learning.

The role of the Brazilian psychological association in advancing research-based psychology in Brazil
Lucia Williams UCSFAR/LAPREV, Brazil; Paula Gomide; Maria Beatriz Linhares
This presentation will describe the Brazilian Psychological Association (SBP), founded in 1971, in the city of Ribeirão Preto, by well-known Brazilian researchers from the Universidade de São Paulo. Since then SBP has been organising an Annual Convention held in different Brazilian cities, where approximately 2000 participants gather for four days to attend workshops, keynote presentations, symposia, and present a large number of posters. Among other goals, SBP strives to promote psychological research, as well as the teaching and application of psychology to enhance human well-being. SBP publishes the journal Temas em Psicologia (Psychological Themes). The Association gives annually three of the best poster presentations in the categories undergraduate, Master and Doctoral levels. SBP’s relationship with other Brazilian psychological societies will be discussed. A description of our 41st Annual Meeting, which took place at the city of Belém, last October, will be included. It was the first time that SBP held a meeting in the Amazon region, with participants from 5 adjoining regional States, with many positive results. Analysis of some of the challenges involved in promoting scientific Psychology in Brazil, a country with the largest number of such professionals, will be presented. The presentation ends with a preview of our 2012 Annual Meeting which will take place in the city of São Paulo (October 10-13). This meeting will be held jointly with FIAP, an Association which assembles Psychological Associations from Spain, Portugal and Latin America.

Social representations of professor and difficulties in the implementation of a psychology curriculum
Anna Edith Bellicco Da Costa UFMG, Brazil
The aim of this study is to identify difficulties in implementing a curriculum, structured according to Psychology Curriculum Guidelines (DCEP), in Brazil, considering the social representations of professors about the contribution of disciplines taught by them to achieve the required skills and competences. Subjects: 44 teachers. Instrumental: Likert scale, four choices of answers concerning to the contribution of the taught disciplines to develop those skills and competences. 68% of teachers answered the scale. 72% of the disciplines were evaluated as contributing wholly, or in part, to achieve the skills and competences. Three disciplines were seen as offering little contribution. The high number of professors who did not respond to the scale showed as: covert resistance to the curric-
Academic skills: Hitting the target through effective "funneling"

Hestie Byles University of Pretoria, South Africa; Juan-Claude Lemmens

The aim of this research project is to evaluate the value added by the psychology academic skills programme offered by the Faculty of Humanities at the University of Pretoria with the focus on continuous improvement. The academic skills programme has been offered by the Faculty to all first year students since 2000. Transfer and subsequent utilisation of academic skills however did not seem to realise after students completed the programme. This appeared to be largely due to the diverse needs of the different disciplines within the Faculty. Consequently a different approach started to evolve, and currently the programme focuses on students who are academically at-risk based on their first semester academic results. In an attempt to crystallise and transfer academic skills, a more discipline specific academic skills programme was developed and implemented for selected disciplines in 2010. Senior students are trained as skills tutors to scaffold generic academic skills relevant to their specific discipline. In 2011, 39 students enrolled for the psychology skills programme. Data from semi-structured interviews, though limited, seem to suggest that the tutor and students experienced the programme positively. However, portfolios of evidence and students’ second semester marks show that skills transfer and crystallisation are still not realised. Obtaining these results from a discipline specific programme would appear to indicate that the diversity of needs, even within a more homogeneous group, is still vast. As a result improvement of the programme will now incorporate a larger web based component to allow for students’ individual needs and levels of academic readiness.

Integration of scholarly teaching, assessment, and Scholarship of Teaching and Learning (SoTL) in psychology

Keelah Laura Dickson Northern Arizona University, United States of America

This presentation highlights critical intersections of scholarly teaching, SoTL, and assessment in psychology, which benefit students, faculty, institutions, and the discipline of psychology. While scholarly teaching, assessment, and SoTL differ in definition, intention and outcome, the shared goal of enhanced student learning fuses these endeavours. Scholarly teaching involves reflection and the use of empirical based evidence to guide the choice of pedagogy. Assessment involves systematically gathering, analyzing, and interpreting evidence to determine how well student performance matches explicitly stated standards and using the resulting information to document, explain, and improve performance. SoTL involves systematically investigating questions related to teaching and student learning with the goal of enhanced learning, improved teaching, and publicly available peer-reviewed scholarship that contributes to the body of knowledge in higher education. Psychology educators, who teach that psychology is a science, need to apply scientific inquiry to our teaching and student learning. We are stewards of psychology, embodying the standards of psychology by promoting scientific understanding and application of psychological knowledge. Given that psychology has generated tremendous quantities of research that document our understanding of how people process, retain and use information, we should be at the forefront of this movement. SoTL serves as a model for the union of science and application in the classroom, helps teachers engage in scholarly teaching, and also provides the framework for classroom assessment.

The influence of online games motivations on addiction of middle school students: Quantile regression analysis based on data of ten provinces and cities

Wen Fangfang School of Psychology, China; Bin Zuo School of Psychology, China

This paper explores the influence of online games motivation on addiction, using online game motivation scale and online game addiction scale, to survey 38640 middle school students from ten provinces and cities in China. Quantile regression analysis shows that there are significant effects of online game motivation, including game features, emotion-catharsis, achievement-seeking and relationship-meeting, on online game addiction. These effects show an upward trend with the rise of the level of addiction. For the highly addicted players, with the rise of the level of addiction, the effects of game features, emotion-catharsis and relationship-meeting perform a declining trend on the addiction, while the impact of achievement-seeking shows an upward trend. The most important motivation of middle school students’ online game addiction is achievement-seeking, followed by emotion-catharsis, then game features and relationship-meeting.

Internship for early childhood education program at a national university in Argentina

Maria Garro Universidad Nacional de San Luis, Argentina

The poster describes the characteristics of the Internship for Early Childhood Education Program at the National University of San Luis, Argentina, which is conceived as a special type of practicum or field instruction that differs from other advanced courses or other training activities for become preschool teacher. The poster describes the internship as characterised by the group psychosocial support and training considering the interaction between university student-teachers and university professors and children and preschool teachers within the kindergarten that received the interns. The main goal of the internship is to revalue the function of the preschool teacher as an adviser or collaborator within kindergarten institution. In such a way, internship’s activities include training workshops, didactic seminars as well as contracts in which both students and professors undertake to carry out certain tasks and share responsibility agreements. Finally the poster analyses the proposal that each university student develops her or his own portfolio assessment, which is one of the innovative activities of the internship. Portfolio assessment enables students to record, evaluate and improve their learning. In that sense, portfolio assessment can be considered as a developing story, which allows to show not only the successes of learning but also psychological experiences and even what students imagine and dream.

In the process of communication: The discursive style used by students

Ana Gonzalez-Celis University National of Mexico, Mexico; Ruiz Edgardo

In the process of communication, function and meaning of language become relevant as part of learning, hence the importance of studying the discursive styles used by students. A qualitative methodology was used as the unit of scientific analysis. The procedure was eight Biology Laboratory practices of four hours each. A group of university students were videotaped, and their work transcribed, for content analysis, with a qualitative method of social science applied to large amounts of text. By encoding the observable properties of the texts, we made operational definitions to organise the data. The speech styles were grouped into three processes: to ask, to answer and to discuss, each subdivided into categories. The results are thus presented by category in descending frequency, without being mutually exclusive. To ask: the categories that appear most frequently are: to demand (60%), to confirm (22%) and to direct their peers (20%). To reply: the categories are: to doubt (49%), to claim (33%) and to direct their peers (25%). To discuss: the categories are: to correct (42%), to lead (22%) and to instruct their counterparts (17%). The results show students are sharing their experience, yet are unable to coordinate working together. The conclusion is essential to change the strategies used by students, in order to promote and encourage planning, management and collaborative practice so as to contribute to learning.

PhD training in a cross cultural context

Judi Homewood Macquarie University, Australia; Theresa Winchester-Seeto; Christa Jacenijk-Traweger

The involvement of international candidates in postgraduate research degrees has been an important goal and privilege of Western higher education institutions. For many candidates English, the language of research, is not their first language. This poster will present the results of a multi-university study within Australia, where semi-structured interviews and focus groups were conducted with candidates and supervisors working together in a cross cultural context. All candidates must make the transition from the learning styles needed in a taught degree to the skills needed for successful completion of a PhD. This research identified “intensifiers” that interviewees specified as making situations more difficult and/or complicated for candidates and supervisors: language; cultural differences in dealing with hierarchy; separation from the familiar; separation from support; cultural difference, stereotypes; time to complete; and what happens when the candidate returns home. The website that contains the resources (video clips, written scenarios) developed from the project will be presented.
Student-oriented psychology lab enhances student’s perceptions of work quality and study attitudes
Victoria Kazmerski Pennsylvania State University, United States of America; Kimberly Cook; Ashley Turner

The environment is known to have an impact on workers’ physical and cognitive productivity. This has been documented in a variety of workplaces, such as cockpits (van Erp, et al., 2006) and hospital settings (Bagnara & Tartaglia, 2007). Environmental influences can occur in more common settings as well, such as offices and classrooms. Most research in educational settings has been in K-12 classrooms. Only a small body of work exists in the college setting. For example, room size and windows relate to changes in GPA (Hertzog, 2007) and students’ learning improves as related to enhancements to a campus building (Lilyblade, 2005). This study looked at the relationships of environment and students’ learning and feeling about their learning in an undergraduate psychology lab. Data were collected in the semester after the lab opened (N=56) and again a year and a half later (N=76). Students rated physical qualities, work qualities, and attitudes about the psychology lab. Students’ ratings were overall positive, however, were higher in the first administration for all three areas (Physical, t(108) = 3.73, p < .01; Work Quality, t(108) = 3.81, p < .01; Attitude, t(108) = 4.14, p < .01). In conclusion, we found that environment influences students’ perceptions of work quality and improves attitude toward working in the lab and general feelings of being associated with psychology. However, this effect diminishes over time. Having an open lab environment may help enhance the student-centered focus of a small undergraduate psychology programme.

Therapist metamorphosis: Beginner and experienced
Christine Laidlaw NMMU, South Africa; Christopher Hoelsom

The research aimed to trace the development of psychologists as therapists within a South African context. Two distinct career levels were explored in relation to a competency model, a skills development model, and a developmental phase model of psychotherapists’ professional development. Through purposive sampling five intern psychologists and six registered psychologists with at least seven years post-qualification client contact participated in semi-structured interviews, couched in the social constructionist position. The texts of the participants’ experiences were thematically analysed. The research found that a number of aspects fostered the development of psychotherapists. Life experiences of participants featured personally wounding events or highlighted participants in a helper role. The theoretical orientation(s) of participants were influential in their development, yet adjusting to clients’ needs was of overriding importance. Participants emphasised a strong therapeutic relationship with clients as the centrepiece of psychotherapy and depicted the therapeutic process using diverse metaphors. Catalysts for professional growth included personal therapy, ‘unforgettable cases,’ group supervision and, for established psychologists, professional workshops. Shifts in competency were recognised by intern psychologists, namely, dissolution of naïvety, reduced anxiety regarding clinical work, greater flexibility in the therapeutic process, decreased inappropriate responsibility for clients’ progress, and negotiation of their personal and professional lives. Established psychologists voiced gaining more confidence through years of practice and yet acknowledged some anxiety which fostered humility. The small sample was a limitation of the study which in future research could be extended across additional geographic regions.

Strategies for management of a large size university class by applying applied behavior analysis (ABA) principles
Mami Mitachi Seisa University, Japan

The purpose of this study is to demonstrate how Applied Behavior Analysis (ABA) principles can be used to develop strategies to manage a large size classroom at the university level. In Japan, a serious problem persists in a large-size class (100 or more students), is disruption of the instructor’s lecture by students talking. Tsukada & Sato (2006) demonstrated the effectiveness of using ABA principles in order to solve this problem. Their intervention was to take away an attendance sheet, which was counted for grading points, from students talking in class. In 2010, the author taught 451 students, officially registered for ABA class. As expected, the noise level from students’ talking during lectures was extremely high. To solve this problem, the author intervened using several different management strategies based on ABA principles. To create each strategy, an ABC (Antecedent–Behavior–Consequence) paradigm (three-term contingency paradigm) was applied. The author changed Antecedent and/or Consequence strategies to reduce the noise level of students’ talking. Also, the students were asked which strategies were effective for this purpose. At the end of the term, the author compared six intervention strategies and found that the teacher moving toward talking students was most effective in reducing the noise level.

Student or teacher? Complementary teaching and learning roles in an extended programme in the humanities
Luvalle Naude University of the Free State, South Africa

Both first year students and lecturers (their fellow learners) are often underprepared for the challenges of higher education. Many voices in the higher education arena call for the implementation of educational scaffolding to ensure access with success. The Faculty of the Humanities at the University of the Free State invested in an Academic Facilitation programme (AFS) with the aim of providing first year students with a supportive platform for integrating crucial developmental skills (such as academic literacy and life skills) with the academic content of disciplinary mainstream modules. This presentation reports the findings from empirical research that result from a three year mixed method action research project that was conducted parallel to the implementation of the programme. Embedded in the overarching philosophical and theoretical perspectives of developmental and social psychology, as well as transformative and experiential learning, this research project is specifically intended to explore the underlying determinants of success in the AFS and involves the investigation of both student and staff responses in the AFS. Quantitative data regarding the predictors of success will form the first part of the discussion. Next, the presentation will report on the qualitative experiences of both students and lecturers. From this information, the presentation continues with an explanatory appraisal of the reciprocal learning between students and lecturers. An argument will be made for building capacity through this pedagogic model and how the extent and depth of reciprocal learning can be mobilised and energised.

From teaching to hosting: Transformative counselling psychology encounters
Boshadi Semenya University of South Africa, South Africa; Khumoetsile Modutla; Maria Papaikonomou; Diederik Kruger; Juan Nel University of South Africa, South Africa

The re-development of a South African undergraduate module in psychological counselling forms the basis of this reflexive intervention. The module ‘Transformative Counselling Encounters’ commenced in 2010 and is taught by way of open and distance learning to about 1800 students annually. We present a theoretical justification and design principles used in the module. The provenance of this curriculum differs from traditional teaching of counselling in psychology. Often teaching tends to be overly complex or factual, too broad or encyclopaedic, or to involve very simplistic recipe-based transmissions. These pitfalls are a function of unchallenged modernist and instructivist self-organising frames. Rather than being guided by an objectified and distanced progressive accumulation of facts, theories and techniques, we are guided by an aesthetic sensibility and inter-relational ethos of relationships, epistemologies and pragmatics. A non-linear, evocative, recursive and unpredictable model of counselling is highlighted to address intricacies of language, culture, mental models, aspirations, distress, suffering and becoming. The module is guided by metaphors and sensibilities of: Encounters, diverse peoples, hosting, transformation and maintaining, crisis and trauma, dancing with change, dialogical encounters and self-encounter, vivification, relatedness, limitations, possibility, boundaries, and self-reflexivity. In this paper we posit an ecological and soulful, yet multiply paradigmatic approach to counselling. Curriculum innovation is an arduous route, and can be contradictory to educational tangents of compliance, notional efficiencies, expanding managerialism, and prescriptive professional regulations and rigidities. Our emergent model is shared as a potential way to break through resentment and entropic complacency of learner, teacher, educational and professional systems.

Sport psychology at Rhodes University
Gary Steele Rhodes University, South Africa; Sumania Nanabawo; Jarryd Byron; Caryn Bell; Tracey Fleming; Storm Scott

This poster presentation will explore the development of the sport psychology programme at Rhodes University, which began in 2007, and will place emphasis on the work conducted in 2011. This includes information on the structure of the
programme and research projects that were conducted, which covered a range of topics, including coping strategies in rugby, scoreboard pressure in cricket, the use of mental imagery in golf, cohesion in basketball, motivation in motocross racers, attitude formation toward sport psychologists, fear of failure for team sport players and individual sport players, the investigation of Psychological Skills Training (PST) and mental toughness in cricket and road running, and the development of PST and mental toughness programmes in cricket and archery. These empirical research projects used a range of qualitative and quantitative methodologies, with some of the research projects investigating the use of Action Research in developing PST and mental toughness programmes. In addition, a brief discussion of the professional training on which the department is embarking will be presented, which includes a Service Learning practical that involved students conducting different workshops with a number of provincial age-group cricket teams. Components of the programme will be described and excerpts, abstracts, and visual material will be included to illustrate the development of the sport psychology programme.

Promoting responsible environmental behaviour of school students through a social marketing approach
Suresh Sundaram Annamalai University, India

The purpose of the present research is to increase the Responsible Environmental Behaviour (REB) of school students through the school based social marketing intervention. The social marketing tools of prompts, models and commitment constituted the intervention. A quasi-experimental, pre-test, post-test design was used. Environmental behaviour pre-assessment was done on the students of three randomly selected schools out of which one school received the intervention. Results showed an increase in responsible environmental behaviour by the students of the intervention group over that of the control group. The findings of the study showed that school-based social marketing intervention is good in promoting responsible environmental behaviour.

Designing learning outcomes to assess thinking processes in psychology courses: Application of Donald's taxonomy
Debra Swoboda York College/CUNY, United States of America; Steven Grazon

Designing courses around learning outcomes is best practice in higher education: Learning outcomes steer the focus of instruction from learning content to learning discipline-related knowledge and practices, and make explicit the thinking processes necessary for successful learning. While Bloom’s (revised) taxonomy is commonly used to create learning outcomes that delineate what students will be able to do upon course completion, the utility of its application to disciplines and to courses at all levels in the disciplines is problematic, since disciplines place value or priority on certain cognitive operations over others, and some disciplines and courses require cognitive operations that in Bloom’s taxonomy are not identified or subsume otherwise discrete thinking skills. An alternative framework for constructing learning outcomes that overcomes these limitations is Donald’s Learning Processes – a six-item taxonomy that emphasises thinking processes versus cognitive domains and accommodates distinctive thinking processes intrinsic to the different disciplines and to courses across different levels and sub-disciplines in a discipline. The purpose of this post is to acquaint viewers with the existence of Donald’s taxonomy and to show examples of learning outcomes in syllabi created for courses in (and outside) the discipline of psychology using Donald’s framework. The presenters will demonstrate why Donald’s taxonomy is superior to Bloom’s for crafting learning outcomes and how Donald’s taxonomy can be used to effectively map learning outcomes across courses in the psychology major.

Life beyond third year: Using peer mentoring to assist graduating students transition out of university
Sophia Xenos RMIT University, Australia; Lorelle Burton; Andrea Chester United States of America

Contemplating entry into the workforce can be a daunting process for students as they prepare to complete their undergraduate degree. Final year psychology students can find this process particularly challenging, given that many do not proceed into postgraduate psychology programs and are left to contemplate their options. Assisting students in this period of transition and improving their work preparedness skills is crucial. This project used a repeated-measures within-subject design to deliver a peer mentoring program across two Australian universities (RMIT University and University of Southern Queensland). In the program, final year psychology students mentor first-year students and, through this process, develop important work preparedness skills that can be used in their later transition into the workplace. The transition in-transition out (TiTo) model that underpins this research is designed to benefit both first and third year psychology students and is based on Lizzie’s (2006) five senses of student success: Connectedness (e.g., student-to-student relationships), capability (e.g., clarifying expectations), resourcefulness (e.g., university procedures), culture (e.g., academic integrity) and purpose (e.g., students’ sense of vocation). This paper will focus on the impact of the program on the third-year student experience. The paper will report on the pre-and post-test scores for third-year students on measures exploring the five senses of success, learning approaches, personality, university experiences, preparedness for entry into the workforce, and perceptions of peer mentoring. The results will be used to inform the development of effective practices that promote successful transition of students beyond university.

Session Type: Invited Address
On the role of personological variables in effective teaching and studying
Nicholas Skinner King’s University College, Canada

Hough much is known about the contribution of a teacher’s presentional style to effective teaching, the role of personality factors is less well understood. In the present research, a series of simulation studies examined the impact on teaching success of (a) extraversion-introversion and emotional stability (as measured by the Eysenck Personality Inventory), and (b) approaches to problem solving (as assessed by the Kirton Adaption-Innovation Inventory). In sum, teaching effectiveness was predicted by extraversion, emotional stability and adaption (“doing things better”); teachers perceived to be less effective were characterised by emotional lability and innovativeness (“doing things differently”). In parallel investigations with students, classroom success was the best predicted by introversion, whereas academic failure was connected with emotional lability. (Academic dishonesty was correlated with extraversion and surprisingly emotional stability). Adaption was associated with academic success, and a preference for lecture-based, information-focused teaching, innovators gravitated toward concept-change-focused, discussion-based instruction. Given the relative immutability of such core temperamental dimensions, such results suggest that the characteristics of effective teachers and students are more likely to be the product of heredity than teacher training programs or instructional techniques.

Session Type: Invited Symposium
Symposium title: Psychology in Argentina
Convenor: Maria Richaud

Postgraduate studies and research in Argentina
Isabel Mikulic University of Buenos Aires, Argentina

Academic postgraduate training is beginning to emerge in Argentina. However, it is highly regulated by laws, government decrees, and university resolutions. According to this series of regulations, there are three types of postgraduate courses: Specialisations, master’s, and doctorates. Each of these has its own profile and degree, institutional conditions for teaching, syllabus characteristics, academic body requirements, and prerequisites concerning equipment, library, document centers, and other related matters. The LESIS put into force in 1995 requires that postgraduate degrees be certified. This task has been delegated to an organisation created by the LESIS, the National Commission for University Evaluation and Certification (CONEAU). The LESIS states that the processes for certifying specialisations, master’s, and doctorates postgraduate courses must be carried out according to the Ministry of Culture and Education in consultation with the University Council. As far as funding is concerned, only 18.8 percent of postgraduate activities receive funding from sources outside the university. The financing of postgraduate courses comes from the student’s registration fee. The supply of postgraduate degrees in Argentina increases each year, the main growth focuses in the postgraduate courses offered by public institutions, and by type of postgraduate course, the segment of greatest growth is the specialisation and master’s, and the rate of expansion is much greater than that for doctorates. However, it is possible to consider the expansion of postgraduate education as a trend to be strengthened in the future.

Session Type: Invited Workshop
Workshop teaching and learning with technology: Developing instructional media for psychology education
Thomas Ludwig Hope College, United States of America

Converging evidence from educational research supports the use of multimedia instructional materials,
both to engage students and to increase their comprehension of key concepts. The first part of this workshop will summarise the research findings and suggest some guidelines (with demonstrations) for effectively using interactive media to increase student engagement and motivation, to promote discussion, and to enhance understanding of complex topics. The second part of the workshop will focus on the development of multimedia materials, using a variety of methods and software tools ranging from off-the-shelf commercial products to freeware and open-source projects. Special attention will be given to the problems of creating multimedia materials and materials that can be used by persons with visual or auditory impairments. The workshop will conclude with suggestions for sharing these materials as a step toward creating a "global instructional resource library" for the study of psychology. Workshop participants will leave with ideas, strategies, resources, and tools for creating their own online tutorials, interactive demonstrations, and simulations of psychological experiments.

Session Type: Symposia

Symposium title: Early precursors of school achievement in reading and mathematics
Convenor: Wolfgang Schneider

Effects of kindergarten compensatory support and its impact on subsequent school readiness
Marcus Hasselhorn, German Institute for International Educational Research, Germany; Hermann Schoeler; Wolfgang Schneider

Recent research on the prediction of school performance clearly indicates that preschool prevention and intervention programmes can have long-term positive effects. To evaluate the implementation of compensatory support regarding school-relevant skills during the last year before school entry in the German state of Baden-Württemberg, more than 900 children participated in a longitudinal study with three preschool measurement points starting about one-and-a-half year before school entry. Another two measurement points were realised at the beginning and in the end of Grade 1 to assess the acquisition of reading and math at school. Data analyses concerned the following three questions: (1) Does compensatory support provided in kindergarten help in developing sufficient levels of school-relevant precursor skills (such as phonological awareness, letter knowledge, and basic math competencies) during the last year before school entry? (2) Can the probability of school-readiness for children at-risk be enhanced by the projects prevention attempts? (3) Are positive effects of compensatory support in kindergarten related to progress in elementary school in the sense that transfer effects can be found for the acquisition of reading skills and mathematics during the first year of schooling? As a main result, our data analyses did confirm positive effects of the compensatory support on school relevant precursor skills during the last year of kindergarten, and also showed that after the prevention chances for children at-risk to cope with the demands of elementary school increased considerably. However, the question regarding transfer effects on the acquisition of reading and math skills during the first year of schooling could not be clearly answered by the available data. In sum, the effects of the implemented compensatory support programme turned out to be rather positive.

Bilingual profile effect: The gap between receptive and expressive language
Karin Keller University of Basel, Switzerland; Lorissa Troesch

Bilingual immigrant children and monolingual native-born children differ not only in their level of local language development, but also in their language competence profile. Research on the bilingual profile effect shows that bilingual children have further developed decoding skills, but a more limited vocabulary in each language (Oller, Pearson, & Cobo-Lewis, 2007). It remains an open question if the profile bases on a transfer of structures from the first language or on individual characteristics. The language skills were assessed at two points of measurement (with an interval of 15 months) with a standardised language development test (Grimm, 2000). The sample includes 416 children (51% girls; 21% with German as monolingual first language, 7% with German as bilingual first language, 72% with German as second language) at the age of 34 to 53 months. We expect that (1) already in the early language development the difference between productive and receptive skills is bigger in the second language for bilingual children than in the first language for monolingual children and (2) the gap between receptive and productive skills remains stable. (3) In the subsample of children with German as a second language it is analysed if the profile depends on the linguistic distance between the first and second language as well as on cognitive, socioeconomic and personality characteristics. The results show that in the second language acquisition, like in the first language acquisition, high correlations exist between the single subtests, but the receptive language skills score more than one standard deviation above the expressive language skills (p < .001). The hierarchical regression analyses for detecting associated factors with the modality gap reveal that not the distance between the first and second language is relevant, but the cognitive skills are associated with the profile (R² = .05; p < .01). The higher the cognitive skills were, the better were the receptive language skills compared to the expressive language. This study contributes to the basic knowledge of the early second language development. The data show that the bilingual profile emerges not only after many years of development, but already in an early stage of second language acquisition, before the first 50 words are acquired. The findings demonstrate that for bilingual children specific language diagnostics are important and from an intervention perspective the question arises if the productive language should be promoted more.

Typical and atypical development of elementary school basic numerical skills: Longitudinal study
Karin Landerl University of Graz, Austria; Bern Schneebberger

Processing of numbers and numerosities has been identified as a central component underlying arithmetic development. Deficits in this domain are assumed to be causally related to dyscalculia. Up to date, empirical evidence comes mostly from cross sectional studies, while longitudinal evidence is scarce. The present study investigated the developmental trajectories of symbolic and non-symbolic numerical processing in 42 dyscalculic and 42 typically developing children during the elementary school years. Basic numerical processing skills (non-symbolic comparison of magnitudes, symbolic comparison of one- and two-digit numbers, physical comparison, dot counting, number line estimation) were assessed five times (beginning and middle of Grades 2 and 3 and beginning of Grade 4). Developmental changes concerned mainly the efficiency of numerical processing while the overall pattern of numerical processing was consistent across the study period. Results also confirmed earlier findings that dyscalculic children show generally less efficient number processing reflected by specifically prolonged response times. Furthermore, their symbolic distance and compatibility effects appeared to be more distinct than among their typically developing peers. No major qualitative differences were observed for the priming-distance effect for symbolic number comparison and for non-symbolic numerical processing, i.e. both groups showed similar subtitising and counting patterns as well as a stable non-symbolic distance effect from second grade on. Overall, results suggest that the integration of two-digit numbers as well as conscious numerical decisions based on symbolic representations pose a particular challenge in dyscalculia.

Early precursors of school achievement in reading and mathematics
Wolfgang Schneider Department of Psychology, Germany

In this symposium, we discuss various approaches to identify important precursors of reading and mathematics performance that can already be assessed either before school entrance or immediately thereafter. Researchers from Austria, Germany, Switzerland, and the United Kingdom will present longitudinal studies. For instance, using a very large database of tens of thousands of children in England, Peter Tymms, Christine Merrell and their colleagues assessed the relative importance of measures collected at the ages of 3, 4, 5 and 6 to attainment in reading and maths at age 11, as well as characteristics of the schools and the teachers included in this study. These data come from large-scale monitoring projects run by the Centre for Evaluation and Monitoring at Durham University, UK, with data representative of the country. In a German study supervised by Marcus Hasselhorn, Wolfgang Schneider and their colleagues, a large sample of kindergarten children were recruited about 18 months before entering elementary school and carefully screened regarding their cognitive competencies. Children at-risk were given specific treatments during the last year of kindergarten, and long-term effects on school performance in reading and maths were subsequently assessed. Similar approaches were used by Karin Landerl and her colleagues in Austria and Alexander Grob and his team in Switzerland. One major aim of the symposium is to identify early precursors of subsequent school achievement that seem to be influential in all of the countries represented in this symposium.
Early indicators of reading and mathematics attainment
Peter Tymms Durham University, United Kingdom; Christine Merrell
This paper will explore the relative importance of measures collected at the ages of 3, 4, 5 and 6 years to attainment in reading and mathematics at age 11, as well as characteristics of the schools and teachers. The data for this study come from two large-scale monitoring systems known as ASPECTS (Assessment Profile on Entry for Children and Toddlers) and PIPS (Performance Indicators in Primary Schools) run by the Centre for Evaluation and Monitoring (CEM) at Durham University, UK. Several thousand children are included in the sample. The children in the sample were assessed on entry to pre-school at age 3 with ASPECTS. This was a one-to-one assessment of their early language and mathematical development. Some pre-schools also completed optional assessments of personal, social and emotional development, and motor development. The same children were then assessed with the PIPS On-entry Baseline at the start of school. This was a one-to-one assessment of early reading and mathematics development which was repeated at the end of that first year. When the children were age 6 and later at 11, their reading, mathematics, vocabulary acquisition and non-verbal ability were assessed. Multi-level modelling will be used to explore the importance of predictors of attainment taken from multiple time-points in the early stages of education on later outcomes and the impact of different teachers and schools.

Symposium title: Globalization of psychology education: Challenges and promises
Convenor: Remo Job
Psychological literacy and global citizenship
Jacquelyn Cranney The University of New South Wales, Australia
Psychological literacy is the capacity to apply psychological science to meet personal, local and global needs. Psychological principles can be applied in a number of different domains, including to self and close others, local communities (e.g., employment settings), and global contexts. A pragmatic taxonomy of psychological literacy includes scientific literacy, employability, and global citizenship. Oxfam (1997) defines a Global Citizen as someone who “is aware of the wider world and has a sense of their own role as a world citizen; respects and values diversity; has an understanding of how the world works economically, politically, socially, culturally, technologically and environmentally; is outraged by social injustice; participates in and contributes to the community at a range of levels from local to global; is willing to act to make the world a more sustainable place; takes responsibility for their actions”. The ways in which these aspects of global citizenship relate to the concept of psychological literacy will be discussed, as will the implications for psychology education and and for social issues.

Global wiki perspectives on InterTOP resource
Remo Job University of Trento, Italy; Aimee Ferreira
InterTOP (International Teaching of Psychology Network, http://interteachpsy.org) was created for international scholars, administrators, and instructors from around the world. It is intended to provide opportunities to discover different resources, available throughout the world, for teaching and training in psychology at all levels of education. Currently it contains comprehensive information about various resources collected by author. It is impossible, however, for an individual to access all the resources available around the globe. Collective efforts may be needed to compile the information from different countries. Wiki technology used in the InterTOP web site gives such an opportunity. Further development of InterTOP will be discussed.

Overview
Remo Job University of Trento, Italy; Aimee Ferreira
The symposium will discuss various aspects of globalisation in psychology education: exchange of students, global teaching resources, on-line interactive psychology media, global electronic psychology textbooks, and outcomes of global psychology education. Presenters: David Myers, Hope College, USA, Global electronic psychology textbooks: challenges and perspectives Thomas Ludwig, Hope College, USA, Interactive psychology media for global psychology education: tutorials, online activities, and simulations of psychological experiments. Remo Job, University of Trento, Claudio Tonzar, University of Urbino, and Lorella Lotto, University of Padova, Italy, Bilateral exchange of students and joint degrees in psychology: legal constraints and possibilities. Jacquelyn Cranney and Sue Morris, The University of New South Wales, Australia, Psychological literacy and global citizenship Victor Karandashev, Aquinas College, USA, Global Wiki perspective on InterTOP resource. Discussant: Saths Cooper, South Africa

Interactive psychology media for global psychology education: Tutorials, online activities, and simulations of psychological experiments
Thomas Ludwig Hope College, United States of America
Over the past thirty years a wide range of computer-based multimedia teaching resources have been developed for psychology. As we consider the globalization of psychology education, it seems clear that technology-enhanced teaching resources will play an increasing role in the future. This presentation will summarise the research on the value of multimedia learning and the effective use of multimedia in the classroom and in online and blended courses. Guidelines and examples will be provided for developing interactive psychology media for classroom use and to extend learning beyond the classroom. Special attention will be given to the problem of creating multilingual materials and resources that can be used across different ethnic and national contexts. The presentation will conclude with suggestions for sharing these materials as a step toward creating a “global instructional resource library” for the study of psychology.
Increasing the work readiness of Australian university case study

David Myers United States of America

What are the challenges faced by textbook authors who wish to present the world of psychology to an international, multicultural audience? How, for example, can someone who resides in a particular place and time harvest and present research and everyday examples from around the globe - or is that an impossible goal? And how can pedagogical materials simultaneously be made more culturally sensitive and more affordable in contexts with many low-income students? I will enumerate some of the challenges and promises, including possibilities and obstacles for future web-based, interactive e-books that might deliver state-of-the-art, low-cost, locally adaptable content.

Symposium title: Improving psychology by internationalizing the curriculum: Global learning at Northern Arizona University case study

Convenor: Sherri Mccarthy

Global learning at Northern Arizona University case study

Sherri Mccarthy Northern Arizona University-Yum, United States of America

This symposium will focus on the Global Learning Project at Northern Arizona University, a model project for infusing international content and experiences. First, Dr. McCarthy will provide an overview of the trends within psychology to internationalize curriculum over the past decade. Next, system-wide changes within a specific university which encourage faculty and students to embrace international content, experiences and service projects will be described by Dr. Charles. Then, how these changes specifically influence the psychology department, how international content is infused in course content and how success at meeting these goals is assessed will be addressed by Laurie Dickson. Finally, how these changes are operationalised in teaching psychology classes will be summarised, and a student who experienced the results of an internationalised education will briefly summarise the advantages and serve as discussant.

Symposium title: Innovations in developing graduate work-readiness capabilities

Convenor: Rob Ranzijn

Increasing the work readiness of Australian psychology undergraduates through an experiential learning placement

Janet Bryan University of South Australia, Australia; Rob Ranzijn

Existing undergraduate psychology programmes in Australia are characterized by (a) the integration of teaching with research, but (b) limited practice-based learning. This educational model assumes that a grounding in the scientific basis of psychology necessarily precedes professional training which should be restricted to the postgraduate level. Due to the restricted number of research and professional placements at postgraduate levels, the model fails to accommodate the majority of psychology undergraduates who do not proceed to professional training, leaving them poorly prepared for the workplace. Many undergraduate students enter psychology degrees with the aim of progressing into further professional psychology training and are therefore disappointed if they are unable to progress. Undergraduate students persistently criticize the lack of practical skills training and the consequent negative impact on future careers. Therefore there is growing recognition that the current model does not serve the interests of three-year graduates, the community or industry very well. This limitation is currently being addressed at the University of South Australia. We have modified our curriculum to include innovative practice-based learning experiences and a dedicated placement course to enhance graduate work readiness and professional identity. This paper describes the rationale for and evaluation of this experiential learning placement.

The role of capstone experiences in scientific literacy, employability and global citizenship

Jacquelyn Cranney The University of New South Wales, Australia

The traditional role of the capstone experience in the final year of the psychology major is reviewed, followed by an introduction to the concept of “psychological literacy”, defined as the capacity to apply psychological science to meet personal, local and global needs. A pragmatic taxonomy of psychological literacy includes scientific literacy, employability, and global citizenship. The design, implementation and evaluation of a new capstone course for psychology majors is discussed, with particular emphasis on learning, teaching and assessment strategies relevant to employability. Capacity for transferability of these strategies is also considered.

Teaching developmental psychology to enhance the work readiness of psychology undergraduates

Rob Ranzijn University of South Australia, Australia

Developmental psychology is conventionally taught in one of two ways: by life stages (Infancy, Early Childhood, etc.) or by topic (Cognitive Development, Social Development, etc). This paper presents a different way of teaching this topic which has been in place for the last two years, using a Pathways to Development framework which demonstrates how particular events and circumstances can have cascading, cumulative and long-term effects on development in multiple interrelated domains. This evidence-based approach demonstrates to students that an intervention at one point in time can prevent adverse developmental effects later in the lifespan and instead lead to enhanced life outcomes. Throughout the course students are shown real-world examples, by means of current employment advertisements, of ways in which their knowledge and skills in developmental psychology can be used in a large variety of health and human service occupations. Student feedback shows that this has demonstrated in a meaningful way the relevance of studying psychology. A similar approach could be used when teaching other psychology topics. The underlying message is that a three-year degree in psychology provides an excellent foundation for a large range of satisfying careers.

Development and trial of an evaluation tool to improve work placement outcomes

Kathryn Von Treuer Deakin University, Australia; Sophie Keele

Work placements enable students to apply knowledge and skills gained in the classroom to authentic work settings. These experiences are recognized to facilitate the acquisition of generic skills related to work readiness and employability. Placements are a popular feature of university courses, yet placement experiences vary substantially across work environments. Placement units differ from traditional coursework units and as such a consistent and universal approach to evaluating these less tangible aspects of the curriculum appears lacking. A standard tool which consistently evaluates placements would enable universities to more rigorously monitor and subsequently improve the placement experience. The primary aim of this study was to design and trial a standardized tool to evaluate placement settings and experiences. To design the tool, a qualitative study was conducted (n=56) and examined the views of placement stakeholders (i.e., students, university and industry placement supervisors/coordinators, course graduates) regarding what attributes of the placement experience should be evaluated. Data were thematically analysed leading to a 28 item evaluation instrument. Face validity feedback on the tool from placement stakeholders was very positive. In addition, an initial trial with students (n=22) also demonstrated a favourable response to the use of the tool. Although further trials are required, the results of this study provide a promising way forward in the use of a standardized instrument that can be completed by students to evaluate and improve placement experiences and outcomes.

Evaluating the use of assessment centre methodology to enhance work readiness in psychology students

Kathryn Von Treuer Deakin University, Australia

Work placements have a positive impact on work readiness and graduate employability. Within a well-monitored learning environment, students can maximise their strengths and improve areas of weakness. Development and Assessment Centres (DACs) are typically used in corporate settings to provide development feedback to high potential employees. The primary aim of this project was to evaluate the application of the DAC methodology to assessing and subsequently enhancing the professional competencies of students within the placement milieu. A sample of postgraduate students (n=58) undertook a range of simulated work activities. Comprehensive feedback was provided and individual development plans were prepared, which were subsequently addressed during work placements. A mid-point review conducted by workplace supervisors provided timely feedback relating to general work characteristics, competency attainment and development needs. A more thorough assessment of professional competencies was conducted at the conclusion of each placement, comprising self assessments and evaluations provided by on-site supervisors, with the aim of modifying
learning goals and associated behaviours in subsequent placements. Feedback gathered from students has been very positive. Performance evaluations as measured by behaviourally based ratings scales completed by the students and their workplace supervisors confirmed the positive effect of this methodology, with improvements noted across the placement trajectory. The DAC methodology appears to offer a much needed strategy for not only assessing professional competencies, but also providing a standardized way forward with regards to setting goals for placement and providing the student with ongoing formative feedback.

Symposium title: Multicultural training in psychology: Experiential techniques, social justice, human rights and implications for interdisciplinary training
Convener: Ayse Ciftci

Incorporating social justice multicultural perspectives into graduate training: A global perspective
Fred Bemak George Mason University, United States of America

It is well established that multicultural training is critical to meet the demands of our rapidly globalising world. Culturally diverse groups co-exist side-by-side in many countries, while various ethnic and racial groups are moving across traditional regional community boundaries within their home countries, and across international borders, contributing to rapidly growing pluralistic societies. Psychologists from around the world must be able to work with a deep understanding and appreciation of the history, culture, sociopolitical, and psychological elements of various societies in order to effectively work across cultures. Simultaneously it is vital for psychologists to address the social injustices that numerous cultural groups face and incorporate this as a critical component of psychological interventions. This presentation will explore how to incorporate social justice multicultural perspectives into graduate level training programmes. To lay the foundation for the presentation a brief examination of the relationship between multiculturalism and social justice will be discussed, followed by a description of the Classroom Without Walls training programme model, and a presentation about a cross-cultural intervention model, the Multi-Phase Model of Psychotherapy, Counselling, Human Rights and Social Justice. Finally the presentation will explore the myths and realities of empowerment as a key element in training and discuss the promotion of multicultural social justice training in a global world.

Creative experiential multicultural graduate training
Rita Chi-Ying Chung George Mason University, United States of America

Multicultural training in psychology: Experiential techniques, social justice, human rights and implications
Ayse Ciftci United States of America

Multicultural training is a core aspect of psychology training. Even though different training models and terminologies have been proposed over the years, one certainty exists that we need to continue changing our training models with the changing world. As educators, we have a responsibility to train our students to work with diverse clients in a complex and changing world with the fundamental ethical principles. Furthermore, future psychologists must learn how to address the social injustices that exist in the world as well as become trainees for others. In this proposed symposium, we will discuss key issues related to multicultural training with presenters from three different countries (New Zealand, Turkey, United States). Each presenter is currently involved in multicultural graduate training in psychology in the USA. Our first presentation will focus on three different experiential techniques to help students take an action by using innovative transformation techniques. Our second presenter will focus on social justice and describe the Classroom Without Walls training programme model and a cross-cultural intervention model, the Multi-Phase Model of Psychotherapy, Counselling, Human Rights and Social Justice. Our third presenter will discuss fundamental ethical principles in multicultural training. Our last presenter will explore the psychologist’s role in becoming the multicultural educators for other professionals across disciplines.

Psychologists becoming trainers in developing cross-cultural competencies across other disciplines
Ayse Ciftci United States of America

Globalisation has drawn diverse groups of people from all over the world closer together, broadening world views and epidemiological lenses, and making the world an ever-increasing interlocking community. The direct and indirect influence of globalisation can be seen at the cultural, personal, institutional, and psychological level. The effects of globalisation on the workforce and higher education is strikingly evident, and there has been a surge of education initiatives aimed at better preparing students to compete in an increasingly competitive global job market. All fields of study (e.g., engineering) are influenced by globalisation, necessitating a need for drastic institutional, programmatic, and curricula reform. Consistently, across disciplines, cross cultural competency is conceptualised as an acquired or learned trait that an individual either has or does not have, instead of viewing it on a continuum ranging from not competent to minimally competent to extremely competent. The failure to both conceptualise and understand this competency on a continuum and to consider personality factors are two of the most problematic issues in extant literature, both of which severely limit "real world" applicability and validity of existing conceptual models. The field of psychology, specifically counselling psychology, has become a leader in cross-cultural diversity and multiculturalism. For this reason, much can be gained from looking to the psychology profession and drawing upon extant literature in the field. In this presentation, I will present relevant cross-cultural training models from different disciplines, and discuss my collaboration in an interdisciplinary project to develop global engineering competencies funded by National Science Foundation.

Is multicultural education necessary to ethically serve humanity?
Neal Rubin United States of America

The theme of the conference suggests that the field of psychology might establish a particular purpose in our global community. In order for service to become emblematic of the contribution of psychology to humanity, psychologists must be taught and trained with this value in mind. Identifying service as a fundamental aim for psychologists, then, defines a central component of the development and identity of psychologists. To achieve the aim of service to humanity as a core professional value, it is imperative that 21st century educational models integrate a means to this end. Traditionally, the aspirational values of our profession are documented in statements of our ethical principles. The Universal Declaration of Ethical Principles for Psychologists designed by the International Union of Psychological Science (IUPsyS) sets forth such aspirations. As this historic document outlines, there are additional values which must accompany service in order for the delivery of that service to fulfill associated professional values. One critical component is cultural sensitivity with an accompanying respect for human rights. The answer to the question posed in the title of this paper is emphatic, "yes". The purpose of the proposed paper, then, is to outline how education and training in multiculturalism is associated with our fundamental ethical principles. Performing service while respecting the integrity of others is another core value. Therefore, without appropriate education and training in these values, we risk undermining the goal of service we aspire to, namely, the call to service for humanity.
Advanced research training seminars for early-career researchers from low-income countries

**Symposium title:** PANEL: Advanced research training seminars for early-career researchers from low-income countries  
**Convenor:** Nick Hammond

**Nick Hammond IUPsyS, United Kingdom**

The Advanced Research Training Seminars (ARTS) Programme is jointly organized by the International Union of Psychological Science (IUPsyS), the International Association of Applied Psychology (IAAP), and the International Association of Cross-Cultural Psychology (IACCP). ARTS have been held biennially since 1992 in conjunction with major international congresses of these organisations. Their aims are intended to build capacity, facilitate exchange, and promote dialogue among early career psychologists working in majority world, low income, and countries in transition, leading to the promotion of excellence in scientific research and other scholarly activities. The ARTS Programme will have taken place just prior to the 2012 Congress. This symposium will explore the effectiveness of the ARTS Programme in meeting its aims, drawing on evidence from both the 2012 programme and earlier programmes. We will consider the perspectives of the three sponsoring organizations, of ARTS participants and of ARTS seminar leaders. The symposium will address the benefits for individuals attending ARTS, the wider benefits of capacity-building within the participants’ countries or regions, the international collaboration or networking resulting from ARTS, benefits to the sponsoring organizations, and the sustainability of benefits from ARTS. Finally, the Symposium will consider alternative models for, or developments to, ARTS to help the programme meet its aims more effectively and efficiently in the future.

**Symposium title:** Psi Chi: Advice for students  
**Convenor:** Martha Zlokovich

**Developing effective leadership through Psi Chi**

**Susan Amato-Henderson** Michigan Technological University, United States of America

Characteristics of effective leaders will be presented as revealed through scenarios in which leadership action is necessary. The scenarios will be relevant to academic situations involving both students and faculty. Topics of leadership to be discussed through the scenarios include typical knowledge required to be an effective leader, skills possessed by good leaders, and the strategies or styles most often used by quality leaders. Leadership styles have been shown to impact group climate (i.e., by good leaders, and the strategies or styles most required to be an effective leader, skills possessed through the scenarios include typical knowledge of academic situations involving both students and faculty feelings, standards that have been set and the feedback or rewards in place, the clarity individual group members have about their role within the organisation, and the commitment members have toward a common goal. Truly exceptionally leaders are skilled at using a multitude of leadership styles, depending upon the context. Finally, resources and opportunities for the development of leadership skills for both students and faculty within Psi Chi, the International Honor Society in Psychology, will be presented.

**Psi Chi: Promoting excellence in scholarship and advancing the science of psychology**

**John M. Davis** Texas State University-San Marcos, United States of America

Psi Chi was established in 1929 during the 13th International Congress of Psychology held at Yale University. The purpose of Psi Chi is to encourage, stimulate, and maintain excellence in scholarship of the individual members in all fields, particularly in psychology, and to advance the science of psychology. Since its founding in 1929, Psi Chi has grown into a major psychological society and has installed more than 1075 chapters and inducted more than 553000 lifetime members. Although founded at an international congress, Psi Chi was for many years exclusively a national honour society and chartered chapters and inducted members only within the United States. In recent years, however, Psi Chi leaders and members made the decision to offer Psi Chi membership and benefits internationally.

**Preparing for graduate school: Short and long-term strategies**

**Maria Lavoy Florida Institute of Technology, United States of America**

This part of the symposium will focus on what undergraduates can do throughout their college years to best prepare themselves for graduate school application and acceptance. It will focus on the importance of both short and long-term strategies. The discussion will cover what students can do to prepare for graduate school, in general, as well as for specific discipline areas within psychology. The topics covered will include making faculty connections, finding field placements, determining how much volunteer work or practical experience in psychology or related areas is enough, taking advantage of research opportunities, attending and presenting at annual meetings and conferences, preparing for the GRE, and the value in joining clubs and honor societies. The information shared will be relevant for all levels of undergraduates.

**Psi Chi’s effort to do more than believe in diversity**

**Randall Osborne** Texas State University-San Marcos, United States of America

Psi Chi (The International Honor Society in Psychology) recognizes that diversity is one of the most important initiatives we have undertaken. An appreciation for the power of diversity is essential for global security, social justice, and promoting change. We understand “diversity” starts within. Active learning enhances interpersonal skills and enhanced interpersonal skills facilitate growth along Bennett’s (1993) continuum of intercultural sensitivity. Critical thinking skills are a precursor to interpersonal effectiveness which are essential for effective multicultural skills. Active learning is a four-step process: 1) Recitation - state known facts or opinions; 2) Exploration - analyze the roots of those opinions or facts; 3) Understanding - awareness of other views and of the difference (s) between one’s opinions and those of others; 4) Appreciation - full awareness of the differences from step 3.

**Publishing in Psi Chi’s journal**

**Martha Zlokovich Psi Chi International Honor Society, United States of America**

Psi Chi, the International Honor Society in Psychology, has published the Psi Chi Journal of Undergraduate Research since 1995. For 16 years the Journal has fostered and rewarded the scholarly efforts of undergraduate Psi Chi members by publishing only empirical research that has been peer-reviewed by psychology faculty. Over the years, the editors have maintained both high standards for undergraduate research excellence and a tradition of mentoring students through the publication process. In 2011 the Psi Chi Board of Directors opened journal submission to all Psi Chi members, allowing graduate students and faculty (who have at least one student co-author) to publish as well. To best reflect its expanded scope, the Journal was renamed Psi Chi Journal of Psychological Research. As in the past, all first authors must be Psi Chi members at the time of submission. This session will provide advice on submitting to the Journal and provide information on the review process. Specifically, we will cover submission guidelines, online submission process, what happens during peer-review for undergraduate manuscripts compared to graduate student and faculty manuscripts, advice on responding to the editor’s letter, and engaging the revision process. The session will also cover common writing mistakes to avoid, use of American Psychological Association publication style, the role of the faculty mentor for undergraduate students, and how Psi Chi members and nonmembers can access journal articles.

**Symposium title:** Psychological literacy as a global outcome of undergraduate psychology education  
**Convenor:** Jacqueline Cranney

**International community-based work placements to enhance students’ learning**

**Jacqueline Akhurst York University, United Kingdom**

Work-based learning is gaining in importance as psychology programmes are required to demonstrate the development of students’ employability skills in an increasingly globalised world. Many psychology students are motivated to do community-based work, prompted by their desires to contribute to social justice. Since an important career direction for psychology students is the ‘third sector’, it is important that we provide community-based learning (CBL) for our students. This paper explores UK psychology students’ experiences of a three-week CBL, accommodated as part of the credit-bearing Psychology of Work module that students take towards the end of their second year. Over the past three years, 35 students have been accompanied to South Africa and Tanzania. They have worked with local partners, providing an ‘ex-
tra pair of hands in a number of workplaces. To complete their module requirements, the students reflect on these experiences in terms of their own skill development and in relation to the theories they have covered and see 'come to life' in the workplace. Drawing from naturally occurring data collected at the debriefing stage, the richness of students’ learning is illustrated. The students reported on the deeper insight related to their own work-related skills and on the impact of their cross-cultural experiences. In addition, the CBL is discussed from an Activity Theory perspective, to illustrate points of confluence and tensions in such community-based initiatives in the interactions between students, community partners and faculty.

Psychological literacy as a global outcome of undergraduate psychology education
Jacquelyn Cranney The University of New South Wales, Australia

These presentations by education scholars from several countries will allow a comparison of how psychological literacy is defined and taught around the world. Cranney and Morris give an overview of relevant theory and practice regarding psychological literacy. Denson and Ing report on high-quality engagement with curricular diversity activities (institutionally structured opportunities for students to engage with diversity) and with diverse peers (positive diversity interactions) are associated with improved intergroup attitudes and civic engagement outcomes, part of psychological literacy. Mead describes how psychologically literate educators, leading by example, can influence students' sustainability behaviour in the classroom. Akhurst describes developing psychological literacy within international community-based work placements for British undergraduate students. Chester and colleagues report on a peer mentoring program designed to increase psychological literacies for new and graduating students. Zlokovich describes how Psi Chi, the International Honor Society in Psychology, has a variety of resources that can be used by educators to help students develop psychological literacy. Martin and colleagues report on data from beginning students with the Epistemological and Ontological Perspectives of Students Scale, arguing that this scale can be used to track the development of psychological literacy in undergraduate students. First, we provide an overview of the literature and draw connections between the developmental and cultural aspects of racial diversity and educational psychology and psychological literacy in higher education. We discuss key theories about how people learn and focus on the impact of racial/cultural diversity. We discuss how diversity addresses strengths and gaps in the literature and how educational psychology relates to psychological literacy and the psychologically literate citizen. In the second part, we present findings from a recent study conducted at one Australian university to examine whether undergraduate students’ views and attitudes towards diversity and their university diversity experiences stimulate the development of psychological literacy. Specifically, we focused on two attributes needed to function effectively in a global society: positive intergroup attitudes and civic engagement. The findings demonstrate that high-quality engagement with curricular diversity activities (institutionally structured opportunities for students to engage with diversity) and with diverse peers (positive diversity interactions) are associated with improved intergroup attitudes and civic engagement outcomes. The findings also reveal that poor quality engagement with diverse peers (negative diversity interactions) is negatively associated with gains in these outcomes. These findings are consistent regardless of students’ pre-university experience with diversity and their openness to diversity.

The role of racial/cultural diversity in university in developing psychological literacy
Nida Denson University of Western Sydney, Australia; Marsha Ing

This presentation consists of two parts: first, a discussion of the developmental and cultural aspects of racial diversity in higher education, and second, findings from a study examining the impact of diversity on the development of psychological literacy in undergraduate students. First, we provide an overview of the rationale for the importance of psychological literacy in developing psychological literacy. We discuss how diversity addresses strengths and gaps in the literature and how educational psychology relates to psychological literacy in higher education. We discuss key theories about how people learn and focus on the impact of racial/cultural diversity. We discuss how diversity addresses strengths and gaps in the literature and how educational psychology relates to psychological literacy in higher education. Specifically, we focused on two attributes needed to function effectively in a global society: positive intergroup attitudes and civic engagement. The findings demonstrate that high-quality engagement with curricular diversity activities (institutionally structured opportunities for students to engage with diversity) and with diverse peers (positive diversity interactions) are associated with improved intergroup attitudes and civic engagement outcomes. The findings also reveal that poor quality engagement with diverse peers (negative diversity interactions) is negatively associated with gains in these outcomes. These findings are consistent regardless of students’ pre-university experience with diversity and their openness to diversity.

Symposium title: Psychological literacy as a global outcome of undergraduate psychology education 2

Peer mentoring to increase psychological literacies for new and graduating students
Andrea Chester United States of America; Sophia Xenos; Lorelle Burton

First and final year undergraduate students have unique transition issues. New students are managing their integration into the discipline and university life, working out the psychological literacies that will be the basis of their programme. Final year students are managing decisions about work or further study and making choices about how to use the psychological literacies consolidated during their undergraduate psychology programme. This project, implemented in one face-to-face and one online programme, brought first and final year psychology students together in an embedded mentoring model designed to develop the psychological literacies of both groups of students. Mentors, who were final year students taking a course on mentoring and career preparation, worked in pairs with small groups of first year students in class time on the first year assessment tasks. The project used a repeated measures, within-subject design to explore the impact of the mentoring programme on both groups of students. Results reported here will examine the impact of the mentoring programme on both first and final year students, with a particular focus on development and consolidation of psychological literacies.

Student epistemological and ontological beliefs, reasons for studying psychology, and professional interests
Frances Martin University of Newcastle, Australia; Stephen Provost; Amy Peacock

A critical aspect of psychological literacy is the adoption of a scientific approach to the discipline, which may not be natural for students of a humanistic and caring profession. Students in first-year psychology units (N=266) completed a survey containing questions about their reasons for studying and professional aspirations in psychology, and the Epistemological and Ontological Perspectives of Students Scale (EOPSS). Factor analysis of the EOPSS revealed three factors reflecting an Empiricist Orientation (EO), a Spiritual Orientation (SO), and a Prac- tical Orientation (PO). The degree program enrolled in did not influence the first two orientations, but students in psychology programs were more likely to accept the value of research that was not immediately practical in nature. There were some relationships between the EOPSS and students’ reasons for studying psychology and their belief in the importance of an understanding of mathematics for the practice of psychology, but students’ goals for professional practice were only weakly related to the EOPSS. The divergence between the EOPSS factors identified and the implicit or prior structure of this instrument may be due to the very early stage of development of these students’ psychological literacy. This instrument provides a potential vehicle for the longitudinal study of students’ acquisition of metacognitive capabilities across their degree study, and can inform our teaching processes in order to more closely match the articulation of ideas within psychological literacy to students’ level of acceptance and understanding.

Psychological literacy around the world: Theory, research, policy and practice
Sherri McCarthy Northern Arizona University-Yum, United States of America

Psychological literacy is a newly-emerging construct currently gaining in attention, especially in relation to undergraduate psychology programs in the U.S., UK and Australia. In other parts of the world, university psychology training follows somewhat different models and, correspondingly, concepts related to psychological literacy may take a somewhat different form. Based on experiences with psychology education systems in other regions of the world, I describe various models of psychology education used at both secondary and tertiary levels of education. I summarise how needed components, definition of and transmission of psychological literacy may differ in various countries based on local needs and cultural contexts. I also show how, despite regional differ-
Teaching psychology as a core stem discipline

James Bray
Baylor College of Medicine, United States of America

Psychology is the process of evolution and change through advances in neuroscience, genetics, and translational science. The core scientific efforts are referred to as science, technology, engineering, and mathematics (STEM) disciplines. According to the United States National Science Foundation, STEM disciplines include social sciences and psychology. Psychologists can provide valuable insights into the development of and human responses to technological advances. However, psychologists are not always included in research initiatives and public policies for STEM disciplines.

In 2009, American Psychological Association President James H. Bray commissioned a presidential task force, chaired by John Dovidio, on Psychology as a Core Science, Technology, Engineering, and Mathematics (STEM) Discipline. The recommendations from the task force report were adopted by the APA and are being implemented to ensure that psychology is included as a core STEM discipline.

This presentation will discuss (1) an overview of the STEM task force report; (2) implications for training psychologists as STEM professionals; and (3) public policies that need to be addressed to support psychology training as a STEM discipline.

Preparing psychology graduates to be relevant and competitive today: Malaysian experience

Chee-Leong Goh
HELP University College, Malaysia

Traditionally a psychology undergraduate degree has been seen as providing a foundation for students before they pursue their specialisations at the postgraduate level. The reality however, in Malaysia and in most countries in the developed and developing world, is that the majority of undergraduate psychology students are now proceeding directly to the workforce following the completion of their bachelor’s degree qualifications. Furthermore, in emerging psychology markets like Malaysia, the variety of job options available to psychology graduates has been growing exponentially over the past 10 years, with each demanding slightly different skill-sets. At the same time many Malaysian students still head to universities all over the world to pursue their postgraduate qualifications. This presentation will explore how a Malaysian university has adapted its curriculum, in terms of content, as well as teaching process and assessment, to meet these new realities. These include realigning learning outcomes, integrating transferrable skills into psychology modules and the introduction of new assessment methods particularly in research methodology.

Changing face of psychology education, accreditation and professional registration in Australia

Jacques Metzer
University of South Australia, Australia

Psychology education in Australia has a long history, since the first courses were taught at the University of Sydney from the 1880s as part of philosophy, and from 1921 in a semi-autonomous department of Psychology, at that time the only one in Australia. Since that time and to the present, nearly all Australian universities (38 public universities and 4 private universities) now have accredited degrees in Psychology, with two or three non-university institutions recently joining the offerings of these degrees. Psychology accreditation in Australia, particularly in recent years, has been changing, as have registration (licensing) requirements and administration. While the former has been conducted nationally for some 40 years, registration has only recently been conducted on a national basis with all Australian states and territories agreeing to surrender registration under individual state statutes to a national scheme: the Psychology Board of Australia. The Board has heralded important changes to professional registration, including specialist (endorsed) registration, mandatory continuing professional development, substantially increased supervision requirements for both supervisors and registrants. Mandatory registration for academic researchers has been considered, though rejected. Pathways to registration via the tertiary education system will be discussed, together with some of the obvious tensions and conflicts in Australian psychology, as well as its articulation with other nations’ systems.
to enable them to conduct public mental health research and use research for mental health system strengthening. The course uses technologically-mediated distance-learning modes, and a supervised dissertation. In this presentation we reflect on the process of setting up the MPhil in Public Mental Health, and consider important current debates about capacity development in Africa, including questions of how to best build research capacity, as well as challenges of offering technologically-mediated training courses across Africa.

Improving addiction care: Postgraduate training at the University of Cape Town
Sharon Kleintjes University of Cape Town, South Africa; Dan Stein; Sonja Pasche; Bronwyn Myers
In comparison with data from other countries, South Africa has a particularly high lifetime prevalence of substance use disorders, estimated at 13.3% of the population. Despite high prevalence rates, treatment rates remain relatively low compared to needs. A key reason for low treatment rates is the lack of expertise among professionals for the detection and treatment of substance use disorders. Addiction care workforce development is essential to the success of a comprehensive strategy to reduce drug- and alcohol-related harm within South Africa. In response to this need, the University of Cape Town’s Postgraduate Diploma in Addictions Care has been designed to equip social workers and health professionals with the necessary skills to provide evidence based treatment and aftercare services for children, adolescents and adults with substance use disorders. This presentation will provide an overview of the programme and reflect on lessons learnt from the 2011-2012 inaugural group of 22 professionals enrolled for this training.

Framing questions of capacity building in psychology and related disciplines in Africa
Anthea Lesch Stellenbosch University, South Africa; Leslie Swartz
This presentation provides a framework for a session focusing on capacity building in psychology in Africa, with an emphasis on Southern Africa. It is well established that the need for skills, services, research, and evidence in Africa is great but that levels of capacity are low. We review differing approaches to understanding what capacity is, how it can be built, how it may inform practice, and how it can be measured. We shall show that the term "capacity" has a range of meanings, but cannot be fully understood without an appreciation of a range of strategies for developing, sustaining and enhancing capacity. We need innovative approaches both to building capacity but also to assessing the impact of capacity building, especially in the longer term.
Research Area: Theory and Philosophy

Session Type: Papers

Image and unconscious: The ontopsychological contribution to the study of dreams
Marino Capasso AIO-AEO-FOIL, Italy; Gabriella Palumbo

The paper first reviews historical, theoretical, and clinical aspects of dreaming as seen from ancient ages to Freud, Jung and today’s theories. Then proposes three interconnected criteria that reflect Meneghetti’s advancement regarding the understanding of dreaming. Freud views dreams as mental phenomena with which to understand how the mind functions, but believes that dreams are solely the ‘guardians of sleep,’ and not, in themselves, vehicles for unconscious psychological work and growth until they are interpreted by the analyst. Meneghetti departs from Freud and he continues with a genuine breakthrough in terms of knowledge and codes of interpretation pertinent to all that is expressed through symbols and signs, highlighting the importance of the link between the symbolic and the real. Dreams are the holistic mirror of the organic and functional activity of our existence. It speaks by documenting the physical and historical reality of the subject and is formalised by the individual’s own vital needs. It does imaginative projections that identify the real situation of the dreamer on the biological, psychological and ontic levels. The oneric graphic shows the error or the success according to a hierarchy that goes from (1) the biological sphere; (2) the affective sphere; (3) the sphere of collaborators and social relationships. The ontopsychological contribution in the scientific study of dreams will be explained. In particular the three oneric criteria: (1) functional nature for the person of the object or context indicated by the symbol; (2) causal effectuality of the symbol; (3) semantic field.

Memory replication, a hypothesis for a new existence
Marcos Cavalcante Faculdade Integrada Tírandentes, Brazil

With scientific studies and knowledge of various branches of science such as genetics, psychology, embryology, neurology, biology, anthropology and other areas of science, based on theoretical Darwinian evolutionism and Richard Dawkins’ theories, it raises the hypothesis of a genetic memory in which the individual will have existential memories experienced in the past and possibly even return to an awareness of a psychic self present in a future generation with no memory or spiritual bond. This phenomenon can be verified with the activation of genes responsible for the conscience of the individual, being a random set every generation with this function replicates from the previous generation, and over successive generations until the probable activation of the same set is achieved, which would bring an awareness of the psychic 1 primordial. The results of this discussion are controversial in both science and religion and further studies should be made to affect a greater understanding of the subject.

An integrated theory of behaviour
Surendra Nath Dubey K.S. Sekat P.G. College, India

Behaviour includes an individual’s actions, reactions, activities, responses, movements, processes etc; that is, any measurable response of an individual to a stimulus or to a mental process. Each individual has its unique behaviour pattern, behaving differently in different situations. The theory provides an account of the factors that shape the behaviour of an individual. It deals with the method of measurement, control and prediction of the behaviour. The theory puts forth many psycho-socio-cultural determinants of behaviour. Genetic factors are crucial in building a base for the behaviour to grow, within a cultivating milieu of psychological, cultural and social factors. Childhood is the most important stage I (0 to 5 years), in which culture and the traditions of the family (Sanskar and Sanskriti). These factors give thrust for the development of a unique behaviour pattern of the child. Though family, culture and society have influence on behaviour throughout one’s life span, during childhood, their impacts are most prominent. In stage II (6 to 12 years), besides food, water, and safety, health, clothing, housing, education, health and power are the prominent factors determining behaviour. Stage III, spreading through age 13 to 18, sex is the dominant determinant of behaviour. During stage IV (19 to 60 years), again sex, along with money, power, caste, religion, prestige, quality of food intake, thought processes, the organisation in which a person works, sayings in the society, literature, and place of residence, are the directing forces on behaviour. A behaviour can be predicted by investigating and understanding the determinants initiating and strengthening the behaviour.

Emotional rhetoric: A proposal for a sentential discourse analysis
Glauco Enciso Domínguez Universidad Autonoma de Barcelona, Spain; Ali Lara

This is our approach for a discourse analysis using rhetoric as a platform in analysis of emotional discourses in everyday life. Our analysis proposal has been fuelled by classical and modern rhetoric, and we take three analytic tools useful in grasping emotions: figures, arguments and sequences. This work is framed on Affective Turn and is based on three characteristics: Relatedness, Movement and Autonomy (Lara, Enciso, 2011) Therefore, the use that is given to each of those aforementioned rhetorical tools, respectively corresponds to each of those emotion’s characteristics. We use the analysis of the figures to explore the relationship, arguments to expose the notion of movement sequences and rhetoric as a tool to explain the autonomy of affect. The examples in which we show how to use tools are drawn phrases from everyday life, quotidian phrases used to express feelings. The aim of this is to provide elements for an AD proposal that uses the rhetoric by considering some other historical developments of the discipline beyond the constrained field of neo-rhetoric. At the same time we explore the possibility of a kind of AD that serves to other epistemic sources and which its analytical products correspond to a “not based on words” reality. The study of discourses of emotions developed from the Affective Turn instead of from discursive Social Psychology, opens the field of action of the AD and leads us to rethink the possibilities of different branches as important as the rhetoric.

The quest for self-satisfaction: Theories and concepts
Salif Farooqi University of Delhi, India

Life poses many questions such as the reason for one’s birth, the purpose of life, the goals one wants to pursue, etc. Such questions, if left unanswered, lead to a state of unknown displeasure and unhappiness. These questions keep on confronting the individual no matter how rich or successful the person becomes. Self-satisfaction, the sense of absolute fulfillment with oneself and ones accomplishments, is a way to find answers to such questions. It is the quest for self-satisfaction that helps the individual in finding answers to such troubling questions. Over the years there have been a number psychological theories and concepts that inherently signify the quest of seeking self-satisfaction. This paper identifies such theories and concepts and elucidates how they can enable individuals towards the path of seeking self-satisfaction. The paper explores the theories of Victor Frankl, Carl Rogers, and Abraham Maslow with an emphasis on their concepts of will to meaning, becoming oneself, and self-actualization respectively. Along with these theories, the paper also explores the concepts of intrinsic motivation, self-awareness, and delay of gratification with respect to self-satisfaction. The seeking of self-satisfaction guides in coping with the unpredictable and unstable nature of life and helps in bringing about a certain calmness and composure within an individual. The quest for self-satisfaction should, thus, be the major element of life.

Undisciplined appropriation: Methodological meditations on international psychology
Joseph Hamer Duquesne University, United States of America

Few phenomena that call for our attention these days lend themselves neatly to disciplinary territories. In the U.S., disciplinary boundaries are vigilantly guarded, and the incessant affirmation of the superiority of one’s discipline over others only serves to disclose the doubt that accompanies lack of knowledge of those other disciplines. What most clearly reveals the artificial fragmentation of social reality by the social sciences are the numerous subfields, for example, psychological anthropology and cultural psychology; some anthropologists study emotion and cognition and some psychologists study culture. International psychology cannot avoid being entangled in issues of culture and power. My interest is in exploring the methodological questions pertaining to this. I would argue that the quantitative study of culture is incoherent, at least if one engages even minimally with the last 60 years of phenomenological, critical, post-colonial, and post-structural theories of culture. I contend that psychology is in need of methodological innovation and even appropriation. This presentation is a response to the question, what is and should be the place, if any, of ethnography in psychological research? I will describe some of the developments of ethnography in anthropology. After arguing for the importance of ethnographic methods in research dealing with psychology and culture, I highlight the
challenges such methods entail when taken up by Western scholars conducting research in the global south. For this I will draw on my own research on post-election violence in Kenya, examining the relationship between knowledge and violence.

Who are the bleeps we are really?: Reflections concerning identity, fantasy, and reality
Andrea Hurst
NMMU, South Africa
This article addresses the kind of interpersonal exchange, not too uncommon I suspect, in which the problem of establishing the so-called "real" identity of the participants in the encounter intrudes itself forceful enough to occasion the mute expi-
tative that is symptomatic of trauma: that is, the sense that one has suddenly lost one’s footing in an abyssal "hall of mirrors"; a disorientating interplay between reflexively sensitive personae and projections. Assuming that there are real people behind these personae, between whom genuine connec-
tions can be established, how is this real identity to be understood? Who are we really, and what precisely does a genuine connection entail? Although one certainly may be deceived, this question concerning what it means to be real, in the sense of genuine or true, presupposes that it is possible, on the grounds that truth does not inhabit what is rigidly over-certain, but emerges from the recogni-
tion of a flexible or mobile uncertainty, to tell the difference between projected and real identities, and therefore between distressing non-encounters among fabricated phantasms and the "partial-jouis-
sance" (which is neither pleasure nor satisfaction) of salutary "missed encounters" among uncertain real selves. In short, this paper explores the means that Lacanian psychoanalytic theory offers, insofar as this is achievable through insight produced by re-
flexive engagement with texts, to find protection from fantasy’s shadow world and to configure and preserve personal integrity as a "real" person capable of honest self-appraisal.

Nature and history in the history of psychol-
ogy
Gordana Jovanovic Belgrade University, Psycholo-
gy, Serbia and Montenegro
The aim of this paper is to explore the functions of two important concepts – nature and history – in the history of psychology. The most important psycho-
ological theories (Wundt and Dilthey’s psycholo-
gies, behaviorism, psychoanalysis, Piaget’s genetic structuralism, Vygotsky’s cultural-historical theory, humanistic psychology, cognitive psychology) will be analysed in view of their reference to nature or history in conceptualizing psychological pheno-
mena and in understanding the epistemology of psy-
chology. The naturalistic and historical accounts provided by psychology will be related to other socio-cultural discourses (for example, Wundt within
the German post-Hegelian academic culture or psychoanalysis in the context of cultural pessi-
mism). In this way socio-cultural meaning and implications of naturalistic and historical paradigms shall be elucidated. Finally, two recent approaches – evolutionary psychology (Tooby & Cosmides) and positive psychology (Seligman) will be analyzed with regard to their reference to nature and history as explanatory patterns and to the preceding history of psychology. Additionally, their possible relation to discourses of the end of history, promoted at the same time, will be discussed. While naturalism is certainly the dominant paradigm in psychology, it would be important to explore conditions of emerg-
ence and reception of psychological theories which were oriented toward history as the main category in defining human phenomena (Dilthey, Vygotsky). What are the social implications of dis-
cursive marginalization of history within psycholo-
gy? Relying on Danziger it could be argued that with descriptions of human subjects as historical objects, psychology deprives them of means to act as self-conscious subjects of history and of their own lives.

Relationship between the readiness for risk and creativity under social instability
Natalija Mihejeva
RISIEMA, Latvia
In the present article the data of modern research of creativity and risk appetite is summarized, and the relationship between these two phenomena is con-
sidered. The goal is to carry out the theoretical research of readiness for risk-taking under the social instability of representatives of the different social groups in Latvia. Analysis of the theoretical prima-
ry sources was conducted. The following was ana-
lized: the scope of an inquiry of creativity and creative individuals; and the risk appetite and scope of an inquiry of risk in psychology. Planning of empirical research and operationalizing of group selection was also conducted. Creativity is a multi-
faceted phenomenon that has to be explored in the interdisciplinary discourse. Risk appetite can be a prerequisite for the ability to express creativity.

Supplementing performativity with performance: Theory and method
Tracy Morison
Rhodes University, South Africa
This paper explores the relationship between the theoretical notions of "performativity" and "perfor-
mance." We propose that these concepts may be used together in such a way that allows for a fuller description of gender construction and a concrete analytical strategy. In recent years, the notion of transforming or ‘doing’ gender has become popular as gender theorists increasingly draw on the work of Judith Butler. However, the concept of performativ-
ity, upon which the idea of gender-as-performance is based, has been misunderstood and misread. ‘Performativity’ is frequently confused and conflated
with 'performance' in the dramaturgical sense. In doing so, theorists depart from Butler’s original thesis. This confusion hinges on understandings of the intentionality and agency of the subject - that is, the degree to which the subject is active in gender construction, as opposed to being discursively con-
strained. For Butler, performativity is not intention-
al or analogous to the self-display implied by ‘per-
formance’. Her work has, however, been critiqued for discursive reductionism and a top-down ap-
proach that denies agency. Theorists have ques-
tioned whether we might not at least consider some of gender to entail performance. Following on from this argument, we propose that ‘performativity’ may be carefully supplemented with 'performance.' Drawing on narrative theory, we present a perfor-
mativity/performativity approach, which acts as a dual lens, offering a synthetic view of subjectivity and allowing analysts to attend to gender construc-
tion in narration as both discursively constrained and an active construction.

Religion and the authoritarian corruption of spirituality: The case of Christianity
Richard Oxtoby
South Africa
In this paper I take up Eric Fromm’s analysis of religions into the two categories of Humanistic and Authoritarian and apply that analysis to the case of Christianity. I shall argue that there exists within all branches of Christianity fundamental differences between a humanistic and a radically different au-
thoritarian religion. These two co-exist in uneasy, generally unrecognised tension, the personality of the believer being the deciding factor in which of these uncomfortable bed-fellows predominate in the life of that individual. The hallmark of the human-
istic face of Christianity is the stress placed on the ethical principles of love, compassion, humility and authenticity. By contrast, the authoritarian face of Christianity emphases obedience to what is gen-
erally claimed to be "the will of God", but which is in fact the will of those who have managed to work their way into the upper echelons of some particular branch of the religion. The use of punishment in this world (as in the prescribed penances of the Roman Catholic confessional, and the threat of excommunication), and the development of a the-
ology which leaves the fear of an eternity of suf-
ferring hanging over the heads of those who have the temerity to criticise the edicts of those at the top end of the power hierarchy in their particular branch of Christianity will be a particular focus in this paper.

Rethinking "self" in treating psychopatholo-
gy and enhancing normal growth
Mohammad Rahman
Princess Marina Hospital, Bangladesh; Tarun Gayen
Understanding self is a very important task for all in an age of uncertainty, when many of our "selves" are experiencing fragmentation and fragility, threat-
ening healthy growth, resulting in our personal and interpersonal maladjustment. Present study explores the possibility of employing self and self-related constructs in different psychological interventions. Among many versions of the genesis of self, in this theoretical paper, self has been viewed as a socio-
cognitive construct, and hence amenable to change in favour of therapeutic and normal growth of the individual. Observations from the applied field sug-
gest that there are many areas of psychopathology which are better explained as dysfunction or dimin-
ished function of the self-categories, than any other constructs in psychology. Extensive literature re-
view and clinical data from psycho-therapeutic work, which have implications for any form of self-categories, have been critically studied and the significant role of self has been identified in the preparation of this paper. Clinical areas such as: suicide, substance abuse, adjustment problems, cou-
ples issues, depression, anxiety based disorders, body-dysmorphism, self-harm, and personality dis-
orders, are among the probable disorders, where identification and processing of self-related issues have deemed to have an immense role. In conclu-
sion, the paper argues that the question of self deserves critical attention by psychologists in all sectors: theoretical, empirical, as well as applied practitioners, to re-vitalise the further growth and
dimensions of psychology, to adapt themselves as scientists and professionals, to cope with the demands of the present time.

**Corpority in the contemporary world**

Vitor Sampaio PUC-SP, Brazil; Marilise Bassani PUC-SP, Brazil

The secondary role the human body acquired during the philosophy history, granted the development of the concept of psychotherapies focused on reason and speaking. Under the phenomenological perspective, the body presents itself as a phenomenon that’s felt daily as our own existence. Following Heidegger’s concept, this work describes and analyzes the body as bodyhood, the constitutive structure of Dasein’s being-in-the-world. We will focus on the daily routine, the daily bodyhood, and the psychotherapist as a caretaker of everyday routine. Under the concept of contemporaneity, the body is seen as an object stemmed from the production and consumption logic, centrally placing the human existence between production and merchandise. During the therapeutic process, can we observe and learn from the body in an opposite way than this productive logic rationale? Could the therapist follow up his patient through the unveiling of his body as a fundamental dimension to his own existence? How does the therapeutic process favour this unveiling? By answering these questions, we show Dasein’s bodyhood, where the observation “what do we do with our body?” actually means, “what do we do with our existence?” Our existence is launched in the world we live in. From these considerations, we understand the existential-phenomenological therapeutic process favours the unveiling of the bodily dimension of the human, by approaching the patient from his bodyhood. Thus, this approach returns the patient to "himself", through his more appropriate existential dimension, the bodyhood.

**Idea-logical constructions of childhood**

Shalzy Savahl University of the Western Cape, South Africa; Stef Stembrouk; Charles Malcolm

The theoretical conceptualisation of childhood in the social sciences has traditionally been aligned to the developmentalism and socialisation theory. Recent theorists have shown how the concept functions ideologically to establish taken-for-granted meanings about children. Using the social constructionist theoretical framework, the primary aim of the study is to explore the extent to which the meanings that children assign to ‘childhood’ are ideologically configured. It is essentially offering an ideological analysis through an elucidation of the existing power relations between children and society and how these relations are perpetuated and manifested in children’s discourses. The study follows a qualitative methodological design premised on the child participation framework. A series of focus groups was conducted with 56 thirteen year old children. Depth hermeneutics, was utilised within a discourse analysis framework to analyse and interpret the findings. The key finding of the study was that the meanings that children assign to childhood are ideologically configured. The essence of this configuration is adult society’s mobilisation and control of the meanings of childhood, which functions to maintain relations of domination. The outcome of this on children’s meaning assignation and constructions of childhood is characterised by a consensus-contestation dichotomy as children appear to both accept and resist the ideology. The study concludes by advancing the notion that childhood should be conceived of as an ideological configured construction, and not merely as a discursive construction, functioning within various social contexts.

**Narrowing paths: Closing gates**

Ashwin Singh University of Zululand, South Africa; Eldon Wait

At the outset of academic study, the gates of opportunity tantalise people’s ambitious eyes with the alluring prospect of obtaining a tertiary education that will allow them employment. The predilection that people find themselves in, creates and, inadvertently, obfuscates the choices that people make in their lives. Psychology has had a deplorable track-record in light of being used as a tool of Apartheid rule, but this has not deterred students from choosing psychology as a course, in the (mis)belief that it will lead to the promissory path to a successful career in psychology. Comparatively, students choose philosophy in the hope that this course may possibly bring forth an iota of critical thinking purported by the job-market as a necessary requirement for gaining employment. Why students choose to study psychology and philosophy as electives? How do their choices impact upon their personal and academic lives? Finally, to what extent will their final destination be determined by the choices made? The study will be longitudinal in order to facilitate an in-depth understanding of course choice. The population will be the University of Zululand students, wherein the sample will be students from first year up to and including PhD students. The study will attempt to provide a view of how the student numbers which explode at the outset in terms of the enormous classes at first year narrowly progress to post-graduate studies, where a handful of students are admitted into the gates of such prestigious study due to selective criteria.

**The exhibitionary complex and the education of desire**

Ross Truscott University of Fort Hare, South Africa

Tony Bennett’s Foucault-inspired concept of the “exhibitionary complex”, developed apropos of 19th century museum practice, has been influential across a range of academic disciplines. Yet despite its ‘psychological’ dimension of theorising, the exhibitionary complex has been largely ignored by social psychologists. Perhaps most useful is its capacity to bring into critical focus processes of the constitution of the modern citizen-subject. Following Bennett, much work utilising the exhibitionary complex has looked at the instrumentation of the conduct and perception of a museum-going public, the way museums work to discipline the behavioural and perceptual ‘bad habits’ out of an emerging national community. In this paper, I put Bennett’s concept to work in the context of a post-apartheid South African music festival, and my aims are twofold. Firstly, to make a set of observations on the cultural and racial politics of post-apartheid South African nationalism and the psychic life of the normalised national subject. And secondly, to suggest some methodological possibilities for more psychologically-oriented analyses utilising the exhibitionary complex. In this regard, we might look not only at the instrumentation of conduct and perception, but also at how regimes of exhibition – in this instance a regime of staging – work to educate desire. I suggest that the exhibitionary complex can be usefully paired with a psychanalytically informed notion of fantasy, this being one function ascribed to fantasy in psychoanalytic theory, to educate desire.

**From the medical model to the dialogical model for managing uncertainty**

Gian Piero Turchi University of Padova, Italy; Valeria Gherardini; Paolo Ferrari

The psycho-social consequences involved into the growing requests to Psychology are not only connected to psychopathological conditions but also to elements linked to the uncertainty due to the global economic crisis. These scenarios generated precariousness conditions linked to different human life ambits (workplace, family, neighbourhood). Psychology serves humanities into ambitus based on the uncertainty of the development of interactive configurations and these features give the operative models troubles to keep a effective-perspective. The objective of this contribution is to propose praxis of a psychological model that is no more linked with the medical ambit but offers guide lines to the System of Services, towards the new challenges focused on the community health. The proposal is based on the assumption that reality is a dialogical configuration discursively generated. The management of the uncertainty is given by referring to an operative model that is not focused on the diagnosis of "what" the person is, not centred on the term of "cause" or aimed at healing, but on the promotion of the management of different dialogical configurations that generated the people help request. The objective of this operative model is to promote a "life approach" that allows to people to autonomously manage the new challenges the current days uncertainty imposes.

**Tact knowing and genetic structuralism: Some striking similarities between the concepts of Michael Polanyi and Jean Piaget**

Burkhard Vollmers University Of Hamburg, Germany

In general, the theories of Michael Polanyi and Jean Piaget are considered to be of different philosophical origin. At first sight the two concepts focus on different topics: knowledge that cannot be expressed in words (Polanyi) and cognitive development (Piaget). Nevertheless, the main thesis of this paper is that these two concepts have one central epistemological idea in common: unconscious, incorporated structures regulate prescriptively and holistically the processes of knowledge in human beings. This thesis is supported by some distinct similarities between Polanyi and Piaget. (1) Both authors refer to the Berlin School of Gestalt Psychology (Köhler, Wertheimer, Duncker). Polanyi and Piaget appreciate the holistic view on thinking, but both were of the opinion that Gestalt Psychology conceives the individual as a passive one. The Gestalt Laws of perception and of thinking are too mechanistic. Therefore, a more constructivist
view on mental processes is necessary to overcome restrictions of Gestalt Psychology. (2) Piaget and Polanyi argue against positivistic assumptions that consider physical stimuli, at the same time exterior and atomistic, to be basis of processes of knowledge. Instead Piaget and Polanyi conceive inner regulations of subjects as basis of human thinking and acting. These regulations cannot be verbalized completely. (3) Piaget and Polanyi emphasize the subject in their epistemologies. Polanyi focused on the perceptions of persons. In contrast, Piaget focused on the actions of persons.

Origin of evolutionary aesthetics and discriminating with evolutionary aesthetic psychology
Juan Wang Beijing Forestry University, China; Fei Zi
The establishment of the scientific aesthetic should be attributed to German psychologist Fechner. He studied aesthetics related problems within the experimental psychology paradigm and summarised 16 kinds of aesthetic principles. The psychoanalysts, Gestalt psychology and Humanistic school, analysed the form and content of aesthetics respectively. Research into aesthetic psychology gradually entered the rush hour. The theory of evolution which begins to be popular in the 19th century, and the results of existing evolutionary psychology research, provide powerful support for the development of aesthetic psychology. This paper briefly outlines the origin and development of aesthetic psychology, and the influence that the perspective of evolution has on aesthetic psychology research. Through discriminating between evolutionary aesthetics and evolutionary aesthetic psychology in the object of study, the methods and the problems that should be solved, the author also summarises the relationship, differences and similarities between these two fields.

Study on core in psychology: The unifying psychology
Zhong Weidong The Unifying Psychology Workshop, China
Is there a core in psychology? If there is one, what is it and what does the core do for human beings? The various genres of psychology mirror the different sides of the discipline. Amid these sides is a core in psychology, which is the key consideration of the unifying psychology. Humanistic psychology turns a blind eye to the impact of mental depressions on human beings in preventing the attainment of self-actualization personality. Psychoanalysis has been accused of flouting with mysticism and irrationality. Yet the unifying psychology manages to solve these problems. The rational definition of unconscious in the unifying psychology (definition of subconscious in psychoanalysis is sensuous) is: It is memories that take shape due to human-being’s suffering from corporal agony, being anesthetized, emotional hurt or some negative impact. Their contents can distort the perception of their own beings.

© 2004; Ackerman, 2008).

The ontological nexus: Reflections concerning knowledge and subjective reality
Paolo Zenorini AIO-AEO-FOIL, Italy
The paper first reviews historical and theoretical approaches to knowledge and subject’s activity as seen from antiquity to contemporary society. In particular, starting from the scholastic concept of ‘accidents’, Husserl’s notion of epoché will be discussed. ‘Accidens’ refers to something that occurs in a certain way, a set of facts and phenomena that has nothing to do with the ‘substance’ of what is occurring. Substance is a psychic form, a reality with intentionality, underlying all sensible phenomena. Hence, in order to find this substance, we need to look beyond all its accidental features (its appearance and phenomenology). This is the process Husserl referred to as ‘epoché’. The individual’s unconscious, complexes and psychological dynamics are also phenomenological and Husserl’s contribution in understanding the objective world of being (or world of life) will be explained. Then, the ontopsychological contribution that reflects Meneghetti’s advancement in this scientific analysis will be discussed.

The obliger biases in prosocial behaviours
Fei Zi Beijing Forestry University, China
This article purports to examine a phenomenon coined by the author as “obliger bias,” which occurs when an obliger (a person who believes that he is trying to help others) shows blindfold oblige behaviours without enough empathy and understanding of the obligee (the person whom the obliger tries to help), thus leads to “obliger-obligee conflicts”. The author suggests that the obliger bias is a common phenomenon during the practice of psychotherapy, parenting, and social activities. The author proposed two types of obliger biases. Type I occurs when the motivations of the oblige behaviours are self-oriented, while Type II occurs when the motivations are altruistic. According to the subjective feelings (anti-pathetic or satisfactory) aroused with the obligee and the realistic effects (negative or positive) of the obligors behaviours, the author further classifies Type I and Type II obliger biases into three sub-types respectively. The author tries to explain such phenomenon as bystander effect (Darley & Latané, 1968), parent-child conflict, and so forth, from the point of view of obliger bias, and coined a concept “obliger abashment” (the traumatic emotional memories within in individuals who helped others but received negative responses in earlier life, especially in childhood) to explain the bystander effect. The author also suggests some method for decreasing obliger-obligee conflicts. The present article, focusing mainly on the psychological processes of the obligers, contributes some new ideas to the field of studies on help-recipient trade-offs (e.g., Kerenck, 2003; Kirkpatrick, 2004; Ackerman, 2008).

Session Type: Posters

Art and artist personality: An innovative ontopsychological perspective on creativity and art
Elisa De Sants AEO-SAIO-Foil, Italy
The article presents a contemporary perspective on art and creativity. Usually official culture defines the artistic worth of an artist regardless of her/his wellbeing, or lack thereof; indeed, it seems that suffering is a sort of quality trademark. Analysing the personal history of artists, this is found wanting or even a failure, most of the time, if not always.

The methodological implications of Chinese cultural psychology
Tian Hao Beijing Forestry University, China
Cultural psychology can be understood on several levels. We can take it as an extension of the research domain, as alternative theory, or a transformation in the methodology of psychology. Chinese traditional culture has abundant psychological thinking. However, we always take the Chinese cultural psychology as theoretical assumptions to be proved. The major contribution of Chinese cultural psychology should be to provide an unique and universal methodology. The methodological implications of Chinese cultural psychology can be analysed from the holistic approach, the humanistic research aims, the associated definition, and the experienced validation method.

Phenomenological description of embodied experience: A case of puppet performance in Japan
Haruka Okui Kyoto University, Japan
This paper contributes to studies of embodied experience through an observation of nonverbal interaction in a Japanese puppet performance (Ningyo Joruri), which originated before the 16th century. Unlike in most areas of the world, a puppet performance in Japan is not for children but for adults, which is achieved without loss of literary excellence, requiring sophisticated body techniques. The puppeteer’s perception and cognition of their own body is unique, because their three bodies are devoted to manipulation of a single puppet; the main puppeteer operates the head and the right hand of the puppet, a second puppeteer operates the left hand, and a third operates the legs. Although three
puppeteers manipulate the puppet following traditional arranged rules, onstage they sometimes feel as if they themselves are manipulated by the puppet. If this would be possible, who is the agency of the puppet action? In order to comprehend those experiences of the puppeteers, first, I describe the puppeteers’ cognitive schemata of their action, through analysing their channels of communication. Second, I investigate those experiences by the phenomenological theory of Maurice Merleau-Ponty, who analyzed “body schema”, “intercorporeality”, and “everyday agency between subject and object”, and third, I add a new point of view to his phenomenological theory about nonverbal interaction among three (or four) bodies.

**Innate predisposition to causal agency**

**Lucia Regolin** University of Padova, Italy; **Elena Mascioletti; Giorgio Vallortigara; Francesca Simonian**

Humans display a striking capability to perceive the so-called “causal agency,” (an animate entity’s action on other objects), which would imply sensitivity both to physical causality (a cause-effect relationship between two motion events), and animacy (the capability of an object to have self-produced motion). The role of experience in the origin of these sensitivities, however, is still a matter of dispute. These issues were recently incorporated in the theory of core cognition, a prominent hypothesis in the current cognitive science, postulating a set of core knowledge systems available in early life, and shared between species. The present experimental research contributes the first evidence of experience-independent sensitivity to physical causality in newborn babies, and to animacy in naïve newly-hatched domestic chicks. Hours-old babies demonstrated the ability to discriminate, and significantly prefer, a physical causality stimulus (Michotte’s Launching effect) to matched control events (e.g. a delayed launching). These results support the hypothesis that humans possess an early available basic mechanism sensitive to certain spatio-temporal cues of the causal event, independently of any prior visual experience. Naïve newly-hatched chicks, on the other hand, exposed for some time to the typical Michotte’s launching effect and subsequently required to freely choose between the two objects presented during exposure, consistently showed preferences associated with the self-propelled one. Overall, these findings support the idea of an evolutionarily, ancient, predisposed neural mechanism in the vertebrate brain for the detection of causal agency and animacy, and pave the way to the investigation of its neural basis.

**Theories of psychology: Evolving towards greater effectiveness or wandering, lost in the jungle without a guide?**

**Steven Wallis** Fielding Graduate University, United States of America

Generally, we believe that we are advancing the field of psychology because our researchers and practitioners are, “adding to the storehouse of knowledge.” However, from the perspective of evolutionary theory, such an increase is understood as merely additive and does not truly represent an evolutionary advance. This raises an important question: Are we truly advancing as a science, or are we merely lost in the jungle? Building on the work of Faust and Meehl and subsequent insights developed by Wallis, it seems possible to determine the potential effectiveness of a theory based on a rigorous and objective analysis of the structures of logic within the theory. The present study is the first to apply that method to theories of psychology. For data, the present study will use theories drawn from top psychology journals over the past century. Those theories will be rigorously analysed to objectively quantify their structures of logic. The results of this preliminary study will be plotted over time to indicate the extent to which the theories of psychology may be said to be evolving, or not. The poster will identify methods that scholars and practitioners are likely to find useful when evaluating theories. Also, the poster will identify opportunities to accelerate the process of theory evolution and the creation of more effective theories. Additionally, the claims raised by this presentation may provide interesting and challenging questions.

**Spatial schema in social thought**

**Barbara Tversky** Columbia/Stanford, United States of America

Perhaps because our actions in space are fundamental to our lives, spatial thought is fundamental to abstract thought. Up/down, near/far, left/right and others take on rich meanings, notably in our social thoughts and interactions. Going up takes effort and power, farther things are harder to see, to interact with, and are reflected in social thought and action.

**Directionality effects in scene depiction: Evidence from representational drawing**

**Jyotsna Vaid** United States of America; **Keen Liew; Anatoliy Kharkhurin; Kayoung Lim**

Previous studies have found directionality biases in the representational drawing of objects and scenes. Most readers of left-to-right writing systems show a preference for orienting objects to face to the left and/or for positioning agents on the left side of the page. By contrast, right-to-left readers show either no directionality biases or a tendency for a rightward-facing of objects and/or positioning of agents (Vaid, 2011; Vaid, Rhodes, Tosun, & Esilami, 2011). Biases in scene representation have also been noted in studies of spatial attention, memory, and aesthetic preference. The present study examined factors affecting directionality biases in the drawing of static scenes vs. scenes with implied movement. The findings are discussed in terms of an extension of the motor imagery hypothesis.

Symposium title: Increasing necessity of a global perspective on Psychological Research: Stand point of Pan American Psychologists

**Convener: Aluisio Lima**

Think global, act local: New outcomes in the psychology of creativity and giftedness

**Sheyla Blumen Pontificia Universidad Catolica, Peru**

The psychology of creativity and giftedness in Latin America is on a turning point: From experimental studies that aim to establish the impact of the programs on the promotion of creativity and talent development, to action-research studies focus on the factors related to ethnic-linguistic diverse groups. The development of assessment and intervention programs to serve the gifted in the Latin American region are analysed following three studies: (a) In the first study a meta-analysis of the assessment and intervention programs for the gifted, by type and country, is presented; (b) the second study analyzes the re-conceptualization of creativity in Latin America, as a significant variable in the identification of the gifted; and (c) The third study analyzes the differences in public policies for talent development in Latin America, including a newly created boarding academy for gifted youths in Peru. Finally, the need to think global is discussed, and recommendations for building-up international research networking are suggested.

Symposium title: Luria’s Romantic Neuro-psychology in the XXI Century

**Convener: Boris Velichkovsky**

Romantic stance in psychology and cognitive-affective neuroscience

**Boris Velichkovsky** Technische Universitaet Dresden, Russian Federation

In the last chapter of his autobiography, Luria referred to his favourite version of psychology as “romantic science”. Indeed, the essence of his approach can be described by the principles of romanticism formulated on the eve of XIX Century. These include assumptions of semantic complexity (even inscrutability) of the world, the primacy of activity, developmental changes, individual and cultural-historical specificity. These views seem to be shared by the members of a narrow interdisciplinary circle of his friends and colleagues: L. Vygotsky, N.Bernstein, A.N. Leontiev and R. Jacobson (who wrote a book on romanticism in science). Similar views were common among such classics of Western
psychology as Gestaltists, F. Bartlett, J.I. Gibson and Donald Hebb. The romantic stance is of the same heuristic value today as it was during the past two centuries. We illustrate this by our results from new experiments combining neuro-imaging and analysis of eye movements. In these studies, the brain reactions to events followed by events’ meaning and not physical similarity of stimuli patterns, supporting the idea of active and meaningful processing of information by the human brain.

Symposium title: Metatheorizing in psychology: Historical, philosophical, and cultural perspectives (First symposium) Convenor: Ilya Garber

Metatheoretical issues for a fully societal psychology: Materiality, discourse, power and person

Rachel Falmagne Clark University, United States of America

This talk considers psychological theorising as one grain of analysis in transdisciplinary investigations that integrate material, institutional, discursive and agentive constituents of social processes. Poststructuralism, feminist theories, critical race theory, social theory and cultural studies pose new, fruitful challenges for psychology. Four critical issues are addressed from an integrative metatheoretical perspective that problematises dualisms as unproductive. First is the need to reflect the interplay of the material and discursive constituents of the social order, the internal politics of culture, and the power-infused gendering and rationalisation of the social order at all levels of organisation. Second, while endorsing poststructuralist critiques of the Cartesian notion of a unified, stable self, I argue against the radical shift toward a nonsubstantial, fluid notion of subjectivity, and submit that a (reconstructed) notion of person is ontologically necessary as the anchor of processes of social constitution and as the substrate of agency. Third is the dialectic of the particular and the general in knowledge production, implicated in the problem of generalisability in qualitative research and in the need to honour the internal complexity of social groupings in social theory. A notion of concrete generality is introduced, that preserves particularisation while also enabling broader social interpretations. Fourth is the presumed irreconcilability of discursive and cognitive approaches to conceptions of the subject. A new construct of interiority is presented, grounded in a discursive view of the subject, that recognises the inseparability of the psychological and the social while positing a (preconceived) ‘mental space’ as the anchor for thought.

Conducting predictive studies of science: Benefits, feasibility and some recommendations

David Faust United States of America

Nearly all methods within the history and philosophy of science for studying scientific occurrences and the success and failure of scientific undertakings are primarily retrospective or explanatory and not predictive. The relative neglect of predictive designs when studying science restricts methodological power and potential prescriptive yield. Subjecting proposed explanations and rational reconstructions of scientific processes and progress to predictive tests can provide a powerful supplemental means for refining our knowledge of the factors that promote or inhibit scientific success. Using meta-scientific methods – more rigorous means to study scientific occurrences and events – as an exemplar, I will present a series of proposals and suggestions for conducting feasible short- and long-term predictive studies that may assist in answering key questions in the history and philosophy of science, such as features that most favour the ultimate success of theories.

Three tendencies of modern psychology

Ilya Garber Saratov State University, Russian Federation

Based upon V. Klokchko’s transactive analysis, three interrelated tendencies of modern psychology are considered: The shift from T. Kuhn’s paradigms that do not play instrumental role in psychology to syn tags; from scientific method to applied technology, and from mono-cultural psychology, Americocentrism, and Eurocentrism to cross-cultural psychology.

Critical integrative metatheory: New methods to evaluate psychological theories and models

Steven Walls Fielding Graduate University, United States of America

If psychology is to serve humanity, we must have useful theories (models, schema, etc.). Previously, we have been unable to evaluate theories "on the page" with any degree of rigour. So, we have had no way to determine if the theory is likely to be effective in practical application. A growing body of literature, both philosophical and empirical, takes up the question of evaluating theories in terms of promising results. For the present study the object of analysis will be a sample of theories of psychology. This study will apply new methods that have proven useful in analysing theories of management, organisations, ethics, systems, and policy. These methods include a form of "propositional analysis" that is essentially "integrative" and involves the quantification of specific logical structures within each theory. An integrative approach is one that combines qualitative and quantitative methods for rigorous critical analysis. This study identifies those theories that are more likely to be useful in practice based on their complexity and their specific and quantified logical structures. Additionally, this study identifies specific and significant benefits that might be gained through a rigorous integration of multiple theories. Finally, this study calls for the adoption of new policies and procedures for reviewing journal submissions that will accelerate the advancement of our field. And, in the process, allows us to choose better theories for research and practice so that we may more rapidly improve our ability to serve humanity.

Metatheory in an international context: Critical psychology and its variations

Thomas Teo York University, Canada

Critical psychology has become an international movement with centers in North America, Europe (particularly Britain, Germany, Denmark, and Spain), Latin America, Africa (particularly South Africa), and Oceania. Self-identifying critical psychologists come from all continents. Although many critical psychologists endorse the primacy of practice, critical thinkers have contributed significant ideas to metatheory. I begin with the German social philosopher Max Horkheimer (1895–1973) and his 1937 article entitled "Traditional and Critical Theory" in order to elucidate topics of current relevance in psychological metatheory. Following his stream of arguments, I suggest that psychological objects are socially preformed through the historical character of psychological objects and events as well as through the historical character of our understanding, and that knowing subjects are intertwined with the psychological objects that they study. I analyse how critical psychologists could overcome the separation between individual and society, value and research, and knowledge and action. I ask whether critical psychology's ethical-political purpose of a just organisation of society that meets the needs of all its members is still a valid goal. Finally, I discuss the notion that the psychological individual is embedded in contexts and that the psychologisation of society takes place under power, the Americanisation of global subjec-
Metatheorizing in psychology: Historical, philosophical, and cultural perspectives
Thomas Teo York University, Canada
Metatheory in psychology concerns theorising about the knowledge and practice of this discipline. In order to achieve this goal metatheory needs to be devoted to fostering discussions at the interface of psychology and philosophy, history and culture. In this symposium we will address some of the ontological, epistemological, ethical, historical, and critical issues in psychological theory and inquiry as well as the implications of psychological theory and inquiry for philosophical issues. In keeping with metatheory’s interdisciplinary mission, psychology, history, culture, and philosophy are construed broadly to encompass a diversity of forms of inquiry such as conceptual, speculative, theoretical, empirical, clinical, historical, literary, and cultural research. This symposium focuses on the informed, innovative, and critical exploration and discussion of psychological ideas and practices in both their scientific and philosophical dimensions and interrelationships. The symposium is divided into two parts: In the first part we discuss the inseparability of person and society on the background of contexts of power, the possibilities of prediction, recent disciplinary trends in the field of psychology, and the usefulness of theories for practice. In the second part, we discuss the interrelation of emotion and cognition in the process of scientific research, the problem of indigenisation of psychology, the relevance of historical psychology for general psychology, and the significance of critical psychology. Possibilities and limitations of metatheory in psychology are discussed and contextualised.

Symposium title: Spatial schemas in social thought
Convenor: Barbara Tversky
Social and motivational influences on spatial perception
Simone Schnall United Kingdom; Dario Krpan
Unlike social judgments, perceptual judgments are anchored in concrete reality and should not depend on social context. However, recent research suggests that perceptions of physical space, such as estimates of hill slant, are constrained by social and motivational considerations. In particular, availability of social support, and motivations to engage with the environment are shown to lead participants to view hills as more or less steep. These findings are consistent with the economy of action approach, which proposes that space is viewed as a function of afforded action.
Motorcycles have a lower sensorial conspicuity than cars, especially because of their small size. Accident studies indicate that the most common accident happens at intersections where the motorist refuses the right of way because he hasn’t seen the motorcycle. In the past, the sensorial conspicuity of motorcycles was improved by the use of Daytime Running Lights (DRLs) which became compulsory in many countries. This safety benefit is presently losing ground because passenger cars also increasingly use DRLs. In two experiments we evaluated (1) if car DRLs produce detrimental effects on motorcycle detectability, and (2) whether motorcycle detectability in a car DRL environment can be enhanced by innovative motorcycle headlight ergonomics. Photographs of real-world traffic scenes were shown to participants who had to detect vulnerable road users (motorcyclists, cyclists, pedestrians) in the presence or absence of car DRLs. Motorcycles were signalled by a standard or three configurations. The findings of the first experiment clearly show that car DRLs created "visual noise" that decreased the detectability of motorcycles compared to conditions where car DRLs were not lit. In the second experiment it was shown that colour coding (i.e., a yellow motorcycle headlight) was the most effective way of improving motorcycle detectability. An additional light on the motorcyclist’s helmet was less effective, and a triangular configuration was not effective at all. The study suggests that more attention should be paid to motorcyclists when introducing car DRLs. It also shows means for defining a new visual signature for motorcycles.

Change detection in traffic scenes: The effect of driving experience
Yan Ge Institute of Psychology, CAS, China

Allocation of attention is a very important issue in driving safety. This study is focused on the visual skill gap between novice and experienced drivers. A flicker paradigm of change detection was used to investigate visual attention in traffic scenes. A 2 × 2 (experience: novice, experienced drivers) × 2 (change type: appearance, disappearance) × 2 (object of change: traffic sign, pedestrian) mixed design was manipulated to explore the effect of experience and information features. The results showed: (1) Appearance or disappearance of pedestrians was more easily detected than that of traffic signs. (2) Changes in the central view were harder to detect than in the left or right view. (3) Drivers could find more changes in the central view than the control group. Data of eye movements are also shown in this paper. These results revealed a better allocation mode of visual attention in experienced drivers. These results may also provide a useful methodology for future investigation of a wide range of visual processing issues in driving research.

Complexity of traffic scenes and mental workload in car driving
Rainer Hoeger Leuphana University Lueneburg, Germany; Thomas Rhek; Marco Wietfeld

The degree to which someone is mentally preoccupied by a traffic scenario depends on factors such as traffic density, roadway arrangement, number of different participants, and the amount of distracting objects. It can be assumed that with increasing complexity of these aspects, the mental workload of the driver is growing. In a series of studies traffic scenarios were characterized by measuring their structural complexity. These complexity measures were compared to the experienced mental workload of the car driver. To investigate these relationships in detail from the driver’s perspective, videos of different dynamic traffic situations were recorded. These videos were then analysed by calculating the structural complexity of each video-frame on the basis of a luminance-change algorithm. In a further step these videos were shown to participants who had to judge the mental demands relating to the different traffic situations. The judgments were continuously registered by a hand-held potentiometer so that a time-series of mental workload values resulted. Correlation analyses between the time-series of mental workload and the numeric measures of complexity revealed substantial correlations. The results show that the judged mental workload relates to certain traffic situation, and can be predicted to some extent by a formal complexity analysis of the traffic scene. Considerations are suggested relating to the extent to which continuous complexity measurements can be used to predict driver fatigue.

How do passengers affect drivers’ propensities of angry driving? Differences between supervisors and friends
Tian-Yi Hu Peking University, China; Xiao-Fei Xie Peking University, China

This research examined the different effects of supervisors and friends as passengers on drivers’ propensities for angry driving. Study 1 asked drivers to freely imagine a passenger either as his/her supervisor or friend. Results showed that drivers’ propensities of angry driving was raised when the passenger is a friend compared with driving alone, while a supervisor passenger would reduce anger propensity, which was consistent with generally accepted social norm. In study 2, drivers read a description about either an aggressive supervisor or a cautious friend. Results showed that the effects of passengers on drivers’ angry driving propensities were correspondingly reversed, indicating that a clearer behavioural standard conveyed by a passenger would have a more crucial effect on drivers. Self-monitoring traits moderated the effects in both studies. The moderation effects were different for self-monitoring ability and self-monitoring propensity, such that self-monitoring ability played a more important role in a standard-free situation and self-monitoring propensity a more important role in a standard-set situation. Impressions management processes were discussed with respect to these findings.

Irrational risk perceptions after the Fukushima accident? It depends how you ask the question
Verena Klussmann University of Konstanz, Germany; Britta Renner; Katja Neumann

We compared general risk perceptions of different hazards (e.g., nuclear power vs. hydropower) with personal risk perceptions (i.e., the risk for a peer) and assessed changes in risk perceptions after the Fukushima accident. A first online survey was conducted in 2010 (N=550) and a second one two weeks after the Fukushima accident in 2011 (N=1094). Participants were asked to select today’s five biggest risks for health and to rate the likelihood of health problems due to the hazards for an average peer. Using an across hazards assessment, nuclear energy was rated as being the sixth biggest health risk prior to the accident, but as being the third biggest risk thereafter, χ²(3)=39.38, p=.001, OR=2.18. Moreover, technological risks were clearly overemphasised: Only five (Study 1) or four (Study 2) behaviour-related risks ranged among the top 10 leading risks. Asking for personal risk perceptions, in contrast, resulted in relative accurate estimates: participants rated nine behavior-related risks (e.g., smoking) as most perilous. The perceived risk of nuclear energy for an average peer increased only slightly from 3.4 (SD=1.9) in 2010 to 3.7 (SD=1.92) in 2011, t (1642)=3.04, p=.002, g2=.01. Obviously, heightened nuclear risk perceptions diminished when people took an across person perspective. Also, the overemphasis of technological risks can be qualified when people base their judgements on a more concrete, person-related framework. Thus, certain ways to ask questions erroneously facilitate the “mass panic” assumption.
Fatal injuries in Gauteng children: Occurrence and psychosocial development stages
Karín Pretorius MRC, South Africa
Injuries are a major cause of death globally. In South Africa, where the injury death rate is 157.8 per 100,000 population, traffic accidents are a leading cause of death in children aged 10 to 14 years, and children are considered more vulnerable to injury than adults. The aim was to investigate the role of psychosocial development phases in childhood injury risk and exposure. Data were obtained from the National Injury and Mortality Surveillance System; focused on fatal injuries in Gauteng from 2008 to 2009. Age groups were divided along Erikson’s psychosocial theory of development. The average age was 9.4 years, and most children were male (66.2%). The majority of children were black, and the most common scene of injury was the road. In early childhood, burns were the most common type of injury. Pedestrian injuries were common during preschool (32.1%) and school age (33.1%), and in adolescence, homicide was the most common (33.8%), followed by transport-related deaths (31.1%) and suicide (16.5%). In infancy, the most common cause of injury death was undetermined. The exposure to environmental and social risks to childhood and adolescent injuries change as children become older and experience different levels of autonomy, psychosocial development, and age-specific social challenges. It is imperative to understand the nature of these risks when considering the safety of children, and to be aware of the manner in which risks evolve from infancy to adolescence.

Cognitive factors in driving safety
Wei Na Qu Institute of Psychology, China
Statistical data showed that 74% of traffic accidents were due to human errors. And the literature showed that the ability of cognitive operations of drivers could predict their driving safety. Four driving-related tasks were used to investigate the relationship between performance of cognitive tasks and driving safety. 20 drivers (10 experienced and 10 novice) were asked to perform four tasks, including attention-span, spatial cognition, multi-target motion tracing, and spatial speed estimating tasks. The results showed that all tasks can differentiate the two driver groups. All four tasks are valid to measure drivers’ ability of cognitive operations.

Fatalistic beliefs, accident explanations, and safety-related behaviors
Ngoeutsa Robert Université de Grenoble2, France, France; Kouabenan Remi
Explaining accidents is a central element in defining preventive actions. Kouabenan (1999) showed that naive explanations of accidents deserve as much attention as explanations given by experts. However, both expert and naive explanations are biased by several factors (Slovic et al., 1981). For example, because of the complexity of accident situations and the uncertainty they generate, individuals tend to rely on their beliefs to explain events and even to act with respect to the risks involved (Kouabenan, 2007). Fatalistic beliefs are a concern in this matter (Norenzayan & Lee, 2010). However, little is known about the link between such beliefs and explanations, or about the mediating effect of beliefs on explanation-related safety behaviors. We hypothesize that beliefs, and notably fatalistic ones, influence not only the nature of the explanations provided for an accident, but also safety behaviors. Five hundred and twenty-five Cameroonian road users (mean age 32) responded to a hetero-administered questionnaire about fatalistic beliefs, explanations of accidents, and accident-related safety behaviors. As expected, accident explanations partially mediated the effects of fatalistic beliefs on safety behaviors. The more fatalistic participants were, the more they explained accidents in terms of external factors involving the driver (b = -.14, t(499) = 4.86, p < .01) and the more they tend to adopt unsafe behaviors (b = -.23, t(499) = 7.07, p < .01). The results are discussed in light of approaches that argue for considering beliefs and representations in accident diagnosis and prevention.

Risk perception, transportation priorities and travel mode use in the urban Norwegian public
Torbjørn Randmo Norwegian University of Science and Technology, Norway
Public travel modes are judged to be more environmentally friendly compared to the use of private modes and, consequently, a policy demand aimed at enhancing the public’s use of public transportation is preferred. The aim of the present study was to analyse differences in risk perception and accessibility of travel modes among users of public as well as private modes. In addition, two groups of respondents with different transportation priorities were compared on the same factors. The first group of respondents prioritised travel mode convenience and health and environmental issues while the other group gave more priority to flexibility and comfort. The results are based on a questionnaire survey carried out during Spring 2011 among a random sample of residents of the city of Oslo (n = 512). The results showed that frequent users of public travel modes were giving most priority to travel mode convenience and health and environmental issues while frequent users of private modes gave more priority to flexibility and comfort. There were significant differences in risk perception due to transportation priorities, while these priorities were totally non-significantly related to the accessibility of travel modes. The main conclusion of the study was that a policy aimed at reducing the use of private transportation in urban areas may be more effective if countermeasures are directed at reducing the possibility further for use of private travel modes compared to increasing the access to public transportation.

Psychosocial determinants of suicide attempts among black South African adolescents: A qualitative analysis
Hilda Shilubane University of Venda, South Africa; Shaganamom James; Bart van den Borne; Arjan Bos; Robert Ruiter; Priscilla Reddy
In South Africa, one in five adolescents attempts suicide. Suicide attempts continue to rise. We aimed to identify psychosocial target points for future educational interventions. One-to-one semi-structured interviews were conducted to explore psychosocial factors associated with past suicide attempts among suicide survivors in Limpopo province, South Africa. A total of 14 adolescents (8 girls and 6 boys) who recently attempted suicide were interviewed. Lack of knowledge of available counsellors, conflicts in interpersonal relationships, perceived accusations of negative behaviour, inadequate social support, past family and peer suicide attempts, and poor living circumstances were factors found to be related with suicide attempts. This study suggests that accessibility to counselling is essential in the prevention of suicide among young people, at both the individual level and family level.

Comparing the driving behaviour of novice and young drivers: The influence of affective states
Felix Siebert University of Lunenburg, Germany; Rainer Hoeger; Hans-Ruediger Pfister; Michael Oebl
Although general car safety has increased and accident numbers have decreased in the last years in Germany, the percentage of novice and young car drivers involved in heavy car accidents remains high. Young drivers between the age of 18 and 20 cause 71% of the accidents in which people are injured in Germany. In many countries, novice and young drivers under the age of 25 account for the largest share of traffic crashes and fatalities. Traffic psychological research hypotheses that a two-fold effect leads to maladjusted driving of young and novice drivers, the lack of driving experience as well as the youthfulness of young drivers. Therefore, both groups and effects have to be analysed individually. Since research also shows that maladjusted driving behavior caused by affective states is a main contributor to traffic accidents, this study analysed the influence of affective states on driving with regard to novice and young drivers. Affective states (positive vs. negative valence) were induced in participants, and subjects were then asked to drive predefined routes in a driving simulator covering different road designs, e.g., expressways or country roads, since the driving task is partly determined by the demands of the road environment. The results indicated that in general, novice and young drivers showed more risky driving behaviour in a positive affective state. On motorways however the inexperienced novice drivers showed more careful driving behaviour compared to young, more experienced drivers. Implications for further research and applied issues will be outlined.

Where are the parents? Personal, familial and contextual challenges to caregiver involvement in a child safety intervention in South Africa
Ashley Van Niekerk MRC-UNISA, South Africa
Injuries are a serious global health threat to young children, with this threat disproportionately concentrated in Africa. There is some recognition that the physical and psychosocial environments and aspects of the injury-inducing agent may be as important as the behaviour of the child and adults directly involved in an injury event. Despite this multi-factorial understanding, there have been per-
sistent attributions of childhood injury to deficiencies in parental knowledge and safety behaviour. The available injury prevention research has considered the levels of parental knowledge, attitudes and actions that may avert or contribute towards child injury. There are, however, considerable and extensive challenges faced by caregivers in their promotion of child safety in impoverished home and community settings. This presentation will highlight the personal, familial and contextual challenges articulated by caregivers involved in a community-centred child safety promotion intervention. The intervention was implemented in a low-income setting in the Western Cape, South Africa, with caregivers central to the implementation of the intervention strategies. The study data were captured in caregiver interviews and focus groups, and analysed using content thematic analysis. Caregiver understanding of the intervention purpose, rationale, and benefits, and their contribution to the intervention are explored to afford greater insight into caregiver awareness, understanding and commitment to this child safety promotion intervention within their community. The study foregrounds the importance of caregiver experience and highlights their insights to understanding essential enablers and barriers to appropriate child injury prevention interventions.

Childhood burn injury in South Africa: towards a social justice agenda
Ashley Van Niekerk MRC-UNISA, South Africa
Childhood burn injury is a neglected development and social justice issue in South Africa and throughout Africa. Burn injury is often catastrophic for individuals and their families, and typically leaves disabling scars, not only to the skin or the body of the affected child, but also to her or his psyche, with significant psychological, educational and social impairments. There is a preponderance of burns amongst poor marginalised communities and families, with a concentration in South Africa amongst black children. Despite the country’s social transformation, its current stability and its relative wealth, most blacks continue to report higher levels of impoverishment and hazardous housing conditions, and consequently poorer living conditions and overall health. These structural and psychosocial impoverishments associated specifically with burn injury often co-vary, and accumulate for greater exposure to burns. Despite the pronounced contextual foundations to childhood burns, international and South African burn prevention agencies have not prioritised interventions specific to these identified circumstances. This paper argues for interventions directed at the impoverished infrastructures of vulnerable communities and families. These interventions include reducing income differentials and the impact of these, including improved access to safer housing, affordable and safe electricity and electrical appliances.

Developing and evaluating a unitary model for predicting the fitness to drive
Marco Vetter SCHUHFIRED GmbH, Austria; Rudolf Debelak
In traffic psychology, practitioners are regularly required to assess the fitness of patients with a neurological impairment to operate a motor vehicle. A common question is whether methods used for assessing “fitness to drive” in a non-clinical population can be generalised for clinical populations. This study investigates the utilisation of a short test battery for the prediction of the fitness to drive, measured by a standardised driving test. Three samples of 222 healthy drivers (58 female; mean age = 59.23, SD = 18.06), 109 stroke patients (21 female; mean age = 51.39, SD = 8.92) and 70 traumatic brain injury (TBI) patients (12 female; mean age = 36.00, SD = 9.68) worked on four ability tests assessing resistance of attention, decision speed, perceptual speed, divided attention and field of view, and performing a standardised driving test. The contribution of the four tests, on predicting the fitness to drive in healthy drivers was analysed by the means of a linear logistic regression analysis and a non-linear additive regression analysis. The results of the analyses indicate that the non-linear regression model obtained from the analysis of the data of the healthy drivers, also allows the prediction of driving fitness in stroke and TBI patients. This is an indication that the analyzed test battery can be applied to non-clinical as well as clinical populations.

Differences in attitudes towards traffic safety and driving behaviour in the native and immigrant population in Norway
Hans Brende Lind Norwegian University of Science and Technology, Norway; Torbjørn Rundmo
The aim of the present study was to examine differences in driver risk attitudes and behaviour in the native and immigrant population in Norway. The results are based on a self-completion survey carried out among a representative sample of the Norwegian public (n = 1624). The response rate was 33%. The sample consisted of 49.7% females and 50.3% males. 91% of respondents were of Norwegian origin, 5% of non-Western origin, and 4% of Western origin. Multivariate analysis of variance showed significant differences in driver risk behaviour due to country of origin, but no differences in traffic safety attitudes. Post hoc bonferroni analysis showed that non-Western immigrants reported safer driving behaviours than respondents of Norwegian origin. The results indicate that differences in self-reported behaviour are not mediated by attitudes.

Driving anger and driving anger expression of Chinese and Japanese drivers
Michael Oehl Leuphana University of Luneburg, Germany; Chunping Zhaung; Felix Siebert; Pei-Luen Rau; Taro Kanno
Although car safety has increased progressively, and the safety of road environments has been improved, the numbers of traffic accidents in Japan and especially in China still remain alarmingly high. Despite traffic, psychological research has shown that emotions leading to maladjusted driving behaviour are the main contributors to traffic accidents. It is currently far from clear to what extent emotions are influencing driving behaviour in Asian countries like China and Japan. In many countries driving anger was found to correlate significantly with risky and aggressive driving behaviour leading to a higher probability of getting involved in traffic accidents. So far, studies on this critical issue are lacking in most Asian countries. The current study aims to bridge this gap. We examined the reliability and validity of a Chinese and Japanese version of the Driving Anger Scale (DAS) and of the Driving Anger Expression Inventory (DAEI). Preliminary results point to the tendency that Japanese drivers experience less driving anger compared to drivers in the US. Moreover, cross-cultural differences in the expression of driving anger between Chinese, Japanese and drivers from western countries are evident. Implications for further research and traffic safety will be outlined.

Attentional requirements in different driving scenarios
Kristen Pammer Australian National University, Australia; Caroline Blink
Looked-but-failed-to-see accidents that occur when driving map precisely onto the psychological phenomenon called Inattentional Blindness (IB). IB occurs when a viewer fails to see an unexpected object that is clearly visible, particularly if they are concentrating on an additional primary task. In this study, a static IB task was used with driving related stimuli to explore whether an unexpected stimulus (US) is more likely to be seen in country or city-related driving scenarios if it is congruent or incon-

automated vehicles
Comfort and adaptive cruise control in highly female participants. We are design (2x2x4x5): 2 (participant gender) x 2 (generation) x 4 (levels of perceived congruency) x 5 (levels of popularity). We are interested to investigate risky behaviours in the context of the 21st century, studying psychological associations of university students. The hypothesis is that gender promotes differences in the valuation of safe behaviour. Specifically, high-risk behaviour improves a man’s reputation, while it decreases reputation in women. Participants are 80 freshmen students from the Adolfo Ibáñez University (Viña del Mar Campus): 40 men and 40 women between the ages of 18 and 20. We prefer to exclude students couring their major in psychology. The study is an Experimental design (2x2x4x5): 2 (participant gender) x 2 (gender of experimental stimulus) x 4 (combination of descriptions) x 5 (levels of popularity). We are expecting to find that social reputation in men who behave unsafely could increase, while women could decrease their reputation by high-risk behaviour. As soon as men behave more safely, they decrease their popularity, while in women the opposite can occur. In addition, the qualifications assigned by male participants can be different to those assigned by female participants.

University young male: Risk behaviour and social reputation
Ariel Quezado Universidad Adolfo Ibáñez, Chile
Wilson and Daly (2001) describe Young Male Syndrome as a behaviour pattern in which men have a high probability to use risky and violent behaviour to achieve reproductive interest in women. Culture provides a set of behaviours to improve this reproductive achievement. We were interested to investigate risky behaviours in the context of the 21st century, studying psychological associations of university students. The hypothesis is that gender promotes differences in the valuation of safe behaviour. Specifically, high-risk behaviour improves a man’s reputation, while it decreases reputation in women. Participants are 80 freshmen students from the Adolfo Ibáñez University (Viña del Mar Campus): 40 men and 40 women between the ages of 18 and 20. We prefer to exclude students couring their major in psychology. The study is an Experimental design (2x2x4x5): 2 (participant gender) x 2 (gender of experimental stimulus) x 4 (combination of descriptions) x 5 (levels of popularity). We are expecting to find that social reputation in men who behave unsafely could increase, while women could decrease their reputation by high-risk behaviour. As soon as men behave more safely, they decrease their popularity, while in women the opposite can occur. In addition, the qualifications assigned by male participants can be different to those assigned by female participants.

Contextualising pedestrian-motor vehicle crash involvement in Ghana
Enoch Teye-Kwadio Stellenbosch University, South Africa
Despite mounting global evidence that pedestrians are the most vulnerable group of road users and traffic victims, little empirical research attention has been given to this hidden epidemic in Ghana. The purpose of this study was to explore pedestrian mobility and travel experiences as well as driver-pedestrian perceptions of one another’s road use attitudes and behaviour regarding pedestrian-vehicular crash involvements. A case study design, in-depth interviews, and focused group discussions were used with 26 participants. Interviews and discussions sought pedestrian views about their travel experiences, traffic risk perception and behaviour, road infrastructure, and their opinions about drivers. With drivers, discussions focused on their perception of pedestrians’ road use attitudes, behaviour and role in road traffic accidents. Qualitative content analysis indicated that pedestrians perceived poor road design and signage, and congested environment, as key determinants of pedestrian-automobile crashes. Besides, person error and general risky road user behaviour were described as contributory factors to road accidents. Drivers appeared dissatisfied with the general disinterest in prosecuting pedestrians for traffic violations in the country. The findings suggest that there is much victim-blaming in motor-vehicle crashes. Traffic engineers and urban and feeder road planners should develop programmes that address the carnage on the country’s roads involving pedestrians. These programmes should also seek to reduce the unsafe road use behaviour of drivers whose vehicles kill pedestrians. Road safety officials should involve parents and guardians in safety campaigns given the over-representation of children in pedestrian casualties.

Comfort and adaptive cruise control in highly automated vehicles
Felix Siebert University of Lüneburg, Germany; Michael Ohle;Wiebke Mahfeld;Hans-Ruediger Pfister; Rainer Hoeper
Clearance errors are the fourth most frequent cause of accidents with injuries in traffic in Germany. With the first successful tests and the long-term deployment of highly automated vehicles with adaptive cruise control, clearance errors might decrease in the long run. Due to the high degree of automation, the role of the driver changes from having an active part in the driving of the vehicle, to a reactive monitoring task. In addition to legal and security concerns, it is unclear what effect this change of the driver’s task has on the comfort of the driver when trailing another vehicle. In this experimental study, one crucial aspect of future automation, the distance kept by the automated car, was examined in a driving simulator. The distance between the automated vehicle and another vehicle driving ahead was varied in different driving situations. The experienced comfort during the drive was measured with a newly developed questionnaire. Results of the study suggest that the distance maintained by the automation affects the comfort experienced by the driver as a function of the situations. Results also suggest that drivers perceive the distance to headway vehicles differently when they drive an automated car. Traffic provisions in Germany demand a clearance of at least 50 meters when driving 100 km/h. This distance was rated far having a high discomfort by participants in our study. Results will be discussed in terms of their impact on the design of future vehicle automation and adaptive cruise control.

The "back in the drivers seat" programme for overcoming driving anxiety
Jacqueline Trifitt Hill Street Psychology, Australia
The "Back in the Drivers Seat" programme assists people who have driving anxiety to understand and manage their anxiety and build confidence to start or recommence driving. The programme has achieved positive outcomes and has been particularly beneficial for people who have been involved in motor vehicle accidents. The paper will provide an overview of the programme and results achieved.

The effect of fear, threat and efficacy on message acceptance in road safety advertising.
Yaoshan Xu Institute of Psychology, CAS, China
The current study examines the effectiveness of fear appeal on the behavioural intentions of participants to perform safe driving behaviour in the Chinese context. Specifically, a fear-evoking message about wearing seatbelts was examined in terms of a persuasive process (emotion arousal, threat appraisal and coping appraisal), as well as a range of persuasion outcomes (attitude and behavior intention). 120 participants received either fear-based or neutral messages and completed the same questionnaire. As predicted, the results found that while fear appeal could lead to the respondents’ emotional and cognitive responses, their coping appraisal, rather than their emotion arousal, was indentified as the key component influencing the effectiveness of fear appeal. The results also revealed evidence of greater effectiveness of fear appeal on licensed drivers than on unlicensed drivers. Practical implications of the study were discussed.

Session Type: Symposium

Symposium title: Psychology in Malaysia
Convenor: Chee-Leong Goh

Evaluation of an intervention programme for Mat Rempits (illegal motorcycle racing gangs)
Rozmi Ismail Universiti Kebangsaan Malaysia, Malaysia
This paper describes the implementation and evaluation of a pilot intervention programme for Mat Rempits (Illegal Motorcycle Racers), which was carried out by Universiti Kebangsaan Malaysia, under the Centre of Adolescent Empowerment. This programme was officially named as the ‘Adolescent Empowerment Camp’ in order to reduce the risk of stigmatisation by the general public. It is the first organised attempt in Malaysia to engage this group of marginalised individuals. Through this programme, youths who have been involved in illegal motorcycle activities were encouraged to change attitudes and behaviours, and to develop their potential. In a span of approximately three months, the intervention program was carried out in a series of five different camp-based modules involving both indoor and outdoor activities. A total of 68 actual and 33 control subjects participated in this study. Results showed that self-esteem, resilience and leadership improved. In addition, there were significant differences in self-esteem and leadership between the control subjects and the intervention group. Adolescents who are involved in illegal motorcycle races show lower self-esteem and leadership and they are less resilient when compared to the general population of adolescents. This implies the need for continuous intervention programs to empower at-risk youth.
Association of earthquake experiences and reproductive health events with depression and anxiety: October 2005 earthquake in Pakistan
Jasim Anwar The University of Sydney, Pakistan; Kaye Brock
The association between reproductive and mental health among women with post-disaster experiences is under-researched. This presentation reports the results and implications of a cross-sectional study on mental health in Pakistani women of reproductive age following an earthquake event. A random sample of 387 Pakistani women of reproductive age (15-49 years) with earthquake experience completed the Centers for Disease Control reproductive health assessment toolkit. They also took the Hopkins Symptom Checklist-25, and the Harvard Trauma Questionnaire. The association of either depression or anxiety with socio-demographic variables, earthquake experiences, reproductive health and access to health facilities was estimated using multivariate logistic regression. Women with worse reproductive health events such as having a stillbirth, having had an abortion, having had abnormal vaginal discharge or having had genital ulcers, were at significant risk of depression and anxiety. Effects were exacerbated with loss of resources for subsistence and separation from family following the earthquake event. The relationship between women’s post-earthquake mental health and reproductive health, socio-economic status, and health care access is complex and explained largely by the socio-cultural role of women. The mental health of women affected by the earthquake is associated with low socio-economic status, separation from family, poor reproductive health outcomes and limited access to appropriate health facilities. Socio-cultural influences and access to health care may predispose them to risk adverse health outcomes from post-earthquake trauma.

Posttraumatic stress and growth in tsunami relief volunteers
Braj Bhushan IIT Kanpur, India; Che Leping
The primary aim of the current study was to explore how the direction of counterfactual thoughts influences posttraumatic stress (PTS) and posttraumatic growth (PTG). 20 female relief volunteers who had participated in the post-tsunami relief operations in the coastal areas of Tamil Nadu were assessed for proactive coping, dissociative experiences, PTS and PTG. Multivariate analysis of variance (MANOVA) and multiple discriminant analysis were performed to identify the key underlying dimensions affecting PTS and PTG. The main effects of amnesia, depersonalization and percentage of dissociation were highly significant. In turn, these dimensions were significantly related to dissociative experiences (amnesia and depersonalization) and family type whereas capacity for absorption determined avoidance symptoms. The main effects of proactive coping were significant for relating to others, new possibility, spiritual change, appreciation of life and total PTG score. The amnestic symptom of dissociation had a significant influence on intrusion and total trauma score as well as all the dimensions of PTG. The capacity for absorption significantly affected avoidance and total trauma score besides relating to others, personal strength, and spiritual change dimensions of PTG. The main effect of depersonalization was significant for intrusion, relating to others, new possibilities, spiritual change, and total PTG score. Discriminant coefficients suggested the significance of relating to others and proactive coping. It also suggested the importance of intrusion, avoidance and appreciation of life.

Evidence that nutritional supplements enhance psychological resilience following earthquakes
Neville Blamiped University of Canterbury, New Zealand; Julia Rucklidge
Natural disasters expose communities to severe distress and trauma. Short-term, everyone may be affected, and a minority experience long-term adverse consequences. Individuals, families, community groups, local and regional organizations and institutions may be affected. Thus, enhancing individual resilience to disaster would have many benefits. The catastrophic earthquakes in Christchurch, New Zealand (beginning 04 September 2010 and continuing during 2011) provided an opportunity to study the impact of nutritional supplements (containing vitamins, minerals, and antioxidants in various formulations) on psychological resilience. Study 1 involved 33 adults all with a pre-quake diagnosis of attention-deficit hyperactivity disorder and baseline measures of depression, anxiety, and stress. They were contacted by telephone 7 and 14 days after the initial 7.1 magnitude earthquake (widely damaging but without fatalities), and re-administered the psychological tests. The 16 taking a nutritional supplement showed reduced levels of anxiety, depression, and stress. Study 2 began two months following a 6.3 aftershock that destroyed the central city killing 182 people. 87 adults recruited from the general population were randomly assigned to take one of two micronutrient formulas, completed baseline assessments of psychological well-being and trauma symptoms were assessed weekly for four weeks, and followed up at one month. 25 control individuals were assessed at baseline and at four weeks. Those taking nutritional supplements showed significant reductions in psychological symptoms over the trial. Micronutrient dietary supplementation is a practical public health intervention that may enhance psychological resilience following a natural disaster.

Dialectical behaviour therapy for patients with posttraumatic stress disorder related to childhood sexual abuse
Martin Bohus Central Institute of Mental health, Germany; Anne Dyer; Kathlen Priebe; Antje Krueger; Regina Steil
Posttraumatic stress disorder (PTSD) and borderline personality disorder (BPD) are frequently co-occurring sequelae of childhood sexual abuse (CSA). Cognitive-behavioural treatments are effective in reducing CSA-related PTSD symptoms, but it remains unclear whether PTSD after CSA can be treated successfully in the large group of patients with co-occurring BPD. We hence developed a treatment program (PTSD-DBT) for these patients combining principles of Dialectical Behaviour Therapy (DBT) and trauma focussed interventions. Women with CSA-related PTSD were randomised to either a 12-week residential DBT-PTSD program or a treatment-as-usual wait list. About half the participants (n=33) met the diagnostic criteria for co-occurring BPD while the others did not (n=41). The primary outcomes were reduction of PTSD symptoms as assessed by the Clinician-Administered PTSD Scale (CAPS) and by the Posttraumatic Diagnostic Scale (PDS). On average, both the CAPS and the PDS improved significantly more in the treatment group than in the control group (mean change 30.1 vs. 1.29 and 0.73 vs. 0.09, respectively). Between-group effect sizes were large and highly significant for both patients with co-occurring BPD and those without. Accordingly, neither the severity nor the number of BPD symptoms was significantly related to treatment outcome. Analysis of adverse events revealed no increase in dysfunctional behaviour. Our findings clearly indicate efficacy of the newly developed DBT treatment program, and show that a diagnosis of BPD does not preclude efficacious treatment.

A relational psychoanalytic exploration of the intergenerational transmission of trauma from mothers to their adult children
Bruce Bradford University of Cape Town, South Africa
Historically, psychosocial analyses of trauma have explored experiences of political violence, in which various forms of violation of one person, race, gender, ideology or sex by another have been described. The implications of interpersonal trauma on the self have been well documented in literature which debates the impacts of traumatic rupture on self and society. Less thoroughly investigated is the manifestation of the mother’s traumatic psychic contents in the attachment relationship between
mother and child. This work, derived from the author’s doctoral dissertation, investigates intergenerational transmission from mothers with a history of interpersonal trauma to their adult children, in the context of the relationship between mother and child. The research aimed to articulate conscious and unconscious relational and intrapsychic processes by which trauma is transmitted. Contemporaneous relational psychoanalytic theories are central to the analytic orientation of this work. The fusion of psychoanalysis with attachment theory has contributed significantly to the analysis, emphasizing the unconscious processes underlying attachment between mother and child. Through the use of psychoanalytic case study methodology with phenomenological research methods, the research revealed the connection between a mother’s dissociative process and the transmission of trauma. The pattern of avoidant attachment was central to the process of transmission, reflecting an insight which differs from current theoretic positions. The results have direct implications for psychotherapists’ work with family systems, considering the histories of trauma which influence relationships.

Relationship between intimate partner violence, HIV-related stigma and mental health among people living with HIV

Elsie Breet; Soraya Seedat; Ashraf Kagee

This study examines the relationship between intimate partner violence, perceived HIV-related stigma, and symptoms of PTSD and depression among persons living with HIV. We recruited 209 South Africans living with HIV by means of a combination of convenience and network sampling. Participants completed a battery of questionnaires that included an assessment of intimate partner violence, HIV stigma, the Beck Depression Inventory, and a PTSD symptom scale. We regressed variables of interest on the independent variables, intimate partner violence symptomatology and HIV-related stigma. The linear combination of demographic variables, IPV symptomatology and HIV-related stigma accounted for 4.9% of the variance in PTSD symptomatology and 5.6% of the variance in depressive symptoms. Among females, 1.9% and 1.2% of the variance in PTSD and depressive symptoms were explained, respectively. Among males, 26% and 9.5% of the variance in PTSD and depressive symptoms were explained, respectively. Recent and remote IPV did not significantly account for variance in either PTSD or depression. Our findings suggest that a combination of IPV and HIV-related stigma play a potentially important role in accounting for symptoms of PTSD and depression in men living with HIV, but perhaps less so with women. We discuss the implications of these findings in the context of the elevated prevalence of HIV, intimate partner violence and common mental disorders in many communities in South Africa.

Preventing violence in Jamaican schools

Orlean Brown Earle Northern Caribbean University, Jamaica

This research presents an overview of current school violence prevention practices in Jamaica. Convenience sampling was used to select 204 teachers with a modal age group of 31–40 years throughout Jamaica. Respondent scores on the School Violence Questionnaire and Research Protocol were used to provide the data for the study. It includes a summary of a mixed-methods survey of violence and violence prevention in schools of which the survey participants included educators and practitioners, such as school counsellors in the Jamaican school system. The results indicate that a significant proportion of the respondents have observed school violence and have had to contend with violent behaviours in schools ($q^2 (1, n = 195) = 132.93, p<0.01$). Ninety-nine percent of the teachers expressed the opinion that schools needed to be more serious about discipline. These results suggest the need for interventions that seek to develop programmes to help students who exhibit violent behaviours in schools. The presentation incorporates relevant research that provides information regarding characteristics and consequences of appropriate instructional programmes that are applicable to at-risk youth, educators and parents. Data has also been collected from over 800 students at the primary and secondary levels, and the presentation will provide a comparative review of how teachers and students view the issues of school violence and how violence can be prevented in schools.

Developing a school-based, action research model for the psychological intervention of children with complex trauma

Susan Cahill York St John’s University, Ireland

Developments in psychological therapy practice with fostered or adopted children are moving toward a dyadic model (working with the child and his or her carer[s]), in preference to individual therapeutic interventions. The rationale behind this paradigm shift is the supposition that correcting attachment injuries is best achieved within the context of healing attachment relationships. Symptomatology associated with children presenting with complex trauma includes behavioural problems due to dysregulation, disturbances of attention, cognition, and consciousness, distortions in self-perception and meaning, interpersonal/relational difficulties and somatisation. It is therefore understandable that these children have differing degrees of behavioural, social and educational difficulties at school. On the premise of treating children within their environment and relationships, this paper outlines the development of a school-based action research model intervention that developed in the process of clinically treating a child with complex trauma who had been suspended from school. The theoretical models and structure of the process will be discussed in detail, with emphasis on collaboration, cooperation and knowledge sharing. Some of the difficulties that prevented advancement, plus accomplishments that provided the motivation to continue to work educationally (with a therapeutic bias), with a child presenting with challenging behaviour in a school setting, will be illustrated. The model, although in its infancy, has received funding to provide a specific learning environment for children with complex trauma in order to retain these children in mainstream schooling. Learning from experience and predicting some of the challenges will be reflected upon.

Child sexual abuse workers’ emotional experiences of working therapeutically in the Western Cape

Charlotte Capri Lentegeur Psychiatric Hospital, South Africa; Lou-Marie Kruger; Mark Tomlinson; Marcia Johnson; Fischer Hakan

South African child sexual abuse (CSA) workers active in low-income communities in the Western Cape bear witness to stories of sexual and physical abuse, and of pervasive poverty, violence, hunger, and deprivation. North American, British, and European CSA workers’ emotional experiences have been captured in the literature, and a gap remains to be filled by those of South African CSA workers. This study focuses on the emotional experiences of CSA workers who engage therapeutically with sexually-abused children in the Helderberg basin of the Western Cape. The qualitative study employed an exploratory inductive research design. Data collection took place by means of semi-structured interviews with CSA workers who work therapeutically with sexually-abused children. The research contributes to knowledge of working with CSA in South Africa by exploring the emotional experiences of those who help sexually-abused children, and by investigating the psychological impact the work has on CSA workers active in Western Cape low-income communities. It also introduces possibilities for supervision of, future research into, and working...
Meaning making in response to the traumatic loss of a child
Angeline Chan University of the Witwatersrand, South Africa; Gillian Eagle
Recent research supports the theoretical premise that healthy forms of bereavement include meaning making as a coping response to loss as well as a move away from Freud’s original postulation regarding the importance of decathexis as necessary to a healthy resolution of grief. However, traumatic bereavement produces particular kinds of difficulties in meaning making and the possible resolution of this kind of loss. The presentation reports on a study that explored responses in relation to the traumatic loss of a child through homicide in a sample of 7 parents (2 pairs, 3 mothers) who were identified through the Compassionate Friends (CF) chapter in Highlands North, Johannesburg and volunteered to take part in the study. Semi-structured interviews were conducted, recorded, transcribed and subjected to an interpretive thematic content analysis. The thematic content analysis revealed that meaning making responses in relation to the loss of a child through homicide are complex and that somewhat unexpectedly, parents experienced expectations from others to engage in particular kinds of meaning making as counter-productive and alienating. Issues concerning the simultaneous introjection of and decathexis from the lost child also proved enlightening. Meaning making also involves both some degree of trauma resolution and the recognition of what the loss of the significant other entails. The paper also explores the choices and decisions that parents report as being important in response to the traumatic loss of their child and suggests some useful pointers for those who encounter traumatically bereaved individuals in the course of their work.

The impact of continuous trauma: Exploring the limitations of existing diagnostic frameworks in violent areas in Cape Town
Sarah Crawford-Browne University of Cape Town, South Africa; Arlene Benjamin
The experience of living in violence-prone neighbourhoods in Cape Town, where people survive under the ongoing threat of danger, differs markedly from the traumatic experiences in countries from which mainstream trauma theory and interventions have emerged. An incident of violence here may be one event of many, within a lifetime of threatened community and criminal violence. The South African Stress and Health Study (Stein et al., 2008) identified a low prevalence of Post Traumatic Stress Disorder (PTSD), despite a high national level of violence. The authors propose that this experience of “continuous trauma” is a sub-category of PTSD, sharing many of the symptoms and associated symptoms, but with a distinctive pattern of impact, presentation and recovery. In this paper, the term “Continuous Trauma” is explored as a mental health presentation arising from living in a neighbourhood with high levels of gang, community and criminal violence from an early age, where violence has been witnessed or experienced repeatedly, and where the person recovers within this context of ongoing threat. Drawing on participatory research methodology, the authors describe the violence in one such community, Hanover Park and offer interview material to suggest an initial formulation of the elements of “continuous trauma”. An individual, family and community framework is used to consider the multiple levels of impact.

A community play with a group of boys as a therapeutic way of connection
Chanelle De Beer UNISA, South Africa; Mark Southwood; Bekebe Makwusa
A play as an expressive therapeutic intervention was used to assist a group of boys in working through previous traumatic experiences. The play was written based on the stories of the boys and their caregivers in a safety-home (Itumeleng) in Sunnyside, Pretoria. Many of the boys are estranged from their family members and this play gave them the opportunity to experience a sense of connection with the larger community. Using one of the boys as a case study it was noted how the play provided a platform for him to work through some of his traumatic experiences and memories through enactment. As he participated in the play, he had the opportunity to experience a sense of belonging, as he had suffered from previous rejection and victimisation. A number of different stakeholders were involved in the project. Connection with other community members was made possible; the community support provided to him helped him to shape and discover his identity. Reflections of some of the stakeholders involved in the project will be explored. The play was regarded as being a valuable therapeutic intervention within this specific context in bringing people together and forming a sense of connectedness and relatedness within the Sunnyside community. The play entailed a story of hope and new beginnings that was possible despite one’s difficult past.

Brain activation of subliminal earthquake-related experience priming impact on the Stroop task in trauma-exposed people
Xue Du
Post-traumatic stress disorder (PTSD) has been associated with cognitive control impairment, and emotional regulation difficulties, but the relationship between cognitive control and emotional regulation in non-PTSD, who personally experienced the trauma is still unclear. Therefore, in this study, we selected 16 victims of the China great Sichuan earthquake (12/5) without PTSD (survivor group), and 14 control people (control group), to investigate the brain activation of subliminal earthquake-related experience priming impact on the Stroop task by using functional magnetic resonance imaging (fMRI). Our results found that during incongruent versus congruent condition, the brain regions involving cognitive control (e.g. prefrontal cortex) were activated in all people, and there was no significant difference between groups. Interestingly, the survivor group mainly showed significant enhanced activation in the ventral anterior cingulate cortex (vACC) and the bilateral parahippocampal gyrus during congruent minus incongruent condi-
Impact of critical incidents among Jamaican police: reviewing conventional wisdom on the role of self-reported coping as a moderator

Jessica Dunn University of Nottingham, Jamaica; Nigel Hunt

Police stress has received considerable attention in occupational health research throughout the late 20th and early 21st century, with policing being regarded by some as “the most psychologically dangerous job in the world” (Axelbre and Valle, 1978). Many of the noted job stressors associated with police work include frontline operational duties and organisational factors, yet much of the international research in policing overlooks developing nations where crime, violence and poor working conditions are most visible. Existing research often draws on self-report measures to identify: (i) the appraisal of these chronic and acute occupational stressors as part of a transactional process and (ii) the moderating effect of police coping mechanisms in the stressor-strain relationship, some of which has yielded fragmented results. A key problem is the measurement of ‘stress’ itself. The reliability of self-report data on stress is arguably problematic because there is often a suppression of conscious awareness of emotion particularly among police who are immersed in an occupational culture that advocates courage and hardiness. 648 frontline Jamaican police officers selected from high and low risk communities completed an interviewer-administered survey, which identified typologies of critical incidents and investigated the impact of events, perceived coping and physical health. Results suggest there is incongruence between reported coping and actual coping ability among police and challenge the efficacy of methodologies that rely purely on self-report mechanisms to capture relevant attitudes and behaviour. Recommendations for future research and practice are discussed.

Mother-infant attachment: reflective functioning in mothers with histories of childhood abuse and neglect

Karin Ensink Université Laval, Canada

Despite growing research attention, still relatively little is known concerning the impact of childhood experiences of abuse and neglect on the intergenerational transmission of attachment from mother to child. This study presents findings of a prospective, 20-month follow-up study in 57 mothers with histories of abuse and neglect and their infants, examining relationships between maternal attachment and reflective functioning, and infant attachment. Pregnant women were screened using the Parental Bonding Instrument (PBI). Women reporting low parental care on the PBI were further evaluated with the Childhood Experience of Care and Abuse Interview (CECA), and the Adult Attachment Interview (AAI) was administered to assess attachment, unresolved trauma, global reflective function (RF-G) and reflective functioning regarding traumatic experiences (RF-T). Infant attachment was evaluated with the Strange Situation Paradigm (SSP) when children were 17 months. Results showed that the majority (83%) of infants presented as unresolved. In mothers who were classified as unresolved, 67% of infants were disorganised, and 70% mother-infant dyads had corresponding attachment classifications. Maternal attachment style and infant gender were the only predictors of infant attachment security, while unresolved trauma, infant gender and RF-T, but not RF-G, predicted infant disorganised attachment. The findings of this study highlight the importance of trauma, gender and reflective functioning in the intergenerational transmission of attachment in mothers with a history of abuse.

Mentalisation in middle-childhood: An initial study of the validity of the child reflective functioning scale

Karin Ensink Université Laval, Canada

The main goal of the present study was to examine the validity of a measure specifically designed to assess reflective functioning or mentalisation activated in an attachment context during middle-childhood. Participants were 94 mother-child dyads divided in two subgroups. The clinical group consisted of 46 dyads where the child has a history of intrafamilial (n = 22 dyads) or extrafamilial (n = 24 dyads) sexual abuse. The community control group was composed of 48 mother-child dyads, selected to broadly match the socio-demographic, age and gender characteristics of the abused group. Child and mother reflective functioning were assessed using videotaped and transcribed data gathered using the Child Attachment Interview and the Parent Development Interview. The results showed that the Child Reflective Functioning Scale proved reliable, with excellent intra-class correlation coefficients for both self- and other-understanding indicators. Meaningful differences in reflective functioning between sexually abused and control children supported the discriminant validity of the Child Reflective Functioning Scale. Finally, the association between child reflective functioning and child sexual abuse was consistent even when controlling for child age and mothers’ reflective functioning. The implications of these results are discussed.

The psychological impact of Somali piracy on seafarers: Assessment and intervention

Michael Garfinkle Seamen’s Church Institute, United States of America

Over the past few years, the incidence of maritime piracy off the coast of Somalia has greatly increased. The victims of Somali piracy are unarmmed members of the merchant marine, made up of nationals of all countries. While previous industry research assessed the economic impact of piracy on global trade, the plight of the seafarers was overlooked. In 2009, the Seamen’s Church Institute (U.S.A.) initiated the first-ever study of the psychological impact of piracy on seafarers with the aim of describing this impact and providing guidelines on assessing and treating pirate-related trauma. After recounting the history of piracy, this paper describes the baseline stressors in being a seafarer, including economic pressures and interpersonal stressors, as well as the heightened stress of the risk of piracy. Accounts of those indirectly and directly affected by piracy are provided from interviews conducted face-to-face in Port Newark, U.S.A., as well as over Skype. The sample is comprised of seafarers who have or who have not been directly impacted by piracy and of nationals from throughout Southeast Asia, Europe, Eastern Europe, and the Americas. The sample was gathered by convenience at the Port of Newark and by those who wrote to the researcher in response to a call for participation. The nature of this traumatic experience is considered before recommendations for assessing seafarers post-captivity are offered. Interventions to help affected seafarers are offered in light of clinical and cultural considerations.

Healing trauma by using Peter Levine’s Somatnic Experiencing approach

Cecile Gerike South Africa; Susan Kriegler

Somatic Experiencing® was developed by Dr. Peter Levine following his observation that animals in the wild do not get traumatized even though daily they are faced with life threatening situations. He came to the conclusion that as the neo-cortex evolved in humans, our ability to override our instinctual responses also came online. This ability left us with a vulnerability to being traumatized. The Polyvagal theory of Stephen Porges helps to explain how the uncompleted “freeze” response in the ANS manifests as un-discharged hyper-arousal, dissociation, helplessness, and a sense of social disconnection. Utilizing a case study from the war in Iraq, it is demonstrated how SE helped a survivor to tune into physical sensation, which creates the space for the body to reconnect with the innate healing response. Using the principles of “tiration” and “pendulation,” the client is assisted to swing back and forth between memories of the life-threatening situation and pleasurable, life-affirming memories and sensations. This naturalistic process resolves symptoms by gently discharging the high levels of ANS arousal associated with trauma, and helping the body return to a more manageable level of functioning.

Isolating, degrading, exploiting as correlates of self-concept among school adolescents in Ota, Nigeria

Abiodun Gesinde Covenant University Ota, Nigeria

Emotional maltreatment of children and adolescent is a subtype of abuse which has been in existence since antiquity and has garnered considerable studies. Studies on identification have shown that it is multidimensional in nature consisting of terrorising, degrading, corrupting, rejecting, isolating, exploiting, and ignoring. The magnitude at which children and adolescents suffered emotional maltreatment of isolating, degrading, and exploiting has been found to be very startling. While studies have shown the impact of several dimensions of emotional abuse on human behaviours there is lack of empirical information on the combine and separate effects of isolating, degrading, and exploiting on self-concepts of adolescents. This descriptive survey design of ex-post facto investigated this phenomenon. Two hundred adolescents selected through purposive sampling technique
from fifteen private secondary schools in Ota, Nigeria participated in the study. Questionnaire on Seven Dimensions Emotional Maltreatment at Home (QSDEMH, α = 0.84) and Adolescent Personal Data Inventory (APDI, α = 0.81) were used to generate data. Two research hypotheses were tested at 0.05 alpha level and multiple regression analysis indicated that the three independent variables jointly accounted for 26.2% of the variance in self concept (R2 = .262) and separately contributed differently to the prediction of self concept (Isolating β = -0.202; t = 4.441; p < .05). It is recommended that psychological intervention programmes currently available in schools should be enhanced.

Effects of visuo-spatial interference while processing emotional information: Implications for traumatic stress disorders

Rebecca Godard Université Paul Verlaine, Metz, France; Javier Barchenilla; Cyril Tarquinio

The aim of this research was to replicate Holmes et al. (2009) study in which the realisation of a cognitive task (Tetris game) has an effect on later recall of images of a “traumatic film” was demonstrated. In this study, participants who played Tetris had fewer flashbacks than those who did not. We wish to know if these results can be duplicated systematically. We make the hypothesis that the execution of a complex cognitive task in the immediate aftermath of an exposure to a critical event would reduce flashbacks and modified the emotional treatment of information. Forty-six participants were included in this study. The Impact of Event Scale (IES) of Horowitz and a general questionnaire we have developed (individual characteristics and medical history) were used. Participants watched a video composed of potentially traumatic scenes. Following this exposure, all participants filled in the scales and questionnaires. Then, half of the participants (experimental group vs. control group) have played Tetris. Participants completed a diary for a week in which they noted if they had image revivals of the video scenes and to specify their nature. A week later, the participants return their journal and complete IES. Unlike Holmes et al. (2009) results, there are no significant difference between the number of intrusion reported by the control group and those reported by the experimental group (t(44) = .459; p = ns). However, we note a significant difference between the two group (t(44) = 1.336; p < .05) concerning distress associated with intrusions reported in the journal.

How do resource loss and cognitive appraisal predict PTSD and stress symptoms in earthquake survivors?

Bencio Gutierrez-Dona Universidad Estatal a Distancia, Costa Rica

Conservation of Resources Theory (COR) assumes that stress occurs when: (i) individuals’ resources are threatened with loss, (ii) individuals’ resources are actually lost, or (iii) individuals fail to gain sufficient resources following resource investment. Transactional Stress Theory (TST) defines stress as a particular relationship between the person and the environment that is appraised as taxing or exceeding his or her resources and endangering his or her well-being. This study was aimed to evaluate how resource loss and cognitive appraisal predicts PTSD, anxiety, depression, and somatisation in survivors of the 2009 Costa Rica earthquake. Data were gathered using questionnaires from a sample of N = 200 survivors two and five months after the disaster. A set of correlations, GLM-multivariate analyses, and hierarchical regressions were calculated to evaluate assumptions. After controlling for demographics and the experience of previous trauma, resource loss accounted for a higher percentage of variance in anxiety, depression and somatisation. As for predicting indicators of PTSD, results showed that cognitive appraisal of loss/damage accounted for higher percentages of variance in re-experience, avoidance, and arousal. Results suggested that resource loss was a better predictor for anxiety, depression, and somatisation, whereas cognitive appraisal of loss/damage was a better predictor for PTSD. The findings are discussed considering differences between TST and COR, and recent advancements in human stress and natural disasters research.

An exploration into the patterns of PTSD symptoms in South African residents

Kelly Holland University of the Witwatersrand, South Africa; Niicky Israel

Using thirty-eight residents from the Linden area of Gauteng, the research examined the prevalence of PTSD symptoms in residents living in a high crime area using the IES-R. Participants were dichotomised into those that had experienced a high-crime impact and those that had experienced a low-crime impact in terms of non-crime related traumas, primary crime-related traumas and secondary crime-related traumas based on information obtained from a crime experience questionnaire. The research investigated whether a different pattern of symptoms was evident for those participants who reported being affected by crime and those who did not. Additionally the impact of secondary-crime trauma was investigated using an open-ended question analysed through qualitative conventional content analysis. Participants’ preferences for being informed of crime occurring were examined similarly. Results indicated that many participants experienced the post traumatic stress cut-off proposed in literature. However differences were not found between the high and low impact groups for each category of trauma. Further results indicated significant differences between those reporting being affected by crime on the IES-R total as well as the intrusion and hyperarousal subscales but not on the avoidance subscale. Participants indicated that they preferred to be informed about ongoing crime as they were better able to protect themselves. However, the results from the qualitative data revealed secondary crime had a negative emotional impact which linked with many PTSD symptoms, specifically hypervigilance. Collectively, results suggested that secondary crime-related trauma may be creating PTSD symptoms in addition to direct experiences of crime.

Time perspective in psychic trauma

Olga Kassovska Mosk State University, Russian Federation

In this presentation, trauma is shown as a temporally non-linear phenomenon – temporal unity includes the past, present and future in the life story of a personality. Disrupted temporal unity of traumatised persons can be restored in “temporal work” (Magomed-Eminov) for example, by constructing a life narrative and acting in life by helping others. It is shown that the break between future and past created by trauma could be restored by constructing autobiographic identity in personality work (20 years of readjustment of veterans of Afghanistan, Chechnya). Higher intensity of trauma demands more “personality work”, hence higher levels of post-traumatic growth could be obtained. The study was conducted on 190 participants of military conflicts. The sample was divided into 2 contrast groups by intensity of trauma, each group was split according to the level of PTG: It showed that higher levels of post-traumatic growth correlate positively with a high level of trauma and do not correlate with a lower one. The study shows that high levels of post-traumatic growth predicts positive and active attitudes towards the past and the future (according to ZPTI, MMI, qualitative analysis). Those who managed to overcome trauma had an active social life. To integrate the past and future of traumatised people, one has to do “temporal work” on the personality to remake one’s past; constructing a new life story by acting in real life and taking care of others. This causes positive personality changes.

Early intervention in families at risk of abusing and neglecting their children

Katrina Lines ACT for Kids, Australia

The trauma children experience through abuse and neglect can have life long impacts on their psychological, social, cognitive and emotional functioning. Ideally, interventions addressing child maltreatment should occur before harm occurs. Such early intervention programs are designed to target families at risk of abusing or neglecting their children. Parents with problems such as substance abuse, mental health issues, homelessness, unemployment and domestic and family violence are offered assistance for their own issues and with parenting. This paper presents a description of, and outcomes from, an early intervention program in Queensland, Australia. In the Active Parenting Program, psychologists and other professionals work with families in their homes to assist them to learn new parenting, problem solving, communication, child discipline and coping skills. Parents are assisted with intergenerational trauma and other personal issues that put their children at risk of abuse and neglect. Participants were 389 families,
with an average of 3.6 members per family. Twenty-three per cent of families identified as Indigenous Australian. Analyses of the differences between pre and post outcome measures indicate that, on average, families make significant improvements in all domains of functioning. Effect sizes indicate a very robust and consistent pattern of positive change. Results also indicate that the longer the family is engaged in the program, the more likely it is that they will experience positive outcomes. Thus, early intervention programs can reduce the risk of children experiencing abuse and neglect.

Combining psychotherapy and trauma releasing exercises in the treatment of trauma

Helena Loubsers, South Africa

There is increased evidence that trauma is a multi-level experience, affecting individuals on a physical, emotional, mental, behavioural, spiritual and energetic level. Psychological approaches to the treatment of trauma tended to focus more on cognitive, emotional and behavioural facets, neglecting the physiological changes that occur during a traumatic event. Further, most trauma interventions are only suitable to be implemented on an individual basis, while the need for treatment are far greater than can be provided through conventional therapy. Neurologically trauma can be viewed as a response in the nervous system rather than the event itself. Symptoms of trauma arise when residual energy from the fight/flight/freeze/fight experience is not discharged from the body. Trauma releasing exercises (TRE™) (Bercelli, 2005) is a body therapy that release deep tension from the body by evoking a self-controlled muscular shaking response called neurogenic tremors. This restores the body to deep relaxation and balances the autonomic nervous system. Thereafter it is easier for a traumatized person to process the trauma on a psychological level. TRE™ can also be administered to groups thereby reaching more traumatized individuals. It can fruitfully be combined with other psychotherapies, yet little attention has been paid to this combined treatment approach. The aim of this paper is to (a) introduce TRE™ as body therapy in the treatment of trauma, (b) propose an integrative approach to trauma treatment combining TRE™ and psychotherapy, and (c) present a case study illustrating the use of TRE with other psychotherapeutic modalities.

Correlates between professional quality of life and vicarious traumatatisation in health-care providers of cancer patients

Aaron Majuto, University of Botswana, Botswana

This study attempts to establish the relationship between professional quality of life and vicarious traumatisation among healthcare providers of cancer patients in Botswana. Data were collected through a cross-sectional survey in Botswana among 83 health care providers of cancer patients. The two instruments used were Trauma and Attachment Belief Scale (TABS) and Professional Quality of Life Scale (ProQOL). Presence and levels of trauma were established by computing t-scores from responses on the TABS using the profile autoscore sheet and interpretation table from the test manual. Across the ten subscales, the minimum score recorded was 13 (other safety) followed by 24 (self intimacy) and 24 (self control) indicating minimal disruption in these areas. The maximum or highest t-scores recorded were 80 (other trust), 80 (self trust), 79 (other esteem), 74 (self control), 73 (self safety) and 72 (self intimacy), indicating that these areas were where there was an extremely high level of disruption in the sample. The scores for the three subscales of the professional quality of life, compassion satisfaction (CS), burnout (BO) and compassion fatigue (CF) were: 39.26, 40.7 and 33.01 respectively. All the three scores were out of a possible 50. Results indicate a high level of burnout (40.7) followed by compassion satisfaction (39.26) and compassion fatigue (33.01). Bivariate correlations between TABS and ProQOL were run and yielded r = -.11 (not significant) indicating a weak negative relationship. Suggestions were made about the provision of mental health counseling services to health care providers of cancer patients in Botswana.

After the deluge

Wayne Mann, RHealth, Australia; Amundo Scott, James Scott, RHealth, Australia

On the 10 January 2011 an extraordinary turn of climatic events transformed what is ordinarily a dry and at times arid Australian countryside into a flood ravaged community. Despite lives lost and properties destroyed, this event displaced populations and communities and left many homeless. The Lockyer Valley (West of Brisbane) has become known as “Australia’s Ground Zero”. Health care professionals, including the researchers, were mobilised to provide counselling to flood-affected victims in this area. The objective of this study was to identify common coping strategies amongst the respondents contextualising these strategies within the broad context of their rural existence. Cognisance of the researcher’s anecdotal evidence after his involvement with victims of the Merriup Point flood disaster in South Africa (1994) served as valuable cross-cultural background information. Data was collected from 102 flood victims in The Lockyer Valley who told their stories of how the floods traumatised them, as well the way in which they coped with the trauma. This qualitative data gathering was analysed by coding and thematic analysis as defined in the Grounded Theory Approach. Amongst others, the following common coping strategies have been identified: community awareness and involvement; support of extended family networks; resilience to the hardships of rural existence and trust in government support and infrastructure. In conclusion, the participant’s stories highlighted the enduring courage of individuals and the importance of spreading stories of encouragement to others in similar situations.

Wrestling with moving forward: Role of collective trauma in reconstructing African societies

Nomfundo Mogapi, CSVR, South Africa

The formalisation of post-traumatic stress disorders in the 1980s has been invaluable in developing an understanding of the impact of violence on individuals and its accompanying interventions to address its consequences. It has, however, failed to address or develop an understanding of the collective impact of violence, particularly in societies that have experienced widespread trauma and human rights violations. Collective trauma remains deeply embedded in the memory of citizens and is counter-productive when attempting to strategise and find constructive ways of moving forward. This paper aims to highlight the importance of acknowledging and developing an understanding of collective trauma in reconstructing societies that have experienced endemic violence and human rights abuses and makes apparent the limitations of using individual approaches in dealing with traumatic stress in these contexts. The paper goes further to discuss possible interventions for dealing with collective trauma and how this contributes to the appropriate and successful rebuilding of peaceful societies. The paper draws on the Centre for the Study of Violence and Reconciliation’s (CSVR) 20 years’ experience of dealing with violence and its impact on South African society and draws on the work that the organisation has engaged in with other African countries such as Angola, Kenya, and Zimbabwe.

Findings from an epidemiological catchment area: Quality of life and social support in relation to trauma

Eva Monson, McGill University, Canada; Danielle Routhier, Alain Brunet, AiHua Liu

Studies conducted on convenience samples suggest the existence of an inverse relationship for quality of life and trauma exposure/posttraumatic stress disorder (PTSD). The same has been found for social support. However, it remains unclear if these findings would apply (i) in an epidemiological sample, and (ii) to individuals with a current versus remitted diagnosis of PTSD. The present study reports data from a large community-based epidemiological catchment area study conducted in the south west of Montreal (N = 2399) broken down according to trauma exposure and PTSD diagnostic status (Current PTSD, Past PTSD, No PTSD in spite of trauma exposure, and No trauma exposure). An inverse relationship of decreased quality of life with increased trauma exposure and PTSD diagnostic status was replicated within the study sample. Mean levels of social support were not significantly different between PTSD and No PTSD groups. Subscale scores were examined in depth revealing that compared to the Current PTSD group, individuals with remitted PTSD had lower mean scores on certain domains than compared to the No PTSD groups. This research allows for a much needed broadening of our understanding of quality of life for individuals with current and remitted PTSD.

Finding the lost girls: Sudanese refugee women’s experiences relating to forced relocation

Jennifer Mootz, Texas Woman’s University, United States of America

Since 1983, the country of Sudan has been ravaged by a civil war. Two million people have died and four million people have been forced to relocate from their homes. Many have become refugees and relocated to the U.S. There is a dearth of literature regarding Sudanese refugees’ experiences. The literature that does exist tends to focus exclusively on men or the Lost Boys of Sudan. Because refugees may have varying relocation experiences due to their gender, the researcher conducted a narrative analysis study with seven Southern Sudanese refugee women, asking ‘What is the experience of...
Sudanese refugee women relating to the process of forced relocation? She used the Grounded Theory Method to analyse her interviews. Themes emerged relating to stages in the women’s migratory process: Pre-Departure Life, Departure, Migration, Temporary Resettlement, and Relocation to Host Country. Although the women did not utilize psychological terminology such as traumatisation, their most salient memories related to the witnessing of death, violence, and separation. Additionally, the researcher found that three primary protective factors were present in several of the stages: faith, social support, and hope (primarily that their children will have a better life). From the women’s Pre-Departure Life through their Relocation to Host Country, there are important differences that exist in the narratives of the women who relocated to a refugee camp and the women who relocated to an urban setting. The results indicate that a combined model using resource-based and attachment theory might best suit the women’s experiences as a refugee.

Posttraumatic stress disorder: Examining the cross-cultural facts and fantasies

Solomon Mumah Kenyatta University, Kenya; Chimwe Itecha; Agatha Ogwo

This study assessed the prevalence and extent of severity of PTSD cases among a selected cohort of Kenyan workforce following a recent article in ‘Scientific American’ entitled ‘The Post-Traumatic Stress Trap’ that focused on criticisms of the syndrome of PTSD. According to the author, “the defining criteria are too broad leading to rampant over diagnosis”, the concept itself is flawed in that it mistakes natural processes for dysfunction, and the misdiagnosis of soldiers leads to them becoming mired in the Veterans Administration system which encourages chronic disability. Participants (academia, bankers, actuaries, scientists, researchers, air transport staff, national security staff, IT specialists and workers in the hospitality industry) (N=62) were each screened for PTSD following a medical referral using a structured, clinician-administered PTSD interview. Results indicate that Kenyan workers exhibited minimal rates of PTSD (3-month prevalence amongst 18-52 year olds is 1.6%) based on the PTSD Checklist (PCL) which suggests that scores of 45-50 provide the best discrimination between cases and non-cases. But although PTSD is common among patients seeking care at medical clinics, little is known about the performance of screening instruments for PTSD in these settings. Thus, the facts and fallacies as they apply to the Kenyan populace are examined in light of lengthy and extensive experience in treating professionals with PTSD, and selective review of the vast research literature on the syndrome which has accumulated over the past two decades.

Psychological aspects of trauma and its resolution: The road to national healing in Zimbabwe

Julia Mutambura Midlands State University, Zimbabwe

Several traumatic events have taken place in Zimbabwe, which have posed serious threats to the individual’s wellbeing. Typically, owing to homeostatic mechanisms, people are resilient to most of these threats. However, there are times when the complex interaction between the individual and the environment is characterised by an incongruity between the individual’s adaptive capacity and the demand placed on the individual in the face of cataclysmic events beyond normal human experience, thus leading to trauma. This article seeks to delineate the psychological aspects of trauma and how they can be resolved. Specifically, we examine the causes, symptoms and differential reaction to trauma. We then stress the physical, psychological and neuropsychological sequel to trauma and illuminate on how it is a precursor to psychopathology. The article will then reflect on how trauma can be resolved at micro and macro level. We conclude by suggestions for pathways to national healing in Zimbabwe.

Origin of maltreatment: Exploratory study on the intergenerational transmission of child abuse types

Raquel Oliveira UIPES, Portugal; Joao Maroco UIPES, Portugal; Lucia Pais

Our objective was to assess if, in cases of intergenerational transmission of maltreatment, a transmission of abuse typologies occurred, and determine the abuse context. An exploratory study was developed with a convenience sample of 10 child aggressors, who had been victims of abuse. For data collection, a semi-structured interview and socio-demographic questionnaire were used. Content analysis was performed to study the textual data. Fisher’s test to assess the possible dependence between the suffered and inflicted types of abuse, and principal component analysis to explore associations between categories, were conducted. In 7 cases an intergenerational transmission of physical abuse was identified, in 2 psychological abuse, and in 2, neglect. No statistically significant association was found between the suffered and inflicted abuse typologies. The categories Family Environment (218 registration units-r.u.) and Intra-family Relationships (151 r.u.) presented the highest r.u. number, and the categories Sexual Abuse (1 r.u.) and Aggressor as Recognized Identification Figure (4 r.u.) the lowest. The results showed that the context where the abuse occurs is better explained by a two-dimensional model: ‘Maltreatment and Social interactions’ and ‘Abuse Context, Feelings and Perceptions.’ Strong associations were found between psychological and physical abuse, interpersonal relationships, feelings towards abuse and toxic habits/consumptions as the main cause for abuse; and between being the only victim of aggression, perceiving other as an identification figure and negative feelings towards the aggressor. The transmission of abuse typologies was not significant. However, associations between contextual aspects were found and are discussed along with limitations and implications.

When the past visits the present: Imagery rescripting to update traumatic memories underlying PTSD and avoidant personality disorder

Anita Padmanabhanunni Rhodes University, South Africa; David Edwards Rhodes University, South Africa

This paper describes a systematic case study of the treatment of a South African rape survivor with posttraumatic stress disorder (PTSD) and avoidant personality disorder (APD). Intrusive memories, a core feature of PTSD, often persist because of thematic and affective links to adverse childhood memories and the need to maintain a set of dysfunctional beliefs around which the self is organized. In such cases, successfully addressing PTSD requires transforming early maladaptive schemas (EMS) contained in early memories and thereby transforming the goal structure of the Self Memory System (Conway et al., 2004). This case study is one of a series investigating the transportability of Ehlers and Clark’s cognitive therapy (CT) in addressing rape-related PTSD in the South African context. Systematic case-based research offers a nuanced understanding of experiences and processes that typically evade group comparison research and is well-suited for testing clinical models in developing countries where resources to conduct clinical trials are limited. This presentation focuses on the use of imagery rescripting and cognitive restructuring, key interventions in CT, to update the meanings underlying distressing childhood memories maintaining PTSD and APD. Treatment resulted in complete resolution of PTSD intrusions and significant change was evidenced in cognitions underlying APD and self-report measures of PTSD, depression and anxiety. The paper provides support for theories about the role of intrusions in protecting self-coherence and evidence that rescripting distressing childhood memories is an effective way to address early maladaptive beliefs maintaining PTSD and APD.

What doctors want. Psychological support in private emergency hospital units: A South African perspective

Lynn Preston University of South Africa, South Africa; Hester Roets

The study reported in this paper is aimed at exploring the views of South African medical staff in an emergency hospital unit with respect to psychological support services. This study is a result of practical work experience where we work in conjunction with medical personnel in trauma units in three private hospitals. In order to improve our collaboration and services, we decided to do formal research on the medical personnel’s needs and to define the role of psychological support in these specific settings. With the active development of health psychology, the traditional role of the therapist in his/her rooms, attending to patients has dramatically changed. Various alternative roles and situations like trauma assistance have presented challenges for psychologists pushing them out of their comfort zones. In South Africa the challenges are more complex and intense, as the client/patient, him/herself is faced with unique and extreme situations. Self-completed questionnaires and interviews are (will be) used to determine health professional’s opinions of the value and role of psychological support services in the emergency unit in terms of diagnosis, feedback and possible referrals for instance in cases like attempted suicide. This research will provide insight into health professional’s staff needs and psychological support service providers’ functions, in South Africa, in an emergency hospital unit.
Post-traumatic growth and multiple trauma-tisation: The case of South Africa
Esther Price University of the Witwatersrand, South Africa
Over the past two decades, researchers have explored positive changes reported in the aftermath of traumatic events. Of these positive changes, the most studied is Post-traumatic growth (PTG). Post-traumatic growth has been conceptualised by some as a process that begins with the struggle with adversity, while others have proposed that it may be best conceptualised as a desirable outcome. However, most of this research has explored PTG in people with traumatic illness diagnoses (e.g. cancer or bone marrow transplant), in people who have experienced a shared natural disaster or generally, in samples of people who have experienced, on average, one traumatic event. South Africa represents a unique population, in this regard, as recent research suggests that the average South African adult reports experiencing two or more traumatic events in their lifetime. In addition to its traumatic political history, South Africa has one of the highest crime rates in the world. For these reasons, researchers in the field have raised the question of whether or not post-traumatic growth would be observed or even valid in the South African context. This research explored PTG in a sample of trauma-exposed South Africans. Findings suggest that post-traumatic growth was evident in this sample and it may best be conceptualised as a process. PTG is further explored in relation to post-traumatic stress symptomatology, depression and anxiety. Findings are discussed and implications for practice and for future research are discussed.

Dreams and trauma
Lynne Radomsky University of Western Cape, South Africa
This paper presents a qualitative analysis of a pilot study exploring the relationship between the effects of trauma on children’s dreams and the use of dream images in the therapeutic process. Based on the theory of C. G. Jung and dream interpretation, a group of 12 children between the ages of 7 and 12 years were asked to share their dreams after experiencing trauma. The trauma varied from individual child abuse to the witnessing of trauma associated with gang-related violence. South African youth are exposed to an unacceptably high rate of violence and associated trauma, many of whom present with Post Traumatic Stress Syndrome. An individual case study is presented in greater detail in order to illustrate the results of the pilot study. These results seem to indicate that the opportunity to relate to traumatic experiences in this way facilitated the children’s ability to integrate their experiences, improved concentration levels and availability to learning. In addition, improvement in general behavioral patterns such as increased levels of responsibility and awareness of self and other were noted. Suggestions for further research with respect to larger sample groups and implementation in schools are included.

Trauma and attitudes toward justice, reconciliation and coexistence in child survivors of the Rwandan genocide
Heide Rieder University of Konstanz, Germany; Thomas Elbert
To attain peaceful coexistence is a major challenge in post-conflict societies as negative feelings toward "the other group" may persist and sustain mental health problems. Our question was, how do descendants, raised in families of victims or perpetrators, differ in their mental health status, and share attitudes on justice and reconciliation in their community. A community-based sample of child survivors of the Rwandan Genocide (N=129) was randomly selected in the Muhanga district, part of the Southern Province of Rwanda. The Rwandan adjusted event scale was used and PTSD symptoms were established by means of the Posttraumatic Diagnostic Scale (PDS). Situational attribution of violence, attitudes toward reconciliation and local justice, and the relationship to the peer group were rated on a Likert Scale. Descendants of Victims showed a higher level of exposure to traumatic events (U=870, p<.000). The prevalence of PTSD was estimated 22.4% in the victim and 1.6% in the perpetrator group. Descendants of perpetrators showed more positive attitudes toward reconciliation (r=.32, p<.000), but not toward local justice (r=.117, p<.19). Again, situational attribution of violence showed to be more frequent in this group (r=.36, p<.000). Negative attitudes toward justice and reconciliation were linked to a higher level of PTSD symptoms (r=-.35, p<.000). The study demonstrates that traumatic exposure and PTSD symptoms are associated with attitudes toward justice and reconciliation and that these were linked to the family’s role during genocide.

The role of premigration and post migration factors on the mental health of refugees from Sudan and Burma
Robert Schweitzer Queensland University of Techno, Australia
There are over 16 million refugees and asylum seekers around the world and another 26 million internally displaced people due to conflicts of various forms. Many have been confronted by the terror associated with war, trauma and loss. The impact of such events on mental health and well-being can be profound. This paper examines a range of factors studied over the course of almost a decade on the well-being of people from Sudan and Burma seeking refuge in Australia. We have been involved in a series of studies involving structured interviews and an assessment battery including the Harvard Trauma Questionnaire, the Post-migration Living Difficulties Checklist and Hopkins Symptom Checklist to assess pre-migration trauma, post-migration living difficulties, and a range of mental health outcomes in samples of Sudanese and Burmese ethnic groups. Participants reported multiple and severe pre-migration traumas. Post-migration living difficulties made unique contributions to mental well-being above and beyond those associated with pre-migration challenges. While exposure to traumatic events impacted on participants’ psychosocial well-being, post-migration living difficulties had greater salience in predicting mental health outcomes of people from refugee backgrounds. High levels of somatisation in people from Burmese backgrounds point to a nuanced expression of distress. Yet, resilience and positive post-trauma changes were also apparent. Findings have implications for service provision in terms of implementing appropriate interventions to effectively meet the needs of people exposed to traumatic events and the loss associated with displacement. Results may also inform proactive programs aimed at promoting resilience and growth.

Re-imagining social suffering within a post-conflict context: A critical social psychology perspective
Puleng Segalo University of South Africa, South Africa
In this paper, I interrogate and examine the notion of social suffering, specifically highlighting its shrinkage, and eventual absence, within social psychology. I offer an invitation to psychology to critically look at how we understand suffering and the “after shocks” (displacement, family disruption, intergenerational hauntings, physical and mental trauma), the importance of remembering, including gender as a unit of analysis in our work, and reclaiming the social within social psychology. The meaning of suffering and memory within psychology has for a long time been viewed mostly from a “pathologizing” standpoint, which, it has been argued, has multiple limitations. Viewed as pathologi- city, people’s suffering may become universalised thereby leaving out broader contextual (social, environmental, political, historical, economical, etc.) aspects that have been shown to play a role in the subjective experience of various forms of suffering. Psychology has for a long time been quick to diagnose victims of traumatic experiences from an individualistic perspective, almost always posi- tioning the ‘problem’ within the person. Within psychology, post traumatic stress disorder (PTSD) has become the way to operationalise suffering, and I worry this has occluded how suffering lives in a body, a family, a community; through cogni- tions, memory, and embodiments; in voice and in silence; over time, and in ‘after shocks.’ The present paper aims to offer suggestive ideas on how critical psychology can move forward in the study of suffering.

Childhood maltreatment experiences among adults with substance abuse problems
Sheeba Shamsudeen Christ University, India
The present study was an attempt to examine the relationship between current substance abuse, retrospective reports of childhood maltreatment and associated trauma symptoms in adulthood among males and females. This exploratory study investigates the relationship between these variables and compares the differences between males and females using the ASSIST substance screening tool, the Childhood Trauma Questionnaire and the Trauma Symptom Checklist. The data were collected from two addiction treatment centers in Bangalore City, India (N=80). The data were analysed using Correlational Analysis and Multi Variate Analysis of Variance (MANOVA). The research has found that there is a significant relationship between substance abuse, types of childhood maltreatment and the associated trauma symptoms. The study also revealed that there is a significant gender difference in substance abuse related to tobacco and alcohol, types of childhood maltreatment such as physical and sexual abuse, and trauma symptoms like depression, anxiety and sleep disturbances. The findings of this study have implications for mental health professionals to offer more sensitive treatment interventions for individuals with substance
abuse problems by routinely addressing childhood maltreatment and issues related to it.

Promoting posttraumatic growth in newly recruited police officers: A randomised controlled trial
Ian Shochet Queensland University of Tech, Australia; Colette Roos; Cameron Craig; Jane Speak- speare-Finch; Astrid Wurfi
Emergency service personnel experience elevated levels of exposure to potentially traumatising events through the course of their employment. Such high levels of exposure make individuals in these roles vulnerable to psychological difficulties and may result in post traumatic stress disorder (PTSD), depression or unhealthy levels of alcohol consumption. However, posttraumatic growth (PTG), or positive post-trauma changes, are also afforded by these same levels of exposure to potentially traumatising events. A Randomised Controlled Trial with 411 new police recruits from 6 cohort intakes were randomly allocated to either a training as usual program or the Promoting Resilient Officers (PRO) program. This paper focuses on determining if participant’s perceptions of posttraumatic growth differed between the control and intervention groups. A mixed models analysis was used to account for both random and fixed effects and to better accommodate missing data in the repeated measures factors. Results demonstrated that overall growth scores changed over 3 time points (p = 0.05) and that the posttraumatic growth dimension, relationships with others, was significantly different (p = 0.008) from baseline at time 2 (following completion of the respective programs) as well as at time 3 (3 months later). It is suggested that providing a cognitive framework for considering an individual’s positive post-trauma changes may facilitate a more positive post-trauma resolution. These preliminary results show promise for encouraging PTG through training. Further work is now needed to demonstrate the potential to promote positive mental health.

Our children in crisis: Child abuse cases at the Sunlight Safe House in Johannesburg
Alexandra Spyrellis South Africa
Child abuse and neglect is a serious concern in South Africa and significantly undermines the development and wellbeing of children affected by it. This study aimed to explore the types of abuse that were reported for children removed from their families by child protection units in Gauteng, and placed at the Sunlight Safe House; an after-hours facility by child protection units in Gauteng, and placed at the Sunlight Safe House between 2008 and 2011. Our objectives were to present findings that demonstrate the potential for trauma education and training in the use of social support networks among refugees. These data indicating higher endorsement of PTG through training. Further work is now needed to demonstrate the potential to promote positive mental health.

Depathologising stress reactions in clients: ship® (spontaneous healing intrasystemic process) as a positive psychological perspective
Jo Steenkamp Private Practitioner, South Africa
Although the science of positive psychology has been acknowledged for the past fifty odd decades, it has not been widely adapted. ship® has established itself as a science that does not only focus on health and well-being, but also focuses on healing and personal growth. ship® has established itself in this realm as a psychological technique which does not only focus on mental illnesses with its accompanying diagnosis and treatment. In this presentation there will be scientific deliberation about the negative effects pathological bias can have on the client’s psychological and physical mechanisms of healing. A case study will be presented to demonstrate the applications of ship® to address alleviating the ‘psychosomatic symptoms’ (or healing messages) clients may have. The positive effects of the psychological body’s autonomy and ability to self-regulate will be discussed. The focus is not on changing a client’s experience or treating a dis-ease, but on creating a platform to identify these healing messages. During ship®, the clients’ healing reactions are validated and facilitated to run its natural cycle so that it may complete its unique self-correction integration process. Integration implies growth and freedom of chronic dis-ease manifestations.

Bereavement, traumatic stress, and behavioural reactions of tsunami survivors
Damodar Suar Indian Institute of Technology, India; NamitaDas Das; Lakmi Hota
This study examines whether the death of family members in a disaster intensifies traumatic stress and behavioural reactions of tsunami survivors. Data were collected interviewing 416 adult survivors from nine semi-urban habitations of Nagapattinum district in state of Tamilnadu (India) 14 months after the tsunami. The traumatic stress was assessed using inventories of posttraumatic stress, depression, positive and negative affectivity, physical health symptoms, fear, anxiety, and alcohol consumption, family conflict, suicidal thoughts, and fear were also assessed. Results reveal that the members of bereaved families have suffered from more posttraumatic stress, depression, negative affect, anxiety, deteriorated physical health, and less positive affect than the members from nonbereaved families. Bereaved survivors have reported more alcohol consumption, family conflict, suicidal thoughts, and fear, than nonbereaved survivors. Bereavement in the family is found to be a risk factor for traumatic stress and behavioural reactions.

Can terror challenge values and stable traits?
Sonia Suchday Yeshiva University, United States of America
Terrorism has a devastating impact on victims eliciting anger and rumination, and may challenge basic values such as forgiveness. As part of a larger study on psychosocial aspects of health and well-being, college students in Mumbai, India completed self-reports assessing trait anger (Spielberger), rumination (Trait Rumination Scale), and forgiveness (Importance, Forgiveness of Others, Self-Forgiveness) on two occasions – summer of 2008 (N=331, Females=268, Mean Age=18.7 years (SD=0.89) and summer of 2009 (N=201, Females=147, Mean Age=18.8 years (SD=1.06)). Mumbai was severely attacked by terrorists on 11/26/2008. Independent sample-tests computed on the anger, rumination, and forgiveness scales comparing the two groups of college students – 2008 versus 2009 – indicated that participants in 2009 were less likely to endorse forgiveness as an important value (Mean=14.22 versus 13.48, p<0.05), rated themselves lower on their ability to forgive others (Mean=5.34 versus 5.00, p<0.05), and reported higher trait anger (Mean=22.6 versus 23.3, p<0.05) and trait rumination (Mean=40.3 versus 42.8, p<0.01). Ability to self-forgive did not differ significantly in the two groups. Trait anger (r=.10, p=.03) and trait rumination (r=-.33, p<.001) both negatively correlated with forgiveness of others. These data indicating higher endorsement of anger and rumination and lower forgiveness after a terrorist attack compared to before, may allude to the ability of a terrorist attack to challenge basic values such as forgiveness in addition to eliciting anger and rumination.
PTSD and psychoactive substance use among Israeli veterans
Meir Teichman Tel-Aviv University, Israel; Yona Teichman; Ety Cohen

The study explores the relationships between PTSD and the use and abuse of psychoactive substances among Israeli veterans diagnosed with severe and chronic PTSD. 201 veterans who met the diagnostic criteria for severe and chronic PTSD were interviewed. They had fought in one or more of the following campaigns: the Yom Kippur War (1973); the first Lebanon War (1982); the second Lebanon War (2006) and during the intifada (Palestinian civilian uprising). The data included demographic details, detailed information on the participants’ use of psychoactive substances (coffee; tobacco; alcohol; prescription drugs abused or used without a physician’s prescription or against medical advice; cannabis; and hard drugs such as heroin and cocaine), intensity of PTSD symptoms anxiety, depression, and harshness as a measure of resilience. All questionnaires were in their Hebrew version. Main findings were as follows: (a) Prevalence of substance use and abuse among the veterans was significantly higher than in the general Israeli adult male population. (b) Substance use/ misuse among the PTSD respondents was related to the intensity of their post-traumatic symptoms, to their levels of anxiety and depression and to low levels of resilience. In addition, significant relationships were found between substance use, PTSD and participation in combat casualty evacuation. (c) Misuse of medications was the most common form of abuse substance, and was significantly related to the intensity of PTSD symptoms. Finally, in light of the results, the role of social workers working with PTSD patients is discussed.

AIDS as a venereal embodiment of post-apartheid trauma
Danielle Faye Tran SOAS University (London), United Kingdom

AIDS has become a taboo topic in South Africa as the disease has reached epidemic levels. But as drama therapist Nebe notes: “Art can play a critical role in grappling with unimaginable loss and trauma”. My paper explores how post-TRC (Truth and Reconciliation) literature perceives and engages with AIDS as a venereal embodiment of post-apartheid trauma. I break- away from the Eurocentric approach to trauma theory by analysing the representation of AIDS in diverse South African novels - Phaswane Mpo's Welcome to our Hillbrow and Jonny Steinberg’s Three Letter Plague. The main themes of discussion are stigma, secrecy and fear. By resituating trauma in a framework that is coherent with a specific non-western culture, I attempt to broaden our understanding of trauma across different cultures, opening up innovative ways of dealing with trauma. I examine whether my selected texts exhibit traumatic stressors, transforming them into “traumatic narratives”. For Cathy Caruth, a “traumatic narrative” oscillates between death and life, between the story of the unbearable event and its unbearable survival”. I also interrogate whether these texts gain freedom from trauma through what Saul Friedlander defines as ”closure”. I thus highlight how narrative can be used to promote dislo-

sure, becoming a medium which encourages patients to work through their trauma, broadening the prospect for therapeutic engagement. Through focusing on novels, I also consider how inventive AIDS literature helps to overcome the difficulty of transcribing trauma.

Ship(r) for trauma: A practical psychological trauma debriefing method for acute trauma
Jacq Van Der Walt South Africa

SHIP(R) for Trauma is a practical psychological debriefing method used with clients after acute traumatisation (e.g. exposure to crime, natural disasters and assault). It is based on the theoretical model of SHIP(R) that is covered in the article "Introducing SHIP(R) as a psychotherapeutic model to access the body memory of traumatised clients: depathologising expressions of trauma" as published in the South African Journal of Psychology, volume 41 (4), 2011. In this presentation the six key elements of this positive psychological approach will be discussed. Research, based on self-reporting questionnaires by clients before and after treatment, is presented that proves its effectiveness. The SHIP (R) debriefing method is part of this South African model, which was developed over the past 20 years. The value of this method is that it regards trauma as self regulation processes and spontaneous reactions, which are validated and facilitated to run its natural cycle of healing. The focus is on the integration of emotional pain, fear, helplessness and traumatic psychological memory as well as body memory. This healing process prevents the development of negative coping styles as well as tendencies towards disassociation and disconnection and, in the long run, the development of continuous trauma symptoms, e.g. posttraumatic stress disorder.

DSM-IV posttraumatic stress disorder in a multi-ethnic population: How well does our diagnostic lens fit?
Kempie Van Rooyen Nelson Mandela Metropolitan University, South Africa; Tanja Lambert

Much has been written about the influence of context on the experience of posttraumatic stress disorder (PTSD). Certain comments in the literature point to a polarisation on the issue of how universally applicable the PTSD diagnostic criteria are. On the one end of this continuum some argue that PTSD is a Westernised and culture specific disorder that does not fit non-Western experiences. On the other end are proponents of the PTSD diagnosis as a natural phenomenon, with such proponents relying on biological findings that distinguish traumatic stress from normal stress responses. The presentation provides results from a study that evaluated the fit of the current DSM-IV diagnostic criteria on a multi-ethnic South African sample (n=49). PTSD symptoms were measured using the Posttraumatic Checklist Civilian (PCL-C). Data analysis consisted of Cronbach alpha coefficients, item-item correlations, item total correlations and factor analysis. The range of correlational methods used above indicated a good ‘fit’ for the use of the diagnostic criteria of PTSD as measured by the PCL-C. Notable exceptions included the relatively weak contribution to diagnostic efficiency of memory disturbance and hypervigilance for the sample used in the study. The presentation concludes with the limitations of the study (notably heterogeneity and sample size) and recommendations for diagnosis and future studies are made.

The psychologist’s role in responding to those affected by disasters
Kempie Van Rooyen Nelson Mandela Metropolitan University, South Africa; Greg Howcroft; Nerina Blackburn

Currently some confusion exists as to how psychologists should best respond to those affected by disasters. Some have argued that early intervention is essential, and others that early formal psychological intervention has no useful role in immediate posttrauma response. In this qualitative study (n=5), the purpose was to explore and describe the experiences of psychologists who had responded to disaster situations, to see what could be learned about the most appropriate role for a psychologist to take in such situations. Data was collected with semi-structured interviews and analysed using content analysis. Results indicated that the role of the psychologist became important in managing treatment processes such as, inter alia, screening, deciding on the timing of intervention and meeting the needs of survivors. Other non-treatment factors such as dealing with politicians and the media, and issues around the general training of psychologists, also emerged from the analysis process. Recommendations include that a psychologist may be more efficiently used as a consultant in the immediate aftermath of mass disasters, rather than taking on the normal primarily treatment oriented role. Finally the limitations (notably the sample size and indirect nature of the data collection procedure) of the study and directions for training and future research are discussed.

Culture and posttraumatic stress disorder (PTSD): Findings and ongoing research illuminating a proposed conceptual framework
Kempie Van Rooyen Nelson Mandela Metropolitan University, South Africa

It is widely accepted that the understanding of any psychological disorder needs to be contextualised within cultural parameters. The notion that current diagnostic taxonomies are not always universally applicable does not mean that all symptoms are not applicable. This paper presents a framework that is aimed at being a starting point from which to delineate universal and culture specific elements of posttraumatic stress disorder (PTSD). The framework follows the possible influence of cultural factors on (a) the formation of an intrusive memory, (b) an understanding of how such a memory becomes pathological, and (c) how symptoms are expressed from the intrusive memory core of PTSD. While the framework presents certain elements (e.g. intrusive memory and core schemas) as centrally important, the focus is on a heuristic framework that allows for the study of the dynamic interaction between potentially universal and cultural factors and how this interaction may produce the symptom profile generally seen with PTSD. While this framework has been presented previously and is
in the process of being published, the current paper incorporates some findings from a recent study that illuminates some of the implicit hypotheses. Finally planned and ongoing research is presented as examples of how the implicit hypotheses of the framework can be tested.

Trauma victimisation in school: A retrospective pilot study with university students
Lucia Williams UFSCAR/LAPREV, Brazil; Paloma Albuquerque

When marked by violence the school may be a place of risk for children’s development. Results of a pilot study conducted with University students illustrating long term effects of prior school victimisation will be presented. The goal of the study was to characterise the worst events students had in their schooling prior to university, as well as to investigate the relationship between such type of victimisation and traumatic symptoms, particularly Post-Traumatic Stress Disorder (PTSD). Participants were 46 University students who answered the Brazilian version of the SATS-R (Student Alienation and Trauma Survey-Revised), as well as the PCL-C (Post-traumatic Stress Disorder Checklist – Civilian Version) after signing Informed Consent. The first instrument involves description of the most stressful school experiences, as well as identification of thoughts, behaviours and feelings associated with such experiences. According to retrospective data, 10.9% of students presented some PTSD symptoms; 4.3% of participants had scores falling in the clinical significant range for PTSD; and 13% had symptoms of depression. In addition, 80% of the participants who scored positively for PTSD in the past, also scored positively in the PCL-C presently, suggesting that individuals victimized in school may have some vulnerability for PTSD in the future. Although the study calls attention to the long term effects of school victimisation, results should be interpreted with caution given its pilot nature. This study is being replicated with approximately 600 students; statistical analysis will be conducted to correlate school victimisation and PTSD.

PTSD in relocated adolescents and social support and coping style after Sichuan earthquake
Jing Wu Renmin University of China, China; Li Lei; Xinchun Wu

This study aims to examine the Posttraumatic Stress Disorder (PTSD, including Intrusion, Evade, and Increasing Awareness symptoms) status of the secondary and high school students affected by relocation, and its relationship with social support and coping style. The results showed that one year after the Wenchuan earthquake, the PTSD rate of 793 students is 12.3%. PTSD incidence rate of students relocated to another place of the same province is significantly lower than those relocated to another province and those locally relocated. Girls’ PTSD score higher than boys, senior one students score higher than other graders, and students relocated to other places of the same province are significantly lower than local ones and those relocating to other provinces. Total social support score is significantly negatively correlated with PTSD symptom score. Different sources and types of social support could negatively predict Evade and Increasing Awareness symptoms and positively predict Intrusion symptoms. Positive cognitive coping style is significantly negatively correlated with PTSD, while escape coping positively so. Both social support and coping style cannot moderate the relationship between re-location and PTSD.

Expected trauma
Faezeh Zand Department of Psychology, Copenhagen, Denmark

Before being dispatched to Afghanistan, Danish soldiers are encouraged to write a letter of farewell to their families, a letter that also gives them an opportunity to express specific requests for their own funeral, should they be killed in action. This expression of awareness of the potential mortal danger during dispatch is a source of extreme stress that the soldiers handle in different ways. Research into trauma and traumatic experience has not focused on this source of stress. In a qualitative survey of 20 Danish battle troops, their course of action and handling skills in relation to the expected experience of strain in relation to their well-being has been examined very thoroughly. Four different tools of examination were used in the three phases: before the dispatch, after returning home and 18 months after. The concept of Anticipated Trauma and the way the 20 soldiers dealt with it will be presented and discussed.

Sustained attention performance and PTSD symptoms in Sichuan earthquake orphans and non-orphans
Xingli Zhang Institute of Psychology, China

The aim of this study was to examine sustained attention performance and PTSD symptoms in a sample of 281 orphans and non-orphans (146 boys and 135 girls) aged 8 to 16 years (M =12.7 years, SD =1.72) who experienced the Sichuan Earthquake in China. The Continuous Performance Test (CPT) was administered to measure children’s sustained attention, and the Children’s Revised Impact of Event Scale (CRIES) was employed to evaluate children’s PTSD symptoms. The results found post-earthquake orphans experienced significantly more intrusion (P = 0.009) than pre-earthquake orphans and more avoidance (P = 0.047) than non-orphans. Post-earthquake and pre-earthquake orphans who had a high possible risk of PTSD made more false alarms than non-orphans (F (1,155) = 3.33, P = 0.070; F (1,193) = 4.54, P = 0.034). This study revealed that the arousal symptoms of PTSD significantly positively correlated with performance of CPT for higher possible risk of PTSD. It also indicated that intrusion and arousal symptoms significantly positively correlated with false alarm of CPT in this population. However, there was no significant correlation found in those with a low-risk of having developed PTSD. These findings showed evidence of cognitive developmental stages, from vigilance to numbness and avoidance. The post-earthquake orphans were still in a high level of vigilance and the non-orphans with high possible risk of PTSD were the most concentrated and least impulsive. Given the potentially mutual relationship between sustained attention and PTSD symptoms, a duplex informant, duplex measure approach in the decision of educational plans for these children is strongly recommended.

Session Type: Posters
Effect of a cognitive-behavioural intervention programme on prematurely born infant parents’ post-traumatic stress reactions
Marina Brice University of Latvia, Latvia; Sandra Sebre

The aim of the present study was to look at the effectiveness of a brief four-session cognitive-behavioural intervention (CBI) programme in reducing the post-traumatic stress reactions of mothers and fathers of prematurely born infants in comparison to a control group. Premature births constitute 5-6% of all births in Northern Europe and potentiate a severely stressful event for parents susceptible to the development of Post-Traumatic Stress Disorder (PTSD). The CBI programme was developed to minimise these reactions in order to facilitate the parents’ ability to better engage with their prematurely born infant. The CBI programme includes psycho-education, anxiety management techniques, exposure and cognitive restructuring exercises. At present data has been collected from 20 mothers and 20 fathers whose infants was born prematurely, who indicated post-traumatic stress symptoms and who agreed to participate in the CBI programme, as well as from a matched control group. Before participation in the CBI programme and one month after participation, they were interviewed with the Clinician Administered PTSD Scale (CAPS, Weathers et al.). The preliminary analysis points to differences by gender in the post-traumatic reactions of mothers and fathers before CBI, as well as differences in the degree of symptom change, with mothers reporting greater decrease in symptoms after participation in the programme. The implications call for the necessity to differentially address the stress reactions of the mothers and fathers of prematurely born infants.

A cross-cultural comparative analysis: Risk and protective profiles of student victims and aggressors of interpersonal violence
Jacqueline Conley University of the West Indies, Barbados; Michael Edwards

This paper examines interpersonal violence in the Caribbean and in the United States. The data was collected from a convenience sample of 156 university students from the Caribbean and compared against a previously collected sample of 118 university students from the United States. The Conflict Tactic Scale-2 and CDC Depression Scale were used to assess for interpersonal violence and depression. Prevalence and incidence rates for interpersonal violence are reported. In addition, correlation analyses revealed significant positive relationships between the interpersonal violence factors for gender and geographical regions. Analysis of covariance was utilised to examine the effects of culture and gender on interpersonal violence with depression as a covariate. Significant differences were found between geographical regions and gender on several variables. Recommendations for future research are presented particularly around inclusion of qualitative approaches to
The case of adult Bosnian Muslim male refugees in Chicago: Current health behaviour outcomes and PTSD symptomatology

Lejla Delic-Ovcina Chicago School of Professional Psychology, United States of America

This study examined whether a relationship exists between the presence of Posttraumatic Stress Disorder (PTSD) symptomatology and health behaviour outcomes. The study also examined the severity of PTSD symptomatology and particular health behaviours, among adult Bosnian Muslim male refugees residing in the greater Chicago area more than a decade after their arrival in the United States. 637 Bosnian Refugees in Chicago Questionnaires (BRQ) were included in the data analysis. This study found a statistically significant relationship between the presence of PTSD symptomatology and the respondents’ general health rating, recentness of a dental visit, and smoking frequency. A statistically significant relationship was found to exist between the severity of PTSD symptomatology and engagement in physical activity, availability of healthcare coverage, and sufficiency of funds for healthcare services. This study highlights the need for further studies among Bosnian refugees, as well as other refugee populations, long after their permanent resettlement in their host country, since most of the current programmes and policies focus on newly arriving refugees, with very little focus on long-term and ongoing follow-up.

Intimate partner violence and emergency room advocacy-based services: An Italian practice

Francesca Esposito ISPA-IU, Italy; Pedro Costa ISPA-IU, Italy

Intimate Partner Violence is currently recognized as a serious and complex public health issue that affects physical, sexual, and emotional health. Identifying women victims of intimate partner violence to offer them adequate support has become a serious concern for surgical and hospital emergency room professionals. According to this need, hospital-based and emergency room-based advocacy programmes to screen and support women victims of I.P.V. have become a part of a growing international trend. In Italy, however, it is only in the last few years that this trend started and it is only available in major cities and hospitals. With these considerations, the present contribution reports on the experience of the Sportello Donna H24 (Woman Helpdesk H24), an advocacy counselling service located in the Emergency Room of the San Camillo Forlanini Hospital of Rome. Provided by BeFree Social Cooperative against trafficking, violence, and discrimination, an association of feminist advocates founded in 2009, this service adopts a community intervention and gender-oriented approach aimed at offering psychosocial and legal counselling to women victims of physical, psychological, economic and/or sexual violence from their partners, 24 hours a day. Data from this innovative service were collected through participant observation and professional cases’ narratives, and high-light routine intervention aspects as the general organisation of the service, professionals’ roles and attitudes toward victims of intimate partner violence so as to promote a reflection on the possible ways to implement these new services.

Perceived discrimination and post-traumatic stress disorder in intimate partner violence victims

Cassandra Groth Nova Southeastern University, United States of America; William Dorfman; Verónica Juanes; John Lewis

Intimate partner violence (IPV) against women has reached epidemic proportions; interestingly, research has shown that Hispanic female victims report significantly greater trauma-related symptoms, higher rates of post-traumatic stress disorder (PTSD), and lower levels of self-esteem than non-Hispanic female victims. Some factors that may increase the risk of developing PTSD are perceived discrimination and experiencing race-related stress. This study will investigate the relations between PTSD severity in Cuban female victims of IPV, their rates of perceived discrimination, and their exposure to race-related stressors. It is hypothesized that Cuban female victims of IPV will report significantly higher rates of perceived discrimination and race-related stressors in comparison with Caucasian female victims of IPV. Furthermore, Cuban participants will report more severe symptoms of PTSD than Caucasian participants. Participants will meet criteria for PTSD based on the Structured Clinical Interview for the DSM-IV-TR Axis I Disorders (SCID-I/NP). Instruments will include the SCID-I/NP, the PTSD Checklist-Specific, the Discrimination Stress Scale, and the Race-Related Events Scale. A one-way analysis of variance and a multiple hierarchical regression will be used to analyze the data. Results of the present study may provide empirical evidence for greater symptom severity of PTSD in Cuban female victims of IPV compared to Caucasian victims due to greater perceived discrimination and race-related stressful events. This study can give crucial support to multicultural therapy, suggesting individualized treatment, by displaying how discrimination and race may create unique dimensions of PTSD.

Justification of domestic violence by women

Gloria Gurrola Universidad Autónoma del Estado, Mexico; Alejandra Maisen; Julieta Garay; Patricia Balcazar; Juana Esteban; Josa Virseda

The aim of this study was to determine the construction, by women living in violent relationships with their partners, of the reasons for the violence to which they are subjected. We worked with 30 women who are attending psychological counselling services at the State of Mexico Attorney General Victims of Crime Office. The techniques used were the autobiography and in-depth interview. The results indicate that women construct the violence, exerted on them by their partners, under two visions. The first involves the causes such as alcohol use, pressures at work or loss of work, economic pressures or the man’s immaturity. The second relates to motives such as not doing the housework well, going out alone or talking to other men. We conclude that both constructions tend to remove responsibility from the perpetrator of the violence he exercises, the causes tend to attribute reasons of an external nature, and beyond the man’s control, while the motives, refer to conscious intentions and willingness to abuse associated to disciplining the woman so she complies with the culturally and socially established roles.

Post traumatic negative cognitions within panic attack-PTSD model

Jelena Harlamova University of Latvia, Latvia; Sandra Sebre

The aim of the present study is to examine the association of post traumatic negative cognitions within the panic attack-post traumatic stress disorder model. Various studies have shown that both negative cognitions and panic attacks are significant in maintaining post traumatic stress disorder (PTSD) symptoms, and that there is significant comorbidity between PTSD and panic attacks. However, there is a need for greater exploration of these relationships in order to provide more effective treatment approaches. Participating in this study were 60 respondents with PTSD symptoms who had experienced trauma. They completed the following questionnaires: Post traumatic Cognitions Inventory (Foix et al.); Post traumatic Stress Diagnostic Scale (Foix); and the Panic and Agoraphobia Scale (Bandelow). All three measures were translated from English to both Latvian and Russian languages. The study respondent was able to complete the questionnaire in his or her most frequently used language, since both Latvian and Russian are spoken in Latvia. Good internal reliability ratings were indicated for all three questionnaires, in both Latvian and Russian versions. Preliminary results show strong correlations between negative cognitions of self, panic attack manifestations and PTSD symptoms. Negative cognitions of self are the strongest predictors of PTSD. Results are discussed in relation to treatment approaches which address the role of different forms of negative cognitions and panic attacks in the maintenance of PTSD symptoms.

Probation officers’ conceptualisation of externalising behaviour in juvenile offenders

Elisabeth Inomaa-Bustillos Alliant International University, United States of America

The significant prevalence of endured trauma and developmental limitations in incarcerated juveniles has been widely documented. Thus, it is pertinent that probation officers are adequately trained and capable of recognising subtleties of affect and conduct that possibly attest to underlying experiences of trauma and developmental limitations in the juvenile offender when formulating adjudicative recommendations, institutional disciplinary actions, and treatment referrals. This exploratory study intends to examine how externalising behavior of juvenile offenders are conceptualised by probation officers. Correctional officers employed at various juvenile detention facilities and field offices in the state of California will comprise the participants in this study. Each participant will be given a vignette depicting either a female or male juvenile offender, and possessing either average or well below average cognitive function (IQ score of 70 or 100). Each participant will provide behavioural conceptualisations, as well as adjudicative and disciplinary recommendations based on the case information provided in the vignette. This author predicts that
probation officers will primarily endorse punitive adjudicative and disciplinary recommendations in response to the behavior depicted in the vignette, regardless of gender or cognitive abilities. The researcher also predicts that probation officers will be more likely to identify underlying trauma in the female juvenile, but will not demonstrate an ample understanding of general traumatic manifestations of behavior and affect in juvenile offenders.

Dissociative identity disorder and the possibility of infanticide
Veronica Juanes Nova Southeastern University, United States of America; Hillary Howrey Nova South-estern University, United States of America
This poster will discuss the possible relationship between disorganised attachment, neglect, and infanticide using a forensic case study of a woman diagnosed with dissociative identity disorder. The case will look at how alters were formed early in childhood, and how dissociation impacted her development and her eventual infanticide. It will also present a hypothesis on how dissociation may impact re-victimisation of abused women. In this case, depersonalisation occurred during multiple rapes, and the dissociative effect may have led to triggers that would facilitate further depersonalisation when specific sexual assault cues were present in the environment. The case study looks at a woman who committed infanticide, and will examine the potential consequences sexual abuse can have on intercourse and pregnancy, and the possibility of infanticide with women who have these symptoms. In previous research pregnancy was found to be traumatising for women who had previous sexual abuse during childhood, and that women with dissociative disorders sometimes have amnesia about giving birth, and that denial of the entire nine months of pregnancy is possible. In this case, the woman in question had intermittent amnesia about her pregnancy, the process of giving birth, and amnesia about the act of infanticide. This case study is consistent with the research, and additionally shows the dramatic, and possibly deadly, consequences of not identifying and treating the issues surrounding sexual abuse and pregnancy.

Is comprehensive sport psychology a scientific psychology?
Gilles Lecoaq ILEPS, France
This communication explores and examines the interactional and narrative elements of the rehabilitative journey, focusing on dimensions of addictions and emotions. So, we’ll hypothesise that excessive sport practice is a mechanism to help a person to avoid a time of emotional stress and that injury and pain are mechanisms to help a person to reconnect with this time of emotional stress. Twice we will structure our communication: - firstly, from two avatars created when human performance is the only way of life, the excess and the exclusion, we’ll demonstrate how a fragile identity is not a pathological symptom in the field of sport. We will re-investigate what is a normal sport-life. So, between coping and addiction, we will distinguish what are the meanings of a commitment in an excessive physical practice. Secondly, we will explain why writing about a traumatic injury would reduce athletes’ mood disturbance and stress during rehabilita-
tion. Finally, we will conclude about some meanings of comprehensive sport psychology. This proficiency’s comprehensive approach clearly includes helping athletes enhance performances as well as helping athletes enhance their psychosocial health, development and well-being. So, we will explain how some scientific fields are interested in a comprehensive sport psychology.

Sudden and violent workplace death: The adequacy of institutional responses in meeting surviving families’ needs
Lynda Matthews The University of Sydney, Australia
In 2008, the International Labour Organisation announced that each year more than two million people die from workplace accidents and diseases worldwide. Australia’s response to workplace death has been to call for improved occupational health and safety (OHS) and workers’ compensation arrangements. The human toll of workplace death and wellbeing of traumatically bereaved families must be considered when contemplating changes to legislation. International research, however, has focused on OHS, prevention, and post-trauma stress management; research which seldom touches on workers’ families. Evidence indicates that families will seek support/information through informal personal networks and through formal services provided by OHS and workers’ compensation systems to assist with their traumatic loss. Little evidence exists of the adequacy of these institutional responses to families’ needs or of long-term exposure to regulatory processes, such as incident investigations and coroner’s enquiries, on families’ recovery. This study used detailed in-depth interviews to explore seven families’ experiences (covering 18 family members) of institutional responses to sudden and violent workplace death in the construction industry and the impact of these systems on their recovery. Participants revealed a bereavement complicated by insensitive institutional responses and interactions that did not respect or acknowledge surviving families as a victim of work-related death. Exposure to procedural uncertainty and lack of information that continued for many years led to a sense of isolation and abandonment. A model of work-related death that enmeshes well-defined concepts from organisational justice in a ‘demand-control-support’ stress framework provides direction for interventions and thereby improved outcomes for families.

The efficacy of mindful meditation for post-traumatic stress disorder patients
Sang-Bok Lee Kangnam University, Republic of Korea
The clinical efficacy of mindfulness training has been shown in treating PTSD, substance abuse (Dakwar et al., 2009), cardiovascular disease (Sale-mo & Nidich, 2006), and stress-induced and psychosomatic illness (Grossman et al., 2004). This study demonstrated the efficacy of mindful meditation for post-traumatic stress disorder patients who experienced traumatic brain injury accidents. It was hypothesised that mindful meditation training would help PTST-related patients recover from emotional suffering or pain, and that this training would reduce the patients’ negative emotions such as depression, pain and loneliness as well as enhance the patients’ quality of life and positive emotions. Ten PTSD-related brain injury patients (n=10) were selected as the participants for this study. A total of twelve sessions were given to the participants and the t-test on the mean of each scale measuring emotional variables was administered. The results indicated a significant reduction of negative emotional variables and the enhancement of positive emotional variables.

How to prevent child maltreatment: Proposing a primary prevention project
Raquel Oliveira ILEPS, Portugal; Lucia Pais
Violence against children is an important public health issue, directly affecting millions of individuals every year. The intergenerational transmission of maltreatment is one of the main causes for current child abuse and neglect. Given the importance of intervening and preventing abuse, this study aimed at the development of an interview protocol that enables the assessment, in a hospital context, of which mothers and fathers were victims of maltreatment, as well as developing a prevention protocol to be implemented in an obstetrics unit. A total of 10 child abusers were interviewed using the proposed interview protocol, comprising 16 open-ended questions concerning the respondent’s childhood. A socio-demographic questionnaire was also used to enable the sample’s characterisation. The interviews were analysed through content analysis. The interview protocol successfully assessed four general types of maltreatment: who the aggressor was, experience of aggression, feelings towards the perpetrator, causes of maltreatment, social relations, perceived identification figure and self-perception as an aggressor. This information allowed the development of a content analysis grid, with a total of 21 categories. The results highlighted the utility of this protocol in the identification of cases that may require an early intervention. Thus, we propose a 3-stage study for the development of an effective prevention programme: 1st Pilot study; 2nd Development of an index; 3rd Implementation.

Secondary traumatic stress, adjustment in therapists who work with sexual violence survivors
Christina Samios Bond University, Australia; Lisa Abel; Amber Rodzik
Due to their secondary exposure to the traumatic events disclosed by clients, therapists who work with sexual violence survivors are at risk of experiencing secondary traumatic stress, which includes symptoms such as fear, sleeping difficulties, and intrusive images (see Stamm, 2010). Because therapist self-care is paramount for quality delivery of mental health services, there has been increasing interest in identifying factors that may protect therapists from the impact of secondary traumatic stress. We examined whether the negative effects of secondary traumatic stress on therapist adjustment would be buffered by perceived benefits from trauma work. Sixty-one therapists, who work with sexual violence survivors, completed measures of secondary traumatic stress, perceived benefits and a range of adjustment indicators. Hierarchical multiple regression analyses demonstrated that secondary traumatic stress predicted higher scores on depression (β = .46, p = .001) and anxiety (β = .36, p = .012), and lower scores on satisfaction with life (β = -.33, p = .021) and positive effect (β = -.44, p
years after a traumatic experience at a Japanese school. The tragic incident occurred on June 8, 2001 when a man entered the school and stabbed students and teachers with a knife. Eight students were killed and thirteen students and two teachers were seriously injured. Many students witnessed the scene and they suffered from psychological trauma. Just hours after the incident the response team, the Mental Support Team (MST) was organised, with participants from 10 organisations including universities, police, government ministries, and counselling centers. A 24-hr hotline, outreach programs, free counselling for families and teachers, and psycho-education for teachers and parents were provided. After the acute phase the MST stayed at the school and kept on supporting students, teachers and parents to reduce students’ post-traumatic stress-related symptoms, somatic complaints, functional impairment, and anxiety due to exposed to a school crisis. Subsequently after early intervention, the team kept on supporting them on psycho-education, counselling, consultation on class contents, school events and so on. Support on the academic ability and social skills came to be needed in these days. This long-term intervention resulted in students’ well-adjustment at school. The implementation of the support system with school staff and effectiveness of the school-based long-term intervention was discussed for both positive and negative aspects.

The therapist: Art
Rosemare Visser University of Pretoria, South Africa

Trauma work with children is intrinsically challenging from a developmental perspective. When the children and therapists have neither language nor culture in common, the challenges are exacerbated. Studies suggest that childhood trauma can have a lasting impact on mental health in later years. Social breakdown, urbanisation and poverty are correlating factors in the epidemiology of trauma experiences. South African townships, and informal settlements, provide vulnerable environments for children with regard to traumatic events. At Itoseng Clinic in the Mamelodi Campus of the University of Pretoria, an art activities programme as intervention for local children has been developed, and is regularly run, with some encouraging results. Group art classes are offered to children to investigate art as means of expressing and dealing with trauma and environmental challenges, otherwise extremely difficult through language alone, especially with child intervention. A mini interactive art exhibition as more-dimension "poster" will be used at the congress to share experiences, and further stimulate discussion, in this regard. Interested parties will be asked to participate in some art activities typically used in the project.

Resilience to the development of posttraumatic stress disorder associated with common KIBRA alleles
Sarah Wilker University of Ulm, Germany; Stephanie Kolassa; Christian Vogler; Birke Lingenfelder; Thomas Elbert; Franka Thurm; Dominique de Quervain; Andreas Papasotropoulos; Iris Kolassa

Posttraumatic Stress Disorder (PTSD) results from the formation of an associative network, which stores sensory-perceptual representations of traumatic memories. Because the KIBRA gene is associated with long-term memory, we hypothesized that common KIBRA alleles influence the risk for developing PTSD. Traumatic load and PTSD diagnosis were assessed in two independent African samples who faced severe traumata (N=392, Rwanda; N=421, Northern Uganda). DNA samples were taken and array-based single nucleotide polymorphism (SNP) genotyping was performed. The influence of all tagged KIBRA SNPs and traumatic load on PTSD development was estimated using logistic regressions with correction for multiple comparisons in the Rwandan sample. To replicate the identified associations, hypothesis-driven association testing was performed in an independent Ugandan sample. A new association of two neighboring SNPs in near-perfect linkage disequilibrium, rs10038727 and rs4576167, with lifetime PTSD was discovered in the Rwandan sample. While each traumatic event added to the probability of PTSD in a dose-dependent manner in both genotype groups, carriers of the minor allele of both SNPs displayed a significantly diminished risk (p=0.007, OR=0.29). This protective effect was confirmed in the independent Ugandan sample. This study reveals a new association between two KIBRA SNPs and resilience towards PTSD development, indicating that this memory-related gene might be involved in neuroplastic processes that occur in the aftermath of traumatic events and lead to the develop-
Secondary traumatic stress in mental health workers in Turkey

Ayten Zara Istanbul Bilgi University, Turkey

In the course of working with victims of traumatic events, mental health workers themselves can fall victim to secondary traumatic stress reactions. It is well known that secondary traumatic stress is experienced both similarly and somewhat differently by trauma workers. This research investigated the secondary traumatic stress amongst mental health workers in Turkey. Two hundred and five mental health workers from different professional backgrounds participated in this study. The research data was collected from professionals working in the East, South-East and West Regions of Turkey. This research has found a high level of secondary traumatic stress in mental health workers. Mental health workers with personal trauma history and who work in East and South-East Regions of Turkey reported more secondary traumatic stress. Specializing in working within the traumatic stress field, and receiving supervision were found to have a preventive effect against secondary traumatic stress. This study suggests that mental health workers who work with trauma victims are vulnerable to secondary traumatic stress and that personal, professional and organizational support therefore play an important protective role for them in continuing working. The information gathered from this study is crucial for planning mental health services to target at risk mental health professionals for early interventions. The findings of this research are important with regards to facilitating work with traumatized people and preventing mental health workers from becoming stressed.

Session Type: Invited Symposia

Symposium title: Aviation
Convener: Robert Bedford

Proposed endocrinology protocol
Mmatjiata Pooe Institute for Aviation Medicine, South Africa

While selected endocrine diseases such as Diabetes Mellitus have been incorporated into aeromedical certification protocols, there is a paucity of aeromedical literature regarding most endocrine diseases. This protocol will attempt to establish a coherent and comprehensive guideline to the aeromedical certification of persons with endocrine disorders.

Proposed haematology protocol
Happy Shube South Africa

Man remains the weakest link in the interaction between man, machine and the aviation environment. This presentation focuses on the effect of different haematological conditions on aviation safety. Best practice from other countries including America, Canada and Australia as well as the ICAO guidelines were taken into consideration. Topics include anaemia, polycythaemia, leukaemia, lymphomas and haemoglobinopathies. A workshop involving local expertise was held in order to arrive at proposed guidelines that should be considered when drafting a haematology protocol for the South African Civil Aviation Authority.

Symposium title: Crisis, disaster and trauma: Italian research
Convener: Fatima Caddia

Emergencies as a dialectic process involving order and chaos
Maria Teresa Fenoglio Ordine Degli Psicologi, Italy

The past ten years have seen Italian emergency psychologists reaching a significant level of professional growth derived from interventions in the field, the last of which, the Abruzzo earthquake, involved the mobilisation of more than 300 psychologists. This and other direct interventions enhanced our skills and opened new scenarios for our profession. Complexity, urgency, dramatic interruption of normal routines, lack of adequate resources are inherent to emergency situations. In these contexts psychologists’ primary task is to integrate their efforts into a system of five operating levels. The first one, the Diversity Level, concerns the specific situational characteristics and the impact on victims. The second one, the Culture Level, has to do with cultural features and diversities. The third operating level, Psychology as a Science, entails a theoretical frame of references, adequate training and ethical principles. The fourth operational level, the Guidelines Level, refers to International, European and national guidelines. The fifth level, Civil Protection, involves the role assigned to psychologists in the Civil Protection system and chain of command. Despite the so called, ‘tyranny of the notion of trauma’, professional thought has received much impulse from the challenge represented by mass and community needs as well as from exposure to unexpected resilience capacities.

The CISOM (Italian Emergency Body of the Order of Malta) in emergency situations
Pierluigi Policastro Italy

Scientific literature on emergency psychology stresses the importance of psychological support to victims and rescuers. Natural disasters may produce long-term effects in the psyche, compromising individual adaptation capacity. Psycho-social interventions need to take into consideration the characteristics of the territory and of the inhabitants’ life routines in order to guarantee efficiency and efficacy of interventions. These are the premises on which the work of the Italian Criteria for Psycho-social Intervention in emergencies due to natural disasters (June 13, 2006) are based. The present work is meant to analyse a few presuppositions in the field of human relations in emergency situations and is a reflection on trauma psychology and the experience of psychological support in emergency situations as acquired by CISOM.

Using blogs in emergency contexts: An instrument to elaborate trauma
Pierluigi Policastro Italy

To survive we must tell stories* Umberto Eco Narration is a way to organise thought. When we narrate we elaborate events and make them understood by trauma workers. This research investigated the secondary traumatic stress amongst mental health workers in Turkey. How to face team work organisation in contexts of maximum emergency

Pierluigi Policastro Italy

In a context of emergency, a first aid/emergency team has to face various levels of complexity. The operative groups have to meet priority and urgency criteria of intervention and to involve the responsibility not only of the members of the team itself, but also of local institutions and of other organisations. Communication with the residents and all those concerned will also be important. It is very important to analyse the context in its complexity in order to define the macro-areas of intervention, through a process which is constantly aware of developments and problems, aimed at the best coordination of all the elements of the system. The methodology of the first phase of the intervention involved the provincial members of CISOM (Italian Emergency Team of the Order of Malta), with a course on experiential active methodologies, based on the studies of R. W. Revans. This methodology was then applied in an emergency context. The results of this have shown that the introduction of a new approach to the emergency context, which was applied after the Val di Vara disaster (October 25, 2011), has marked the start of a new way of dealing with problems. In this approach, which alternates action and reflection, rescuers are enabled to enact more efficient intervention plans. It was concluded that the restructuring of the approach to interventions has brought available solutions within the scope of the emergency teams. It was however found that the greater demands and responsibilities involved generated a mechanism of regression.

Strategies for negotiating undisclosed paternal identity in the home among young people in South Africa

Mzikazi Nduza University of The Witwatersrand, South Africa

South Africa is characterised by high levels of absent fathers. Little research has been done to look at how children go through dealing with living with an unknown and absent father in South Africa. This study focuses on the experiences that young people go through and which strategies have they adopted in order to cope. One-on-one, gender matched, semi structured interviews were conducted. A tape recorder was used and data were transcribed verbatim. The main focus of the research questions was on the way that children with absent unknown fathers dealt with the pain and distress that they experience. Gender might not play a role in the strategies employed by the youth when dealing with this question. However the coping strategies appeared different for the different sexes. Informal coping strategies and formal strategies were adopted at different times depending on availability. Informal strategies for coping with their distress included talking to peers who are experiencing the same problem. Others found clandestine ways such as keeping a diary of emotions. This research shows that men are just as emotionally and painfully affected by absence of their fathers disconfirming beliefs that boys are often not seen as experiencing distress or emotional pain from the absence of their fathers. Strategies that children with absent fathers adopt are important in informing the manner that they will allow for researchers and for people to understand how to assist children growing up without their fathers.

Dynamics of stigmatization and discrimination on intention to disclose among PLWHA: A qualitative assessment

Peter Olapegba North - West University, Mafikie, Nigeria

The HIV and AIDS pandemic has today become an issue of global concern. UNAIDS (2010) estimated that about 33 million adults are HIV positive while Xu & Wu (2011) reported that more than 15 million children are orphaned by the HIV scourge. Some psychosocial factors contributing to the challenge of combating the HIV phenomenon include stigmatization and discrimination. Research findings have shown that HIV positive individuals are reluctant to disclose their status and access medical care because of the fear of stigmatization and discrimination. Adopting a qualitative approach, this study investigated the dynamics of stigmatization and discrimination on intention to disclose HIV status. In-depth interviews (IDIs) and a focus-group discussion were conducted. A thematic analysis indicated that there exist stigmatization and discrimination at individual and societal levels against people living with HIV and AIDS, these were as a result of the way HIV and AIDS were presented and represented at the initial stage as a condition that defies any solution. Media representations over time presented HIV and AIDS as dreaded monster that cannot be tamed. In addition, cultural factors also fuel stigmatization and discrimination; there is still the belief that infected people are promiscuous and in some places HIV infection is seen as divine punishment for sin. One other factor enhancing stigmatization and discrimination is a lack of effective policy framework to protect PLWHA from stigmatization and discrimination. It is concluded that stigmatization and discrimination are still prevalent, to combat them there should be effective legislations and enforced policies to protect PLWHA. Also, media adverts should exclude subtle stigmatization representations while cognitive restructuring and attitudinal change programmes should be aggressively embarked upon for the larger society to adopt the right attitude toward PLWHA.

Identity constructions; Feminist research methodologies

Nadia Sanger Human Sciences Research Council, South Africa

Very little research has been conducted on the Cape Flats in the Western Cape of South Africa, and there are similarly minimal accounts of feminist engagement with the Cape Flats’ communities of South Africa. These mostly working-class, ‘coloured’ communities and the persons who inhabit them, have generally not been the subject of research in current South Africa. This presentation will reflect on the methodological processes and practices that I engaged while conducting comparative research among gender non-conforming persons on the Cape Flats of South Africa, and those residing in middle-class ‘coloured’ communities. The presentation will focus on two particular concerns: first, the multiple ways in which gender, class, race and sexuality mediate and complicate each other in “the field”, and second, the usefulness of reflexive feminist epistemologies and methodologies in conducting research on subjectivity and identity.

Symposium title: Mental health, neuropsychiatry assessment and integrated health services

The temporal dimension in psychotherapy

Daniela Petrolo Sant’Anna Hospital, Italy

Time has many meanings and many dimensions; as many as the numbers of people, experiences, events and life moments. Sometimes individuals’ temporal dimensions reach a meeting point where ideas are shared and start the process of mutual knowledge. In psychotherapy this happens when minds meet on a journey; an experience made of moments and different times that end in a time of revelation, of opportunity and self-knowledge through a synchronous emotional encounter with the other. The presentation of clinical cases will provide a reading of psychotherapy as the meeting of two individuals in time, including a clinical reading of scientific and philosophical phenomena about which mankind has always wondered.

Session Type: Invited Workshops

Conflict, post-conflict and forced migration
Giorgia Dona University of East London, United Kingdom
This workshop examines the psycho-social experiences of individuals who are forced to flee because of conflict, human rights abuses and generalized violence, and it explores the relationship between external displacements and inner journeys in contexts of violence, encampment, settlement, re-settlement, and repatriation. Specific aims of the workshop are to: a) discuss theoretical frameworks (i.e. medical, psycho-social, ecological), for understanding forced migrants psychological experiences within their cultural contexts; b) evaluate the role of psychological concepts (i.e. trauma, acculturation, stress, coping, community healing), for the study of violence, displacement, reconciliation and social integration; c) examine the cross-cultural relevance of western psychological models to the analysis of conflict and displacement; and d) critically analyse therapeutic and psycho-social interventions with forced migrants.

Supervision of early career psychologists
Amie Frewen James Cook University, Singapore; Nenna Ndukwe James Cook University, Singapore
This interactive workshop is targeting early career psychologists who are supervising trainees at varying degrees of experience. We will discuss models of supervision and ways for enhancing skills as a clinical supervisor. There will be opportunities for participants to take part in group discussion, case study analysis and role play. We expect that participants will: 1) Share successes and pitfalls of supervision, 2) Learn more about the theory and practice of clinical supervision, 3) Learn more about the practicalities of supervising trainee clinical psychologists, 4) Develop an awareness of the standards necessary to achieve good self care, 5) Develop an awareness of the standards necessary to achieve good practice in the supervision of clinical trainees.

Using the career interest profile to demonstrate the value of the career construction interview to career counselling
Jacobus Maree University of Pretoria, South Africa
The theory and practice of career counselling need reshaping to enable young people to design successful lives and adapt to changing needs, changing interests and novel work experiences. The general aim of career (construction) counselling (for life designing) is to help persons script their life stories, which makes this approach suitable for exploring personal meanings and for helping people to deal with the many problems involving meaning. The implementation of the Career Construction Interview (CCI) (Savickas) will be demonstrated and attendees will be introduced to the use of the Career Interest Profile (CIP), a social constructionist oriented postmodern instrument aimed at facilitating career counselling by empowering clients to make informed decisions about their career paths, design successful lives and make social contributions. The narrativ approach to career counselling demonstrated here should turn the experience of receiving career counselling into what it was for Epstein, namely the stroke of midnight on New Year’s Eve [offering] the possibility of a new beginning (O’Hanlon).

How to get published in scholarly journals: The art, science and skill of article writing
Jacobus Maree University of Pretoria, South Africa; Anthony Pillay University of Pretoria, South Africa
The aim of this workshop is to assist colleagues (emerging scholars in particular) in their endeavours to get published. Participants attending this workshop should ask themselves why they wish to publish (e.g. recognition, pushing the boundaries of knowledge, testing the water, challenging certain conventions). Participants will be guided briefly through the steps in preparing manuscripts for submission, including the basic steps in writing scholarly articles, establishing a group of critical readers, testing drafts in other forums, for example conferences and seminars, submitting manuscripts to language editors, studying and adhering to journals author guidelines, contacting the editor, and responding to reviewer feedback.

Session Type: Symposia

EMDR in emergency contexts
Fatima Caddia Italy
On October 2008 in Capoterra, Sardinia, three people died and 1300 people were evacuated due to a flood resulting from prolonged heavy rain. Psychological support was requested to assist affected individuals in coping with the emergency. 220 people underwent individual EMDR sessions and 540 were treated in group sessions. Children from nursery and primary schools were also supported with EMDR. Data show that post-traumatic reactions after three months were dramatically reduced in adolescents and children treated with EMDR.

Symposium title: From the individual to the collective: Exploring social transformation through psychosocial interventions

Youth, masculinity, the past, and conceptualisations of trauma in post-conflict Northern Ireland
Elizabeth Gallagher INCORE, University of Ulster, United Kingdom; Brandon Hamber
This paper explores how trauma is conceptualised in relation to a range of interventions with young men in post-conflict Northern Ireland. The study, part of the Trauma, Peacebuilding and Development Project, examines the experiences and perspectives of young men (18-24 years old) in Northern Ireland and the perspectives of those working with the young men. The study focuses on 2 generic Young Men’s Support Groups and 2 Victim/Survivor Groups with a specific focus on the Northern Ireland conflict. A total of 20 clients and 19 staff from the groups were individually interviewed. Semi-structured interview questions and the General Help-seeking Questionnaire (GHSQ) were used to ascertain how groups understand trauma and the impact of the conflict on young men. The study also explored whether young men see themselves as “traumatised” by the conflict, see a need for services in this area and if masculine ideologies impact on help-seeking intentions. The study found that staff and clients conceptualise trauma differently, with staff having a collective understanding of trauma in comparison to young men having a narrower individual understanding. Findings show that masculine ideologies have a negative impact on men’s help-seeking intentions, and that they are less likely to seek help for suicidal thoughts than for other emotional and personal problems. Clients were more likely to seek help from informal sources whereas staff were more likely to seek help from formal and professional sources. Overall findings will be discussed and policy recommendations made.

A field divided: Psychosocial support and peacebuilding in post-conflict settings
Brandon Hamber INCORE, University of Ulster, United Kingdom
In the aftermath of war, two key psychological tasks are to heal the psychosocial wounds of war, and to support peacebuilding processes such as nonviolent conflict resolution and transforming systems of structural violence and oppression. The purpose of this presentation is to examine the conceptual interconnections between these two tasks and to analyse how, in practice, they have evolved as separate and disconnected. Conceptually, there is a reciprocal relation between psychosocial support and peace-
Trauma, peacebuilding and development: towards an integrated psychosocial approach

Brandon Hamber

INCORE, University of Ulster, United Kingdom

The paper outlines the main findings from the Trauma, Peacebuilding and Development Project, a cross-country study supported by the International Development Research Centre, which sought to analyse how psychosocial interventions can contribute to peacebuilding, development and other forms of social transformation. The paper focuses on seven specific case studies, i.e. Sri Lanka; India / Kashmir; Jerusalem / Occupied Palestinian Territories; Guatemala; South Africa; Mozambique and Northern Ireland. All the case studies, through a focus on specific psychosocial interventions (which will be defined in the paper), set out to explore whether psychosocial projects that take the political context into account; map and shadow local understandings of suffering (idioms of distress) and help-seeking behaviour; build resiliency; as well as address needs at different levels (i.e. not only focus on individual trauma) impact more positively upon social transformation. The parameters of the project and the challenges it faced from defining key terms to applying concepts across different contexts will be discussed. Findings from the case studies will be compared with examples of how psychosocial approaches have been used to impact upon peacebuilding, development and social transformation extracted.

Remembering healing and telling: Alternative approaches to trauma care in South Africa

Ingrid Palmary

University of the Witwatersrand, South Africa

This paper presents three case studies of what the authors have termed ‘trauma care’ in contemporary South Africa. The study, funded by SANPAD, drew from the widespread critiques of the medicalised approach to trauma. The research team were concerned with two aspects of these critiques. Firstly, it was clear that migrant groups, and particularly refugees, figured in these debates as a group that highlighted some of the key problems with a medicalised approach to trauma. Secondly, they are a group that face problems of ongoing poverty, racism, marginalisation and often repeated displacement. The trauma cannot therefore, as is the assumption in the DSM diagnosis, be seen as the discrete time-bound event that can be managed psychologically from the vantage point of safety. Our research team, however, also found some of the critiques to be limiting in understanding the experiences of migrants in South Africa. In addition, evidence indicates that very few migrants use mainstream services. Rather than asking how services can be made more relevant to marginalised groups of people, the team decided to investigate how, where and with whom migrants sought respite from violence. In this paper we present three case studies, i.e. trauma care offered within the Pentecostal church; a Zimbabwean self-help group that deals with past violence; and an art based psychosocial intervention for children. Each case study raises new questions about how we define tradition, the local idioms of distress, trauma and support. They show the intersection of trauma with broader processes of development, peacebuilding and social transformation.

Symposium title: Survivorship qualities with trauma

Convenor: Elias Mpofu

Treating post-traumatic stress disorder: Qualitative investigations of SA therapist responsiveness

David Edwards

Rhodes University, South Africa

Therapist responsiveness in making strategic decisions in the conduct of treatment is a central meta-competence for effective practice. The aim of the present research is to develop a clearer articulation of the principles of therapist responsiveness in the treatment of simple and complex PTSD, grounded in actual cases. Often attributed to clinical experience, it is difficult to research formally especially using quantitative methods. A model for responsive treatment of PTSD was derived from a series of systematic case studies that evaluated the transportability of Ehlers and Clark’s cognitive therapy (CT) for PTSD to South African conditions (Edwards, 2010). It included seven areas of clinical focus, two of which, the building of social support and the timing and nature of trauma processing, were examined in a further qualitative investigation. This paper presents further research in which a larger range of cases is examined from a series that now includes 20 cases. Other areas of clinical focus are examined, including attention to the therapeutic relationship, motivational work, and crisis intervention.

Holistic disaster response: A merging medical and psychological intervention post-disaster

Jeanne Leblanc

Private Practice, Canada; Martin Thornton

It is known that “no one who witnesses a disaster is untouched by it.” (Hogan & Burnstein, 2007). Psychologically distressing responses to disaster - although normal - can be pervasive and increase the level of stress and impairment in survivors and responders alike. Initial disaster response is understandably medically-focused on saving lives. In triage levels recommended by the World Medical Association (2006), mental health is the fourth level of acuity - less acute than individuals with minor medical needs who can be treated later by relief workers. In this model, treatment of psychological needs is for those who need reassurance or use of sedative for agitation. While this is consistent with physicians’ mandate for acute medical treatment, not addressing mental health initially creates difficulties, including: (1) increased distress in the patient, support system, and within the treatment milieu; (2) inefficiency in treatment of less urgent medical needs, as somatic manifestations of stress often requires increased physician time (with sometimes limited benefit); and (3) re-traumatisation of survivors, due to repeatedly telling their experience to one professional, followed by the next. In light of these factors, a model of treatment integrating medical and mental health at the inception of disaster response was utilised in Haiti (acute hospital, clinic setting), and in USA post-hurricane. Outcome included improved differential diagnoses, more complete treatment of needs per patient self-report, decreased dispensation of psychotropics (whose efficacy, availability, and side-effects are difficult to monitor), and increased efficiency of treatment time spent per case, by both mental health provider and physician alike.

Trauma counselling as a global human justice issue: Serving humanity

Lisa Lopez Levers

Duquesne University, United States of America

Trauma occurs globally, resulting from interpersonal and community violence, war, large-scale natural disasters, medical crises, and man-made disasters. The effects of psychosocial trauma can be profoundly devastating for individuals and groups of people, shattering core values and changing essential world views. Whether the lived trauma is experienced by marginalised or by mainstreamed populations, certain human justice issues may emerge. The purpose of this paper is to present an overview of the universal relevance of trauma-based counselling issues, as well as an examination of social justice implications. This discussion is informed by the Integrative Systemic Approach to Trauma (ISAT) Model and uses examples from the presenter’s research in Rwanda, Zimbabwe, Namibia, Botswana, Russia, and US. The ISAT Model promotes an understanding of the complexities of trauma theory, research, practice, and supervision. It further emphasises the systemic and reciprocal interrelationships among pre-service training, counselling, in-service training, and supervision. The presenter draws from the research, theory, and practice literatures, offering a comprehensive and integrative conceptual model. While addressing pertinent diagnostic and treatment issues, she explores ISAT, illuminating how various systems and multiple environments require integrative and systemic approaches when dealing with the complexities of trauma. This ecological model incorporates client, clinical, supervisory, consultative, administrative, organisational, societal, and cultural facets of service delivery as well as ethno-medical and indigenous knowledge perspectives.
Post-traumatic growth: Serving humanity by promoting transformation
Yih-Hsing Liu Syracuse University, United States of America

Post-traumatic growth (PTG) is a developmental phenomenon among trauma survivors which has become a focus in current trauma research. Different from the psycho-pathological paradigm, the concept of post-traumatic growth provides an alternative perspective that the traumatised individual has the capacity to grow during the healing process. For example, research among female survivors of sexual abuse has found that resiliency can prevent further adverse effects from trauma. Others have identified the importance of post-traumatic growth in a person’s ability to move forward to higher levels of cognitive and affective development, and have identified how these changes benefit the individual’s everyday function. The purpose of this paper is to explore PTG, in terms of client resiliency, and to describe healing from trauma as a recursive process. This pilot study uses qualitative, phenomenological oriented interview methods to reflect the process of two trauma survivors’ post-traumatic growth in relation to their survivor mission. Six themes emerged from the study that suggests fluid and dynamic self-recovery processes. This investigation also identified questions about how growth and distress may co-exist together, but assist the survivor in moving forward, toward higher levels of functioning. Finally, this inquiry illuminated how volunteerism can be a form of mission fulfillment and can represent an ecological sense of trauma recovery, community healing, and interdependence of human culture. The implications of clinical training, supervision, and future research are discussed.

Survivorship qualities with trauma
Elias Mpfu University of Sydney-Cumberland, Australia

Trauma experience is a part of the human condition, although not necessarily desired or willed by some who are exposed. Many survive trauma experiences and some with disability. The goals of the symposium are to present current models on trauma survivorship which are important for understanding the process of survivorship, and evidence-based treatments; to map the qualities that define trauma survivorship following post-earthquake experience, rape experience or other loss of personal integrity, with or without post-traumatic stress disorder (PTSD). Data from multiple case studies and community sample surveys from Haiti, Pakistan, sub-Saharan Africa, and the USA will be presented and discussed in the context of adaptive capacity and resilience in survivors. Evidence is presented on the effects of therapist responsiveness in mediating trauma survivorship, and also on other health care service qualities associated with sustained survivorship. We consider the survivorship an overarching concept in understanding personal and collective agency in adapting to trauma.

Comparing complex and continuous traumatic stress: Diagnostic and treatment implications
Gillian Eagle Wits University, South Africa; Gill Eagle

Over the past decade there have been increasing attempts to expand or refine the formulation of the impact of extreme life events beyond the scope of Acute Traumatic Stress (ATS) and Post-Traumatic Stress Disorder (PTSD). The introduction of the concept of “Complex Post-Traumatic Stress” has taken hold in the trauma literature despite the fact that this is not a formally recognised category in the Diagnostic and Statistical Manual of Mental Disorders (although perhaps captured under the heading Disorders of Extreme Stress Not Otherwise Specified or DESNOS). In South Africa the complementary construct of Continuous Traumatic Stress (CTS) has also developed considerable purchase since it is understood to characterise a somewhat different set of conditions from those informing Complex PTSD. This presentation explores the conceptual origins of these two characterisations of traumatic event impact and notes some of the similarities and differences between the two. For example, while both constructs attempt to engage with the impact of prolonged and multiple (or poly) exposure impact, Complex PTSD tends to place weight on the longer term impact of necessary adjustment to some form of entrapment or inescapable oppression (now past), whereas CTS emphasises the compromised nature of the recovery context and the impact of realistic appraisal of ongoing sources of threat on already traumatised individuals. This key difference in formulation has implications for diagnostic presentation and also for treatment. These will be explored and elaborated in the presentation, including the role of psychological defences.

Trauma-focused or psychosocial-torture rehabilitation in Africa?
Craig Higson-Smith South Africa

Civil war often attracts international humanitarian response. However, such wars are nearly always preceded, and are often followed, by decades of political instability. During these years, tens of thousands may suffer torture and other gross human rights violations. These victims are supported only by their movements and local networks of health and mental health professionals concerned with human rights abuses. Various models of care for torture survivors have been developed and tested. Several of these are currently being disseminated to international and local agencies concerned with human rights violations. The evidence-based supporting models of humanitarian response are divided between models that emphasise work on victims’ past traumatic experiences, and those that emphasise victims’ current psycho-social wellbeing. This paper includes a review of the evidence based on the strength of which such models are promoted, and then investigates their usefulness to torture treatment centres in Sub-Saharan Africa. Drawing on in-depth interviews with eight senior clinicians from five centres in four countries, the author concludes that the divide between trauma-focused and psychosocial is somewhat misleading. Rather, African practitioners need guidelines that assist them to manage the tension between competing client needs, and to integrate existing models into their treatment practice.

Exploring the intersection between traumatic stress and the practice demands of developing world contexts
Nomfundo Mogapi CSVR, South Africa; Craig Higson-Smith; Sarah Crawford-Browne; Gill Eagle

In developing countries, the provision of mental health services to traumatised individuals, families, and communities typically occurs against a background of chronic social adversity. Many people are trapped in extreme poverty exacerbated by unemployment and inequality, and survive in situations of ongoing volatility and change. Very often traumatic experiences are multiple layered and ongoing. The dominant theoretical positions that guide practice are derived from research and practice in countries with the resources to promote the fruitful interaction of science and practice. In contrast, practitioners in developing countries are often overwhelmed by the needs of their community and the limited resources available to meet those needs. Too often, spending scarce resources on research and theory development is viewed as a luxury, with the result that practitioners in developing contexts remain dependent upon models of work that are not necessarily suited to the needs of their communities. This symposium will bring together the perspectives of developing world practitioners and researchers and offer recommendations to enhance theory, practice, research, and dissemination of knowledge.

Symposium title: Whose needs are we serving? Exploring the intersection between the science of traumatic stress and the practice demands of developing world contexts
Convener: Nomfundo Mogapi

Temporal Nature of the Semantics of Cuining in the Game of Password
Matthew Bolten; Jason Viray; Joanna Wong; Justin Midlot; Annie Chen
University of California, Riverside, USA

The HAL (Hyperspace Analog to Language) memory model has previously been used to understand semantic and associative priming, grammatical categorization and various other memory and language phenomena. In the current study, the HAL model was used to investigate effects in a dynamic language exchange. Participants (research assistants) completed a game of Password in which one participant is given a target word and must give cues to help the other participant guess the target word. Distances computed using the HAL model were used to determine how the contextual similarity of the cues to the target word, guesses to the target word, and guesses to the cues changed over time. The goal of the study was to gain information about how dynamic language exchanges emerge over time, how people might steer each other to a particular concept, as well as how a contextual similarity model can help us learn about these phenomena and the extent to which it can predict human behavior.

Moderating Factors of Context Dependency Effects for Background Music and Reading Comprehension
Birgitte Simpson*; Bridget Robinson-Riegler*
August College, USA

Selective attention tasks have been shown to improve with practice. The current study examines the relationship between practice and the context dependency effect for listening to familiar music while studying: A 2 (low/ high practice) x 2 (music/ no music at encoding) x 2 (music/ no music at retrieval) design will be used to evaluate the effects of practice on the context dependency effect. We hypothesize that a context dependency effect will be found for those who listen to music while studying less than half of the time (low practice). But for those who listen to music more than half of the time (high practice), the context dependency effect will be eliminated or reduced. 160 participants from the August College participant pool will take part in the study. Participants will rate the familiarity of the music, then read a passage either in silence or while listening to music. After a 5 minute distractor task, they will then take a test measuring comprehension of the task. The data will be analyzed using a between subjects, factorial ANOVA. Results Pending.

Mind-body Dualism in Beliefs about Tic Disorders
Jason Parad*
Yale University, USA

Mind-body dualism continues to present an enduring challenge to the field of psychiatry. Whereas in some cases mental disorders are perceived as "psychological" products of the mind, in other cases they are deemed "biological" products of the body. Although past research has shown that this distinction inappropriately invites discrepant clinical recommendations and social judgments, these effects have all been contingent upon explicit suggestions about disorder etiology. Of greater empirical concern is whether the symptoms, rather than the causes, of these disorders can generate similarly biased attitudes. The present study thus tests this possibility using the psychiatric phenomenon of tics. In line with mind-body dualism, our results demonstrate that whereas vocal tics give rise to beliefs about psychological etiology and recommendations for psychotherapy, motor tics lead to beliefs about biological etiology and recommendations for medication. These findings call for increased attention to the way treatment plans are chosen across all psychiatric disorders.

Use of the Brief Symptom Inventory in Emerging Adults
Travis Pashak*; Wells Ling*; Paul J. Handal
Saint Louis University, USA

The purpose of this presentation is to provide the field with normative updates for scores on the Brief Symptom Inventory (BSI), developed by Derogatis and Spencer in 1983, as well as investigate its factor structure in emerging adults attending university. The BSI is a 53-item self-report measure which assesses individual's symptom severity across various areas of mental health, using 5-point Likert type scales. The measure provides a Global Severity Index and subscale scores on Somatization, Obsession-Compulsion, Interpersonal Sensitivity, Depression, Anxiety, Hostility, Phobic Anxiety, Paranoid Ideation, and Psychoticism. This project aims to compare the currently available information on symptom severity norms with contemporary levels of symptoms, as well as investigate whether the nine established subscales remain the best factor conceptualization of psychopathology manifestation in college students. The BSI was administered to two similar samples at a private, religiously-affiliated Midwest university, yielding a total of 725 undergraduate student respondents. They were 74.2% female, with ages ranging from 18 to 24 years old (M=19.44, SD=1.35). The majority identified as White or Caucasian (79.7%) and the most represented class was freshmen (42.8%). Preliminary analyses point toward important differences between established norms and the current sample. Responses yielded a mean score of 0.08 (SD=0.55), which is lower than the established normative mean for emerging adults (M=0.76, SD=0.49) but higher than non-patient adults (M=0.30, SD=0.31). In addition, symptom factor structure and clinical implications are discussed.

Comparison of Violence in the Bible and the Koran through Computational Analysis
Matthew Bolten
University of California, Riverside, USA

Computational models can be used to handle a variety of both methodological and research issues including allowing a comparison of word usage across populations or different texts. One computational model of semantics (HAL) that can learn word meaning and can compute a measure of sim-
Frantz Fanon and Colonialism: A Psychology of Oppression

Blake Hilton* University of Central Oklahoma, USA

The French psychiatrist Frantz Fanon was a prominent psychological analyst of oppression during the 20th century, focusing his work predominantly on the oppression of the black Antillean as well as the Arab of Algeria. This article asserts the congruence of Fanon’s theories, the etiology of several mental illnesses present in the modern Native American population is suggested to be unresolved grief from oppression. The intent of this discourse is that with increased awareness of Native American oppression, the high prevalence of mental illness in this population will be met with greater empathy, aid, and understanding.

Laotian American Adolescents: The Psychological Correlates of Merging Cultures

Alyssa Thanasack*; Jasmine Jaraput; Peter Giorda-no Belmont University, USA

There has been little research devoted to understanding Laotian American adolescents since the first wave of Laotian immigrants arrived in the United States in 1975. Furthermore, little research has been devoted to second-generation Laotian American adolescents. Research has suggested acculturation gaps exist between first-generation and second-generation immigrants, which can influence how parents discipline their children. High acculturation in immigrant adolescents and an authoritarian parenting style have been linked to a high prevalence of delinquent behaviors and low academic achievement in some ethnic groups. However, these phenomena have not been studied directly in Laotian immigrants. It was predicted that an authoritarian parenting style and high level of acculturation to American culture will both be positively related to health-risk behaviors and negatively related to academic success in Laotian American adolescents. Sixty-two Laotian American high school students completed the Parental Authority Questionnaire, the National Youth Risk Behavior Survey, and the Language, Identity, and Behavior Acculturation Scale. Results show partial support for a positive relationship between authoritarian parenting and some health risk behaviors, as well as academic success. There is no support for a relationship between acculturation and health-risk behaviors and academic success. Limitations of this study include lack of control for socioeconomic status, the use of a convenience sample, and not accounting for pre-existing mental problems. Implications for future research are that parenting style is related to health-risk behaviors and academic success, and that there may be other important factors that are linked to onset of health-risk behaviors and low academic success.

The Wet, The Dry: Election Predictions From Tlingit Gendered Geography

Kyle Dexter*; Timothy Lower*; Loren McKnight* University of Alaska Fairbanks, USA

This study utilizes indigenous Tlingit psychological theory of gendered geography or “wet” and “dry” as a means of examining whether a correlation exists between election outcome and Tlingit conceptualizations of surrounding environmental conditions in the state of Alaska. Data for the study comes from the 40 separate voting districts as determined by the State of Alaska Division of Elections. Each voting district was defined as being either a “wet” or “dry” area as it pertains to the Tlingit understanding of gendered geography. Election outcome was designated by the elected officials as being either Republican or Democratic based on the State of Alaska Division of Elections. This is a quantitative study utilizing archival data stemming from past State of Alaska election cycles at both the state and national level races. Initial results suggest the Tlingit psychological theory of gendered geography could be applied to the current voting system as a method of predicting voting outcome. This may also have implications for future studies examining non-Western ontological systems of thought. Recommendations for future research are discussed.

Sibling Birth Order and Sociosexuality

Margaret Hanley* Queens University of Charlotte, USA

Because birth order has been suggested to relate to personality differences among siblings and also to preference in relationships, perhaps there is a correlation between birth order and sexual attitudes and behavior due to early family dynamics. An online study was administered to a sample population of adults ranging in ages from 18 to 55 to determine birth order position, self-perceptions of being traditional or rebellious, closeness in family versus nonfamily relationships, and sexual behavior as measured by the Sociosexual Orientation Inventory-Revised (SOI-R). Previous research may suggest a relationship between ordinal birth position of siblings and sociosexuality in young adults. I predicted that firstborns would perceive themselves as more traditional and lastborns as more rebellious. I predicted that middleborns would have closer relationships to those outside of the family. I predicted that firstborns would be more likely to self-disclose to family. Finally, I predicted that firstborns would have lower SOI-R scores and lastborns higher SOI-R scores. None of the hypotheses in this study were supported. However, in regards to sibling birth order and personality, firstborns did perceive themselves to be more traditional overall compared to both middleborns and lastborns. Although not significant, an interesting finding emerged in regards to birth order and family versus nonfamily relationships. Middleborns rated themselves to be almost two times closer to family versus nonfamily in comparison to firstborns and lastborns. Regarding SOI-R scores, middleborns scored highest contrary to previous research. Research suggests that the relationship between birth order, personality, relationships, and sociosexuality are complex.
subjects experiment, we examine monolingual English-speaking 3- and 5-year-olds’ willingness to help an adult (who speaks either English or Spanish) in four counterbalanced tasks. These tasks test children’s willingness to share various resources (a tool, stickers, and a marker) and to help find a misplaced object. Given children’s strong and early preference for native speakers, it is hypothesized that the children will be less likely to share with and help the Spanish speaker than the English speaker. It is also hypothesized that older children, because of greater exposure to English as the dominant language, will be less likely to help the Spanish speaker than younger children.

Rationales Parents Provide for the Restrictions They Impose on Their Teens

Jacinda Whitley*; Justin Carreras; Kourtnee Rico; Robert D. Laird Xavier University of New Orleans, USA

The purpose of this project is to understand and describe the rationales parents give for their rules and expectations. We are defining rationales as any reason a parent gives their teen for having a particular rule or expectation. A sample 22 parent-teen dyads was recruited using a Craigslist ad and from a high school. Teens were novice drivers, 87% African American, and 82% female. Participants were interviewed about parental structure (i.e., restrictions) and autonomy support regarding driving. Only one of the interview questions was a direct prompt for a parent rationale (“Can you tell me about any discussions you family has about the reasons why you have these expectations?”), but many parents regularly and spontaneously (i.e., without prompting) provided rationales for their rules or expectations throughout the interview. We qualitatively coded parents’ rationales using a five-step process. Three undergraduate research assistants watched video of each interview and identified each rationale provided by the parent (n = 425). One of the research assistants developed an initial classification scheme that coded rationales into 29 categories. Two other research assistants repeated the classification to assess coder agreement. Disagreements were resolved by coding team. Results include descriptive information and rationale examples for each of the final categories, frequency of parental endorsement of each final category, and statistical comparisons regarding the endorsement of each type of category.

Research Area: Engineering/Human Factors

Accidents May Be Due to Too Tiny Safety Margins

Julie Haymaker*; Shaziela Ishak; Mariannella Cla-velo*; Roya Aminiroumand* Ramapo College of New Jersey, USA

Fitting objects through openings requires a high level of accuracy. For instance, children must decide which coin will fit into a slot. Inaccurate decisions may result in injury or property damage. Despite its everyday relevance, few previous studies have measured children’s accuracy at fitting objects through openings. The current study examined 10-year-old children and adults’ functional object knowledge. Participants’ task was to adjust a window (0 to 15cm) to the smallest opening they thought a wooden cube (3.8cm3) would fit through. Each participant gave four estimates that were averaged together. Next, participants were presented with five probe trials at ±0.50cm, ±1.00cm, and 0cm away from their averaged estimate where they decided whether the cube would fit through. Results show that both children and adults gave similar estimates (M=4.52±0.50cm for children and M=4.35±0.50cm for adults, p >.05). Although participants made accurate estimates, they left small safety margins, 16% for children and 12% for adults, that require precise motor control. For the probe trials participants made correct decisions for openings that were +0.50cm, ±1.00cm, and 0cm away from their averaged estimate. However, both groups made incorrect decisions for -0.50cm probe trials. Findings show that by 10 years children’s responses are similar to adult responses. Furthermore, findings highlight that the reason we suffer from accidents is that we neglect to leave a large enough safety margin when going through openings.

The Contrast of Red

Amanda Spolec*; Anne Carrillo Dalmeyer Hendrix College, USA

If an image of a male's face is enhanced with red coloring, will a female rate it as more attractive? Will the male's image also be rated more attractive by a female, if the image has a red background, as opposed to a white background? A study was conducted using the survey method from a sample of ninety-five college age women. A statistically significant result was found using One-Way ANOVA and Tukey HSD Post hoc tests. On average the females rated the red enhanced image, and the original image significantly more attractive than the original image on the red background. There was not a statistically significant difference between the average attractiveness ratings for the original image and the red enhanced image.

Assessing Psychopathy and Serial Murder Utilizing the Homicidal Pattern Disorder Model

David LaBoy* University of Nevada, Las Vegas, USA

This research project focuses on research into the psychology of clinical psychopathy and serial murder. There is a high level of media interest and attention paid to American serial killers. According to popular opinion, psychopaths are serial killers. As a result, this leads to misconceptions as to the types of individuals who commit serial murders. The term “psychopath” is generally reserved for adults, whose personalities are firmly fixed and whose lack of conscience demonstrates the hallmark of psychopathy. A psychopath is characterized as someone potentially capable of committing crimes without guilt or remorse because they feel little or no regret. This type of criminal versatility comes from not being afraid of the consequences. However, psychopaths have a choice; to decide whether, or not, their morals allow them to commit a crime. This research hopes to dispel the common misconception that psychopaths, by definition, are inherently violent and prone to murder; emphasizing that not all individuals who appear to be at risk for psychopathic behavior go on to commit crimes. This research will establish that serial murder falls under a different mental disorder classification altogether, establishing that only a small minority of psychopaths actually become mass murderers, rapists and serial killers.

Research Area: Diagnosis

Sleep Deprivation and Odor Detection Thresholds in Rats (Rattus norvegicus)

Laurian Della*; Sharon Himmanen* Cedar Crest College, USA

The relationship between sleep deprivation and odor detection thresholds was studied in four adult female Long-Evans rats. After establishing the initial odor detection thresholds of the rats, four rats were deprived of sleep for a period 24 hours, and were then recorded for detection thresholds immediately proceeding sleep deprivation, and 43 hours of recovery from sleep deprivation. In order to establish odor detection thresholds, rats were presented with 12 varying concentrations of benzaldehyde, and their odor detection threshold was recorded. Researchers expected that the odor detection thresholds following a 24 hour period of sleep deprivation differ from odor detection thresholds immediately before sleep deprivation, and 43 hours after recovery from sleep deprivation. This study is the first to examine the relationship between sleep deprivation and odor detection thresholds in rats. Results suggest a significant decline in the odor detection thresholds of adult rats following a 24 hour period of sleep deprivation.

Research Area: Industrial/Organisational/Work

The Effect of the Color Red on Attractiveness

Julia Bussberg*; Emily Issler; Holly Bashore San Diego State University, USA

This study investigated the effect of the color red on non-physical attractiveness. According to previous literature (e.g., Gaambys et al., 2010; Elliot et al., 2010), the valence of the effect of the color red is context-dependent. In the current study, college students read a personality description of the target person (either “John” or “Joan”), and then completed a questionnaire, in which they rated the target’s attractiveness, hirability, and sociability. The hypothesis that people will rate the target as more attractive if the personality description were printed on red paper was supported. Interestingly, a negative effect of red was found on measures of hirability and sociability. This study adds to the limited amount of research examining the positive effects of red and shows that the color red may enhance both the physical and non-physical factors that together determine human attractiveness. The results suggest that a red stimulus will have a positive effect on human affect in situations that include the evaluation of opposite-sex partners by functioning as a sexual symbol, but may have a negative effect on human behavior in performance-based contexts that foster competitiveness.
Interview Skills: Stereotype Threat in the Job Selection Process
Joshua Carrasco*; Holly Daniel; Donald Hantula Temple University, USA
Information regarding ethnicity and gender is generally collected by companies and hiring managers to stay compliant with local and federal United States laws. However, it is possible that the questions used to collect these demographics may lead to stereotype threat in job applicants. The purpose of this study is to examine stereotype threat in the interviewing process and the effect it has on pre-employment testing. Focusing on ethnicity and gender, the current study uses priming and tokenism as methods to induce stereotype threat. Participants in this study include undergraduate females who self-identify as either African-American or Caucasian. During the study, each participant is instructed to watch a mock interview for a fictional company. Following the interview, participants are asked to complete a pre-employment test consisting of two parts: numerical and verbal. The last segment of the study is a survey comprised of questions regarding the participant's interview experience. We hypothesize that participants who are primed for stereotype threat during the mock interview will score lower on the pre-employment tests than participants who are not primed for stereotype threat. Results indicate no significance between priming and tokenism conditions and test scores. However, significance was found between race and mean test scores. The minimal number of participants denies a limitation to this study. Moreover, this study is part of a larger study being conducted in conjunction with two additional universities, thus, increasing the number of participants.

Research Area: Personality
Examining Off-Task Behaviors as Regulatory Mediators of Interest and Performance Online
Andrew Choi*; Carol Sansone*; Jonathan Butner; Joseph Zachary University of Utah, USA
Learning via the Internet requires greater reliance on self-regulation (Artino & Stephens, 2009). Online students have easier access to both interesting related materials (e.g., lesson-related videos) and unrelated materials (e.g., social media) (Sansone, et al. under review). Initial results from the Regulation of Motivation and Performance Online (RMAPO) project indicated that students given reasons to value learning basic HTML skills in an online lesson (value-added) spent more time exploring on-task and off-task websites prior to submitting an assignment, relative to control; both were associated with greater lesson interest. This study aimed to examine whether certain off-task websites or patterns of off-task behavior were most beneficial for interest. Off-task websites were coded into the following categories: non-lesson websites related to HTML, indirectly lesson-related websites (image examples), off-task social media (i.e., Facebook), off-task personal interest (i.e., search engine), and off-task other. Participants in value-added conditions (relative to control) were more likely to visit off-task websites indirectly lesson-related (image examples) and websites of personal interest. Further, accessing these two types of websites lead to greater interest and performance (quiz score) at lesson’s end. The findings suggest that students given reasons to value learning may use off-task behavior as strategy to (1) seek additional information related to their developing interest on a topic, and (2) rejuvenate diminished resources through creation of interest. Addition of utility value may thus motivate students to reconfigure their learning process in service of having a more interesting experience using both on- and off-task means (Sansone & Thoman, 2005).

Research Area: Learning
A Cultural Study of Attributions of Sports Fans
John Park*; Kendall Boyd Loma Linda University, USA
Research has shown that individuals make internal attributions for success and external attributions to failures. Studies have further shown that sports fans internalize team success while externalizing team failures (Mann, 1974; Lau, 1984; Wann & Dolan, 1994; Grove et al., 1991). Sports fans experience different responses to their team's performance based on the level of identification they have with their team (Mann, 1974; Grove et al., 1991; Mark et al., 1984; Wann et al., 1999; Wann, 2006). Highly identified fans, those who are passionate about their team, respond to their sports teams more strongly than fans that identify at lower levels (Wann, 1994). Wann has shown that highly identified fans attribute their team's win to internal factors and attribute their team's loss to external factors external attributions more than lowly identified fans. Moreover, it has been shown that cultural orientation influences how the person attributes events such as success and failures (Kashima & Triandis, 1986; Gau & Kim, 2011). It has been shown that collectivists make more external attributions than individualists (Kashima & Triandis, 1986). The cultural differences in the sports fans' attributions have not been sufficiently explored. In this study, undergraduate students at La Sierra University (LSU) and online recruited subjects will participate in a sports experiment where cultural differences in fans' attributions will be assessed. It is hypothesized that sports fans who identify with their team will exhibit higher levels of internal attributions than sports fans that identify with collectivism. The differences in cultural orientation and fan identification are discussed.

The Influence of Mood and Personality Type on Creativity in Problem Solving
Paige Naylor*; Terry F. Pettjohn II*; Jonghan Kim* Coastal Carolina University, USA
Literature generally supports the view that positive mood results in higher creativity. The purpose of this study was to find a condition in which a negative mood results in higher creativity. The design of this study is a two (Mood: positive versus negative) by two (Personality type: extravert versus introvert) between subject design. The hypothesis was that there would be an interaction effect between mood and personality type. Extraverts in a positive mood were predicted to have higher creativity in problem solving and problem finding. Introverts in a negative mood were predicted to have higher creativity in problem solving and problem finding. The sample size was 57 undergraduate college students. Results supported the hypothesis of an interaction effect between the two independent variables. Extraverts had higher scores of creativity when in a negative mood while extraverts' scores were higher when in a positive mood.

Love, Personality and Relationship Satisfaction Scales in Puerto Rico: A Pilot Study
Viviana Padilla-Martinez*; Alfonso Martinez-Tabosa Carlos Albizu University, Puerto Rico
The scientific study of love has been investigated by many researchers like Sternberg and Hendricks and Hendricks. Different instruments have been created to assess love dynamics from a psychological perspective, but none of them have been empirically studied in Puerto Rico. The main purpose of this study is to validate the Love Attitude Scale, Eysenck Personality Questionnaire - Brief Version and the Relationship Scale to be used with Puerto Rican young couples. Literature has identified that Love Attitudes are highly correlated to Personality Styles. These two variables can influence the Relationship Satisfaction reported by a partner. It is crucial to identify personality traits, love attitudes and relationship satisfaction to better understand relationship dynamics and how to improve them. This pilot study is an exploratory pre-experimental design that recruits college students from different universities in Puerto Rico. The participants are 21 years and older and are involved in a relationship. At this moment the research is at the administration process. The study pretends to: (1) identify a description of the sample, (2) item analysis will evaluate the psychometrics properties of the scales and (3) factor analysis will identify if factors found are the same than in past studies in other countries. Results are expected to be similar to those found in other worldwide regions. It is expected to obtain good psychometrical properties of the scales. These instruments will be an important contribution to the evaluation of individuals and couples relationships in Puerto Rico and to better understand relationship dynamics.

Humor Styles, Early Indicators of Psychological Symptoms, and Theory of Mind
Chelsea Patton*; Jennifer Vonk* Oakland Universi ty, USA
In this study 309 undergraduates were assessed regarding humor styles, empathy, theory of mind, and psychologi cal maladjustment via online questionnaires, including Davis’ Interpersonal Reactivity Index (IRI), Baron-Cohen’s Empathizing (EQ), and Eyes test, Derogati’s Brief Symptoms Inventory (BSI), Schute’s Emotional Intelligence scale (EIS), and the Humor Styles Questionnaire (HSQ). We regressed each humor style first on aspects of empathy and theory of mind, then on the subcomponents of the BFI using linear regression analyses. Affiliative humor was significantly predicted by empathizing, theory of mind, anxiety, phobic, and paranoid ideation. Self-deprecating humor was negatively related to empathy and positively related to obsessive-compulsive disorder, phobic symptoms, and interpersonal sensitivity. Self-enhancing humor was predicted by emotional intelligence and obsessive-compulsive disorder. Aggressive humor was negatively related to the IRI index of perspective-taking and positively related to paranoid ideation and hostility. Thus, different humor styles may
Does Perfectionism Predict Procrastination and Self-Handicapping?

Malgorzata Rozko*; Samantha Pinko*; Enrique Jimenez; Dione Johnson
Dominican University, USA

The purpose of this study was to explore relationships between academic procrastination, self-handicapping, and perfectionism. A sample of 110 male and female undergraduate students from a small private liberal arts school completed the Self-Handicapping Scale (SHS), Dominican University Self-Handicapping Scale (DUSHS), Procrastination Assessment Scale-Students (PASS), and Frost Multidimensional Perfectionism Scale (FMPS). Correlational analyses showed a positive correlation between procrastination and self-handicapping, and between procrastination and the two self-handicapping scales (DUSHS and SHS). There was also a positive correlation between one dimension of perfectionism and the DUSHS. There was not a statistically significant relationship between perfectionism and procrastination.

Research Area: Positive Psychology

Understanding Civic Engagement, Sense of Community, and Family Values
Joanne Agsalud*; Mercedes Aponte; Maria Najera; Kelly Petty
Dominican University, USA

The purpose of this study is to identify predictors of civic engagement, specifically investigating the relationship of civic engagement with sense of community and family values. Participants, 70 Dominican University students ranging from 18 to 23 years of age, completed an online survey assessing their levels of civic engagement, sense of community, and family values. Results showed that having higher levels of reinforcements of needs, membership, influence, and shared emotional connection in his or her neighborhood and having family values that emphasized compassion and social responsibility are associated with higher levels of civic engagement. Findings suggest that sense of community and family values do correlate with civic engagement.

Research Area: Race and Racism

Do Media Representations of Africans Affect Stereotypes of African Americans?
Andalisia Lopez* Muhlenberg College, USA

The media serves as an important teaching tool especially when it comes to learning about other people; however, what we learn often involves racial stereotyping. Previous research has found that when Blacks are depicted in the media it is often in circumstances of violent crime, or situations of poverty (Eitman & Rojekci, 2000). Additionally, the media generalizes instances of violence, poverty, and conflict when reporting on African countries (Kenney, 1994). The present study examines how priming participants with positive and negative images of Africans, as well as students’ knowledge of Africa, influence stereotypes of African Americans. We predicted that students who view positive images of Africans will endorse less stereotypes than those who view negative images. Those with high knowledge of Africa will provide less stereotypical endorsements of African Americans. Results will be discussed in terms of media cultivation theory and stereotype maintenance.

An Evaluation of a Pipeline Program to Increase African-American Student Participation

John Park* Loma Linda University, USA

This study explores the meaning shift of the terms, repressed memory and recovered memory, by applying the Hyperspace Analogue to Language (HAL) model of memory. Such an analysis of contextual changes of words through a set amount of time may lead to a better understanding of how history can change the perception of controversial terms. The HAL model uses an inductive learning algorithm to encode contextual usage of word relationships. The model learned from the corpus of newsletters published over a twenty-year span by two antithetical groups involved in the debate on repressed/recovered memory. Word meaning is represented in a 6,000 dimensional state space. The dependent variable of this study is the connotation of terms related to recovered and repressed memory. History (the first and last 5 years of published newsletters) is the independent variable. The results illustrated the changes in semantic neighborhoods of words related to the scientific and legal status of the concepts of recovered and repressed memory. An additional finding was an increase in the use of the language generally used to describe pseudosciences. This trend analysis showed that HAL was able to capture the nuanced meaning shift in discussions about intensely controversial topics.

Research Area: Sexuality

Sexuality and Suicidality: The Mediating Role of Belongingness
Kierstan Monahan*; Caroline Silva; Thomas Joiner
Florida State University, USA

Individuals who identify as homosexual/bisexual are at greater risk for suicidal ideation than heterosexuals (Haas et al., 2011). Concealment of sexual orientation poses a problem because it may lead to greater social isolation and lack of social support. The interpersonal theory of suicide (IPTS; Joiner, 2005) posits that in order to have a severe desire to die by suicide, an individual must experience perceived burdensomeness (i.e., feeling like a burden to others) and thwarted belongingness (i.e., feelings of isolation and extreme disconnection). For this reason, young adults that identify as homosexual/bisexual, but conceal it, may be at greater risk for suicidal ideation and behaviors. The purpose of the current study is to examine the moderating role of belongingness between sexual orientation and suicidal thoughts and behavior. Specifically, we hypothesize that individuals who identify as homosexual/bisexual will report higher levels of suicidal ideation and behaviors, and that this relationship will be accounted for or influenced by thwarted belongingness. Participants completed a series of questionnaires assessing demographics, mood, suicidal thoughts and behaviors, and belongingness, among others. Consistent with previous research, individuals who identified as homosexual/bisexual endorsed higher levels of suicidal ideation and a greater number of lifetime suicide attempts than their heterosexual counterparts and are more likely to have engaged in nonsuicidal self-injury. Preliminary results show that those low in thwarted belongingness had no correlation between sexual orientation and suicidal ideation, but those high in thwarted belongingness showed homosexual/bisexual individuals had higher suicidal ideation.

Help-Seeking and Stressed among Gender and Sexual Minority College Students
Erin Williams*; Caridad Brito
Eastern Illinois University, USA

The presented study assesses the stressed and help-seeking attitudes, experiences, and behaviors among lesbian, gay, bisexual, and transgender (LGBT) and non-LGBT students in rural and urban college settings, in order to compare the students’ stressors and help-seeking, and to examine the role of stressors in help-seeking attitudes. LGBT college students, who may be subject to more stressors than non-LGBT college students, may be further adversely affected in rural college settings. It was hypothesized that LGBT students in rural settings would experience more stressors than LGBT students in non-rural settings, but that college setting may not have the same impact on non-LGBT students; a similar pattern was hypothesized to emerge in terms of help-seeking. A convenience sample of 232 students was obtained and surveyed using the Students’ Stress Rating Score, the Inventory of Attitudes Toward Seeking.
Mental Health Services, and a detailed demographics section. It was found that LGBT students as a whole experienced significantly more physiological stress, and LGBT rural students experienced significantly more social stress, and had a lower propensity for help-seeking. The overall LGBT sample had higher help-seeking behaviors, but was less satisfied with the quality of the mental health care received. Future research should focus on comparing specific types of sexual and gender minorities in terms of their stressors and help-seeking.

Research Area: Trauma

Literature Review on Mediating Factors Between Childhood Physical Abuse and Antisocial Behavior
Lia Rohlehr* Fordham University, USA

Aim: The aim of this review is to highlight the relationship between childhood physical abuse and antisocial behavior and, in particular, to identify factors that mediate this relationship. This review is being done with the goal of understanding what factors can buffer or exacerbate the negative effects of child abuse. Method: Literature from the past ten years was reviewed with the intent of identifying research that focused on mediation of antisocial behavior subsequent to physical child abuse. Seven articles were identified and examined for the strength of the mediators. Attention was also given to factors that reappeared between articles. Outcomes: Several factors were found to mediate the relationship between childhood physical abuse and antisocial behavior. In general, mediating factors fell into one of three categories: family relations, peer relations, and personal behaviors. On one hand, factors found to exacerbate the negative effects of physical abuse included attention problems, involvement with antisocial peers, attitudes about the use of violence, disruptions in cognitive development, and substance use. On the other hand, factors found to buffer the negative effects included parental attachment and school commitment. In particular, parental attachment and involvement with antisocial peers were repeatedly found to play strong mediating roles. Conclusion: When attempting to interrupt the known relationship between childhood physical abuse and antisocial behavior, potential mediators should be assessed. The information obtained in this review can be used for intervention and prevention purposes in known victims of childhood physical abuse. This is especially crucial for adolescent populations.

Research Area: Assessment And Evaluation

Psychometric evaluation of the McGill Quality of Life Questionnaire
Parvaneh Mohammadjkani
The purposes of this study were to evaluate the psychometric characteristics and perform a factor analysis of the McGill Quality of Life Questionnaire (MQOL) in a sample of recovered depressed participants. These participants were assessed with the Structured Clinical Interview for DSM-IV Disorders (SCID) to ensure that they had fully recovered from their most recent episode of depression. They completed a series of self-report measures, including the McGill Quality of Life Questionnaire. Descriptive statistics for the MQOL are presented, and confirmatory factor analysis was used to assess the fit of the hypothesized factor structure. Cronbach’s alpha coefficients were calculated for the questionnaire and each subscale to examine the internal reliability. Internal reliability was found to be high for the overall questionnaire, as well as for each of the subscales, as the coefficient alphas ranged between .58 (for the physical scale), to .88 (for the existential scale). It is suggested that the MQOL can be employed as a tool in research and practice with this population.

Research Area: Cognitive

At the origin of language: nature and nurture in language acquisition
Ghislaine Dehaene-Lambertz
Language processing in adults relies on precise and specialized networks, located primarily in the left hemisphere, around the sylvian fissure. Although different human languages use different sounds, words and syntax, most children acquire their native language without difficulty by following the same developmental path. How can the early organization of the human brain explain this calendar? Thanks to the development of brain imaging, we can now study early functional brain organization and understand the neural biases favouring speech learning in human infants. Results obtained during the first months of life with functional magnetic resonance imaging (fMRI) and event-related potentials (ERPs) show that the neuronal networks engaged when infants listen to speech are close to those described in adults and comprise multiple brain areas that are involved in phonological representations, lexical storing, memory and attention in adults. Furthermore, as in adults, a significant left-right functional and structural asymmetry is observed at the level of the planum temporale. Quantified measures of gray and white matter maturation reveal the complex development of left and right, frontal and temporal areas. The dorsal pathway between area 44 and the posterior temporal areas via the arcuate is efficient very early on, suggesting that frontal areas contribute to speech learning earlier than expected. These similarities between preverbal infants and adults, experts in their native language, suggest continuity in the functional and anatomical structures that underlie language processing. Language development appears thus to rely on a very complex and particular organization of the perisylvian areas.

Effectiveness of treatment based on the child-oriented attachment to reduce symptoms and improve quality of primary school student boys in Isfahan attachment
Farhnaz Shakhniya
This study aimed at therapy effectiveness based on child-oriented attachment method, to decrease depression symptoms, and improve learning quality of primary school boys. The studied sample in this investigation was a 30-person group of student boys at fourth and fifth grades in an elementary school which was chosen according to double sampling, and randomly selected for testing and control groups. To specify child depression rate, the tool used in this study was child depression inventory (CDI). Also the child attachment rate was tested through inventory of parent and peer attachment-revised (IPPA-R). The data were investigated by the way of multivariate covariance analysis. Findings indicated that in the tested group, depression, grades, were remarkably reduced in the testing process, and also in the follow-up process. Attachment quality at the testing time, and grades also remarkably increased. Results indicate that a method based on child-oriented attachment, by focusing on active internal patterns, adjusts the child's attitude to himself and increases self-awareness, self-efficacy, confidence, attachment quality and finally decreases depression symptoms in children.

Research Area: Culture

Experiences of emotional distress and strategies of coping for Xhosa women in a South African township
Sarah Rubin
Life in a township near Cape Town, South Africa includes many hardships and reasons for emotional distress. For Xhosa mothers with young babies, these hardships may be intensified or more difficult to cope with, at least that is what current psychology research on perinatal mental health leads us to expect. Psychological anthropology approaches human suffering from a local, subjective, cultural perspective, asking, “How do people in a specific cultural community experience, narrate, and derive meaning from their everyday lives?” Ethnographic, qualitative interviews and home/community observations of 40 Xhosa mothers over an 18 month period illuminate a culturally and contextually unique engagement with suffering that minimises personal anguish while strengthening social bonds. These Xhosa mothers perceive the hardships of their daily lives as part of a community of suffering and find personal strength and relief in this commonality and perceived normality. This paper discusses some of the experiences that Xhosa mothers face, the strategies of coping for Xhosa women in a South African township, and the bonds. These Xhosa mothers perceive the personal anguish while strengthening social bonds. This paper discusses some of the experiences that Xhosa mothers face, the strategies of coping for Xhosa women in a South African township, and the bonds.
“We keeps it real son!”: How discourses inform and shape resistance in hip hop music
Dumisa Sofika
This study aimed to look at the discourses that go into framing and constructing resistance in hip hop music. It looked at how the cultural terms ‘grinding' and 'hustling' inform and make up a discourse of resistance in contexts where there are few outlets for self promotion as hip hoppers for participants. ‘Hustling' is thereby constructed as a response to difficulties and therefore an act of resistance. It also looked at how hip hop music and culture frame notions of authenticity through the cultural terms of ‘keeping it real' and ‘representing' and how these cultural terms serve as markers of specific identities. The study argues that these cultural terms inform cultural practices. The discourses that emerge from the use of these cultural terms constructs versions of reality that are historically located, that construct and categorise subjects and objects in the world and thereby prescribe ways of acting in the world.

Research Area: Educational

Reciprocal parent-child associations regarding bullying and victimisation: A short term longitudinal study
Phedi Phedonos
The purpose of this study is to examine bullying and victimisation phenomena in relation to parental parameters and a child’s anxious emotional status. Regarding parental parameters, the following factors are examined: maternal and paternal responsiveness, demandingness and overprotectiveness. Bullying and victimisation experiences, as well as stressful and depressive feelings are measured regarding the child. The study constitutes a longitudinal survey, since variables are measured twice in a six-month period of time. It is hypothesised that reciprocal relations will be identified between parental behaviour and the child’s bullying and victimisation experiences. Similarly, reciprocal relations are also expected to be found between the child’s anxious emotional status and bullying and victimisation experiences. A cross-lag structural equation model will be developed in order to describe the main relations and investigate the research questions. The sample of the study consists of 800 students aged 9-12 years (forth, fifth and sixth level) of seven public primary schools in Cyprus, their mothers and their fathers, where data are collected through Likert type questionnaires. The results are discussed in terms of their implications for school practice and prevention/ intervention policies.

Mothers’ personality characteristics and academic performance of elementary students in Ilam city
Farhnaz Shakhniya, Behruz Behrouz, Sholeh Amiri
This research has studied the relation between mother’s personality characteristics, achievement motivation and its effect on academic performance of elementary school students in Ilam. The statistical community was elementary school students studying in elementary schools of Ilam in the academic year 1389-1390 (2011/12). Using a multistage cluster sampling, 200 students were selected. The questionnaire used consisted of 1) the SCL-90-R questionnaire, 2) Herman Achievement Motivation questionnaire (for mothers), 3) Herman Achievement Motivation questionnaire (for students), 4) grade point average as measure of students’ academic performance. The conclusion multivariate analysis of variance and Spearman correlation indicated that there were significant negative relationships between mothers’ obsession, anxiety and depression with students’ academic performance (P<0.05). But there were no relationships between other sub-scales of SCL-90-R Questionnaire and students’ academic performance. Also there was a significant relationships between students’ achievement motivation and academic performance.

Research Area: Environment/Sustainability

A psychological interpretation of Chinese wisdom of sustainability
Ming Li, Beijing Forestry University
The most urgent problem the world is facing is environmental sustainability. The Chinese axial cannon, I-Ching or The Book of Change, presented a cosmological guideline to solve this problem. An interpretation from psychological perspective will be very useful in retrieving the ancient wisdom of sustainability of the fast growing developing country. It will be valuable for both China and the world to utilise its rich psychological cultural heritage. Based on the discourse of The Book of Change, the present paper tries to elucidate 4 subjects for further discussion. (1) The psychological methodology of The Book of Change; (2) The behaviour model of appropriateness of The Book of Change; (3) A new ethic of sustainability implicated in The Book of Change; (4) The existential awareness of the earth and the heaven of The Book of Change.

Role of sexuality and personality traits on creativity in university students
Farhnaz Shakhniya, Behrouz Behrouz, Mohammad Bagher Kajbaf
The information and electronic revolutions, especially in academic environments, has made the prediction of required knowledge for effective encountering with environmental conditions difficult. Former studies showed that mental and personality health is close, or even similar to, creativity. The present paper is to study the relationship between creativity with sexuality, and five personality traits among Isfahan University students. By discussing the modification possibilities of improper personality traits and improving sound personality traits among university students, this paper aims to increase creativity as a sound personality trait. The expected population here includes all technical and engineering college students, and the sample under study includes 200 male and female students randomly chosen. To measure creativity, Torrance verbal creativity inventory, and to measure personality traits, neo personality trait were used. To study the relationship between creativity and personality traits, Pearson correlative test, and to compare scores of males and females, T-independent test were used. Findings of research showed significant, and positive, correlation between creativity and three personality traits, like openness to experience (P>0.05), agreeableness (P>0.05) and extroversion (P>0.05). In addition to these items, there was no significant correlation between creativity and three personality traits, like openness to experience (P>0.05), agreeableness (P>0.05) and extroversion (P>0.05). In addition to these items, there was no significant correlation between creativity and three personality traits, like openness to experience (P>0.05), agreeableness (P>0.05) and extroversion (P>0.05). In addition to these items, there was no significant correlation between creativity and three personality traits, like openness to experience (P>0.05), agreeableness (P>0.05) and extroversion (P>0.05). In addition to these items, there was no significant correlation between creativity and three personality traits, like openness to experience (P>0.05), agreeableness (P>0.05) and extroversion (P>0.05). In addition to these items, there was no significant correlation between creativity and three personality traits, like openness to experience (P>0.05), agreeableness (P>0.05) and extroversion (P>0.05).
In South Africa the parallel existence of Western psychological and African indigenous healing paradigms raises important questions about the relationship between them. The small but growing number of psychologists who are also indigenous healers provides a unique vantage point for the investigation of this relationship at an intrapersonal level. This paper reports the findings of a qualitative study investigating the professional identity of South African clinical psychologists who are also indigenous healers. Employing a psychoanalytic interpretive method focused on exploring participants' identity positions, in-depth interviews with five psychologist-sangomas were analysed to reveal how tensions, conflicts and contradictions concerning dual professional identities are experienced, negotiated and managed. While the meaning of these dual identities and motives for adopting them differed, all participants provided professional self-descriptions reflecting conscious or unconscious identity conflicts and associated anxieties. The interpretive understanding of these involved going beyond participants' consciously intended meanings, drawing on researcher countertransference and salient discourse markers.

Cultural notions of mental illness by elderly indigenous people in a rural community in Limpopo Province, South Africa

Raesetja Mosena

For many years mental illness like all other forms of ill health, has been approached and understood using the biomedical model which maintains that illness is always due to some abnormality in the body's biological mechanism. In recent years, many mental health experts have challenged the universalistic approach and have instead proposed that mental illness and other psychological processes are culture-dependent. In other words, what is defined as mental illness in one culture may not necessarily be seen as such in another culture. The aim of this study was to explore and describe the views of mental illness by elderly indigenous people in one rural community in Limpopo Province (South Africa). A qualitative research method was followed in order to explore and describe mental illness from the perspective of the elderly indigenous people. Ten elderly people were interviewed using unstructured interviews. The interpretive analysis method was used to analyse the data. The results suggest that the respondents understand mental illness to be caused by factors like witchcraft, heredity and substance abuse. In some cases, mental illness is perceived as an invitation for some individuals by ancestors to become traditional healers. Furthermore, the results of the study showed that the respondents tended to believe that mental illness can best be treated through traditional and/or spiritual healing methods. The results are discussed in the light of national and international studies that are aimed at understanding and documenting indigenous knowledge systems, particularly in the area of culture and mental health.
